S1 Interdisciplinary Symposium - International and Interdisciplinary Symposium ... Now Boarding

Laura L. Liptai, PhD, BioMedical Forensics HQ CA/FL, 1660 School Street, Suite 103, Moraga, CA 94556; Carla M. Noziglia, MS*, United States Department of Justice, ICITAP, 305 Ascot Drive, Aiken, SC 29803-7833; Kathryne Bomberger, MA*, International Commission on Missing Persons, 45A Alipasina, Sarajevo, BOSNIA-HERZEGOVINA; Daniel D. Garner, PhD*, United States Department of Justice, ICITAP/Criminal Division, 1331 F Street Northwest, Suite 500, Washington, DC 20530; Morris V. Tidball-Binz, MD*, 4 Chemin des Fleurs, Ferney Voltaire, L'Ain 01210, FRANCE; Duarte N. Vieira, PhD, MD*, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL; Eddy De Valck, DDS*, Parklaan 10, Beigem, B-1852, BELGIUM; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; A.W. Jones, PhD, DSc*, National Lab Forensic Chemistry, , 12 Artillerigatan, Linkoping, 58758, SWEDEN; Deog-Im Kim, PhD*, Catholic University of Korea, Department of Anatomy, 505, Banpo-dong, Seocho-gu, Seoul, 137701, KOREA; Klaus C. Neudecker, MD*, Schirmgasse 268, Landshut, Bavaria D-84028, GERMANY; Rosalind J. Spencer, BSc*, Canada Border Services Agency, 14 Colonnade Road, Suite 280, Ottawa, ON K2E 7M6, CANADA; and Douglas H. Ubelaker, PhD*, Smithsonian Institution, Department of Anthropology, NMNH - MRC 112, Washington, DC 20560*

Educational Objective: After attending this presentation, attendees will be introduced to a diversity of views, a variety of topics and a wealth of knowledge in the field of forensic science that can be used to improve our methodologies as well as promote further research, collaboration, and understanding.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by improving the practice, elevating the standards, and advancing forensic sciences worldwide.

Worldwide forensic research in action will come to you! Preeminent forensic research scientists from ten countries will amaze you. It's a once in a lifetime opportunity to hear from:

International Committee of the Red Cross, Switzerland
International Commission on Missing Persons, Bosnia/Herzegovina
International Criminal Investigative Training Assistance Program, Worldwide
National Institute for Legal Medicine, Portugal
Panel Host: President, Douglas Ubelaker, Smithsonian Institution, Washington, DC

The American Academy of Forensic Sciences (AAFS) serves a distinguished and diverse membership of over 6,200 members, divided into eleven forensic sections representing all 50 United States, Canada, and 62 other countries worldwide. What is our "Forensic Science Edge?" Our advantage or "Edge" is access to preeminent forensic experts worldwide. This symposium encourages international interdisciplinary collegial collaboration that professionally advances us by reinforcing, challenging and/or transforming our thinking.

This symposium is the stuff of which legends are made. See forensic research around the world in action. Toxicology in Sweden! Questioned Documents in Canada! Psychiatry & Behavioral Science in Germany! Physical Anthropology in Korea! Odontology in Belgium! Digital & Multimedia Sciences in the Netherlands! Pathology/Biology in Portugal! General in Switzerland! Jurisprudence in Bosnia/Herzegovina! Criminalistics from ICITAP! And, Engineering from the United States!

International Forensic Science, Victim Identification, Accident Reconstruction

S2 Contemporary Topics in the Forensic Science Community

Tanisha V. Henson, MFS, Medical Examiner's Office - Central District, 400 East Jackson Street, Richmond, VA 23219; Martin K. Overly, MSFS, West Virginia University-FSI, 208 Oglebay Hall, Box 6217, Morgantown, WV 26506; Lindsey E. Crass, BS, 1600 University Avenue, 208 Oglebay Hall, Box 6217, Morgantown, WV 26506; Douglas H. Ubelaker, PhD, Smithsonian Institution, Department of Anthropology, NMNH - MRC 112, Washington, DC 20560; Cheryl D. Hunter*, American Academy of Forensic Sciences, 410 North 21st Street; Colorado Springs, CO 80904; Mary Fran Ernst, BLS*, St. Louis County Medical Examiner's Office, 6039 Helen Avenue, St. Louis, MO 63134; Jason H. Byrd, PhD*, University of Florida, Maples Center for Forensic Medicine, 4800 Southwest 35th Drive, Gainesville, FL 32608; Golden G. Richard, PhD*, University of New Orleans and Digital Forensics Solutions, LLC, Department of Computer Science, New Orleans, LA 70148; Rolf Bremmer, MSc*, Academic Medical Center, Meibergdreef 9, Amsterdam, 1105 AZ, NETHERLANDS; Robin W. Jones, BS*, Bureau of Alcohol, Tobacco, Firearms, and Explosives, United States Department of Justice, 99 New York Avenue, Northeast, Washington DC, 20002; H. Chip Walls, BS*, Miller School of Medicine, Forensic Toxicology Laboratory, 12500 Southwest 152nd Street, Building B, Miami, FL 33177; Robin Bowen, MA*, 1600 University Avenue, PO Box 6217, Morgantown, WV 26506-6217; William E. Folson, MS*, Folson Digital Forensics, Limited Liability Company, 4 Professional Drive, Suite 143, Gaithersburg, MD 20879; Jenna L. Oakes-Smith, MFS*, St. Louis Metro Police Department, 1200 Clark Avenue, St. Louis, MO 63103; M. Lee Goff, PhD*, Chaminade University of Honolulu, Forensic Sciences Program, 3140 Waialae Avenue, Honolulu, HI 96816-1578; Joseph P. Bono, MA*, Joseph P. Bono, MA, PO Box 2509, Leesburg, VA 20177; Jacquelyn M. Jenkins, PhD, Alabama Department of Forensic Sciences, 2026 Valleydale Road, Birmingham, AL 35244; Alison P. Mostrom, MSFS, 536 South Clark Street, Suite 800, Chicago, IL 60605; Amber R. Neitzel, BS, 3842 East Branham Lane, Phoenix, AZ 85042; Taryn M. Mead, BS, 850 Bryant Street, Building 606, San Francisco, CA 94103; Jennifer L. Malone, PhD, Wyoming State Crime Laboratory, 208 South College Drive, Cheyenne, WY 82002; Melissa DeBerry, BA, Mississippi Crime Laboratory, 805 Austin Court, Florence, MS 39073; and Lauren R. Pharr, MA, Louisiana State University, Department Geography & Anthropology, 227 Howe-Russell Geoscience Co., Baton Rouge, LA 70803*

Educational Objective: After attending this presentation, attendees will have a better understanding of the scope of the different fields of forensic science. Participants will learn how the different fields of forensic science work together to each play a significant role in casework. Both casework and research will be presented by the speakers. These presentations will show how casework and research are intertwined and how they both contribute to advancing forensic science. In addition, attendees will learn about each section represented by the AAFS and about the benefits of membership in the Academy. Participants will learn about various cases and research being done by their peers at the posters and slides sessions, and they will learn valuable skills needed to secure a job within the forensic science field at the breakfast session.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing encouragement, tools, resources, and support needed to give new and future professionals the ability to positively contribute to the forensic science field.

For more than a decade, the Young Forensic Scientists Forum (YFSF) has provided a program for new and young forensic scientists ranging from students in both undergraduate and graduate programs to professionals new to their career in forensic science with five years experience or less. YFSF is designed to attract both members and non-members of the American Academy of Forensic Sciences (AAFS). The continuing goal is to provide this audience with topics relevant to their education, training, and skill levels. The program is also designed to provide a comfortable environment for students and new professionals to present to their peers as well as an opportunity to effectively and efficiently network with experienced members and Fellows of the AAFS. The opportunities to present range from presenting at the YFSF Bring Your Own Slides (BYOS) session or the YFSF Bring Your Own Posters (BYOP) session and to showcase emerging forensic scientists. The Emerging Forensic Scientist Award winner is always invited to present his/her award winning paper.

For the AAFS 64th Annual Scientific Meeting in Atlanta, Georgia, the YFSF Special Session will present the theme: "Contemporary Topics in the Forensic Science Community." The special session to be held on Tuesday, February 21, will include speakers who will discuss trends currently observed among various forensic disciplines. With the rise of different types and variations of evidence being submitted to various laboratories, as well as new technologies in evidence examination, the focus of the 2012 forum will be to highlight and educate young forensic scientists on these trends. Lunch is provided to both attendees and speakers who are registered for the special session.

The annual YFSF BYOS, scheduled for Wednesday evening, includes presentations from students and new forensic scientists. The program will continue Thursday morning with the annual YFSF breakfast session with the theme: "Creating the Resume That Will Get Your Foot in The Door." The breakfast session is included in the registration for the special session held on Tuesday. YFSF does not require presenters of BYOS or BYOP to be members of AAFS and does not require they attend the special session but we do encourage them to do so.

One of the goals of the YFSF is to foster relationships between the participants of the session with their peers as well as established members of AAFS and to provide for a smooth transition from student, to emerging scientist, to established member. With the forum group setting provided and the variety of programs offered throughout the week, the YFSF will not only provide academic and relevant technical information to attendees, but will also cultivate relationships that will last a career.

Forensics, Evidence Submission, Current Trends

ES1 The Casey Anthony Trial — From the Defense, Medical, and Scientific Viewpoint

Linda K. Baden, JD, Law Office of Linda Kenney Baden, 15 West 53 Street, Apartment 18 B/C, New York, NY 10019; Jose A. Baez, JD*, 522 Simpson Road, Kissimmee, FL 34744; Haskell M. Pitluck, JD*, 573 Lake Avenue, Crystal Lake, IL 60014; Jane H. Bock, PhD*, Forensic Botany, Limited Liability Company, 5224 Lighthouse Point Court, Loveland, CO 80537-7916; Anthony B. Falsetti, PhD*, ICMP, Alipasina 45a, Sarajevo, 71000, BOSNIA-HERZEGOVINA; Kenneth G. Furton, PhD*, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199; Timothy E. Huntington, PhD*, 175 East Seward Street, Seward, NE 68434; Lawrence Kobilinsky, PhD*, John Jay College of Criminal Justice/CUNY, Department of Sciences, 445 West 59th Street, Room 3263A, New York, NY 10019; Kathleen J. Reichs, PhD*, University of North Carolina Charlotte, Department of Anthropology, Charlotte, NC 28223; Barry K. Logan, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Werner U. Spitz, MD*, Forensic Pathology/Toxicology, 23001 Greater Mack Avenue, Saint Clair Shores, MI 48080*

Educational Objective: After attending this presentation attendees will understand that experts at trial must limit their opinions and conclusions to those which are scientifically supportable despite pressures to tailor testimony to popular community and media sentiment.

Impact on the Forensic Science Communtiy: This presentation will seek to educate all as to the limits of the areas of forensic science testified to by the defense experts in the Casey Anthony trial.

The biggest media case, arguably larger than O.J. Simpson, was the 2011 trial of Casey Marie Anthony for first-degree death penalty murder. This was the first trial that not only engulfed the media but also occurred in the climate of burgeoning social networking, such as Facebook® and twitter®. As a result, everyone worldwide became an armchair juror or lawyer, influenced by rating-conscious talking heads with little understanding of the scientific evidence. Despite the recent pronouncement by the National Academy of Sciences (NAS) Report, the court allowed forensic testimony that had not been validated. The pressure on experts to put forth supportable medical and scientific testimony, despite the unpopularity of the defendant in this case, was great; however, the opinions of scientific experts must be independent of the desires of those who call upon them - unlike the attorneys, they are not advocates for either side.

In 2011 in Orlando, Florida, Casey Anthony was tried for the murder of her two-year-old child Caylee Marie Anthony. Jurors who had not been subject to pretrial publicity were picked by both sides from a different county and sequestered in Orlando, hearing about six weeks of evidence. The result is widely known – that Casey Anthony was acquitted of death penalty murder and all lesser included charges related to the death of her daughter. In order to bolster the emotional argument that the prosecution presented against Ms. Anthony, various forensic disciplines were embraced for the trial. These included not only medical and pathology testimony but also anthropological, entomological, chemistry, toxicology, botanical, and DNA opinions.

The defense claimed that much of the medical and scientific testimony was novel and had exceeded the boundaries of validated forensic science and should not have been allowed in by the gatekeeper. The judge, who did not accept the NAS Report as authoritative, allowed the jury to hear from experts whose opinions and conclusions had never been utilized in court, had not been subject to rigorous error rates, failed to have peer review protocols or quality control, and appeared to fall short of United States Supreme Court standards.

The defense prepared their own scientific conclusions beginning with a second autopsy and anthropological examination. It is important for all forensic experts to understand that at trial the role of the expert and

the jury's acceptance of expert testimony have substantially changed in the past decade.

The controversial nature of some of the testimony allowed to be presented to the jury in this matter, along with the actual systematic assistance provided by the experts for the defense, will be explored so that future forensic experts testifying in any trial, especially a high profile trial, will better understand why jurors accept or reject their conclusions.

This presentation will be a constructive examination of rapidly developing scientific technologies and the National Academy of Sciences concerns as to courtroom admissibility.

Casey Anthony Trial, NAS Report, Unvalidated Forensic Science

ES2 National Missing and Unidentified Persons System (NamUs) Best Practices for System Use

Bruce E. Anderson, PhD, Pima County Office of the Medical Examiner, 2825 East District Street, Tucson, AZ 85714; Randy L. Hanzlick, MD*, Fulton County, Medical Examiner Center, 430 Pryor Street, Southwest, Atlanta, GA 30312; J.C. Upshaw Downs, MD*, Georgia Bureau of Investigation, Medical Examiner, 925 A Mohawk Drive, Savannah, GA 31419; Daniel J. Warren, MS*, Florida Department of Law Enforcement, 4700 Terminal Drive, Suite 1, Fort Myers, FL 33907; Kevin Lothridge, MSM, National Forensic Science Technology Center, 7881 114th Avenue, Largo, FL 33773; and C.W. Billy Young II, BS*, and Carrie B. Sutherland, BS*, National Forensic Science Technology Center, , 7881 114th Avenue, North, Largo, FL 33773*

Educational Objectives: After attending this presentation, attendees will learn best practices for using the NamUs system including case entry, case enhancement, and utilization of NamUs forensic services. At the conclusion of the session, attendees will be able to efficiently navigate, operate, and utilize the NamUs system to assist their agency in applying NamUs to resolve missing and unidentified person's cases.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by showing how increased awareness and use of NamUs offers the promise of reducing backlog of unidentified remains cases in the United States and streamlining the investigation of missing persons by rapidly matching cases across state lines.

The National Missing and Unidentified Persons System, NamUs, combines two databases to assist law enforcement, medical examiners, coroners, and family members in the search for missing persons and the identification of unidentified human remains. The system, to date, has helped resolve over 150 cases of missing persons and unidentified remains. The information presented in the session offers agencies proven best practices for using NamUs to successfully resolve these cases.

This presentation, developed in conjunction with the National Association of Medical Examiners, Georgia Bureau of Investigation, and the Florida Department of Law Enforcement, will outline the benefits and best practices for using NamUs. Death investigators and law enforcement will see firsthand how the NamUs system benefits practitioners in their field. This presentation will be given by registered users from the medical examiner, coroner, and law enforcement fields and will prove vital to the attendees' agencies success with the NamUs program.

First, attendees will be walked through the registration process for becoming a secure user such as law enforcement or a medical examiner or coroner. Once through the registration process, basic and advanced case entry and searching will be demonstrated. Attendees will learn how to enter the best possible case information and use advanced searching techniques based on forensic identifiers such as dental records and tattoos.

Next, the secure user dashboard will be presented, illustrating the benefits of NamUs and its ease of use for users and agencies. The exclusions process and exclusions menu, a significant benefit of the system, will be explained and demonstrated. Under this menu, law enforcement, medical examiners, and coroners can track potential case matches that have been excluded based on forensic examination. The cases are archived so that users can actively monitor these cases for any changes or future comparison.

NamUs rates cases on a star system, from one to five stars, based on the amount of identifiers present in the case record. Five star cases have a higher likelihood of reaching resolution through the system. Identifiers found in five star cases include DNA, fingerprints, and dental records. This presentation will demonstrate how to enter a five star case, or enhance an existing case to five star status. Attendees will also learn how to import all agency cases that reside in the FBI's NCIC database into NamUs electronically, saving them time and money by avoiding manual case entry.

Through NamUs, the National Institute of Justice also offers a wide variety of free forensic service assistance including dental and anthropological services, fingerprint examination, and DNA sampling. This presentation will address how these services are provided, protocols for obtaining the services, and methods for case enhancement using forensic services.

The final topic of the presentation will present system successes. Cases resolved with the assistance of NamUs will be highlighted, demonstrating how the system helps family members, medical examiners/coroners, and law enforcement work together to resolve agency cold cases, bring closure to families and give people their identities back.

NamUs, Identification, Missing Persons

BS1 Postmortem Examination and Personal Identification of Victims of the Great East Japan Earthquake

Yasuhiro Aoki, MD, PhD, Department Forensic Medicine, Nagoya City University School of Medicine, 1 Kawasumi Mizuho-cho Mizuho-k, Nagoya, 467-8601, JAPAN*

Educational Objective: The goal of this presentation is to familiarize attendees with an outline of the forensic investigation of victims of the Great East Japan Earthquake Disaster which was carried out with the assistance of members of the Japanese Society of Legal Medicine (JSLM).

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing foundational knowledge on the features of the Japanese medico-legal system and mass disaster management, and highlighting the role of forensic personnel in the response to overwhelming natural disasters.

A massive earthquake of magnitude 9.0 struck eastern Japan at 2:46 p.m. on March 11, 2011. The epicenter was approximately 130 km off the Pacific Coast of northeast Japan. Strong tremors were observed across a wide area. However, both human casualties and property damage were concentrated on three prefectures (government jurisdictions in Japan), Iwate, Miyagi, and Fukushima, located along the Pacific Coast of the northeastern part of the main island of Japan (Honshu). This was primarily due to the huge tsunami triggered by the earthquake, over 15 m in amplitude and 40 m in run-up height, which engulfed the coastal areas of those prefectures.

Faced with the devastation, the JSLM established the *ad hoc* Disaster Response Headquarters on March 12, 2011, and dispatched member pathologists, physicians, and dentists to the three prefectures in cooperation with the National Police Agency. This was the first time such a headquarters had been established since the society issued a guideline in 1997 for an integrated support system of mass disaster management based on the experience of the 1995 great Hanshin-Awaji (Kobe) earthquake. The first response team consisting of three pathologists and three dentists departed Tokyo at 10:00 p.m. on the same day, traveling in police vehicles due to paralysis of the public transportation network. Examination of victims in Rikuzentakata, Iwate began the following afternoon. Most of the remains were immersed in water and covered with mud, and some victims had suffered extensive burns. Hypothermia was also the cause of death in some cases. The Headquarters successively organized and dispatched JSLM members through July 6, 2011. Some 122 pathologists and physicians contributed a total of 1,090 person-days of work, and 31 dentists performed a total of 298 person-days of work at the disaster sites. Aside from local physicians and dentists associations, the Japan Dental Association and Japan Self Defense Force also sent support teams to the affected areas.

As of July 29, 2011, the remains of 15,645 victims, including 27 non-Japanese, had been recovered, and another 4,984 people were still listed as missing. Approximately 90% of the victims were positively identified, in most cases from personal belongings and body features including dentition. In some cases, identity was established by DNA profiling, and more extensive identification attempts using a computer-assisted dental comparison system and kinship analysis of DNA profiles, which will be important for identification of as yet unidentified victims and yet to be discovered victims, are now in process. The latter is being conducted by the National Research Institute of Police Science and scientific criminal investigation laboratories of regional police headquarters. Fingernails and blood are the first choice source of DNA.

No fewer than 25 countries, regions, and international organizations have sent rescue teams and other specialists to the disaster areas; however, partly because of the language barrier, direct overseas assistance in the examination and identification of bodies has not been possible thus far.

Recently, the Japanese police departments have been increasing the number of prefectural police officers, especially those in charge of the investigation of death scenes and victims. This was effective in handling the large number of remains through wide-range mobilization from outside of the devastated areas. On the other hand, the medico-legal investigation system, such as the medical examiner system, is immature and remains an issue to be addressed from the standpoint of mass disaster management.

Natural Disaster, Personal Identification, Japan

BS2 The Cleveland Cyanide Murder Case: A Multidisciplinary Approach to Crime Investigation Including Chemical Identification, Cause of Death, Capture, and Court Proceedings

Douglas E. Rohde, MS, Lake County Crime Laboratory, 235 Fairgrounds Road, Painesville, OH 44077; Amanda J. Jenkins, PhD*, University Massachusetts Memorial Medical Center, Department of Hospital Labs, 365 Plantation Street, Biotech 1, Worcester, MA 01605; Elizabeth K. Balraj, MD*, 32795 Ledgehill Drive, Solon, OH 44139; and Gary McKee, BA*, Highland Heights Police Department, 5827 Highland Road, Highland Heights, OH 44143*

Educational Objective: The goal of the presentation, is to offer attendees insight into the investigation of a high profile homicide and the cooperation between various governmental agencies and forensic disciplines.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting the complexities of a murder case and a successful team approach to investigation.

On February 24, 2005, a married, 38-year-old mother of two, driving to meet her sister at a movie theater, called a friend to inform her she was feeling nauseous. The female said that she had taken a calcium pill that her husband, a Cuyahoga County physician, gave her just before she left their house. Shortly after the female's cell phone conversation with her friend, she was involved in a low speed automobile accident and was rushed to a local hospital.

When the female arrived at the hospital, she exhibited shallow breathing, an erratic heartbeat, and was unresponsive; however, she had no major signs of trauma. After 30 to 40 minutes of attempting to revive her, the attending physician saw no signs of improvement and pronounced her dead. At the time of autopsy, there was no indication of external injury, and an internal examination showed no evidence of trauma. As a result, the coroner was unable to determine cause of death and awaited toxicology results. Routine toxicology testing, which included volatile, OTC, prescription, and illicit drug screens, did not reveal any unusual substances in the decedent's system.

On March 17, 2005, the husband voluntarily met with the investigating detective and provided a statement concerning his wife's death. In the course of the interview, the husband stated that his wife had been taking prenatal vitamins and calcium supplements. Later that evening, the detective retrieved these items from the home. After this meeting, the husband fled the United States, leaving his children in the care of the decedent's family.

On March 22, 2005, the calcium capsules that were retrieved by the detective were examined by a local county crime laboratory. The chemical examination revealed that nine of the 56 capsules submitted contained cyanide. On April 21, 2005, additional toxicology testing performed on the decedent's specimens revealed 9.1 mg/L of cyanide in her blood. On April 22, 2005, the coroner concluded that the cause and manner of death was homicide by acute cyanide intoxication.

On October 6, 2006, authorities in Cyprus arrested the husband while he was traveling under a false Lebanese passport. He fought extradition in Cyprus until December 12, 2008, when the Cypriot Minister of Justice issued an official surrender warrant. The husband was returned to the United States on January 9, 2009, and arraigned on January 14, 2009.

A jury trial commenced on January 19, 2010, and lasted until March 8, 2010, when the jury returned a verdict of guilty of aggravated murder, as charged in the indictment. The husband appealed his conviction. On May 26, 2011, after a review of the record and pertinent law, the Court of Appeals of Ohio affirmed the appellant's conviction for the aggravated murder of his wife.

Cyanide, Homicide, Multidisciplinary Approach

BS3 Forensic Science and Cultural Heritage – Examination of the Gettysburg Address

Henry Swofford, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Fenella France, PhD*, United States Library of Congress, 101 Independence Avenue SE, Washington DC, DC 20540*

Educational Objective: The goal of this presentation, is to provide attendees with an understanding of a new application of hyperspectral imaging as a non-destructive technique to detect latent fingerprints, specifically on an historical document.

Impact on the Forensic Science Community: This presentation will impact the forensic science community through a discussion of the detection of latent fingerprints on the Nicolay Copy of the Gettysburg Address – one of our nation's most precious documents – using hyperspectral imaging. Through a collaborative effort between the Preservation Research and Testing Division (PRTD) of the United States Library of Congress, and the Latent Print Branch of the United States Army Criminal Investigation Laboratory, progress is being made in the recovery of additional artifacts and information of historical significance through forensic examinations using hyperspectral imaging techniques.

Hyperspectral imaging involves a spectroscopic analysis of materials to distinguish certain materials, one from another, as a function of their differential reflectance and absorption properties across a multitude of wavelengths in the electromagnetic spectrum. The particular wavelengths at which materials reflect and absorb will differ based on the chemical composition of the material giving it a characteristic reflectance spectrum. It is this characteristic reflectance spectrum which distinguishes certain materials. The normal human eye can distinguish the difference in materials based on their color. The color of a material is a descriptive property corresponding to the particular wavelength of electromagnetic energy that is reflected back towards the eye. The brain then detects and defines this reflected energy as a particular color depending on the wavelength of the reflected energy. The human eye is sensitive to distinguishing electromagnetic energy between 390nm and 750nm – commonly referred to as the "visible spectrum." The visible spectrum represents only a very small portion of the entire electromagnetic spectrum which is infinite and continuous. Hyperspectral imaging relies on hundreds of narrow and contiguous wavelengths across the electromagnetic spectrum resulting in characteristic reflectance spectra for each pixel in a digital image allowing the viewer to see the image as a function of the differential reflectance spectra. The hyperspectral imaging technique is undergoing rapid improvements with continuous developments of more powerful imagery sensors and image processing algorithms expanding the technique to be used for a multitude of additional applications.

In 2008, the United States Library of Congress PRTD began utilizing spectral imaging to examine a number of documents having historical interest to our nation including original drafts of the Declaration of Independence, the Gettysburg Address, and the Waldseemüller 1507 World Map, the first map to refer to the continent as America. The application and development of hyperspectral imaging for the preservation of cultural heritage materials and analysis of historic documents provides a powerful non-invasive technique for assessing documents. This technique utilizes an imaging system that captures the spectral response of materials from the ultraviolet, visible and near infrared regions of the spectrum (UV-VIS-NIR) and also reveals obscured or hidden information. The Library imaging system comprises a MegaVision 39 Megapixel monochrome camera (7216 x 5412) E6 back, and APO-Digitar 5, 6/120 lens, integrated through customized software with light emitting diode (LED) illumination panels that span the spectral range of 365nm to 1000nm for reflected, transmitted and raking (side-lighting) imaging modes. Recent advances include the development of a lens that had increased sensitivity in the UV region.

Non-destructive spectral imaging can be used to characterize historic documents by capturing the unique chemical spectral response of composite materials including substrates (paper, parchment, photographic materials) and media (inks, pigments, colorants). Capturing UV, VIS, and NIR spectral data in various illumination orientations minimizes handling of fragile items and allows greater capacity for materials analysis and post-acquisition processing to uncover hidden and obscured text and information. All images are accurately registered, enabling almost unlimited combinations of spectral wavebands for further processing. The integrated system uses low heat and reduced light exposure on the document, ensuring preservation of original materials.

During the examination of these historic documents, multiple latent fingerprints were developed on the Nicolay and Hay copies of the Gettysburg Address. The United States Library of Congress and the United States Army Criminal Investigation Laboratory began a collaborative effort to obtain additional items of historical significance pertaining to President Lincoln for non-destructive forensic examinations with the intent of developing additional latent fingerprints to compare with those on the Gettysburg Address. This presentation will give the attendees a chance to become familiar with the application of hyperspectral imaging for latent print development, view the latent fingerprints which were developed on the Gettysburg Address, and discuss the imaging and processing techniques used to capture and non-invasively develop these prints.

Hyperspectral Imaging, Forensic Documents, Latent Prints

BS4 Theater of the Absurd – Ethics and the Truth Versus the Fiction of the Courtroom

J.C. Upshaw Downs, MD, ForensX, LLC, 11511 Abercorn Street Ext #182, Savannah, GA 31419; and Anjali R. Swienton, JD*, SciLawForensics, Limited, 12447 Great Park Circle, #210, Germantown, MD 20876*

Educational Objective: The objective of this presentation is to introduce the contrasting fictional portrayal of the court in media versus the reality of actual trial practices with the goal of allowing forensic witnesses to benefit from lessons learned–both good and bad–by the presenters.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by allowing the attendee to better understand unrealistic portrayals and expectations placed on the forensic witness by attorneys, juries, and others based on a comparison with media presentations.

The forensic practitioner is challenged with expectation placed on him/her by many interests. These often come to light most directly in the courtroom where counsel for both parties have a vested interest in

substantiating their version of the facts. This adversarial system draws in the neutral practitioner who is faced with expectations of performance from the judge, law enforcement, jury, and others. In the modern era, the media has periodically gone through apparent feeding frenzies of interest in high-profile "case of the century" vignettes with ever-increasing frequency. The particulars of day-to-day forensic work have been glamorized on television in the form of fictional crime dramas and reality television, leaving many viewers expecting investigative miracles from the forensic practitioner. The "CSI effect" is an all too real phenomenon.

Using a compare and contrast case study basis with use of video clips from dramatic courtroom events and actual sworn testimony, the dilemmas for the forensic witness will be presented. The ethical dilemmas for the witness in how to properly convey complex scientific testimony to a lay jury while attempting to stay neutral and objective is a continuing challenge for the witness – even if well-experienced. Trying to ensure that the jury has a complete picture of the science underlying the testimony, while not reading in real or perceived shortcomings, is a challenge. At times, counsel might not ask the appropriate questions or the jury might believe that certain evidence "should be present" when it is not. These are all too familiar scenarios to those who have been in the witness box.

The 2009 National Academy of Sciences Report stressed the need for reinforcing ethics in forensic practice. Trial testimony is often where one's moral code can be put to the test by not only what one says but what is not said and how these ends are achieved. The impartial scientist should hold fast to the purity of the science and, while understanding the possible motives of parties involved, not become an advocate. The witnessess' use of logic should remain that and not become mere rationalization, intended to raise doubt. To this end, the practitioner must be able to convey the difference between "hard" and "soft" science, between reality and illusion.

Areas of specific inclusion would relate to the strength of opinion (that is overstating or understating testimony), misrepresenting facts or underlying principles, and the ethics of being a private versus governmental employee. While any ethical lapses may end with the net result that the ideal of "the truth, the whole truth, and nothing but the truth" is not fully conveyed to the jury, the difference between outright lies, deception, and misleading testimony is an important consideration. Media versions may allow some blurring of an ethical line that must remain clear if the foundation of the science is to remain sound.

Testimony, Courtroom, Ethics

BS5 The Battle of Gettysburg: How Today's Technology Connected Jennie Wade to Abraham Lincoln After 145 Years

Rod Englert, BS, Englert Forensic Consultants, PO Box 605, West Linn, OR 97068; and John Sotos, MD*, 1788 Oak Creek Drive, Palo Alto, CA 94304*

Educational Objective: During this presentation, attendees will learn of historical events being affected by today's technology involving blood patterns, luminol, DNA, bullet trajectory, and clues to President Lincoln's medical condition.

Impact on the Forensic Science Community: The presentation will impact the forensic science community by relating historical events to modern-day scientific technology.

Can state-of-the-art forensic technology shed new light on mysteries that have remained unsolved for more than a century? This presentation reopens two intriguing historic events—the deaths of President Abraham Lincoln and Jennie Wade, the Battle of Gettysburg's only civilian casualty—and puts them under the lens of modern science, subjecting 19th-century evidence to 21st-century technology including DNA analysis and luminescent chemical testing as well as advanced medical diagnostics and bullet trajectory analysis.

The first case discussed will be the shooting of Mary Virginia "Jennie" Wade during the Civil War in 1863. A team of crime scene reconstruction and DNA experts conducted a detailed examination of the Jennie Wade House in Gettysburg and discovered convincing evidence that historic accounts had the facts wrong. Attendees will be walked through significant points in this historic sniper shooting scene, revealing how trajectory analysis can be applied to bullet holes in the original wooden doors to determine that the bullet responsible for killing 20-year-old Wade came from a different angle and locale than originally believed. This presentation will include a reenactment of the crime as it unfolded. The forensic tests performed on the floorboards and the bread trough Wade was said to be leaning over when she was shot to death will also be discussed. Use of Luminol revealed chemical reactions suggesting the presence of bloodstains. Core samples were submitted for advanced DNA testing, which may ultimately determine after 148 years not only whether the blood is human but whether it belonged to Wade.

Equally fascinating from a forensic standpoint are other bloodstained artifacts from the Civil War era, including a lock of hair found in a private safe at the Wade House, which was allegedly preserved from President Abraham Lincoln's autopsy. Medical historian and obscure-diagnosis expert John Sotos of the University of North Carolina School of Medicine has conducted exhaustive research on Lincoln and concluded that, based on his features and symptoms, the president suffered from a rare genetic cancer syndrome that would likely have killed him within months had he not been assassinated. By examining bloodstained Lincoln artifacts, this presentation may be able to expand science's understanding of the sixteenth president's medical condition.

In his presentation, Dr. Sotos will explain how a master diagnostician can analyze clues and pinpoint telltale details in photographic and other historical evidence to determine that Lincoln and three of his four sons had multiple endocrine neoplasia type 2B (MEN2B). The hallmarks of the disease and how they are recognizable in such distinctive characteristics as Lincoln's unusual height and long limbs, sagging face and bumpy lips, fatigue and headaches, perpetually cold hands and feet, as well as the death of three of Lincoln's sons before age 20 and his mother's death at 34, will also be discussed.

The discussion will delve into the applications—and potential breakthroughs—that scientific technology offers to solve crimes, broaden our understanding of history, expand medical knowledge, and provide answers to questions that have eluded experts for generations.

Luminol, Trajectory, Lincoln

BS6 Tables Turned: An Unsuccessful Case of a Newborn Kidnapping by Caesarian Section

Robert J. Morton, MS, Federal Bureau of Investigation, National Center for Analysis of Violent Crimes, Critical Incident Response Group, 2501 Investigation Parkway, Quantico, VA 22135*

Educational Objective: After attending this presentation, attendees will understand the unique dynamics involved in cases of offenders who attack pregnant women to steal their fetuses. This case will highlight the need for forensic sciences to assist in unraveling complex homicide crime scenes.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting the complexities involved in homicide scenes and the need for forensic sciences to assist law enforcement in ascertaining the sequence of events involved in equivocal death investigations.

This presentation is designed to discuss a very rare and bizarre type of homicide where an offender attacks a pregnant woman and forcibly performs a crude caesarian section, removing the victim's fetus, usually resulting in the death of the mother. A case will be discussed where a victim was stalked and attacked by a woman who was intending to steal her fetus

by caesarian section. In this instance, the victim was able to successfully fight off the offender, killing her. Additionally, this presentation will explore the history of newborn kidnapping by caesarian section, as well as the research that has been conducted on this unusual type of crime.

The FBI's National Center for the Analysis of Violent Crime (NCAVC) is routinely consulted by federal, state, local, international law enforcement, and criminal justice authorities in a variety of cases of unusual, bizarre, and repetitive violent crimes, especially homicides. NCAVC assistance was requested by local authorities in regards to a case of a pregnant woman who was attacked by an offender attempting to steal her fetus.

The victim did not previously know the offender. The offender concocted a ruse where a store had mistakenly delivered a package to her residence that was addressed to the victim. The offender was able to engage the victim in conversation regarding the victim's pregnancy learning that the victim was due to deliver in the next couple days.

When the victim went to pick up a second package, she became suspicious and attempted to leave the offender's residence. The offender attacked the victim with a knife, but the victim managed to disarm her, stabbing the offender three times. The victim fled the apartment with the knife and the offender's cordless telephone. The victim was able to contact the police and the offender was transported to the hospital where she died. The victim suffered minor defensive injuries and subsequently delivered a healthy baby.

The police conducted an equivocal death investigation into the case and discovered the offender had previously claimed to have been pregnant four other times. According to the offender, she lost the pregnancies due to miscarriage or stillborn deaths. No one in the offender's family ever visited her in the hospital or attended any funerals for the babies. Further, there were no medical records that substantiated the pregnancies. The offender had gone to great lengths to convince her family she was pregnant. The offender purchased furniture, baby supplies, diapers, and had set up a nursery in her residence. She even wore maternity clothing that was padded to resemble a pregnancy. The offender had a "delivery" kit containing surgical gloves, hemostats, surgical scissors, absorbent gauze, and a plastic clip to secure an umbilical cord.

The investigation revealed the offender was sexually and emotionally abused while growing up. Both of the offender's parents were alcoholics and the offender became the main caregiver to her other siblings. The offender had claimed her father had sexually abused her from ages 7 to 12 years of age, and he was subsequently convicted of molestation and sentenced to 20 years.

This case highlights the unusual dynamics involved in newborn kidnapping cases by caesarian section. It reinforces the role of forensic science, as well as the extensive investigative effort required in equivocal death investigations.

Forensic Science, Fetus Theft, Equivocal Death

BS7 The Tale of the Black Cow, Granny, and How Animal DNA and Branding Experts Exonerated a Man From Wikieup, AZ

Jason D. Ricke, JD, LLM, Mohave County Public Defender's Office, PO Box 7000, Kingman, AZ 86402*

Educational Objective: After attending this presentation, attendees will understand the impact of animal DNA in a criminal case and how jurors may ignore what we, as insiders, perceive as the strongest piece of scientific evidence in a case.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by discussing unique topics of cattle DNA and branding experts. It is imperative to recognize that as our understanding of DNA and comparison science evolves, it reaches into topics previously foreign to these types of scientific analysis.

This presentation will highlight a case arising out of events that took place in Wikieup, AZ, a small ranch town of 150 residents in Northwest Arizona. Everybody sees cattle when driving down country roads, and nearly everyone buys beef in the local grocery store, but how does that meat get from point A to point B? How do we decide who owns livestock that graze out on the open range? What happens when someone is accused of cattle rustling and then lies about it under oath?

When a lawyer takes on a unique area of law, they themselves must become experts in that field. This story highlights one attorney's journey into unfamiliar territory and how experts eventually led to a not guilty verdict at trial.

The defendant was caught with two cattle on his ranch that the State says were not his, one of which had an altered brand. The State asserted that the defendant altered or obliterated the brand on the animal, and then at a cattle ownership hearing in the Kingman/Cerbat Justice Court, lied under oath about when he branded the animal. At the outset of the case, the State had bovine DNA testing done to prove paternity of the two cattle involved, and was going to call as witnesses an animal DNA expert, a branding expert, as well as a veterinary cattle expert. The case looked bad for the defense.

Everything changed when a package from California arrived at the doorstep of the Public Defender's Office containing tissue and teeth of what the defendant claimed to be the mother of the cow with the altered brand, thereby proving these were his cows. In the end, the defense used the same animal DNA expert originally called by the State as well as their own retired branding expert to deal with the evidence against him which resulted in a not guilty verdict.

The greatest surprise of all was not the verdict at trial, but how the jurors perceived the scientific evidence that was presented. The State focused their closing argument on how the defense story was a bunch of bull. The defense waived their hand the other direction and said look at the DNA. Once the verdict was returned, some of the jurors explained that their entire decision was based on something that neither side saw coming.

Attendees may walk away reevaluating their own cases based on the story of the black cow, granny, and a small time ranch hand from Wikieup, AZ.

Animal DNA, Cattle Branding, Comparison Science

BS8 Thomas Krauss Memorial Bitemark Breakfast – Fantasy of Forensics: How Junk Science Failed to Persuade the Jury in the Casey Anthony Case

Jose A. Baez, JD, 522 Simpson Road, Kissimmee, FL 34744*

Educational Objective: During this presentation, attendees will learn firsthand how several attempts to introduce junk science in the courtroom in this mega high-profile case were rejected by the jury.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting the need for sound forensic science and the use of the judicial system as a gatekeeper.

What was dubbed "The Trial of the New Century," the *State of Florida vs. Casey Marie Anthony* posed several problems to law enforcement and state forensic experts. The daily barrage of news coverage in all forms of media resulted in unprecedented coverage. This was the first high profile case that involved social media such as blogs, Facebook®, and twitter®. Instant access was a must. This coverage placed undue pressure on state experts to render several opinions, which were at times questionable, to opinions that fell outside of their area of expertise. Expert witnesses felt this pressure and delivered for the prosecution in the media but delivered more so for the defense during trial.

In July 2008, the worldwide media began to focus on the case of a missing child under what many believed were mysterious circumstances. Caylee Marie Anthony (born August 9, 2005) was reported missing by her

grandmother, Cindy Anthony, on July 15, 2008. Casey Anthony was indicted on charges of first-degree murder and pled not guilty on October 14, 2008. Caylee's skeletal remains were discovered in a wooded area near the family home on December 11, 2008. The prosecution sought the death penalty and the trial lasted for six weeks. On July 5, 2011, the jury found Casey Anthony not guilty of murder, aggravated child abuse, and aggravated manslaughter of a child, but guilty of four misdemeanour counts of providing false information to a law enforcement officer.

In the center of it all was the defendant's vehicle that law enforcement said had the "smell of death." The remains of Caylee Marie Anthony were found less than a quarter mile from the Anthony home. What resulted in trial was a classic battle of the experts with a cutting edge twist. Flying in the face of the recent report issued by the National Academy of Sciences, novel and unproven science was allowed in the courtroom, which resulted in a battle involving every single discipline of forensic science. The prosecution asked the jury to engage in a "fantasy of forensics," which they ultimately rejected. They asked the jury to consider a phantom heart shaped sticker, a phantom stain of decomposition fluid, unverified dog alerts, false computer reports, novel science of air samples purporting to contain the odor of human decomposition, and even a video superimposition of the death of the child where no cause of death was determined. Despite this free-for-all of forensics, and despite the overwhelming inflammatory coverage of this case, the jury saw right through it and rejected the State of Florida's fantasy of forensics. Jose Baez, the defense attorney for Casey Anthony, explores this fascinating case examining not only the use of forensic science within the case but also the role of the media – with the case now being cited as an example of the unfairness of prejudicial pretrial publicity – and the impact that this could have on the rights of defendants.

Forensic, Judicial, Defense

L1 An Analysis of a Mine Incident That Led to Deaths Due to an Unknown Confined Space Hazard

Gerald A. MacIntyre, DVM, 2700 1st Avenue South, Cranbrook, BC V1C 6Y3, CANADA*

Educational Objectives: After attending this presentation, attendees will understand how we are all at risk when dealing with inadequate and erroneous communications. This incident provides attendees with the knowledge that what you are told is not necessarily the facts in scene attendance. We are reliant on exact information that we are given. The information given may result in your own death from complacency.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting cases in which what you are told may kill you. This is a multidisciplinary death investigation of environmental concerns within a mine reclamation.

On December 21, 2001, the Sullivan lead, silver, and zinc mine production was discontinued after 100 years of production. The mine, which is located in Kimberley, British Columbia, Canada, had the dubious reputation of being one of the longest producing mines in the world.

Following production, a reclamation process began and the staff gradually diminished over the following years to a small skeleton staff for maintenance.

The reclamation of the mine site included covering tailings dumps with glacial till. Water drains were placed at the toe of this dump for water quality testing within the dump. A contractor was hired to monitor water quality.

On May 15, 2006, the contractor responsible for monitoring water quality failed to return to his home that evening. On May 17, 2010, the management at the mine site was alerted to the contractor's disappearance. Two employees were dispatched to search for Mr. Ericksen in separate vehicles. Mr. Bob Newcome found Mr. Erickson's truck at the water sampling shed at the toe of number one waste dump. He observed Mr. Ericksen collapsed in the water sampling shed and lying in the shallow water. He called 911 and reported the finding of an unconscious male lying in water. He entered the shed attempting to assess the physical state of Mr. Ericksen. Mr. Newcome also contacted his fellow employee to meet the ambulance at the main entrance gate. When the ambulance arrived, the attendants entered the shed separately. The senior attendant collapsed as she climbed down to assess Mr. Newcome and Mr. Ericksen. The second mine employee stated to the second ambulance attendant that his partner had collapsed. The attendant, in an effort to rescue his partner, fell into unconsciousness.

A Coroner's Inquest was held in July 2009 to investigate the deaths of Robert Newcome, Kimberley Weitzel, Shawn Currier, and Doug Ericksen. Several recommendations were submitted by the inquest jury to prevent a similar occurrence. The intention of this presentation is to discuss the cause of this incident and enlighten the membership of the various communication difficulties that occurred during this tragedy.

The investigation revealed that all four individuals died from an extremely anoxic environment. The cause of the anoxia was determined to include variable environmental and geochemical factors. The glacial till became compacted over the years and did not allow the dump to breath. The chemical reactions created by acidophilic bacteria required oxygen to complete the oxidation of iron within the dump and consequently, oxygen within the sampling shed was utilized and drawn into the dump through the water sampling pipe. The oxygen void within the sampling shed appeared to be replaced with nitrogen from within the dump. There was no indication of anoxia to any of the workers because no odor is associated with this phenomenon. The physiological sequence of events associated with anoxia resulted in hypercapnia and death.

The initial call to the ambulance did, in retrospect, contain all the relevant information regarding a confined space scenario but unfortunately a drowning scenario was used to dispatch the ambulance attendants. They were not prepared mentally to assess an anoxic hazard when they attended the scene and unfortunately died in an attempt to rescue two men that were down upon their arrival.

Environmental Asphyxia, Anoxia, Environmental Anoxia

L2 Odor Mortis: What Is It Anyway?

Jeffrey L. Ashton, JD, 4068 Tenita Drive, Winter Park, FL 32801; Bernard A. Raum, JD*, Levin College of Law University of Florida, PO Box 1149, Newberry, FL 32669; Arpad A. Vass, PhD*, Oak Ridge National Laboratory, 1 Bethel Valley Road, PO Box 2008 MS6120, Oak Ridge, TN 37831-6120; Jan C. Garavaglia, MD*, District 9 Medical Examiner, 2350 East Michigan Avenue, Orlando, FL 32806; and Bruce A. Goldberger, PhD*, University of Florida, College of Medicine, Department of Pathology, 4800 Southwest 35th Drive, Gainesville, FL 32608*

Educational Objectives: After attending this presentation, attendees will learn the significance of the use of *Odor Mortis* to identify sites where human decomposition has occurred, how this evidence is gathered, analyzed in the laboratory, and how this forms as a basis for expert opinion. The attendees will learn applicable rules of circumstantial evidence which govern the use of *Odor Mortis* in court.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by exploring the emergence of *Odor Mortis* capture and analysis will establish a scientific basis for qualified witness at a crime scene or in a laboratory to specifically identify the "smell of death" as they recognize it from their experience and have that identification confirmed by laboratory analysis.

The presentation of a case based upon circumstantial evidence is all about putting the pieces of the puzzle together. Where that case is based largely on scientific evidence, one is faced with an additional challenge. Before the pieces can be arranged in such a way as to show the picture of the defendant's guilt the jury must first understand the evidence. The attorney presenting the evidence must know enough about the science to understand it themselves without allowing their presentation to become so immersed in the science that they lose the jury. This is the true challenge in the presentation of a complex scientific circumstantial evidence case. It is meeting this challenge in general and in particular the use of the concept of *Odor Mortis* in the case of *State of Florida v. Casey Marie Anthony* that will be discussed. Additional discussion will concentrate on the admissibility of the underlying scientific basis of *Odor Mortis* analysis, the expert testimony based upon that analysis, and the use of an expert's sense of smell to identify *Odor Mortis*.

In addition, specific discussion of scientific evidence in this presentation will focus on the development of the decompositional odor analysis database and will include collection methodologies, experimental design, controls, and ramifications of air collection protocols at crime scenes. *Odor Mortis* will be discussed and how the chemical signature of death changes over time. This discussion will end with a summary of how these analytical procedures were used as circumstantial evidence in the Casey Anthony case to confirm the presence of human remains in the trunk of the defendant's car.

For those individuals who smell decomposing bodies on an almost daily basis, they know it is a pungent, unique, and for many, an objectionable odor. How unique is the odor? Most experienced people can say it smells nothing like rotting food, small animals, or fish; however, is that partly because of the quantity of the rotting material we smell? Medical examiners are routinely confronted by these issues. For example, two scenarios involving a medical examiner will be discussed where large quantities of rotting material were associated with a case. The first is where a closed thermal cooler was found by the side of a road with decomposed, liquidized tissue of approximately a foot deep in which bones had sunk to the bottom. Is the smell of the inside of this cooler enough to enable a medical examiner to tell whether this was a rotting deer and not a human? The second scenario involves a driver of a dump truck filled with mildly rotting cow entrails from a slaughterhouse that was in a collision with a freight train on a hot summer day in Texas. Both the driver and the train engine became covered with the entrails that continued to rot in the summer heat while investigators worked the train crash. The smell was pungent and objectionable, but was it unique based on human smell alone? It might be difficult to make an *Odor Mortis* determination in either situation without some sort of scientific determination.

Lastly, toxicological analysis of decomposed remains will be discussed. Such toxicological analysis is routinely performed by forensic toxicology laboratories as an essential component of the medicolegal death investigation process. The presence of drugs and drug metabolites can be used to support a toxicological cause of death. A wide range of specimens are typically available, but the type and condition of the specimen is dependent on the decedent's state of decomposition. The usual specimens include decomposition fluid, solid organ tissue, cranial wash, bone, bone marrow, hair and nails. Toxicological analysis of specimens can also be used to identify products of decomposition. While these findings are not typically reported to the medical examiner, the results may prove useful in investigation and be used to support an *Odor Mortis* finding.

Odor Mortis, Human Decomposition, Circumstantial Evidence

W1 High-Profile Cases: The Los Angeles Experience

Christopher B. Rogers, MD, Lakshmanan Sathyavagiswaran, MD*, and Edward Winter, BA*, Los Angeles County Department of Coroner, 1104 North Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will be familiar with techniques used in handling high-profile cases including media relations, office security, and preparation of the autopsy report.

This presentation will impact the forensic science community by providing practical techniques for handling high-profile cases.

Most medical examiners periodically handle high-profile cases. These cases can be especially challenging because of increased media attention and the need to maintain the security of the medical examiner's office. A thoughtfully prepared autopsy report may help to avoid unanswered questions in the future.

Los Angeles County has seen a number of prominent people become coroner's cases, as well as other cases that have attracted public attention such as officer-involved shootings, deaths in custody, and serial murders. Taking examples from these cases, this presentation will demonstrate methods of handling cases that generate high public interest.

Members of the media need accurate and current information about medical examiner's cases. In order to prepare for high-profile cases, the medical examiner should develop a media relations plan. In larger offices, there should be a few people responsible for media calls and public statements. Smaller offices may specify in advance the resources necessary to handle a large number of media calls. At times the number of calls is so great that it is a full-time job to deal with them. There should be an advance agreement about which section of government will be responsible for media releases in high-profile cases. This will avoid the confusion of having several officials announce different information.

Although there may be pressure to announce results, press releases and other documents should never be prepared in haste. Part of the media plan should give sample press releases for various situations. There is an increasing need to monitor social media, as internet sites can spread misinformation rapidly. The medical examiner's office may need to disseminate accurate information, starting as soon as possible, through social media outlets.

A media relations plan should include provisions for office security. In some cases a large number of news vehicles, grieving fans, or demonstrators block access for employees and others. The decedent must be protected from photographers and curious members of the staff and public. The medical examiner's office must, however, allow access to employees and those whose business is unrelated to the high-profile case. In the past, the police have assisted with security by limiting access to the parking lots.

During the autopsy, as in many forensic cases, details that seem small at first can assume great significance later. The autopsy surgeon should re-read and carefully follow office procedures. Any extraneous photographs (by surveillance cameras, cell phone cameras, etc.) should be prohibited. Photographs, x-rays, documents, and computer files should be secured. Toxicologists and other consultants need to be aware of questions that may come up concerning the case. The typed autopsy report should be proofread several times and checked against primary sources of data. It is possible to find flaws in even the most carefully prepared autopsy report, but they should be minimized to the fullest extent possible.

High-Profile Case, Media Relations, Security

W2 Postmortem Monocular Indirect Ophthalmoscopy Workshop

Patrick E. Lantz, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; Lezah P. McCarthy, MD*, Coastal Pathology Associates, Onslow Memorial Hospital, Western Boulevard, Jacksonville, NC 28546; Candace H. Schoppe, MD*, and Christina J. Tatum, MD*, Wake Forest University, Baptist Medical Center, Medical Center Boulevard, Winston Salem, NC 27157; Stephen Lenfest, MD*, Wake Forest University School of Medicine, Medical Center Boulevard, Department of Pathology, Winston-Salem, NC 27157; and Vivian M. Hathuc, DO*, Wake Forest Baptist Medical Center, Medical Center Boulevard, Winston Salem, NC 27157*

After attending this presentation, attendees will: (1) differentiate between direct and indirect ophthalmoscopy noting advantages and limitations of each technique for the postmortem detection of fundal hemorrhages; (2) discuss the fundal location of retinal hemorrhages relative to their projected aerial image during monocular indirect ophthalmoscopy; and, (3) on a fundal diagram, accurately draw retinal abnormalities observed during monocular indirect ophthalmoscopy with a simple ocular model.

This presentation will impact the forensic community by providing an overview of postmortem monocular indirect ophthalmoscopy, facilitating skill acquisition, and evaluating practical training.

Postmortem examination of the retina has relied on ocular evisceration. In most medical examiner/coroner jurisdictions, ocular enucleation is not a standard autopsy procedure unless child abuse is suspected, thus creating observational bias when citing the prevalence of postmortem fundal findings such as retinal hemorrhages (preretinal, flame-shaped or splinter, and dot/blot), perimacular retinal folds, retinoschisis, and postmortem artifactual retinal folds. Postmortem Monocular Indirect Ophthalmoscopy (PMIO) permits examination of the decedent's posterior fundus and portions of the peripheral retina. The required equipment necessary for PMIO is relatively inexpensive and when compared to direct ophthalmoscopy. This technique is less affected by corneal clouding, lens opacity, or vitreous hemorrhage. PMIO uses a focal light source and an aspheric, convex condensing lens. An excellent source of coaxial illumination is a halogen, xenon surgical, or procedural headlamp. This light source creates a collimated beam of light and permits the examiner to stabilize the condensing lens with both hands. Current aspheric lenses range from +14 to +40 diopters and come in different diameters permitting a field of view of 35°-55°. Postmortem corneal opacity may cause the fundus to appear hazy; however, by gently removing the epithelial layer of the cornea, the emergent image is usually of adequate quality to readily detect lesions such as fundal hemorrhages and retinal folds.

Learning how to perform and become proficient at PMIO can be perplexing and intimidating. Most pathology residents and forensic pathology fellows have limited exposure to indirect ophthalmoscopy. Because the projected aerial image is inverted and laterally reversed, precise descriptions or recording of fundal abnormalities can be challenging. Unlike binocular indirect ophthalmoscopy with a teaching mirror attachment, an instructor and the fellow or resident cannot view the projected aerial image simultaneously during PMIO. To address these learning obstacles, it is necessary to develop tools and models to facilitate skill acquisition. An hour or two with an inexpensive ocular model can shift the learning curve of the resident, fellow, or forensic pathologist substantially to the right demonstrating how to correctly position the light source and hold the indirect lens.

This workshop consists of three sessions. An initial discussion reviews the technique of PMIO, highlighting the optics, the equipment, and examples of abnormal fundal findings found at autopsy by PMIO. Next, attendees will have a realistic learning experience by practical hands-on training with a procedural headlamp, an aspheric indirect lens, and a simple ocular model containing a variety of retinal abnormalities observed at autopsy. The ocular models have variably sized "pupillary" openings and some will have clear acetate over the openings to simulate corneal glare. Facilitators will assist attendees in positioning the procedural headlamp, holding the indirect lens, viewing the projected aerial image, and accurately recording the retinal abnormalities. Following practice visualizing and diagramming numerous fundal images, attendees will be evaluated with a series of unknowns. Self-assessment of technical skill training and review of the unknown retinal findings concludes the workshop.

Forensic Science, Postmortem Monocular Indirect Ophthalmoscopy, Retinal Hemorrhages

W3 Advanced DNA Mixture Interpretation and Statistical Approaches

Debra E. Glidewell, MS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297-5205; Debra A. Figarelli, BS*, 7881 North 114th Avenue, North, Largo, FL 33773; Timothy S. Kalafut, PhD*, and Joel D. Sutton, MSFS*, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297-5205; and Robert I. Obrien, BS*, 7881 114th Avenue, North, Largo, FL 33773*

After attending this presentation, attendees will be able to: (1) describe the importance and use of statistics for DNA mixtures; (2) describe all mixture statistical formulas and mixture interpretation approaches outlined in the SWGDAM DNA Mixture Interpretation Guidelines (approved 1/14/10); (3) use multiple approaches to DNA mixture deconvolution and statistical applications; and, (4) be familiar with one software tool for DNA mixture deconvolution.

This presentation will impact the forensic science community by providing attendees with a better understanding of complex mixture deconvolution techniques, the United States Army Criminal Investigation Laboratory (USACIL) software tool, and the application of statistical formulae outlined in the SWGDAM DNA Mixture Interpretation Guidelines.

DNA mixture deconvolution and the application of statistical methods is one of the most challenging aspects of forensic DNA analysis. This mixture workshop will be a hands-on workshop using both qualitative and quantitative approaches to mixture deconvolution. This workshop will review the SWGDAM Guidelines to include the use of analytical and stochastic thresholds, heterozygous peak balance, percent contribution to assess mixture proportions, and stutter considerations.

The NFSTC DNA Services team has trained over 100 forensic DNA analysts in DNA mixture interpretation and statistical applications using the 2010 DNA Mixture Interpretation Guidelines. NFSTC will provide devices for computerized interactive participation by attendees which will allow attendee opinions to be recorded anonymously and seen on a screen. This on screen anonymous feedback allows attendees to see how other laboratories are approaching DNA mixture deconvolution. This information can then be taken back to their laboratories to share with the analytical staff.

Due to the nature of the cases routinely received, the USACIL has years of experience in complex mixture interpretation. USACIL presenters will discuss their methods and demonstrate a software program used by USACIL staff. ArmedXpert™ is a commercial DNA data analysis program developed by the U.S. Army Criminal Investigation Laboratory and licensed to NicheVision Forensics, LLC. The program uses data tables generated from data analysis tools. The user is able to quickly compare samples from multiple tables to one another in a case, between cases, to a laboratory staff database, QC databases, and create tables or cmf files for CODIS entry. In addition, the software uses a proportional allele method to deconvolute two and three contributor mixtures.

USACIL will provide real case examples of complex mixture data that will be worked through as interactive group activities. The panel of instructors will discuss and show how to apply all interpretation and statistical approaches outlined in the SWGDAM Guidelines for each case example. These case examples will then be deconvoluted using the software (ArmedXpert™) employed by USACIL in order to compare the manual versus automated deconvolution results.

When drafting the 2010 SWGDAM DNA Mixture Interpretation Guidelines, one of the goals of SWGDAM was to provide information that would enable greater consistency and accuracy among analysts within a laboratory. This workshop is designed to provide attendees with hands on applications of scientifically acceptable methods for mixture deconvolution. The interactive component is intended to encourage analysts and technical leaders to review their standard operating procedures and validation data in light of the training on these guidelines and to update their procedures as needed.

DNA, Mixture, Workshop

W4 Sex-Related Homicide and Death Investigation: Practical and Clinical Perspectives—Significance of Pornography, Sexual Deviance, Autoerotic Fatalities, Signature and MO, Serial Murder Investigation, as Well as the Increase in African American Serial Killers Involved in These Events

Vernon J. Geberth, MS, PO Box 197, Garnerville, NY 10923; Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, AB T6H 5R8, CANADA; and Barbara C. Wolf, MD*, District 5 Medical Examiner's Office, 809 Pine Street, Leesburg, FL 34748*

After attending this presentation, attendees will: (1) understand the role of fantasy in sex-related death; (2) collect and preserve physical and psychological evidence in sex-related incidents; (3) determine the MO and signature characteristics in crime scenes; (4) understand investigative and behavioral analysis in criminal profiling; and (5) understand serial murder trends.

This presentation will impact the forensic science community by informing the attendees of the dynamics and proper procedures in the investigation of sex-related homicides and death investigations.

Sex-related homicides and deaths occurring during sexual events have drastically increased over the years and claim victims from all walks-of-life (men or women, lovers or strangers, elders, or children). These fatalities may occur from recreational misadventures or sex-related crimes, which are perpetrated by sex offenders and represent the most horrific crimes imaginable. The internet has certainly provided society with technological advances but has also resulted in the proliferation of pornography and easy access to sex-related materials to anyone with a computer or computer access. It is significant that the sex industry, which consists of commercial enterprises providing adult entertainment, earns over $13 billion a year in the United States and how that may influence the increase in sex-related events.

Attendees of this presentation will better understand the significance of sexual deviancy, fantasy, and pornography in sex-related events as well as the investigative and behavioral analysis applied to these types of incidents. Attendees will understand the importance of the collection and preservation of evidence in sex-related events and the attendees will appreciate the impact of Signature characteristics and *modus operandi* as applied to sex-related homicides.

In the first segment, the presenters will provide examples of sexual deviance as well as the paraphiliac considerations in these type death investigations. There are over 35 Paraphilias described in the literature and a number of Paraphilias are cross-associated with sexual homicides. These will be explored at length in the presentation. The presenters with also explore the connection between Pedophilia and the sexual homicide of children with appropriate case studies provided for illustration. The attendees will then be apprised of the current knowledge regarding autoerotic fatalities.

Attendees will be apprised of the current knowledge regarding autoerotic fatalities including definitions, incidence, crime scene characteristics, typical and atypical methods, and victims. It will be demonstrated that the widely-cited incidence of 500 to 1,000 autoerotic deaths-per-year in the United States is no longer accurate. It will be explained that an incidence of 0.2 to 0.5 cases per million inhabitants per year is a better estimate of the incidence of autoerotic deaths. New epidemiological data have demonstrated that this incidence is higher in big cities compared to rural areas. There is no clear evidence of a preferential time-of-day for these deaths, but there appears to be slightly more incidences of autoerotic deaths during summer. Recently, the typical and atypical methods of autoerotic deaths have also been revisited based on the new standardized classification of asphyxia. New data on the crime scene characteristics will also be presented, along with a discussion of four types of atypical victims: non-white female, children, adolescent, and the elderly. This presentation will provide a comprehensive and practical illustration of specific examples and cases with a discussion of the investigative and clinical considerations, which will include pathology, pathophysiology, as well as the investigative and behavioral and forensic aspects of these events.

The second segment of the workshop will focus on the dynamics of sex-related homicides, which includes rape, lust murder, and serial killing. Using a case history format, the importance of "signature" and *"modus operandi"* will be demonstrated to illustrate the application of Investigative and Behavioral Analysis to the crime scene examination.

Current research regarding the frequency of sexual posing in homicide crime scenes and the phenomena of African-American sexual serial killers in the United States will be included. The myth that there are no African-American serial killers has been perpetuated based on media coverage on television and/or Hollywood movies such as: *The Red Dragon, Silence of the Lambs, and Hannibal* which exclusively focus on the white serial killers. However, there has been a drastic increase in the number of African-American serial killers since the 1980's. Only recently, with the arrest and conviction of Anthony Sowell in Cleveland, Ohio and the identification through the use of familial DNA of Lonnie Franklin, Jr. "The Grim Sleeper" that the media has acknowledged the fact that there are African-American serial killers reported on these cases. The current research indicates over 150 African-American sexual serial killers as of July, 2011.

The overall goal will be to provide comprehensive and practical information which will serve an investigative guide in sex-related homicide and death inquiries.

Sex-Related Homicide, Autoerotic Deaths, Serial Murder Trends

W5 Paper Fundamentals for Forensic Document Examiners

Elaine Wooton, MFS, Office of Investigations – Forensic Document Laboratory, Stop 5116, 8000 Westpark Drive, Suite 200, McLean, VA 20598-5116; David Wicker, MS*, Document Security Systems, 28 Main Street East, Suite 1525, Rochester, NY 14614; Kathleen E. Wyles, BS*, Appleton, 100 Paper Mill Road, Roaring Spring, PA 16673; and Peter V. Tytell, BA, Forensic Research, 116 Fulton Street, Suite 2W, New York, NY 10038-2712*

After attending this presentation, attendees will have a better understanding of ASTM training requirements. Individuals with little previous exposure to the subject area will have a comprehensive introduction, those with moderate exposure will have an updated refresher, and those with significant exposure will have had an opportunity to share their knowledge and case experiences with the other participants.

This presentation will impact the forensic science community by establishing and implementing standards for training and practice, and providing a more predictable skillset. The "questioned document" profession has established minimum training requirements which are documented as an ASTM standard; this includes training regarding paper. As both a supplemental initial training and continuing education opportunity, this workshop provides access to technical expertise that geographically dispersed individuals and groups could not realize.

Forensic document examiners are qualified through an apprenticeship process. The types of training required were determined by the profession and are described in the ASTM Standard *E2388-05 Standard Guide for Minimum Training Requirements for Forensic Document Examiners.*

In order to ensure that examiners are up-to-date regarding paper, the all-day workshop will be divided into four sessions: the first will include the history of paper and the paper manufacturing process. The second will cover techniques and casework that involve paper. The third will introduce security papers. The final session will include techniques for the examination of security papers, and casework examples in which security paper played a role.

History: Using extensive artwork and historical images, the "Paper History Timeline" will be shared with workshop participants. In Asia, the Middle East, and Europe, cultures were striving to have something on which to write! Fraud was soon to follow.

Manufacturing Process: Using extensive video, images, and marginally technical explanations, speakers will ensure the workshop participants comprehend the technical complexities that have radically changed the simple process that is papermaking.

Paper Properties and Basic Examinations: Various characteristics are inherent in a single piece of paper given the materials and process used. Knowing what they are, identifying differences, identifying reasonable variations, and deciding what they mean are the fundamental basis of paper examinations. In this session, how the characteristics are affected when paper is acted upon, and methods for assessing the condition of those characteristics will be described. Indented handwriting, fracture match, and paper fiber impressions will be discussed. Participants will be invited to share case summaries.

Security Papers: As the value of a paper document increases, the need to protect that document also increases. Over time, many elements have been changed or added to make documents more difficult to alter or counterfeit. These elements may be printed material, chemical additives, or other security materials (such as fibers or planchettes.) In this session, the entire range of security papers will be described.

Security Papers – Examination Techniques and Case Examples: Counterfeiters have only one job: to fool the person they need to fool. Typically, the person receiving a counterfeit item is not a forensic examiner and the counterfeiter knows this. Many efforts to duplicate security papers are amusing to the skilled document examiner; however, they are sufficient to be accepted as genuine. In this session, technical information regarding

examination techniques and equipment will be provided, as well as examples of cases in which security paper played a role. Some will be of the amusing variety and some of the nearly undetectable variety. In addition, as in the Paper Examination session above, participants will be invited to share case summaries.

Paper, Watermark, Security

W6 Practical Ethics in Forensic Science – A Multidisciplinary Call to Arms

J.C. Upshaw Downs, MD, Georgia Bureau of Investigations, 925A Mohawk Drive, Savannah, GA 31419; Anjali R. Swienton, JD*, SciLawForensics, Ldt., 12447 Great Park Circle, #210, Germantown, MD 20876; Kenneth E. Melson, JD*, Office of Legal Policy, U.S. Department of Justice, 950 Pennsylvania Avenue, NW, Washington, DC 20530; Max M. Houck, PhD*, Analytic Services, Incorporated, 2900 South Quincy Street, Suite 800, Arlington, VA 22206; Barry A.J. Fisher, MS*, 19854 Vintage Street, Chatsworth, CA 91311; Christine Funk, JD*, State of Minnesota, Office of the Public Defender, 919 Vermillion Street, Suite 200, Hastings, MN 55033; Haskell M. Pitluck, JD*, 573 Lake Avenue, Crystal Lake, IL 60014; Joseph P. Bono, MA*, PO Box 2509, Leesburg, VA 20177; Jennifer L.P. Downs, BA*, ForensX, Limited Liability Company, 11511 Abercorn Street Ext #182, Savannah, GA 31419; Jay A. Siegel, PhD*, Indiana University, Purdue University Indianapolis, Chemistry, School of Science, 402 North Blackford, LD 326 D, Indianapolis, IN 46202*

After attending this presentation, attendees will better understand the nature of practical applied ethics, including the history, practice, enforcement, and expectations from a multidisciplinary view. Attendees will understand potential dangers associated with unethical conduct.

This presentation will impact the forensic science community by providing a better understand of the history and nature of ethics as it relates to the practice of forensic science.

"Tainted Science and Testimony Leads to Re-opening of 120 Cases over Last 15 years," "Man Freed After Serving 21 years in Prison Due to Lab 'Oversight?", "State Crime Lab Employee Accused of Biased Analyses and Testimony"

All of these headlines can confront and scare legitimate practicing forensic scientists. At the heart of this fear is wondering how such events could ever occur, since inherent in the practice of forensic science is the requirement for each practitioner to be truthful and beyond reproach. A failure of forensic scientists to act ethically results in serious adverse outcomes. The word "ethical" can be defined merely as proper conduct – doing the right thing, the right way, for the right reason. While seemingly simple to define, the application of being "ethical" is somewhat more obscure. The 2009 National Academy of Sciences Report on the status of the forensic sciences argued for the need for enhanced ethics training within all forensic disciplines. Tacit within this commentary is that there is a significant problem related to practitioner behavior. As most involved in the day-to-day practice of forensic science would argue that they are complying with all extant codes of conduct, there seems to be a disconnect between theory and practice which needs to be addressed. Thus, the question becomes when is ethical, "ethical," and when is it not? As a non-partisan in the adversarial justice system, the scientist should have no stake in case outcomes.

Clearly, as part of the legal system, there must be room for differences of opinion in the forensic sciences. What is not clear, however, is when such differences are so divergent that individuals' ethics are drawn into question. In this workshop, the role of ethics in the forensic sciences from different perspectives will be addressed with the intent of approaching an understanding of when the proverbial ethical line is crossed.

The workshop will include a discussion of practical ethics in forensic disciplines from multiple points-of-view, including historians, theologians, educators, practitioners, law enforcement, witnesses, attorneys, and judges. Presentations will include comparisons to canons of ethics in the existing forensic organizations and in other fields, with possible mechanisms for enforcement of standards presented. The unrealistic expectations of the public may be at least partially responsible for the present intense interest in the field. Recognition of ethical concerns by those in the field and vehicles for whistle-blowing to bring unacceptable behaviors to an end are addressed. Potential outcomes of unethical behavior, especially in the forensic sciences, are presented in a series of case studies.

In the final analysis, all forensic practitioners should remain keenly aware of the inherent ethical dilemmas in the nature of the work and should maintain the highest standards of personal and professional conduct. Transgressions sully the entire field and should not be tolerated. The first step involves knowing the basics and where dangers might lie. This workshop intends to present such a primer.

Ethics, Whistle-Blower, Dilemmas

W7 Preparation and Strategic Planning for Accreditation of Forensic Laboratories Based on the ISO/IEC 17025 International Standard

Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Laurel J. Farrell, BA*, 2935 Spinnaker Place, Longmont, CO 80503; Terry Mills, MS*, 5360 Galberry Lane, Gulf Breeze, FL 32563; Sudhir K. Sinha, PhD*, InnoGenomics Technologies, LLC, 134 LaSalle Street, New Orleans, LA 70112; Marc A. LeBeau, PhD*, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Anja Einseln, MS*, American Society of Crime Directors Laboratory Accreditation Board, 139 J Technology Drive, Garner, NC 27529*

The goal of this workshop is to provide attendees with a general overview of the recourses to meet ISO/IEC 17025 requirements and explain how they may be applied in the context of forensic laboratories to include medical examiner laboratories. After attending the workshop the participants will understand the accreditation process as well as the general requirements to prepare for ISO/IEC 17025 accreditation of forensic laboratories.

This presentation will impact the forensic science community by providing an overview of the accreditation of a multi-discipline forensic laboratory based on ISO/IEC 17025. The workshop is geared towards managers and analysts of international forensic laboratories with little or no exposure to the accreditation process. This workshop will cover definitions of common quality assurance terms, the accreditation process, various accrediting bodies, and the general ISO/IEC 17025 and ILAC G-19 guidelines for forensic laboratories. The workshop will provide realistic expectations of what is required to achieve accreditation and provide an achievable roadmap. The workshop will allow international forensic laboratories to create a strategic plan and timetable to achieve accreditation based on the ISO/IEC 17025 Standard.

Laboratory accreditation is a tool used to evaluate the general competence of a laboratory, and as such, is increasingly expected by clients of forensic and medical examiner laboratories and by the courts. The number of states in the United States and countries internationally mandating laboratory accreditation is growing. The value of accreditation increases in the investigation of international crimes when the accreditation program is based on an internationally recognized standard. Often evidence analyzed by forensic laboratories is at the center of multi-country investigations involving drug trafficking, cyber-crime, identity theft, corruption, terrorism, human trafficking, and other transnational crimes. Multi-country investigations and prosecutions require that the criminal justice systems in one country can use and trust forensic laboratory reports issued by laboratories in other countries. The concept of and mechanism for international uniformity, consistency, and competence of laboratories

through Regional Multi-Lateral Recognition Arrangements and the International Laboratory Accreditation Cooperation (ILAC) Mutual Recognition Arrangements will be explained including many of the acronyms and buzz words in the accreditation world (ISO, ILAC, IAAC, APLAC, AB, CAB, regional cooperations, MRA, and MLA to name a few).

The International Organization for Standardization has thousands of standards that are used worldwide. The standard ISO/IEC 17025:2005 General requirements for the competence of testing and calibration laboratories is the ISO standard currently in wide use for forensic laboratories. How this standard is applied to the accreditation of forensic laboratories will be covered. The workshop will include a general overview of the Management and Technical Requirements sections of ISO/IEC 17025:2005 covering the main issues of each section.

ISO/IEC 17025:2005 covers general concepts that have been proven to provide a sound foundation for effective organizations performing testing and calibrations; however, ISO/IEC 17025:2005 is not specific to forensic science. ILAC's Guidelines for Forensic Science Laboratories (ILAC G19), is an example of an amplification document for forensic laboratories, and will be reviewed to demonstrate the relationship between an ISO standard and an amplification document.

Following the general overview, detailed presentations will be provided on Document Control, Traceability, Measurement Uncertainty, and Internal Audits.

Document Control: The requirements for document control are an excellent area to begin with if a laboratory is just beginning to prepare for accreditation. Specific requirements and strategies for compliance will be provided.

Traceability and Measurement Uncertainty: These topics are new to many in forensic science and specifically to the area of toxicology. Establishing traceability has a significant impact on the quality of laboratory results and measurement uncertainty provides a mechanism to compare test or calibration results between laboratories. Specific applications will be provided in the area of toxicology.

Internal audits are a requirement in ISO/IEC 17025:2005; however, internal audits are also a useful tool in preparing your laboratory for accreditation. How to plan and conduct global, vertical, and horizontal audits will be covered.

Months have been spent preparing for ISO/IEC based assessment and now it is time to submit the application to an accrediting body. Understanding the assessment process minimizes the fear associated with an external assessment. The workshop will step through the process from application through accreditation being granted. The development of the assessment plan will be covered. The methods used by assessors to document conformance with requirements will be presented. These will include document review, case record review, observation of testing or calibration activities, and interviews of laboratory personnel. The general process for remediation of findings of non-conformance will be provided. In addition, tips and techniques for making this process as easy as it can be will be provided.

The workshop will conclude with discussion of the most common deficiencies found during accreditation assessments of various forensic testing laboratories.

This workshop will provide valuable practical guidance to national and international forensic laboratories working towards and maintaining accreditation based on the ISO/IEC 17025:2005 standard.

ISO/IEC 17025, Accreditation, Requirements

W8 Examination and Analysis of Explosives and Device Construction/Components

Chris E. Taylor, BS, United States Army Criminal Investigation Lab, 4930 North 31st Street, Forest Park, GA 30297-5205; Thomas J. Hopen, MS*, Alcohol Tobacco Firearms Forensic Science Lab, 2600 Century Parkway, NE, Suite 400, Atlanta, GA 30345; Jesse Brown, BS*, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Melinda K. McPherson, PhD*, University of Missouri, Columbia, MO; Andrew M. Bowen, MS*, Stoney Forensic, Incorporated, 14101-G Willard Road, Chantilly, VA 20151; William B. Bodrey, Jr., BS*, Gerogia Bureau of Investigation, 3121 Pathersville Road, Decatur, GA 30034; Alan Higgins*, NEK Advanced Securities Group, 110 South Sierre Madre, Colorado Springs, CO 80903; and David A. Green, BS*, Lake County Crime Lab, 235 Fairgrounds Road, Painesville, OH 44077*

After attending this presentation, attendees will be familiar with forensic explosive analysis, microscopical analysis, instrumental analysis, and sample preparation techniques. The attendees will also become familiar with the investigative leads generated by the characteristics of and components used in a device, its container housing, and its firing train.

This presentation will impact the forensic science community by providing an understanding of the principles and practices of explosive material identification, explosive device construction, component characterization, and report writing. This training will provide exposure to a variety of experts and testing approaches that can be utilized in local, state, and federal laboratories.

The increase of domestic and foreign terrorist activities has brought awareness to explosive analysis in local, state, and federal forensic science service providers. From offering general awareness of materials to investigators and first responders to laboratory analysis of explosives, explosive residues, and device components, analysts in this specialized field continue to work together to share information and intelligence. This networking is valuable for sourcing materials and identifying domestic and foreign terrorists, potentially leading to their arrest or capture. Although national and international agencies are involved in this type of work, this workshop will focus on the forensic science practitioner and training in the forensic science testing of explosive materials and device construction/components.

The workshop will provide the foundational knowledge of explosive terms, types of explosions, specific types of explosive compounds and their characteristics. The workshop will present the attendees with an understanding of common approaches to the examination and analysis of explosive residues and materials. The ensuing presentations and activities over the two days will cover physical examinations and chemical analyses, tips on sample isolation and preparation, improvised explosive devices (IEDs), low explosives, high explosives, and homemade explosives (HME's). Microscopical examination and preparation techniques will be enhanced with hands-on exercises. Workshop attendees will have opportunities to reconstruct devices from found evidence and debris. Faculty presenters will discuss specific cases and offer their conclusions. The panel and participants will conclude this session with discussions on appropriate wording and report writing guidelines that will reflect an understanding in the criminal justice, forensic science, and judicial communities.

In addition to the foundational knowledge, the workshop will provide a short review of explosive blast physics (thermal effects, pressure wave, etc.), the types of explosions followed by the types of explosives (primary, high, and low). Individual compounds of each type will be reviewed including their brief history, development, and modern usage. Explosive materials such as black powder, black powder substitutes, flash powders, and smokeless powders will be examined and characterized as a part of a hands-on exercise. The high explosives will focus on commonly seen compounds such as TNT, C-4, and PETN. Plastic bonded explosives, emulsions and modern blasting agents will also be covered. Analytical

approaches will be discussed and the instrumental techniques utilized such as microscopy, FT-IR, GC/MS, and X-ray techniques.

Microscopical analyses have been intimately tied to forensic science since its inception. However, some modern trends have resulted in moving away from the microscope in explosives analysis. This session will focus on the extreme power the microscope can offer the examiner. From searching debris for small pieces of fragmentation and particles to microcrystalline techniques that can identify specific explosive compounds, the microscope is an invaluable tool in the examiner's toolbox.

In the last few years, new trends in explosives have resulted in an increase in the number of homemade explosives (HMEs). This session will familiarize attendees with the current analytical practices related to HMEs. How these devices are developed and used, the types of explosive materials in them, and the chemistry behind their devastating effects will be presented. Lastly, the workshop will offer a brief insight into potential future testing methods to include instrumentation and innovations in explosives detection and analysis that could impact this field.

At the conclusion of this workshop, the attendees will have the knowledge, understand techniques required to pursue the analysis of explosives, and understand of the importance of the materials used in the construction of explosive devices. Participants will be able to utilize the principles taught in the lectures and offered in the hands-on exercises to hone their skills and bring these resources back to their organizations thereby improving on their existing explosive analysis programs.

Explosives, HME, IED

W9 What Did You Just Step In?! Use of Forensic Soil Examinations to Find Out

Kim E. Mooney, PhD, United States Army Criminal Investigation Laboratory, Trace Evidence Branch, 4930 North 31st Street, Building 925, Forest Park, GA 30253; David B. Flohr, MSFS*, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Andrew M. Bowen, MS*, Stoney Forensic, Incorporated, 14101-G Willard Road, Chantilly, VA 20151; David A. Stoney, PhD*, Stoney Forensic, Incorporated, 6405 Woodland Run Court, Clifton, VA 20124; Maureen Bottrell, MS*, Federal Bureau of Investigation, Trace Evidence Unit, Quantico, VA; Thomas J. Hopen, MS*, Alcohol Tobacco Firearms Forensic Science Lab, 2600 Century Parkway, NE, Suite 400, Atlanta, GA 30345; Raymond C. Murray, PhD*, University of Montana, 106 Ironwood Place, Missoula, MT 59803; Christopher S. Palenik, PhD*, and Skip Palenik, BS*, Microtrace, 790 Fletcher Drive, Suite 106, Elgin, IL 60123-4755; William Schneck, MS*, Washington State Patrol, Crime Laboratory, 580 West 7th Street, Cheney, WA 99004; and Marianne Stam, MS*, California Department of Justice, Riverside Criminalistics Lab, 7425 Mission Boulevard, Riverside, CA 92509*

After attending this presentation, attendees will be equipped with sufficient knowledge of soil analysis to either initiate this type of service in their laboratory or suggest improvements to their existing methods for soil analysis. Situational awareness of the need to utilize the analytical services of an outside laboratory for select soil comparisons will also be gained.

This presentation will impact the forensic science community by providing education to those desiring training in forensic soil examinations, as well serving as a reminder about a service that more laboratories may wish to add to their suite of analytical services. This workshop will help to make soil analysis more accessible to the forensic community by demonstrating the limited instrumentation necessary to make this service available. Additionally, the workshop will provide a forum for examiners to discuss the differences in existing techniques, the need for standardization, and the impact of accreditation.

A quick search of the internet for "soil analysis laboratories in the United States" returns a long list of laboratories providing soil analysis for agricultural concerns. However, laboratories providing comparative soil examinations for forensic applications are rare. Though soil analysis is a well-established field of forensic examination, the air of mystery and difficulty has made the "forensic soil examiner" a rare breed.

Proficiency in the field is only maintained through constant practice and continuing education; however, training courses in the discipline are infrequently offered and often cancelled due to a lack of attendees. Laboratories often cite the lack of instrumentation, time, or personnel as the reasons for not providing this service. Much of this can be overcome with proper and efficient training; for the underpinning work in such examinations can be performed without high-end instrumentation. In fact, much of the comparative work can be performed with instrumentation that most forensic laboratories already have available (i.e., polarized light microscopes, automated scanning electron microscope/energy dispersive spectrometer, Fourier transform infrared spectrometers, and x-ray fluorescence spectrometers).

During this two-day workshop, attendees will gain insight into the geological and historical foundations for soil examinations and their practical applications in forensic science. They will gain experience in the application of a variety of laboratory techniques commonly used for forensic soil examinations. Lectures and "hands-on" sessions will include, but are not limited to, the following: the historical basis for forensic soil examinations; geology as related to the formation of soil; soil collection methods; comparative color and texture analyses; the preparation and separation of soil samples for the isolation of the botanical, anthropogenic (man-made), clay, and mineral components of soil; the application of x-ray diffraction and Fourier transform infrared spectroscopy for the identification and comparison of clays; fractionation of the heavy and light mineral components for identification purposes; mounting methods for identification of soil minerals by polarized light microscopy; methods for percent composition comparisons of the heavy and light mineral content; the utilization of automated scanning electron microscopy-energy dispersive x-ray analysis for automated mineral analysis; determination of provenance based upon the sum total of the components identified in soil; report writing verbiage; and significance evaluations.

Attendees will gain, at a minimum, a theoretical and practical foundation for incorporating soil analyses into their laboratory's suite of analytical services. They will also obtain the skills necessary to detect, collect, and preserve soil evidence and to perform minimal comparisons, thereby enabling preliminary evaluation of such evidence for use in their own cases.

Soil, Mineral Analysis, Microscopy

W10 Drug Enforcement Administration U.S. Customs and Border Protection Forensic Mobile Device Workshop

Rhesa G. Gilliland, MS, Drug Enforcement Administration, Digital Evidence Laboratory, 10555 Furnace Road, Lorton, VA 22079; Samuel I. Brothers, BBA*, United States Customs & Border Protection, 7501 Boston Boulevard, Room 113, Springfield, VA 20598; and Lam D. Nguyen, MS*, and Scott D. Roffman, MS*, Drug Enforcement Administration, Digital Evidence Laboratory, 10555 Furnace Road, Lorton, VA 22079*

The goal of the presentation is to assist attendees in the examination of mobile devices in a forensically sound manner through discussion of relevant topics: (1) handling and preservation of mobile devices: attendees will understand proper procedures for collecting and handling mobile devices so as to preserve data for forensic examination; (2) validation of mobile device examination methods: this discussion will present a proposed framework for validating mobile device examination methods and software tools in light of agency accreditation requirements; and, (3) by learning to leverage available resources against their limitations, attendees will be able to relate the *Daubert* standards to the challenges specific to codifying methodologies in an ever-evolving discipline.

This presentation will impact the forensic science community by providing sound strategies and methodologies that can be directly applied to the examination of mobile devices and further the development of the digital forensic discipline.

The following topics will be covered: handling and preservation of mobile devices from seizure to analysis and methods validation with a proposed framework for validating mobile forensic methods and tools.

Attendees will: (1) understand the importance and applicability of the *Daubert* Standards in mobile forensic methods; (2) develop and apply an organizational methodology for software tools validation within the framework of accreditation; and, (3) be able to leverage available resources while understanding their limitations and understand the challenges of codifying methodologies in an ever-evolving discipline.

A review of all cell phone forensic tools and the Cell Phone and GPS Forensic Tool Classification System will be covered in depth. Our world has become saturated with inexpensive digital devices. The ubiquity of these devices has changed the way we do everything, from staying in touch with friends on our smartphones to finding the nearest gas station with GPS technology. Criminals also use these devices to aid in the commission of crimes. GPS devices are used for human and narcotics smuggling, while cell phones are used to deliver text messages coordinating the next terrorist attack. Most electronic devices themselves contain a wealth of information and intelligence for investigators, though the field of digital device forensics is still in its infancy. There is a need for a common framework to classify the plethora of tools released into the commercial marketplace in the last five years. Given the exaggerated claims of software manufacturers, the field of mobile forensics has long since clamored for an understanding of not only how these tools work, but when they should be used. Attendees will be able to categorize any mobile device acquisition tool within a classification system. In addition, an overview of many commercial tools for cell phone data extraction currently available will be discussed. This presentation will provide a common framework for the digital device data extraction tool classification system for the entire digital forensics community.

The Apple iPhone®, utilizes SQLite Databases to store user data and applications that have been installed on the device. A digital forensic examiner trying to access this information through traditional means may miss large amounts of relevant data still present within the database. Because of the way inactive data is marked for deletion, it may be impossible to extract this data through typical database queries. Fragmented sections of these databases may also be found in unused space on the device. While the complete file is not readable by traditional methods, forensic recovery may still be possible. The key to gaining access to this information is to understand how the data is organized within the database structure and the manner in which it has been stored and encoded. Attendees will gain an understanding of how to obtain digital evidence from SQLite databases. Attendees will also gain an understanding of how this information is stored, how active and deleted content within these databases can be extracted, and how to decode the extracted information. An explanation of SQLite data storage structure, encoded data, the use of regular expressions to search for and identify records, and the ability to decode the stored values within the recovered records will also be presented. The storage of call history and text messages utilized by Apple's iOS® on the iPhone® will be specifically addressed and used as an example for how to identify and decode deleted records.

Mobile Forensicx, Apple iOS®, Validation

W11 Digital Photography for Forensic Document Examiners

David Witzke, BA, Foray Technologies, 3911 5th Avenue, Suite 300, San Diego, CA 92103; Ted M. Burkes, BS, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Room 2158, Quantico, VA 22135; and Joseph L. Parker, MSA, 518 Pinegate Road, Peachtree City, GA 30269*

After attending this presentation, attendees will be able to: (1) successfully demonstrate the effective documentation of forensic digital capture techniques as well as explain how digital technologies are used in evidentiary photography processes; (2) successfully complete a hands-on exercise demonstrating the comparison of image resolution and screen (display) resolution, demonstrating the artifacts caused by improper resolution settings and parameters; and (3) successfully complete a hands-on exercise demonstrating the artifacts caused by improper image processing techniques (such as rotating an image, compressing an image, printing an image, etc.). Participant achievement of the training objectives will be evaluated by observing participant behavior in the classroom and assessment of demonstrated practical skills by the instructor.

This presentation will impact the forensic science community by addressing the need for knowledge about the legal ramifications of digital evidentiary photography and best practices for digital evidentiary photography to include acceptable file formats and standards for capturing, storing, printing, transferring, and preserving digital/digitized evidence. It will also provide participants with the acceptable methods and techniques for comparing imaging technologies. The activities will include instructor-led demonstrations and hands-on exercises using image-editing software on the laptop computers participants bring for use in the course.

The Digital Photography for Forensic Document Examiners Training Program is intended for individuals working in a law enforcement field who have limited knowledge and experience using digital technologies in a forensic environment. Upon completion of this program, attendees will have a basic understanding of forensic digital imaging concepts and how various image capture techniques can aid in their investigative process.

It is recommended that attendees taking part in this course have a basic understanding of the Microsoft Windows XP operating system. In addition, it is recommended that all class participants be actively involved in a law enforcement discipline that uses digital imaging technologies.

This is a one-day training program that includes both lecture and hands-on training including note taking. Course instruction also includes a review of best practices and procedures as well as a comprehensive discussion and application of digital imaging techniques.

Digital Photography, Questioned Documents, Digital Imaging

W12 Humanitarian Forensic Science: The Forensic Investigation of Human Remains From Armed Conflicts and Catastrophes

Morris V. Tidball-Binz, MD, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND; Duarte N.P. Vieira, PhD, MD*, National Institute of Forensic Medicine, Lg. da Sé Nova Coimbra, Coimbra, 3000-213, PORTUGAL; Luis Fondebrider*, Argentine Forensic Anthropology Team (EAAF), Rivadavia 2443, 2do piso, dpto.3 y 4, (1034) Capital Federal, Buenos Aires, ARGENTINA; Ute Hofmeister, MA*, International Committee of the Red Cross, Calle 76 No 10-02, Bogota, COLOMBIA; Paul S. Sledzik, MS*, National Transportation Safety Board, Transportation Disaster Assistance Division, 490 L'Enfant Plaza East, SW, Washington, DC 20594; Mercedes Salado Puerto, PhD*, Argentine Forensic Anthropology Team, Av. Rivadavia 2443, Piso 2 Dep.4, Buenos Aire, 1034, ARGENTINA; William Goodwin, PhD*, School of Forensic Medicine and Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM; Shuala M. Drawdy, MA*, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND; Thomas D. Holland, PhD*, Department of Defense JPAC, Central ID Lab, 310 Worchester Avenue, Hickam AFB, HI 96853; Christophe Girod, BA*, Committee on Missing Persons in Cyprus, Karditsis 3, Ayios Andreas, Nicosia, 1100, CYPRUS; Nizam Peerwani, MD*, Office of the Chief Medical Examiner, Tarrant County, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919; and Michael S. Pollanen, MD*, Office of the Chief Coroner, 26 Grenville Street, Toronto, M7A 2G9, CANADA*

After attending this presentation, attendees will become familiar with the main practical considerations for large-scale forensic investigations for the search of missing persons from armed conflicts and catastrophes.

This presentation will impact the forensic science community by exploring the application of forensic science in humanitarian contexts and outlining some of the unique challenges posed to the wider forensic community by investigations into persons gone missing. It will also present some of the solutions identified for assisting forensic practitioners, institutions, and service providers involved in these investigations. A multidisciplinary panel of international experts will share their experiences, lessons learned and recommendations regarding practical considerations for large-scale forensic investigations in the search for missing persons from armed conflicts and catastrophes.

The humanitarian scope of forensic investigations applied in the search of missing persons world-wide requires awareness and consideration of factors rarely encountered in the domestic setting. International public law provisions must be well understood and socio-political factors impacting investigations must be taken into consideration. Forensic practitioners must be aware of the health and safety issues associated with working in foreign environments, as well as unique health and safety precautions necessary in potentially dangerous contexts. The psycho-social needs of the families related to the investigation of victims of conflict should be addressed, including the expectations of the bereaved. The selection and integration of identification methods should be planned with care and should be suitable to the specific requirements of the investigation, including the biological profile-related characteristics of the victims and the needs of the investigation. Resources for large-scale investigations, which are usually limited, should be appropriately managed and suitable for logistically-challenged settings while maintaining quality assurance and ethical conduct. Data gathered during investigative processes must be properly managed, taking into consideration chain-of-custody and confidentiality of the data. It must be decided in advance to whom the data will be shared with and under what circumstances. Utilization of local expertise and resources should be balanced against the needs for confidentiality, neutrality, and impartiality in the investigation at the same time recognizing that long-term investigation and identification processes require local involvement to ensure sustainability. Finally, specific ethical dilemmas related to forensic work and management of the dead in diverse contexts must be addressed, taking into consideration all other planning challenges and constraints. For example, political or prosecutorial pressures may place emphasis on investigative processes for judicial purposes leaving reduced resources for identification efforts. Likewise, reduced resources may force investigators to selectively target specific graves for investigation while leaving other known gravesites untouched, or necessitate the recovery of only a sample of remains within a grave.

As forensic practitioners increasingly become involved in international humanitarian operations, they must adapt their working methods to the specific needs of the investigation, which may differ from the domestic setting. In addition, they must integrate their technical skills into multi-disciplinary teams in order to address the various needs of the investigation and the victims to which the investigations relate. Therefore, it is imperative that practitioners working in large-scale forensic investigations for the search of missing persons from armed conflicts and catastrophes become familiar with the unique challenges that these operations may pose.

Humanitarian, Conflicts, Catastrophes

W13 Estimating Uncertainty in Weights: Hands-On Workshop Using SWGDRUG Document SD3

Suzanne Bell, PhD, West Virginia University, 1600 University Avenue, Oglebay Hall, Room 208, Morgantown, WV 26506-6121; Sandra E. Rodriguez-Cruz, PhD*, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081; Linda C. Jackson, MS*, Department of Forensic Science, 700 North 5th Street, Richmond, VA 23219; and Scott R. Oulton, BS*, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

After attending this presentation, attendees will be able to: (1) reference the SWGDRUG website and all associated resources; (2) understand the concept of uncertainty estimation in the seized drug context; (3) evaluate their weighing procedures and protocols using several different uncertainty estimation tools; (4) design a simple uncertainty budget using Excel; (5) design an uncertainty budget utilizing laboratory control charts; and (6) defend a reasonable uncertainty estimation before their peers and before triers of fact.

This presentation will impact the forensic science community by showing how estimation of uncertainty is a key element of any quantitative data and should be estimated when quantitative data is obtained. The 2009 National Academy of Sciences Report emphasized the need for estimation of uncertainty and accredited laboratories will soon face issues of uncertainty estimation and reporting. This workshop will assist forensic scientists in developing reasonable and defensible uncertainty estimations for an important category of quantitative data.

This workshop will include a hands-on tutorial designed to assist forensic analysts in estimating the uncertainty of weights obtained in a seized drug analysis. Although the target audience is drug analysts, anyone interested in uncertainty estimation will find this workshop useful and valuable. The workshop will be taught at an introductory level. No chemical knowledge is required or assumed. The workshop is built around the Scientific Working Group for Seized Drug Analysis (SWGDRUG, *www.swgdrug.org)* Supplemental Document SD-3, which presents several examples for making reasonable and defensible uncertainty estimates for weight measurements.

Uncertainty is a fundamental part of any quantitative measurement. Uncertainty is not the same thing as error, and recording data with an estimation of uncertainty does not imply that data is somehow suspect. The opposite is true; a quantitative value such as a weight of a drug exhibit, along with an uncertainty estimate, is more valuable in many cases, both to

the laboratory and to the customers it serves. The exercise of estimating the uncertainty associated with an instrument or procedure assists laboratories in improving practices and facilitating more effective and efficient method validation policies. The workshop will present examples of how these tasks can work together to improve laboratory operation.

The first part of the workshop program will include a general introduction to SWGDRUG Recommendations - Part IV C (Quality Assurance/Uncertainty) and Supplemental Document SD-3, followed by a discussion on the basic principles of uncertainty estimation. Statistical and metrological resources will be presented and key statistical concepts will be reviewed. Attendees will also receive useful information related to the selection, requirements, operation, calibration, and maintenance of laboratory balances.

The second part of the workshop will be dedicated to discussions of SWGDRUG Supplemental Document SD-3 (Measurement Uncertainty for Weight Determinations in Seized Drug Analysis). A copy of this document will be provided to all attendees and its purpose and background, within the scope of SWGDRUG's mission, will be discussed. This document contains specific examples of how to calculate the uncertainty associated with weight measurements performed in a laboratory. The basis, assumptions, and background behind each one of these examples will be presented in a format that provides for active discussion with the workshop audience. The workshop presenters will also provide assistance and suggestions on how to present and defend uncertainty estimates to peers as well as legal professionals.

The third part of the workshop will be dedicated to open discussions. Attendees are strongly encouraged to bring examples of specific laboratory models for presentation during this section of the workshop. Examples will be discussed and assistance provided on developing uncertainty budgets. Attendees are also welcomed to bring a laptop computer and data from their laboratory for use during the hands-on portion of the workshop.

Uncertainty Estimation, Seized Drugs, SWGDRUG

W14 Using Pharmacokinetics to Analyze Forensic Toxicology Cases

David M. Benjamin, PhD, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918; Dwain C. Fuller, BS*, Veterans Affairs North Texas Health Care System, Toxicology-B113, 4500 South Lancaster Road, Dallas, TX 75216; Graham R. Jones, PhD*, Medical Examiner's Office, 7007-116 Street, NW, Edmonton, AB T6H 5R8, CANADA; W. and Lee Hearn, PhD*, Miami-Dade County, Medical Examiner's Office, #1 on Bob Hope Road, Miami, FL 33136-1133*

After attending this presentation, attendees will: (1) summarize the basic physiology, pharmacology, and pharmacokinetics required to interpret drug blood and urine levels which have been obtained both before and after death; (2) present confounding issues that limit the interpretation of many quantitative blood test results such as postmortem redistribution, and pharmacokinetics in children; and (3) review approaches to analyzing the complicated Forensic Toxicology case.

This presentation will impact the forensic science community by showing how forensic toxicologists, pathologists, and criminalists are often presented with the results of a single blood test or a single urine test and asked, "Did it kill him/her?", "Was she/he impaired?", and/or "Did it injure him/her?" Such questions are very difficult to answer on the strength of one test result. The workshop begins with a review of the physiology, pharmacology, and pharmacokinetics of drugs, followed by presentations involving postmortem redistribution, postmortem pharmacokinetics, tissue distribution in the ante- and postmortem settings, and the significance of using various sampling sites for blood.

Pharmacokinetics is the study of the absorption, distribution, metabolism, and excretion of drugs. In many instances, determination of the cause and manner of death may be elucidated by analyzing the correlation of the drug's pharmacokinetics and the drug's effect (pharmacodynamics). Forensic toxicologists, pathologists, and criminalists are often presented with the results of a single blood test or a single urine test and asked, "Did it injure or kill him/her?", or "Was she/he impaired?" These questions are very difficult to answer on the strength of one test result. In many instances, the investigating forensic scientist would like to develop an adequate history regarding the time the last dose was taken, the amount, the route of administration, and whether the final dose was a single acute OD, a large OD, or an OD that occurred due to drug accumulation over time, but access to those data are unavailable. In addition, genetic factors regulating drug metabolism, drug interactions, and differences in a drug's pharmacokinetics during toxic dosing (toxicokinetics) impact the analysis of the drug's blood levels and toxic effects.

Though many cases involve the analysis of blood samples obtained from living subjects, in some cases, the blood samples are obtained after death. In the postmortem state, multiple samples obtained from different body sites (e.g., femoral, iliac, subclavian, and cardiac) often show different quantitative results. This may be due to partial absorption from the gastrointestinal tract, incomplete distribution of the drug after ingestion but prior to death, or postmortem redistribution. Cardiac blood is the least reliable. There are four chambers of the heart, and on analysis, all may give different results. Results of blood samples taken from the left side of the heart are less reliable than results obtained from blood samples taken from the right side of the heart because the left side fills from the pulmonary vein (and the lungs are known to accumulate drugs), thus causing the blood to contain higher levels of drug than found in the right heart, which fills from the systemic circulation (vena cavae).

When blood samples have been obtained after death or at autopsy, changes in postmortem redistribution, putrefaction, bacterial contamination, and postmortem production of ethanol may confound the interpretation of the results, unless blood sampling from various body sites and tissues was carried out. In the postmortem state, determining the cause and manner of death may be quite difficult. Moreover, in the postmortem setting, the pharmacokinetics of the drug is altered, as is the volume of distribution (Vd). Using PK and Vd data from antemortem studies and applying them to postmortem data, or using Vd data from adults and applying them to children may lead to major errors in the interpretation of the data and incorrect conclusions about the cause of impairment or death. Attendees will learn how to better apply the principles of PK in their cases, and raise the level of the application of the principles of PK in their practice of forensic toxicology.

Pharmacokinetics, Postmortem Redistribution, Forensic Toxicology

W15 Hell on Earth — Just Another Day at Work: An Overview of the Tri-State Crematory Catastrophe

Kris L. Sperry, MD, Georgia Bureau of Investigation, 3121 Panthersville Road, PO Box 370808, Decatur, GA 30037-0808; J.C. Upshaw Downs, MD*, Georgia Bureau of Investigation Medical Examiner's Office, 925 A Mohawk Drive, Savannah, GA 31419; Mark A. Koponen, MD, University of North Dakota, Department of Pathology, 501 North Columbia Road, Mailstop 9037, Grand Forks, ND 58282-9037; and Greg Ramey, MA*, Georgia Bureau of Investigation, 3121 Panthersville Road, Decatur, GA 30034*

After attending this presentation, attendees will be able to understand how to approach a mass disaster created when large numbers of bodies are not cremated in accordance with standard funeral practice. Participants will also gain an understanding of how multiple agencies interact in dealing with a complex mass disaster. Approaches to public and media involvement will also be discussed.

This presentation will impact the forensic science community by showing lessons learned from a unique incident which created social havoc

throughout Georgia, Tennessee, and Alabama. The impact was felt among thousands of individuals who had sent the bodies of their loved ones to be cremated. This incident also captured national and international attention in the forensic and non-forensic communities.

On the otherwise typical afternoon of February 15, 2002, during the course of the AAFS meeting in Atlanta, GA, a call came in that changed an otherwise beautiful and mild, deep-South winter's day into one of the singularly most macabre events ever imagined. A decade later, the memories are vivid.

Acting on an anonymous call, investigators responded to a scene in the Noble Community of rural Walker County, GA, just 100 miles from Atlanta, the heart of the "new south." A passerby had discovered what were believed to be human remains in a heavily wooded area, adjacent to several residences and the family-owned Tri-State Crematory, serving northeast Alabama, south central Tennessee, and northwest Georgia.

Investigators arrived to find a scene almost defying description – dozens of bodies, in various stages of decomposition, were laid out in a garage. As investigators recovered from the initial shock and continued exploring the property, dozens of bodies, then hundreds were discovered. Eventually, bodies were found strewn in the woods, comingled in pits, comingled in casket vaults, and within several buildings and vehicles on the property. The crematory owner had maintained essentially no records regarding his supposed cremation practices. A full-scale mass death scene investigation ensued, requiring the combined resources of local, state, and national agencies. The National Disaster Mortuary Response Team (D-MORT) was deployed to assist with the processing the unidentified bodies and partial sets of remains. It was eventually determined to represent remains of some 334 individuals. The recovery process alone lasted for three weeks. Eventually, this case became the largest criminal investigation in the history of the state of Georgia, involving over 500 individuals from more than 55 local, state, and federal agencies in the recovery and identification of these remains. Successful and continuous multi-jurisdictional agency interaction was essential to the resolution of the matter, particularly in handling a problem that literally grew with each passing day.

The scale of the recovery and identification process was hindered by multiple factors, including: location, multiple clusters of mini-scenes with varied conditions, lack of defined scene boundaries, unknown and varied postmortem interval of individual cases, and unknown numbers of remains. All of these factors, combined with the intense international interest in the case led to one of the most unusual death investigation cases in the annals of death investigation. This overview touches on the various aspects of the case including initial response, scene assessment and triage, body recovery, identification, family interaction, media interaction, and criminal investigation.

Families and media: The macabre nature of the event resulted in immediate and eventually world-wide interest in the case. Given the intense interest in the case, media interaction became an important factor. A balance had to be struck between the families' rights to be kept informed and public information. Daily interactions included meetings with grieving family members and the national and international press. Dignitaries concerned enough to visit the site included the state's Governor and both U.S. Senators. Superimposed was a criminal investigation, involving some 700 charges and three states. The balance was struck to inform families of progress first and to have one public face associated with the media. The importance of a "family-first" philosophy facilitated a rapid and successful resolution.

Initial response/scene: The challenging nature of the sheer volume (literally hundreds of bodies, including many co-mingled and partial remains) was compounded by the ill-defined crime scene area and the lack of any kind of tentative manifest to facilitate with recovering and processing of the remains. The key to a successful outcome in such a massive undertaking is effective assessment and planning.

Body recovery: The archaeology of body recovery from mass graves and pits, combined with the need for preservation of evidence for potential criminal prosecution, is a fortunately rare occurrence. The early recognition of the nature and scope of the case allowed strategic placement of sufficient resources in a timely manner. The latter, combined with a strong team concept, kept morale high and expedited the initial processing of remains.

Identification: The unique nature of such an aggregate of an unknown number of unidentified partial and complete remains raging from minimally decomposed to skeletonized was compounded by the lack of knowledge regarding numbers of bodies present. Identification concerns were paramount to the families, and as such, rapid protocols for body identification were required. A balance had to be struck between speed and science, with accuracy unquestioned. The identification techniques employed and success/concerns is summarized. The identification process included collection of thousands of DNA samples from family members and lasted almost two years, although an internet inventory of remains with possible identifiers still results in occasional requests for possible identification.

Investigation/Prosecution: The ultimate cost of this man-made disaster to the State of Georgia was approximately 10 million dollars and generated over 100,000 pages of documentation. The perpetrator was charged with 787 counts, including theft by deception, abuse of a corpse, fraud, and giving false statements. He allegedly faced the potential of over 8,000 years in prison if convicted. He eventually pled guilty and was sentenced to twelve years, with credit for time served. Approximately 1,700 family members whose loved ones' bodies had been abandoned joined a class action suit. Settlements reached totaled well over $100 million but were later significantly reduced to approximately $54 million

In the final analysis, this case was about hundreds of families whose loved ones' bodies were left to decompose in the foothills of North Georgia. The overall investigation and close teamwork between the law enforcement, medical examiner, anthropologist, and district attorney resulted in a guilty plea in one of the most bizarre criminal cases of all time and a rapid resolution to the ubiquitous civil litigations.

Motive: "To those of you who may have come here today looking for answers, I cannot give you." said by Ray Brent Marsh upon entering his guilty plea. His attorneys would later allege that the admitted perpetrator of the crime resulting in largest investigation in the history of the state was a victim of mercury poisoning, allegedly from exposure caused by the dental amalgams from cremated bodies.

Crematory, Media, Identification

W16 Applications of 2D and 3D Geometric Morphometrics in Forensic Comparisons

Victor W. Weedn, MD, JD, Maryland State, Office of the Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223; Howard A. Harris, PhD, JD, University of New Haven, Forensic Science Program, 300 Boston Post Road, West Haven, CT 06516; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Mary A. Bush, DDS*, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; H. David Sheets, PhD*, Canisius College, Department of Physics, 2001 Main Street, Buffalo, NY 14208; Alain Beauchamp, PhD*, Forensic Technology WAI Inc., 5757 Davendish Boulevard, Suite 200, Cote St – Luc, QC CANADA; William R. Oliver, MD*, Brody School of Medicine, East Carolina University, Brody Medical Sciences Building, Greenville, NC 27834; Jurrien Bijhold, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, 2497GB, NETHERLANDS; and Nicholas D. Petraco, PhD*, 899 10th Avenue, John Jay College of Criminal Justice, Department of Science, New York, NY 10019*

The goal of this workshop is to familiarize attendees with the possibilities for morphometric comparison in both 2D and 3D formats as well as limitations and possibilities for use in forensic science are discussed.

This presentation will impact the forensic science community by showing methods that are used for pattern recognition in forensic comparison with error rates.

Last spring, the Forensic Sciences Foundation's (FSF) Theoretical Forensic Science Committee sponsored a contest. Mary Bush, DDS from the State University of New York at Buffalo was the winner of this "New Science or Technology to Forensic Science" competition.

Based on the contest, this workshop has been developed to discuss and present different aspects of morphometric comparison in forensic science, with application to odontology, footwear impressions, bullets, fingerprints, facial comparison, wound analysis, and 3D reconstruction.

This workshop will: (1) provide an overview of geometric morphometric (GM) analysis; and, (2) demonstrate the methods for evaluation, measurement, and statistical comparison of shape change/distortion of an object in question. The generation of matching criteria and error rates based on a statistical model are discussed in relation to the work of Dr. Bush. Application of GM methods to bitemarks, fingerprints, shoeprints to 3D visualization of 3D bullet comparison, medical forensics, and facial comparison will be presented. Advantages and disadvantages of the different approaches on comparison of shapes based on pattern recognition in digital images will be discussed.

A well-developed method to describe shape variation between biological specimens is geometric morphometric analysis. GM analysis involves placement of landmark points, curves, or outlines on either two- or three-dimensional images. The landmark data can be extracted and analyzed statistically as a unit. GM methods allow for a quantitative examination of shape by capturing the geometry of morphological structures of interest and preserving this information through statistical analysis. Shape information can be visualized by plotting landmark positions in Procrustes superimposition, a method of optimally matching one shape to another. This can be performed with or without scale. Procrustes distances can be used to summarize variations in populations, to express the degree of similarity of individual specimens, means of populations, or to search for matches between specimens.

Amongst the tools available for statistical analysis is principal component analysis (PCA) with which the principal variations of shape can be plotted and visualized. This allows for determination of which shape aspect is responsible for the most variation. Canonical variates analysis (CVA) can also be used to determine if shape information can distinguish between different categories of data. A range of other standard multivariate statistical methods can also be applied to shape data, allowing applications to a wide range of research questions and practical problems.

There has been much recent discussion in forensic forums concerning what constitutes a match, or what defines two objects as being indistinguishable. It might be stated that two objects are identical when differences in measured attributes fall below measurement error levels, when the differences seen are no longer distinguishable from random effects. Error rates can be established by repeated measures studies, in which the same object is measured multiple times. The Procrustes distance derived from GM analysis can be used as a quantitative descriptor of error, and can be used as a threshold value below which objects might be said to match.

Clearly measurement resolution also depends on the scale of the object being measured, and the resolution (smallest object measurable) of the means used to image the object. For example, in crime scene or accident reconstruction, the resolution required might be fractions of a meter; in a shoeprint, individualizing detail might be separated by cm, in a bitemark the achievable measurement resolution might be on a mm scale, fingerprints on a micron scale, and tool marks potentially submicron.

With these examples in mind, careful attention to the issues of magnification (scale) and resolution is of the first importance. However, GM methods can be applied regardless of scale, as long as the nature of the data is understood. At each level of scale, error rates can be established and quantified.

Using GM methods, large datasets can be statistically compared to explore the issues stated above. Ideally, quantification of the range and types of distortion produced will provide forensic practitioners with quantifiable validations of the quality of example items in the pattern evidence disciplines.

Morphometric, Pattern Recognition, Comparison

W17 Advances in Asphyxia by Strangulation for Pathologists and Anthropologists

Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, T6H 5R8, CANADA; Steven A. Symes, PhD*, Mercyhurst Archaeological Institute, Mercyhurst College, 501 East 38th, Erie, PA 16546; Joao E.S. Pinheiro, MD*, Instituto Nacional de Medicina Legal, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; and Ericka N. L'Abbe, PhD*, PO Box 5023, Pretoria, 0001, SOUTH AFRICA*

After attending this presentation, attendees will have a better understanding and knowledge of the new standardized INFOR classification of asphyxia, best practices of autopsy dissections in strangulation cases, radiology aspect of these cases, anthropology best approach, and updates on the pathophysiology.

This presentation will impact the forensic science community by informing the forensic pathologists and anthropologists of the updates on strangulation and the best practices in these cases.

The classification of asphyxia and the definitions of subtypes are far from being uniform, varying widely from one textbook to another and from one paper to the next. Unfortunately, similar research designs can lead to totally different results depending on the definitions used. Closely comparable cases are called differently by equally competent forensic pathologists/medico-legal doctors. In response to this situation, a unified system of classification was recently proposed. This new standardized classification of asphyxia, called the INFOR classification, will be presented. In the INFOR classification, asphyxia in the forensic context is divided in suffocation (subdivided in choking, smothering, and confined spaces/entrapment/vitiated atmosphere), strangulation (subdivided in hanging, ligature strangulation, and manual strangulation), positional and traumatic asphyxia, and drowning. The controversies around the term mechanical asphyxia will be discussed. Asphyxial games will be presented in relation to this new classification.

The external and internal examination findings in strangulation will be discussed. A proper neck dissection is a key element in the investigation of strangulation deaths. Despite the usefulness of x-rays and computed tomography as ancillary techniques, manual dissection of the neck structures remains the most widely used technique to assess the integrity of neck structures. There are two ways to dissect the neck: *in situ* or *ex-situ*. The *ex-situ* method follows the removal of the neck structures by cutting the muscles insertions of the base of the mouth and gently removing this group of structures from the vertebral column. This *ex-situ* method is superior to the *in-situ* method and the reasons for this will be explained. The method will be described step-by-step, with images of external and internal injuries. The common pitfalls in the interpretation of autopsy findings will be discussed: anatomical variations (e.g., triticeal cartilage), normal mobility or bending of a cartilage or join (with considerations on the rate of ossification of the hyoid and thyroid horns and the sinostosis of the horn/body joint of the hyoid), and postmortem changes.

The incidence of bone fractures in suicidal versus homicidal hangings and manual strangulation will be presented, along with the explanations for these injuries. The accuracy of anthropologist/pathologist interpretations of evidence obtained during autopsy and analysis of bones will be discussed.

The modern understanding of the pathophysiology of hanging and strangulation was significantly changed by the creation of the Working Group on Human Asphyxia in 2006. The results from this ongoing study will be presented. The study of filmed hangings and strangulation has clearly established the agonal responses in these deaths: rapid loss of consciousness (10 s ± 3 s), mild generalized convulsions (14 s ± 3 s),

decerebrate rigidity (19 s ± 5 s), beginning of deep rhythmic abdominal respiratory movements (19 s ± 5 s), decorticate rigidity (38 s ± 15 s), loss of muscle tone (1 min 17 s ± 25 s), end of deep abdominal respiratory movements (1 min 51 s ± 30 s), and last muscle movement (4 min 12 s ± 2 min 29 s). The time to irreversible damages and death in hanging and strangulation will be discussed, based on the study of non-lethal filmed events. The implication of the advances from the Working Group on Human Asphyxia on the understanding of asphyxial games will be discussed.

Asphyxia, Strangulation, Forensic

W18 Deadly by Design: Forensic Toxicology, Adverse Effects of Synthetic Cannabinoids, and Novel Designer Drugs ("Bath Salts")

Barry K. Logan, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Brianna Peterson, PhD*, Washington State Patrol, 2203 Airport Way, South, Seattle, WA 98134; Wendy R. Adams, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Kurt C. Kleinschmidt, MD*, University of Southwestern Texas Medical Center, Deprtment of Surgery, Division of Emergency Medicine/Toxicology, 5323 Harry Hines Boulevard, Dallas, TX 75390; Jillian Yeakel, MSFS*, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; Christine Murphy, MD*, Carolinas Poison Center, PO Box 32861, Charlotte, NC 28232-2861; Gregory A. Schmunk, MD*, Polk County Medical Examiner's Office, 1914 Carpenter Avenue, Des Moines, IA 50314; and Amy Miles, BS*, Wisconsin Laboratory of Hygiene, 2601 Agriculture Drive, PO Box 7996, Madison, WI 53707*

The goals of this presentation are to: (1) make the forensic science community aware of the prevalence and toxicity of the products; (2) educate forensic professionals about the challenges involved in their analysis including sample preparation and analysis; (3) familiarize forensic pathologists and toxicologists with the adverse effects of the chemicals; (4) provide reference case details of circumstances surrounding impairment and criminal acts committed under the influence of the drugs; and, (5) present evidence that the drugs can cause death.

This presentation will impact the forensic science community by increasing awareness of the latest categories of abused drugs which will require changes in current forensic practice and by providing evidence to support the scheduling and control of these dangerous new chemicals, many of which are currently available without restriction.

This program will present information regarding the various classes of synthetic drugs which have recently become popular within the recreational drug using community. Exploration of the highs associated with these drugs has become known as the "research chemicals movement." Compounds used by these groups include synthetic cannabinoid agonists, cathinone derivatives, pyrovalerone derivatives, and many others. Use of these chemicals has significant adverse effects and forensic consequences.

The program builds on basic analytical information presented at the AAFS Annual Meeting in 2011, and will cover the latest developments in the availability, analysis, and forensic toxicology of these new illicit drugs. The scope will include information about the chemicals in circulation, how they are detected and measured, adverse event reports presented to Poison Control Centers, and the involvement of the drugs in impaired driving, suicide, assault, and homicide cases.

Specific presentations will cover the current scope of drugs present in these materials, their legal status, and how the analog and homolog aspects of the federal law should be interpreted. The remainder of the workshop will include a review of current analytical approaches to the identification of the chemicals in seized materials, blood, urine, and tissue, and will include pharmacokinetic data in blood, urine, and oral fluid from controlled administration of a range of the synthetic cannabinoid drugs. The focus of the remainder of the session will be on adverse effects associated with the various compound classes from various medical and forensic perspectives. This will include data from Poison Control Centers derived from calls from the public and medical professionals that have documented hypertension, agitation, paranoia, and seizures following use of synthetic cannabinoid and other legal high drugs. The program also includes case reports of suicides, assaults, and homicides following use of the unscheduled drugs mephedrone and MDPV sold as "Bath Salts" but intended for recreational use. Finally, a series of deaths in which either the synthetic cannabinoid or stimulant type drugs appear to have played a role will be discussed along with the difficulties in testing for use of the compounds and assessing their role in the causation of death.

At the conclusion of the workshop, attendees will be able to describe the various categories of drugs in the synthetic cannabinoid and designer drug categories; select or order appropriate analytical tests to ensure their detection; apply aids to the interpretation of designer drug findings in forensic casework; and recognize adverse effects of the drugs through evaluation of signs and symptoms of use.

Designer Drugs, Synthetic Cannabinoids, Forensic Toxicology

W19 The Anatomy of Error: Dissecting Adverse Events to Strengthen the Forensic Sciences

Susan M. Ballou, MS, and Melissa K. Taylor, BA*, National Institute of Standards & Technology, Law Enforcement Standards Office, 100 Bureau Drive, Mailstop 8102, Gaithersburg, MD 20899; Barbara Gregory, MPH*, Duke University, Duke University Medical Center, 104425, Durham, NC 27710; Deborah Boehm-Davis, PhD*, George Mason University, College of Humanities and Social Sciences, 4400 University Drive, Mailstop 3F5, Fairfax, VA 22030-4444; Scott A. Shappell, PhD*, Clemson University, Department of Industrial Engineering, 130B Freeman Hall, Clemson, SC 29634; and Christopher J. Plourd, JD*, Law Office of Christopher J. Plourd, 1168 Union Street, Suite 303, San Diego, CA 92101-3818*

After attending this presentation, attendees will: (1) learn the fundamentals of human error analysis; (2) define error, active error, and latent error; (3) discuss the origins of error in human and system perspectives; (4) understand human factors impacting performance; (5) describe and apply the different models of failure; and, (6) identify and initiate steps to resolve potential "error traps" in the work environment.

This presentation will impact the forensic science community by providing an overview of the field of human error, illuminate how human factors such as fatigue and bias can negatively impact performance, and educate the attendees on the application of human factor codes to items analyzed in a high profile murder case.

Reviewing the actions and accomplishments of other professions that have successfully dealt with human errors will assist attendees in understanding the fundamentals of error analysis. The medical and aviation professions have conducted extensive research on the subconscious to identify how human performance is helped or hindered by the design of equipment, work environment, and peer pressure. Making corrections or changes according to these revelations have improved performance and mitigated errors within these professions.

Fatigue has long been associated with decreases in human performance. While this is a problem that challenges most industries, those that are human-centric are at an even greater threat. The forensic sciences remain a field that heavily relies on the performance of its analysts and requires 100% accuracy. Unfortunately, crime scene technicians and analysts are just as susceptible to fatigue as other professionals. Operator fatigue has been shown to effect performance after just 18 hours of sustained wakefulness. While reductions in alertness and performance are a problem for workers in general, those who perform tasks, which demand high levels of cognition, are even more susceptible to the effects of fatigue. Fortunately, there are a number of management techniques, countermeasures, and interventions that will be discussed and defined to help mitigate these negative effects.

One aspect of the management technique is the education of staff on the difference between active errors, those events when individuals are in direct contact with physical evidence and latent errors, when the underlying support system comes into question. These topics have been part of the two year effort assigned to the Expert Working Group on Human Factors in Latent Print Analysis, an effort that has recently completed its task. Evaluating approaches to reducing errors in terms of their efficacy, appropriateness, cost, scientific basis, feasibility, associated risks, and quality of evidence have been documented and will be offered.

The class participation portion of the workshop provides an opportunity for the attendees to take the provided information and apply it to an actual criminal case. Applying lessons learned (when back at the crime scene, in the laboratory, or managing staff), work flow is increased when provided an opportunity to experience direct application. Part of the direct application will be segmenting levels of forensic work, using error coding techniques and assigning mitigation activities. A 1992 murder case, the conviction of Ray Krone and the associated bitemark evidence, will be used for this activity.

Therefore, this workshop has direct application to individuals who collect, handle, analyze, manage, and store forensic evidence. It introduces the concept of applying error mitigation techniques to the forensic science profession and provides established guidance learned in other professional fields. An actual criminal case will be presented allowing each attendee to gain experience in the actual error coding process and understand the underlying basis and resulting influence of errors.

Error, Cognitive Bias, Quality Assurance Quality Control

W20 Flawed Forensics: Recognizing and Challenging Misleading Forensic Evidence and Disingenuous Expert Testimony

Andrew Sulner, MSFS, JD, Forensic Document Examinations, LLC, 220 East 57th Street, Suite 200, New York, NY 10022; Joseph J. Maltese, JD*, New York Supreme Court, 130 Stuyvesant Place, 3rd Floor, Staten Island, NY 10301; Linda K. Baden, JD*, and Michael M. Baden, MD*, 15 West 53rd Street, #18B-C, New York, NY 10019; Jose A. Baez, JD*, 522 Simpson Road, Kissimmee, FL 34744; David M. Benjamin, PhD*, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of Pennsylvania, Erie County Court House, 140 West 6th Street, Room 223, Erie, PA 16501; Peter Neufeld, JD*, The Innocence Project, 40 Worth Street, Suite 701, New York, NY 10013; Michael Risinger, JD*, Seton Hall University, School of Law, One Newark Center, Newark, NJ 07102; and Marvin Schechter, JD*, 1790 Broadway, Suite 710, New York, NY 10019*

After attending this presentation, the attendees will be better acquainted with the current problems and challenges facing expert witnesses in various disciplines of forensic science. Attendees will learn how expert testimony or evidence is being challenged as unreliable, or misleading and disingenuous, what methods lawyers use to impeach such testimony or evidence, and the legal basis for excluding such evidence.

This presentation will impact the forensic science community by providing forensic scientists with examples of the problems and challenges they can face when testifying in court. All stakeholders in the administration of criminal or civil justice – experts, lawyers, and judges – will benefit from learning about scientific and evidentiary challenges to expert testimony, testimonial practices that experts should avoid, and the means by which lawyers challenge and judges exclude forensic expert testimony. This workshop will assist forensic scientists and lawyers in recognizing when the testimony of a particular expert witness is misleading and disingenuous and how to challenge and effectively impeach or preclude such testimony.

A multidisciplinary faculty will review actual testimony of forensic specialists in different disciplines. Discussion of cases and reported court decisions will illustrate the problems and ongoing challenges facing forensic scientists testifying in criminal and civil cases. Critical knowledge about when and under what circumstances, testimony or evidence introduced by forensic scientists will be challenged as being misleading or disingenuous, and how such challenges take place in the adversarial process of our judicial system will be discussed.

The uses and limits of cross-examination to reveal weaknesses in the testimony of forensic scientists will be explored, and examples involving misleading and disingenuous testimony by toxicologists, pathologists, and other forensic scientists will be examined and discussed from a scientific and legal standpoint, and from the perspective of the forensic scientist, the trial lawyer, and the judge. Actual cases in which deficiencies in report writing and incomplete or misleading testimony by forensic practitioners contributed to wrongful convictions will be reviewed and analyzed, and recommended solutions designed to correct this problem will be discussed.

Workshop attendees will learn about the true meaning of the different types of casework "peer review" occurring within the forensic community, the methods lawyers can use to impeach disingenuous testimony concerning such peer reviews, and the legal basis for excluding peer review testimony by the actual reviewer.

High profile criminal defense attorneys will discuss cases involving flawed and fabricated scientific evidence. The lead defense attorney in the recent, highly-publicized capital murder prosecution of Casey Anthony, which resulted in not guilty verdicts on all charges involving the death of the defendant's 2-year-old daughter, will discuss the challenges he faced before and during the lengthy jury trial, as well as the methods used to impeach the forensic evidence presented by the prosecution.

Attendees will become acquainted with the principles and pitfalls involving courtroom testimony in the wake of the National Academy of Sciences (NAS) Report and recent court decisions defining the parameters of forensic testimony. Specific examples of courtroom testimony will be utilized to illustrate problems in fingerprint comparison, tool mark identification, and bitemark analysis. Various aspects of testimonial evidence will be specifically targeted, such as the use of terminology in rendering a conclusion. The validity of subjective analysis and the intermingling of scientific principles will be addressed in the context of probability assertions. How the forensic practitioner handles the dual problems of explaining key forensic discipline definitions and producing appropriate back-up materials in buttressing validity will also be examined.

Finally, attendees will learn about the misleading use journal articles, treatises, and studies or experiments to substantiate or attack the basis for an expert opinion in the pre-trial and trial phases of a court proceeding, and the manner in which judges scrutinize and evaluate such evidence. Attendees will also learn about the ethical implications for a trial judge faced with disingenuous expert testimony and the nature of the ensuing judicial response.

Flawed Forensics, Misleading Evidence, Disingenuous Testimony

W21 Innovation in Forensic Image and Video Analysis

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Jurrien Bijhold, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, 2497GB, NETHERLANDS; Richard Vorder Bruegge, PhD*, Federal Bureau of Investigation, OTD-DES, Building 27958A, Pod E, Quantico, VA 22135; William R. Oliver, MD*, Brody School of Medicine, East Carolina University, Brody Medical Sciences Building, Greenville, NC 27834; and Leonid I. Rudin, PhD*, Cognitech, 283 S Lake Avenue, Suite 230, Pasadena, CA 91101*

After attending this presentation, attendees will understand how to validate forensic methods in image restoration and limitations and possibilities of forensic multimedia investigation.

This presentation will impact the forensic science community by providing an overview of the new developments and needs in forensic research.

During this workshop information will be provided on new developments of forensic investigation of (digital) images and video streams and the use of 3D computer modeling in forensic investigations. The workshop will be interactive and many examples of case material will be shown.

Traditional sources of images as evidence concern crime scene photography, and more specifically, photographs of fingerprints, tool marks, shoe prints, and other impressions. A short overview of image processing techniques is given. Special attention is given to the introduction of artifacts by image processing (e.g., FFT on fingerprints), quality assurance, and validation aspects. During the last decades, the use of CCTV-camera systems and digital cameras on phones has become widespread. Typical questions concern the quality and the selection of images from a specific camera in a multi-camera-recording, and combining the information. Digital processing of video streams for presentation and storage purposes, and the compression techniques that are applied in digital CCTV-systems, lead to questions about the integrity and authenticity of recordings. In addition, questions about image interpretation like facial recognition, body height, car speed (often in low resolution), time lapse, or compressed images have increased. A special discussion will be given on image analysis.

Since more images are being processed for forensic investigation, new methods have been developed for answering questions about the interpretation of images. Examples given: is it possible to read a license plate number? Is a suspect, or his car, the one depicted in the image? What is the body length of the robber or the speed of a car? Gait analysis, and, is it possible to do a reconstruction of an accident or a shooting incident from the information in these images? Methods for image comparison, facial comparison with non standardized images, image reconstruction, and measurement in images are presented and discussed. Special attention will be given to measurement uncertainties of the results and the impact on the conclusions from these investigations.

Common sources of video streams and images are video recordings from handy cams, digital photo cameras, the internet, and cellular phones. Typical questions about these recordings concern the integrity and authenticity of the recordings, the data compression techniques used, the synchronicity of sound and images, compensation for camera movement, and the conversion of a video stream to a higher resolution image. This session will focus on methods for state-of-the-art image enhancement techniques such as contrast, stretching, and deblurring, as well as super resolution, stabilizing, and automatic tracking methods. It will also cover the issue of erased video files, and how to recover these when they are partly erased.

The state-of-the-art methods for camera comparison will also be presented, examples of comparing Photo Response Non Uniformity with software. With this method a camera can be linked to a camera. Also the cautions of identification and limitations of the technique are discussed, and solved with likelihood ratios.

The methods are discussed also in relation to forensic medical image analysis and possibilities within pathology, with many practical examples. Computing speed for some of the image analysis methods (especially for high volume of data), and the possibilities of fast parallel computing with GPU's and CUDA for forensic video applications are discussed.

Finally, an overview on the use of 3D computer modeling in forensic investigations will be provided because these techniques have an impact on traditional crime scene photography. Computer models and animations have been recently used for analyzing video by superimposition of computer generated views of the model on the video images, for the visualization of complex scenarios in animations and for testing scenarios against video footage and evidence in crime scene photographs. Examples: the reconstruction of car accidents from photographs, analysis of blood spatter patterns from photographs using a computer model of the crime scene, the visualization of wound channels in computer models of human bodies, the reconstruction of bullet trajectories, the reconstruction of a burglary using the limited information in dark images from a multi-camera video recording, and the analysis of firework explosions from video recordings, photographs, and geographical data. Special attention is given to modeling techniques, the accuracy of the models, the methods for visualizing uncertainties, and possibly erroneous suggestions coming from these visualizations. 3D video fusion for use in casework is demonstrated.

Multimedia, Video, Medical

S1 Interdisciplinary Symposium - International and Interdisciplinary Symposium ... Now Boarding

Laura L. Liptai, PhD, BioMedical Forensics HQ CA/FL, 1660 School Street, Suite 103, Moraga, CA 94556; Carla M. Noziglia, MS*, United States Department of Justice, ICITAP, 305 Ascot Drive, Aiken, SC 29803-7833; Kathryne Bomberger, MA*, International Commission on Missing Persons, 45A Alipasina, Sarajevo, BOSNIA-HERZEGOVINA; Daniel D. Garner, PhD*, United States Department of Justice, ICITAP/Criminal Division, 1331 F Street Northwest, Suite 500, Washington, DC 20530; Morris V. Tidball-Binz, MD*, 4 Chemin des Fleurs, Ferney Voltaire, L'Ain 01210, FRANCE; Duarte N. Vieira, PhD, MD*, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL; Eddy De Valck, DDS*, Parklaan 10, Beigem, B-1852, BELGIUM; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; A.W. Jones, PhD, DSc*, National Lab Forensic Chemistry, , 12 Artillerigatan, Linkoping, 58758, SWEDEN; Deog-Im Kim, PhD*, Catholic University of Korea, Department of Anatomy, 505, Banpo-dong, Seocho-gu, Seoul, 137701, KOREA; Klaus C. Neudecker, MD*, Schirmgasse 268, Landshut, Bavaria D-84028, GERMANY; Rosalind J. Spencer, BSc*, Canada Border Services Agency, 14 Colonnade Road, Suite 280, Ottawa, ON K2E 7M6, CANADA; and Douglas H. Ubelaker, PhD*, Smithsonian Institution, Department of Anthropology, NMNH - MRC 112, Washington, DC 20560*

Educational Objective: After attending this presentation, attendees will be introduced to a diversity of views, a variety of topics and a wealth of knowledge in the field of forensic science that can be used to improve our methodologies as well as promote further research, collaboration, and understanding.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by improving the practice, elevating the standards, and advancing forensic sciences worldwide.

Worldwide forensic research in action will come to you! Preeminent forensic research scientists from ten countries will amaze you. It's a once in a lifetime opportunity to hear from:

International Committee of the Red Cross, Switzerland
International Commission on Missing Persons, Bosnia/Herzegovina
International Criminal Investigative Training Assistance Program, Worldwide
National Institute for Legal Medicine, Portugal
Panel Host: President, Douglas Ubelaker, Smithsonian Institution, Washington, DC

The American Academy of Forensic Sciences (AAFS) serves a distinguished and diverse membership of over 6,200 members, divided into eleven forensic sections representing all 50 United States, Canada, and 62 other countries worldwide. What is our "Forensic Science Edge?" Our advantage or "Edge" is access to preeminent forensic experts worldwide. This symposium encourages international interdisciplinary collegial collaboration that professionally advances us by reinforcing, challenging and/or transforming our thinking.

This symposium is the stuff of which legends are made. See forensic research around the world in action. Toxicology in Sweden! Questioned Documents in Canada! Psychiatry & Behavioral Science in Germany! Physical Anthropology in Korea! Odontology in Belgium! Digital & Multimedia Sciences in the Netherlands! Pathology/Biology in Portugal! General in Switzerland! Jurisprudence in Bosnia/Herzegovina! Criminalistics from ICITAP! And, Engineering from the United States!

International Forensic Science, Victim Identification, Accident Reconstruction

S2 Contemporary Topics in the Forensic Science Community

Tanisha V. Henson, MFS, Medical Examiner's Office - Central District, 400 East Jackson Street, Richmond, VA 23219; Martin K. Overly, MSFS, West Virginia University-FSI, 208 Oglebay Hall, Box 6217, Morgantown, WV 26506; Lindsey E. Crass, BS, 1600 University Avenue, 208 Oglebay Hall, Box 6217, Morgantown, WV 26506; Douglas H. Ubelaker, PhD, Smithsonian Institution, Department of Anthropology, NMNH - MRC 112, Washington, DC 20560; Cheryl D. Hunter*, American Academy of Forensic Sciences, 410 North 21st Street; Colorado Springs, CO 80904; Mary Fran Ernst, BLS*, St. Louis County Medical Examiner's Office, 6039 Helen Avenue, St. Louis, MO 63134; Jason H. Byrd, PhD*, University of Florida, Maples Center for Forensic Medicine, 4800 Southwest 35th Drive, Gainesville, FL 32608; Golden G. Richard, PhD*, University of New Orleans and Digital Forensics Solutions, LLC, Department of Computer Science, New Orleans, LA 70148; Rolf Bremmer, MSc*, Academic Medical Center, Meibergdreef 9, Amsterdam, 1105 AZ, NETHERLANDS; Robin W. Jones, BS*, Bureau of Alcohol, Tobacco, Firearms, and Explosives, United States Department of Justice, 99 New York Avenue, Northeast, Washington DC, 20002; H. Chip Walls, BS*, Miller School of Medicine, Forensic Toxicology Laboratory, 12500 Southwest 152nd Street, Building B, Miami, FL 33177; Robin Bowen, MA*, 1600 University Avenue, PO Box 6217, Morgantown, WV 26506-6217; William E. Folson, MS*, Folson Digital Forensics, Limited Liability Company, 4 Professional Drive, Suite 143, Gaithersburg, MD 20879; Jenna L. Oakes-Smith, MFS*, St. Louis Metro Police Department, 1200 Clark Avenue, St. Louis, MO 63103; M. Lee Goff, PhD*, Chaminade University of Honolulu, Forensic Sciences Program, 3140 Waialae Avenue, Honolulu, HI 96816-1578; Joseph P. Bono, MA*, Joseph P. Bono, MA, PO Box 2509, Leesburg, VA 20177; Jacquelyn M. Jenkins, PhD, Alabama Department of Forensic Sciences, 2026 Valleydale Road, Birmingham, AL 35244; Alison P. Mostrom, MSFS, 536 South Clark Street, Suite 800, Chicago, IL 60605; Amber R. Neitzel, BS, 3842 East Branham Lane, Phoenix, AZ 85042; Taryn M. Mead, BS, 850 Bryant Street, Building 606, San Francisco, CA 94103; Jennifer L. Malone, PhD, Wyoming State Crime Laboratory, 208 South College Drive, Cheyenne, WY 82002; Melissa DeBerry, BA, Mississippi Crime Laboratory, 805 Austin Court, Florence, MS 39073; and Lauren R. Pharr, MA, Louisiana State University, Department Geography & Anthropology, 227 Howe-Russell Geoscience Co., Baton Rouge, LA 70803*

Educational Objective: After attending this presentation, attendees will have a better understanding of the scope of the different fields of forensic science. Participants will learn how the different fields of forensic science work together to each play a significant role in casework. Both casework and research will be presented by the speakers. These presentations will show how casework and research are intertwined and how they both contribute to advancing forensic science. In addition, attendees will learn about each section represented by the AAFS and about the benefits of membership in the Academy. Participants will learn about various cases and research being done by their peers at the posters and slides sessions, and they will learn valuable skills needed to secure a job within the forensic science field at the breakfast session.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing encouragement, tools, resources, and support needed to give new and future professionals the ability to positively contribute to the forensic science field.

For more than a decade, the Young Forensic Scientists Forum (YFSF) has provided a program for new and young forensic scientists ranging from students in both undergraduate and graduate programs to professionals new to their career in forensic science with five years experience or less. YFSF is designed to attract both members and non-members of the American Academy of Forensic Sciences (AAFS). The continuing goal is to provide this audience with topics relevant to their education, training, and skill levels. The program is also designed to provide a comfortable environment for students and new professionals to present to their peers as well as an opportunity to effectively and efficiently network with experienced members and Fellows of the AAFS. The opportunities to present range from presenting at the YFSF Bring Your Own Slides (BYOS) session or the YFSF Bring Your Own Posters (BYOP) session and to showcase emerging forensic scientists. The Emerging Forensic Scientist Award winner is always invited to present his/her award winning paper.

For the AAFS 64th Annual Scientific Meeting in Atlanta, Georgia, the YFSF Special Session will present the theme: "Contemporary Topics in the Forensic Science Community." The special session to be held on Tuesday, February 21, will include speakers who will discuss trends currently observed among various forensic disciplines. With the rise of different types and variations of evidence being submitted to various laboratories, as well as new technologies in evidence examination, the focus of the 2012 forum will be to highlight and educate young forensic scientists on these trends. Lunch is provided to both attendees and speakers who are registered for the special session.

The annual YFSF BYOS, scheduled for Wednesday evening, includes presentations from students and new forensic scientists. The program will continue Thursday morning with the annual YFSF breakfast session with the theme: "Creating the Resume That Will Get Your Foot in The Door." The breakfast session is included in the registration for the special session held on Tuesday. YFSF does not require presenters of BYOS or BYOP to be members of AAFS and does not require they attend the special session but we do encourage them to do so.

One of the goals of the YFSF is to foster relationships between the participants of the session with their peers as well as established members of AAFS and to provide for a smooth transition from student, to emerging scientist, to established member. With the forum group setting provided and the variety of programs offered throughout the week, the YFSF will not only provide academic and relevant technical information to attendees, but will also cultivate relationships that will last a career.

Forensics, Evidence Submission, Current Trends

ES1 The Casey Anthony Trial — From the Defense, Medical, and Scientific Viewpoint

Linda K. Baden, JD, Law Office of Linda Kenney Baden, 15 West 53 Street, Apartment 18 B/C, New York, NY 10019; Jose A. Baez, JD*, 522 Simpson Road, Kissimmee, FL 34744; Haskell M. Pitluck, JD*, 573 Lake Avenue, Crystal Lake, IL 60014; Jane H. Bock, PhD*, Forensic Botany, Limited Liability Company, 5224 Lighthouse Point Court, Loveland, CO 80537-7916; Anthony B. Falsetti, PhD*, ICMP, Alipasina 45a, Sarajevo, 71000, BOSNIA-HERZEGOVINA; Kenneth G. Furton, PhD*, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199; Timothy E. Huntington, PhD*, 175 East Seward Street, Seward, NE 68434; Lawrence Kobilinsky, PhD*, John Jay College of Criminal Justice/CUNY, Department of Sciences, 445 West 59th Street, Room 3263A, New York, NY 10019; Kathleen J. Reichs, PhD*, University of North Carolina Charlotte, Department of Anthropology, Charlotte, NC 28223; Barry K. Logan, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Werner U. Spitz, MD*, Forensic Pathology/Toxicology, 23001 Greater Mack Avenue, Saint Clair Shores, MI 48080*

Educational Objective: After attending this presentation attendees will understand that experts at trial must limit their opinions and conclusions to those which are scientifically supportable despite pressures to tailor testimony to popular community and media sentiment.

Impact on the Forensic Science Communtiy: This presentation will seek to educate all as to the limits of the areas of forensic science testified to by the defense experts in the Casey Anthony trial.

The biggest media case, arguably larger than O.J. Simpson, was the 2011 trial of Casey Marie Anthony for first-degree death penalty murder. This was the first trial that not only engulfed the media but also occurred in the climate of burgeoning social networking, such as Facebook® and twitter®. As a result, everyone worldwide became an armchair juror or lawyer, influenced by rating-conscious talking heads with little understanding of the scientific evidence. Despite the recent pronouncement by the National Academy of Sciences (NAS) Report, the court allowed forensic testimony that had not been validated. The pressure on experts to put forth supportable medical and scientific testimony, despite the unpopularity of the defendant in this case, was great; however, the opinions of scientific experts must be independent of the desires of those who call upon them - unlike the attorneys, they are not advocates for either side.

In 2011 in Orlando, Florida, Casey Anthony was tried for the murder of her two-year-old child Caylee Marie Anthony. Jurors who had not been subject to pretrial publicity were picked by both sides from a different county and sequestered in Orlando, hearing about six weeks of evidence. The result is widely known – that Casey Anthony was acquitted of death penalty murder and all lesser included charges related to the death of her daughter. In order to bolster the emotional argument that the prosecution presented against Ms. Anthony, various forensic disciplines were embraced for the trial. These included not only medical and pathology testimony but also anthropological, entomological, chemistry, toxicology, botanical, and DNA opinions.

The defense claimed that much of the medical and scientific testimony was novel and had exceeded the boundaries of validated forensic science and should not have been allowed in by the gatekeeper. The judge, who did not accept the NAS Report as authoritative, allowed the jury to hear from experts whose opinions and conclusions had never been utilized in court, had not been subject to rigorous error rates, failed to have peer review protocols or quality control, and appeared to fall short of United States Supreme Court standards.

The defense prepared their own scientific conclusions beginning with a second autopsy and anthropological examination. It is important for all forensic experts to understand that at trial the role of the expert and

the jury's acceptance of expert testimony have substantially changed in the past decade.

The controversial nature of some of the testimony allowed to be presented to the jury in this matter, along with the actual systematic assistance provided by the experts for the defense, will be explored so that future forensic experts testifying in any trial, especially a high profile trial, will better understand why jurors accept or reject their conclusions.

This presentation will be a constructive examination of rapidly developing scientific technologies and the National Academy of Sciences concerns as to courtroom admissibility.

Casey Anthony Trial, NAS Report, Unvalidated Forensic Science

ES2 National Missing and Unidentified Persons System (NamUs) Best Practices for System Use

Bruce E. Anderson, PhD, Pima County Office of the Medical Examiner, 2825 East District Street, Tucson, AZ 85714; Randy L. Hanzlick, MD*, Fulton County, Medical Examiner Center, 430 Pryor Street, Southwest, Atlanta, GA 30312; J.C. Upshaw Downs, MD*, Georgia Bureau of Investigation, Medical Examiner, 925 A Mohawk Drive, Savannah, GA 31419; Daniel J. Warren, MS*, Florida Department of Law Enforcement, 4700 Terminal Drive, Suite 1, Fort Myers, FL 33907; Kevin Lothridge, MSM, National Forensic Science Technology Center, 7881 114th Avenue, Largo, FL 33773; and C.W. Billy Young II, BS*, and Carrie B. Sutherland, BS*, National Forensic Science Technology Center, , 7881 114th Avenue, North, Largo, FL 33773*

Educational Objectives: After attending this presentation, attendees will learn best practices for using the NamUs system including case entry, case enhancement, and utilization of NamUs forensic services. At the conclusion of the session, attendees will be able to efficiently navigate, operate, and utilize the NamUs system to assist their agency in applying NamUs to resolve missing and unidentified person's cases.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by showing how increased awareness and use of NamUs offers the promise of reducing backlog of unidentified remains cases in the United States and streamlining the investigation of missing persons by rapidly matching cases across state lines.

The National Missing and Unidentified Persons System, NamUs, combines two databases to assist law enforcement, medical examiners, coroners, and family members in the search for missing persons and the identification of unidentified human remains. The system, to date, has helped resolve over 150 cases of missing persons and unidentified remains. The information presented in the session offers agencies proven best practices for using NamUs to successfully resolve these cases.

This presentation, developed in conjunction with the National Association of Medical Examiners, Georgia Bureau of Investigation, and the Florida Department of Law Enforcement, will outline the benefits and best practices for using NamUs. Death investigators and law enforcement will see firsthand how the NamUs system benefits practitioners in their field. This presentation will be given by registered users from the medical examiner, coroner, and law enforcement fields and will prove vital to the attendees' agencies success with the NamUs program.

First, attendees will be walked through the registration process for becoming a secure user such as law enforcement or a medical examiner or coroner. Once through the registration process, basic and advanced case entry and searching will be demonstrated. Attendees will learn how to enter the best possible case information and use advanced searching techniques based on forensic identifiers such as dental records and tattoos.

Next, the secure user dashboard will be presented, illustrating the benefits of NamUs and its ease of use for users and agencies. The exclusions process and exclusions menu, a significant benefit of the system, will be explained and demonstrated. Under this menu, law enforcement, medical examiners, and coroners can track potential case matches that have been excluded based on forensic examination. The cases are archived so that users can actively monitor these cases for any changes or future comparison.

NamUs rates cases on a star system, from one to five stars, based on the amount of identifiers present in the case record. Five star cases have a higher likelihood of reaching resolution through the system. Identifiers found in five star cases include DNA, fingerprints, and dental records. This presentation will demonstrate how to enter a five star case, or enhance an existing case to five star status. Attendees will also learn how to import all agency cases that reside in the FBI's NCIC database into NamUs electronically, saving them time and money by avoiding manual case entry.

Through NamUs, the National Institute of Justice also offers a wide variety of free forensic service assistance including dental and anthropological services, fingerprint examination, and DNA sampling. This presentation will address how these services are provided, protocols for obtaining the services, and methods for case enhancement using forensic services.

The final topic of the presentation will present system successes. Cases resolved with the assistance of NamUs will be highlighted, demonstrating how the system helps family members, medical examiners/coroners, and law enforcement work together to resolve agency cold cases, bring closure to families and give people their identities back.

NamUs, Identification, Missing Persons

BS1 Postmortem Examination and Personal Identification of Victims of the Great East Japan Earthquake

Yasuhiro Aoki, MD, PhD, Department Forensic Medicine, Nagoya City University School of Medicine, 1 Kawasumi Mizuho-cho Mizuho-k, Nagoya, 467-8601, JAPAN*

Educational Objective: The goal of this presentation is to familiarize attendees with an outline of the forensic investigation of victims of the Great East Japan Earthquake Disaster which was carried out with the assistance of members of the Japanese Society of Legal Medicine (JSLM).

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing foundational knowledge on the features of the Japanese medico-legal system and mass disaster management, and highlighting the role of forensic personnel in the response to overwhelming natural disasters.

A massive earthquake of magnitude 9.0 struck eastern Japan at 2:46 p.m. on March 11, 2011. The epicenter was approximately 130 km off the Pacific Coast of northeast Japan. Strong tremors were observed across a wide area. However, both human casualties and property damage were concentrated on three prefectures (government jurisdictions in Japan), Iwate, Miyagi, and Fukushima, located along the Pacific Coast of the northeastern part of the main island of Japan (Honshu). This was primarily due to the huge tsunami triggered by the earthquake, over 15 m in amplitude and 40 m in run-up height, which engulfed the coastal areas of those prefectures.

Faced with the devastation, the JSLM established the *ad hoc* Disaster Response Headquarters on March 12, 2011, and dispatched member pathologists, physicians, and dentists to the three prefectures in cooperation with the National Police Agency. This was the first time such a headquarters had been established since the society issued a guideline in 1997 for an integrated support system of mass disaster management based on the experience of the 1995 great Hanshin-Awaji (Kobe) earthquake. The first response team consisting of three pathologists and three dentists departed Tokyo at 10:00 p.m. on the same day, traveling in police vehicles due to paralysis of the public transportation network. Examination of victims in Rikuzentakata, Iwate began the following afternoon. Most of the remains were immersed in water and covered with mud, and some victims had suffered extensive burns. Hypothermia was also the cause of death in some cases. The Headquarters successively organized and dispatched JSLM members through July 6, 2011. Some 122 pathologists and physicians contributed a total of 1,090 person-days of work, and 31 dentists performed a total of 298 person-days of work at the disaster sites. Aside from local physicians and dentists associations, the Japan Dental Association and Japan Self Defense Force also sent support teams to the affected areas.

As of July 29, 2011, the remains of 15,645 victims, including 27 non-Japanese, had been recovered, and another 4,984 people were still listed as missing. Approximately 90% of the victims were positively identified, in most cases from personal belongings and body features including dentition. In some cases, identity was established by DNA profiling, and more extensive identification attempts using a computer-assisted dental comparison system and kinship analysis of DNA profiles, which will be important for identification of as yet unidentified victims and yet to be discovered victims, are now in process. The latter is being conducted by the National Research Institute of Police Science and scientific criminal investigation laboratories of regional police headquarters. Fingernails and blood are the first choice source of DNA.

No fewer than 25 countries, regions, and international organizations have sent rescue teams and other specialists to the disaster areas; however, partly because of the language barrier, direct overseas assistance in the examination and identification of bodies has not been possible thus far.

Recently, the Japanese police departments have been increasing the number of prefectural police officers, especially those in charge of the investigation of death scenes and victims. This was effective in handling the large number of remains through wide-range mobilization from outside of the devastated areas. On the other hand, the medico-legal investigation system, such as the medical examiner system, is immature and remains an issue to be addressed from the standpoint of mass disaster management.

Natural Disaster, Personal Identification, Japan

BS2 The Cleveland Cyanide Murder Case: A Multidisciplinary Approach to Crime Investigation Including Chemical Identification, Cause of Death, Capture, and Court Proceedings

Douglas E. Rohde, MS, Lake County Crime Laboratory, 235 Fairgrounds Road, Painesville, OH 44077; Amanda J. Jenkins, PhD*, University Massachusetts Memorial Medical Center, Department of Hospital Labs, 365 Plantation Street, Biotech 1, Worcester, MA 01605; Elizabeth K. Balraj, MD*, 32795 Ledgehill Drive, Solon, OH 44139; and Gary McKee, BA*, Highland Heights Police Department, 5827 Highland Road, Highland Heights, OH 44143*

Educational Objective: The goal of the presentation, is to offer attendees insight into the investigation of a high profile homicide and the cooperation between various governmental agencies and forensic disciplines.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting the complexities of a murder case and a successful team approach to investigation.

On February 24, 2005, a married, 38-year-old mother of two, driving to meet her sister at a movie theater, called a friend to inform her she was feeling nauseous. The female said that she had taken a calcium pill that her husband, a Cuyahoga County physician, gave her just before she left their house. Shortly after the female's cell phone conversation with her friend, she was involved in a low speed automobile accident and was rushed to a local hospital.

When the female arrived at the hospital, she exhibited shallow breathing, an erratic heartbeat, and was unresponsive; however, she had no major signs of trauma. After 30 to 40 minutes of attempting to revive her, the attending physician saw no signs of improvement and pronounced her dead. At the time of autopsy, there was no indication of external injury, and an internal examination showed no evidence of trauma. As a result, the coroner was unable to determine cause of death and awaited toxicology results. Routine toxicology testing, which included volatile, OTC, prescription, and illicit drug screens, did not reveal any unusual substances in the decedent's system.

On March 17, 2005, the husband voluntarily met with the investigating detective and provided a statement concerning his wife's death. In the course of the interview, the husband stated that his wife had been taking prenatal vitamins and calcium supplements. Later that evening, the detective retrieved these items from the home. After this meeting, the husband fled the United States, leaving his children in the care of the decedent's family.

On March 22, 2005, the calcium capsules that were retrieved by the detective were examined by a local county crime laboratory. The chemical examination revealed that nine of the 56 capsules submitted contained cyanide. On April 21, 2005, additional toxicology testing performed on the decedent's specimens revealed 9.1 mg/L of cyanide in her blood. On April 22, 2005, the coroner concluded that the cause and manner of death was homicide by acute cyanide intoxication.

On October 6, 2006, authorities in Cyprus arrested the husband while he was traveling under a false Lebanese passport. He fought extradition in Cyprus until December 12, 2008, when the Cypriot Minister of Justice issued an official surrender warrant. The husband was returned to the United States on January 9, 2009, and arraigned on January 14, 2009.

A jury trial commenced on January 19, 2010, and lasted until March 8, 2010, when the jury returned a verdict of guilty of aggravated murder, as charged in the indictment. The husband appealed his conviction. On May 26, 2011, after a review of the record and pertinent law, the Court of Appeals of Ohio affirmed the appellant's conviction for the aggravated murder of his wife.

Cyanide, Homicide, Multidisciplinary Approach

BS3 Forensic Science and Cultural Heritage – Examination of the Gettysburg Address

Henry Swofford, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Fenella France, PhD*, United States Library of Congress, 101 Independence Avenue SE, Washington DC, DC 20540*

Educational Objective: The goal of this presentation, is to provide attendees with an understanding of a new application of hyperspectral imaging as a non-destructive technique to detect latent fingerprints, specifically on an historical document.

Impact on the Forensic Science Community: This presentation will impact the forensic science community through a discussion of the detection of latent fingerprints on the Nicolay Copy of the Gettysburg Address – one of our nation's most precious documents – using hyperspectral imaging. Through a collaborative effort between the Preservation Research and Testing Division (PRTD) of the United States Library of Congress, and the Latent Print Branch of the United States Army Criminal Investigation Laboratory, progress is being made in the recovery of additional artifacts and information of historical significance through forensic examinations using hyperspectral imaging techniques.

Hyperspectral imaging involves a spectroscopic analysis of materials to distinguish certain materials, one from another, as a function of their differential reflectance and absorption properties across a multitude of wavelengths in the electromagnetic spectrum. The particular wavelengths at which materials reflect and absorb will differ based on the chemical composition of the material giving it a characteristic reflectance spectrum. It is this characteristic reflectance spectrum which distinguishes certain materials. The normal human eye can distinguish the difference in materials based on their color. The color of a material is a descriptive property corresponding to the particular wavelength of electromagnetic energy that is reflected back towards the eye. The brain then detects and defines this reflected energy as a particular color depending on the wavelength of the reflected energy. The human eye is sensitive to distinguishing electromagnetic energy between 390nm and 750nm – commonly referred to as the "visible spectrum." The visible spectrum represents only a very small portion of the entire electromagnetic spectrum which is infinite and continuous. Hyperspectral imaging relies on hundreds of narrow and contiguous wavelengths across the electromagnetic spectrum resulting in characteristic reflectance spectra for each pixel in a digital image allowing the viewer to see the image as a function of the differential reflectance spectra. The hyperspectral imaging technique is undergoing rapid improvements with continuous developments of more powerful imagery sensors and image processing algorithms expanding the technique to be used for a multitude of additional applications.

In 2008, the United States Library of Congress PRTD began utilizing spectral imaging to examine a number of documents having historical interest to our nation including original drafts of the Declaration of Independence, the Gettysburg Address, and the Waldseemüller 1507 World Map, the first map to refer to the continent as America. The application and development of hyperspectral imaging for the preservation of cultural heritage materials and analysis of historic documents provides a powerful non-invasive technique for assessing documents. This technique utilizes an imaging system that captures the spectral response of materials from the ultraviolet, visible and near infrared regions of the spectrum (UV-VIS-NIR) and also reveals obscured or hidden information. The Library imaging system comprises a MegaVision 39 Megapixel monochrome camera (7216 x 5412) E6 back, and APO-Digitar 5, 6/120 lens, integrated through customized software with light emitting diode (LED) illumination panels that span the spectral range of 365nm to 1000nm for reflected, transmitted and raking (side-lighting) imaging modes. Recent advances include the development of a lens that had increased sensitivity in the UV region.

Non-destructive spectral imaging can be used to characterize historic documents by capturing the unique chemical spectral response of composite materials including substrates (paper, parchment, photographic materials) and media (inks, pigments, colorants). Capturing UV, VIS, and NIR spectral data in various illumination orientations minimizes handling of fragile items and allows greater capacity for materials analysis and post-acquisition processing to uncover hidden and obscured text and information. All images are accurately registered, enabling almost unlimited combinations of spectral wavebands for further processing. The integrated system uses low heat and reduced light exposure on the document, ensuring preservation of original materials.

During the examination of these historic documents, multiple latent fingerprints were developed on the Nicolay and Hay copies of the Gettysburg Address. The United States Library of Congress and the United States Army Criminal Investigation Laboratory began a collaborative effort to obtain additional items of historical significance pertaining to President Lincoln for non-destructive forensic examinations with the intent of developing additional latent fingerprints to compare with those on the Gettysburg Address. This presentation will give the attendees a chance to become familiar with the application of hyperspectral imaging for latent print development, view the latent fingerprints which were developed on the Gettysburg Address, and discuss the imaging and processing techniques used to capture and non-invasively develop these prints.

Hyperspectral Imaging, Forensic Documents, Latent Prints

BS4 Theater of the Absurd – Ethics and the Truth Versus the Fiction of the Courtroom

J.C. Upshaw Downs, MD, ForensX, LLC, 11511 Abercorn Street Ext #182, Savannah, GA 31419; and Anjali R. Swienton, JD*, SciLawForensics, Limited, 12447 Great Park Circle, #210, Germantown, MD 20876*

Educational Objective: The objective of this presentation is to introduce the contrasting fictional portrayal of the court in media versus the reality of actual trial practices with the goal of allowing forensic witnesses to benefit from lessons learned–both good and bad–by the presenters.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by allowing the attendee to better understand unrealistic portrayals and expectations placed on the forensic witness by attorneys, juries, and others based on a comparison with media presentations.

The forensic practitioner is challenged with expectation placed on him/her by many interests. These often come to light most directly in the courtroom where counsel for both parties have a vested interest in

substantiating their version of the facts. This adversarial system draws in the neutral practitioner who is faced with expectations of performance from the judge, law enforcement, jury, and others. In the modern era, the media has periodically gone through apparent feeding frenzies of interest in high-profile "case of the century" vignettes with ever-increasing frequency. The particulars of day-to-day forensic work have been glamorized on television in the form of fictional crime dramas and reality television, leaving many viewers expecting investigative miracles from the forensic practitioner. The "CSI effect" is an all too real phenomenon.

Using a compare and contrast case study basis with use of video clips from dramatic courtroom events and actual sworn testimony, the dilemmas for the forensic witness will be presented. The ethical dilemmas for the witness in how to properly convey complex scientific testimony to a lay jury while attempting to stay neutral and objective is a continuing challenge for the witness – even if well-experienced. Trying to ensure that the jury has a complete picture of the science underlying the testimony, while not reading in real or perceived shortcomings, is a challenge. At times, counsel might not ask the appropriate questions or the jury might believe that certain evidence "should be present" when it is not. These are all too familiar scenarios to those who have been in the witness box.

The 2009 National Academy of Sciences Report stressed the need for reinforcing ethics in forensic practice. Trial testimony is often where one's moral code can be put to the test by not only what one says but what is not said and how these ends are achieved. The impartial scientist should hold fast to the purity of the science and, while understanding the possible motives of parties involved, not become an advocate. The witnessess' use of logic should remain that and not become mere rationalization, intended to raise doubt. To this end, the practitioner must be able to convey the difference between "hard" and "soft" science, between reality and illusion.

Areas of specific inclusion would relate to the strength of opinion (that is overstating or understating testimony), misrepresenting facts or underlying principles, and the ethics of being a private versus governmental employee. While any ethical lapses may end with the net result that the ideal of "the truth, the whole truth, and nothing but the truth" is not fully conveyed to the jury, the difference between outright lies, deception, and misleading testimony is an important consideration. Media versions may allow some blurring of an ethical line that must remain clear if the foundation of the science is to remain sound.

Testimony, Courtroom, Ethics

BS5 The Battle of Gettysburg: How Today's Technology Connected Jennie Wade to Abraham Lincoln After 145 Years

Rod Englert, BS, Englert Forensic Consultants, PO Box 605, West Linn, OR 97068; and John Sotos, MD*, 1788 Oak Creek Drive, Palo Alto, CA 94304*

Educational Objective: During this presentation, attendees will learn of historical events being affected by today's technology involving blood patterns, luminol, DNA, bullet trajectory, and clues to President Lincoln's medical condition.

Impact on the Forensic Science Community: The presentation will impact the forensic science community by relating historical events to modern-day scientific technology.

Can state-of-the-art forensic technology shed new light on mysteries that have remained unsolved for more than a century? This presentation reopens two intriguing historic events—the deaths of President Abraham Lincoln and Jennie Wade, the Battle of Gettysburg's only civilian casualty—and puts them under the lens of modern science, subjecting 19th-century evidence to 21st-century technology including DNA analysis and luminescent chemical testing as well as advanced medical diagnostics and bullet trajectory analysis.

The first case discussed will be the shooting of Mary Virginia "Jennie" Wade during the Civil War in 1863. A team of crime scene reconstruction and DNA experts conducted a detailed examination of the Jennie Wade House in Gettysburg and discovered convincing evidence that historic accounts had the facts wrong. Attendees will be walked through significant points in this historic sniper shooting scene, revealing how trajectory analysis can be applied to bullet holes in the original wooden doors to determine that the bullet responsible for killing 20-year-old Wade came from a different angle and locale than originally believed. This presentation will include a reenactment of the crime as it unfolded. The forensic tests performed on the floorboards and the bread trough Wade was said to be leaning over when she was shot to death will also be discussed. Use of Luminol revealed chemical reactions suggesting the presence of bloodstains. Core samples were submitted for advanced DNA testing, which may ultimately determine after 148 years not only whether the blood is human but whether it belonged to Wade.

Equally fascinating from a forensic standpoint are other bloodstained artifacts from the Civil War era, including a lock of hair found in a private safe at the Wade House, which was allegedly preserved from President Abraham Lincoln's autopsy. Medical historian and obscure-diagnosis expert John Sotos of the University of North Carolina School of Medicine has conducted exhaustive research on Lincoln and concluded that, based on his features and symptoms, the president suffered from a rare genetic cancer syndrome that would likely have killed him within months had he not been assassinated. By examining bloodstained Lincoln artifacts, this presentation may be able to expand science's understanding of the sixteenth president's medical condition.

In his presentation, Dr. Sotos will explain how a master diagnostician can analyze clues and pinpoint telltale details in photographic and other historical evidence to determine that Lincoln and three of his four sons had multiple endocrine neoplasia type 2B (MEN2B). The hallmarks of the disease and how they are recognizable in such distinctive characteristics as Lincoln's unusual height and long limbs, sagging face and bumpy lips, fatigue and headaches, perpetually cold hands and feet, as well as the death of three of Lincoln's sons before age 20 and his mother's death at 34, will also be discussed.

The discussion will delve into the applications—and potential breakthroughs—that scientific technology offers to solve crimes, broaden our understanding of history, expand medical knowledge, and provide answers to questions that have eluded experts for generations.

Luminol, Trajectory, Lincoln

BS6 Tables Turned: An Unsuccessful Case of a Newborn Kidnapping by Caesarian Section

Robert J. Morton, MS, Federal Bureau of Investigation, National Center for Analysis of Violent Crimes, Critical Incident Response Group, 2501 Investigation Parkway, Quantico, VA 22135*

Educational Objective: After attending this presentation, attendees will understand the unique dynamics involved in cases of offenders who attack pregnant women to steal their fetuses. This case will highlight the need for forensic sciences to assist in unraveling complex homicide crime scenes.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting the complexities involved in homicide scenes and the need for forensic sciences to assist law enforcement in ascertaining the sequence of events involved in equivocal death investigations.

This presentation is designed to discuss a very rare and bizarre type of homicide where an offender attacks a pregnant woman and forcibly performs a crude caesarian section, removing the victim's fetus, usually resulting in the death of the mother. A case will be discussed where a victim was stalked and attacked by a woman who was intending to steal her fetus

by caesarian section. In this instance, the victim was able to successfully fight off the offender, killing her. Additionally, this presentation will explore the history of newborn kidnapping by caesarian section, as well as the research that has been conducted on this unusual type of crime.

The FBI's National Center for the Analysis of Violent Crime (NCAVC) is routinely consulted by federal, state, local, international law enforcement, and criminal justice authorities in a variety of cases of unusual, bizarre, and repetitive violent crimes, especially homicides. NCAVC assistance was requested by local authorities in regards to a case of a pregnant woman who was attacked by an offender attempting to steal her fetus.

The victim did not previously know the offender. The offender concocted a ruse where a store had mistakenly delivered a package to her residence that was addressed to the victim. The offender was able to engage the victim in conversation regarding the victim's pregnancy learning that the victim was due to deliver in the next couple days.

When the victim went to pick up a second package, she became suspicious and attempted to leave the offender's residence. The offender attacked the victim with a knife, but the victim managed to disarm her, stabbing the offender three times. The victim fled the apartment with the knife and the offender's cordless telephone. The victim was able to contact the police and the offender was transported to the hospital where she died. The victim suffered minor defensive injuries and subsequently delivered a healthy baby.

The police conducted an equivocal death investigation into the case and discovered the offender had previously claimed to have been pregnant four other times. According to the offender, she lost the pregnancies due to miscarriage or stillborn deaths. No one in the offender's family ever visited her in the hospital or attended any funerals for the babies. Further, there were no medical records that substantiated the pregnancies. The offender had gone to great lengths to convince her family she was pregnant. The offender purchased furniture, baby supplies, diapers, and had set up a nursery in her residence. She even wore maternity clothing that was padded to resemble a pregnancy. The offender had a "delivery" kit containing surgical gloves, hemostats, surgical scissors, absorbent gauze, and a plastic clip to secure an umbilical cord.

The investigation revealed the offender was sexually and emotionally abused while growing up. Both of the offender's parents were alcoholics and the offender became the main caregiver to her other siblings. The offender had claimed her father had sexually abused her from ages 7 to 12 years of age, and he was subsequently convicted of molestation and sentenced to 20 years.

This case highlights the unusual dynamics involved in newborn kidnapping cases by caesarian section. It reinforces the role of forensic science, as well as the extensive investigative effort required in equivocal death investigations.

Forensic Science, Fetus Theft, Equivocal Death

BS7 The Tale of the Black Cow, Granny, and How Animal DNA and Branding Experts Exonerated a Man From Wikieup, AZ

Jason D. Ricke, JD, LLM, Mohave County Public Defender's Office, PO Box 7000, Kingman, AZ 86402*

Educational Objective: After attending this presentation, attendees will understand the impact of animal DNA in a criminal case and how jurors may ignore what we, as insiders, perceive as the strongest piece of scientific evidence in a case.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by discussing unique topics of cattle DNA and branding experts. It is imperative to recognize that as our understanding of DNA and comparison science evolves, it reaches into topics previously foreign to these types of scientific analysis.

This presentation will highlight a case arising out of events that took place in Wikieup, AZ, a small ranch town of 150 residents in Northwest Arizona. Everybody sees cattle when driving down country roads, and nearly everyone buys beef in the local grocery store, but how does that meat get from point A to point B? How do we decide who owns livestock that graze out on the open range? What happens when someone is accused of cattle rustling and then lies about it under oath?

When a lawyer takes on a unique area of law, they themselves must become experts in that field. This story highlights one attorney's journey into unfamiliar territory and how experts eventually led to a not guilty verdict at trial.

The defendant was caught with two cattle on his ranch that the State says were not his, one of which had an altered brand. The State asserted that the defendant altered or obliterated the brand on the animal, and then at a cattle ownership hearing in the Kingman/Cerbat Justice Court, lied under oath about when he branded the animal. At the outset of the case, the State had bovine DNA testing done to prove paternity of the two cattle involved, and was going to call as witnesses an animal DNA expert, a branding expert, as well as a veterinary cattle expert. The case looked bad for the defense.

Everything changed when a package from California arrived at the doorstep of the Public Defender's Office containing tissue and teeth of what the defendant claimed to be the mother of the cow with the altered brand, thereby proving these were his cows. In the end, the defense used the same animal DNA expert originally called by the State as well as their own retired branding expert to deal with the evidence against him which resulted in a not guilty verdict.

The greatest surprise of all was not the verdict at trial, but how the jurors perceived the scientific evidence that was presented. The State focused their closing argument on how the defense story was a bunch of bull. The defense waived their hand the other direction and said look at the DNA. Once the verdict was returned, some of the jurors explained that their entire decision was based on something that neither side saw coming.

Attendees may walk away reevaluating their own cases based on the story of the black cow, granny, and a small time ranch hand from Wikieup, AZ.

Animal DNA, Cattle Branding, Comparison Science

BS8 Thomas Krauss Memorial Bitemark Breakfast – Fantasy of Forensics: How Junk Science Failed to Persuade the Jury in the Casey Anthony Case

Jose A. Baez, JD, 522 Simpson Road, Kissimmee, FL 34744*

Educational Objective: During this presentation, attendees will learn firsthand how several attempts to introduce junk science in the courtroom in this mega high-profile case were rejected by the jury.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting the need for sound forensic science and the use of the judicial system as a gatekeeper.

What was dubbed "The Trial of the New Century," the *State of Florida vs. Casey Marie Anthony* posed several problems to law enforcement and state forensic experts. The daily barrage of news coverage in all forms of media resulted in unprecedented coverage. This was the first high profile case that involved social media such as blogs, Facebook®, and twitter®. Instant access was a must. This coverage placed undue pressure on state experts to render several opinions, which were at times questionable, to opinions that fell outside of their area of expertise. Expert witnesses felt this pressure and delivered for the prosecution in the media but delivered more so for the defense during trial.

In July 2008, the worldwide media began to focus on the case of a missing child under what many believed were mysterious circumstances. Caylee Marie Anthony (born August 9, 2005) was reported missing by her

grandmother, Cindy Anthony, on July 15, 2008. Casey Anthony was indicted on charges of first-degree murder and pled not guilty on October 14, 2008. Caylee's skeletal remains were discovered in a wooded area near the family home on December 11, 2008. The prosecution sought the death penalty and the trial lasted for six weeks. On July 5, 2011, the jury found Casey Anthony not guilty of murder, aggravated child abuse, and aggravated manslaughter of a child, but guilty of four misdemeanour counts of providing false information to a law enforcement officer.

In the center of it all was the defendant's vehicle that law enforcement said had the "smell of death." The remains of Caylee Marie Anthony were found less than a quarter mile from the Anthony home. What resulted in trial was a classic battle of the experts with a cutting edge twist. Flying in the face of the recent report issued by the National Academy of Sciences, novel and unproven science was allowed in the courtroom, which resulted in a battle involving every single discipline of forensic science. The prosecution asked the jury to engage in a "fantasy of forensics," which they ultimately rejected. They asked the jury to consider a phantom heart shaped sticker, a phantom stain of decomposition fluid, unverified dog alerts, false computer reports, novel science of air samples purporting to contain the odor of human decomposition, and even a video superimposition of the death of the child where no cause of death was determined. Despite this free-for-all of forensics, and despite the overwhelming inflammatory coverage of this case, the jury saw right through it and rejected the State of Florida's fantasy of forensics. Jose Baez, the defense attorney for Casey Anthony, explores this fascinating case examining not only the use of forensic science within the case but also the role of the media – with the case now being cited as an example of the unfairness of prejudicial pretrial publicity – and the impact that this could have on the rights of defendants.

Forensic, Judicial, Defense

L1 An Analysis of a Mine Incident That Led to Deaths Due to an Unknown Confined Space Hazard

Gerald A. MacIntyre, DVM, 2700 1st Avenue South, Cranbrook, BC V1C 6Y3, CANADA*

Educational Objectives: After attending this presentation, attendees will understand how we are all at risk when dealing with inadequate and erroneous communications. This incident provides attendees with the knowledge that what you are told is not necessarily the facts in scene attendance. We are reliant on exact information that we are given. The information given may result in your own death from complacency.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting cases in which what you are told may kill you. This is a multidisciplinary death investigation of environmental concerns within a mine reclamation.

On December 21, 2001, the Sullivan lead, silver, and zinc mine production was discontinued after 100 years of production. The mine, which is located in Kimberley, British Columbia, Canada, had the dubious reputation of being one of the longest producing mines in the world.

Following production, a reclamation process began and the staff gradually diminished over the following years to a small skeleton staff for maintenance.

The reclamation of the mine site included covering tailings dumps with glacial till. Water drains were placed at the toe of this dump for water quality testing within the dump. A contractor was hired to monitor water quality.

On May 15, 2006, the contractor responsible for monitoring water quality failed to return to his home that evening. On May 17, 2010, the management at the mine site was alerted to the contractor's disappearance. Two employees were dispatched to search for Mr. Ericksen in separate vehicles. Mr. Bob Newcome found Mr. Erickson's truck at the water sampling shed at the toe of number one waste dump. He observed Mr. Ericksen collapsed in the water sampling shed and lying in the shallow water. He called 911 and reported the finding of an unconscious male lying in water. He entered the shed attempting to assess the physical state of Mr. Ericksen. Mr. Newcome also contacted his fellow employee to meet the ambulance at the main entrance gate. When the ambulance arrived, the attendants entered the shed separately. The senior attendant collapsed as she climbed down to assess Mr. Newcome and Mr. Ericksen. The second mine employee stated to the second ambulance attendant that his partner had collapsed. The attendant, in an effort to rescue his partner, fell into unconsciousness.

A Coroner's Inquest was held in July 2009 to investigate the deaths of Robert Newcome, Kimberley Weitzel, Shawn Currier, and Doug Ericksen. Several recommendations were submitted by the inquest jury to prevent a similar occurrence. The intention of this presentation is to discuss the cause of this incident and enlighten the membership of the various communication difficulties that occurred during this tragedy.

The investigation revealed that all four individuals died from an extremely anoxic environment. The cause of the anoxia was determined to include variable environmental and geochemical factors. The glacial till became compacted over the years and did not allow the dump to breath. The chemical reactions created by acidophilic bacteria required oxygen to complete the oxidation of iron within the dump and consequently, oxygen within the sampling shed was utilized and drawn into the dump through the water sampling pipe. The oxygen void within the sampling shed appeared to be replaced with nitrogen from within the dump. There was no indication of anoxia to any of the workers because no odor is associated with this phenomenon. The physiological sequence of events associated with anoxia resulted in hypercapnia and death.

The initial call to the ambulance did, in retrospect, contain all the relevant information regarding a confined space scenario but unfortunately a drowning scenario was used to dispatch the ambulance attendants. They were not prepared mentally to assess an anoxic hazard when they attended the scene and unfortunately died in an attempt to rescue two men that were down upon their arrival.

Environmental Asphyxia, Anoxia, Environmental Anoxia

L2 Odor Mortis: What Is It Anyway?

Jeffrey L. Ashton, JD, 4068 Tenita Drive, Winter Park, FL 32801; Bernard A. Raum, JD*, Levin College of Law University of Florida, PO Box 1149, Newberry, FL 32669; Arpad A. Vass, PhD*, Oak Ridge National Laboratory, 1 Bethel Valley Road, PO Box 2008 MS6120, Oak Ridge, TN 37831-6120; Jan C. Garavaglia, MD*, District 9 Medical Examiner, 2350 East Michigan Avenue, Orlando, FL 32806; and Bruce A. Goldberger, PhD*, University of Florida, College of Medicine, Department of Pathology, 4800 Southwest 35th Drive, Gainesville, FL 32608*

Educational Objectives: After attending this presentation, attendees will learn the significance of the use of *Odor Mortis* to identify sites where human decomposition has occurred, how this evidence is gathered, analyzed in the laboratory, and how this forms as a basis for expert opinion. The attendees will learn applicable rules of circumstantial evidence which govern the use of *Odor Mortis* in court.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by exploring the emergence of *Odor Mortis* capture and analysis will establish a scientific basis for qualified witness at a crime scene or in a laboratory to specifically identify the "smell of death" as they recognize it from their experience and have that identification confirmed by laboratory analysis.

The presentation of a case based upon circumstantial evidence is all about putting the pieces of the puzzle together. Where that case is based largely on scientific evidence, one is faced with an additional challenge. Before the pieces can be arranged in such a way as to show the picture of the defendant's guilt the jury must first understand the evidence. The attorney presenting the evidence must know enough about the science to understand it themselves without allowing their presentation to become so immersed in the science that they lose the jury. This is the true challenge in the presentation of a complex scientific circumstantial evidence case. It is meeting this challenge in general and in particular the use of the concept of *Odor Mortis* in the case of *State of Florida v. Casey Marie Anthony* that will be discussed. Additional discussion will concentrate on the admissibility of the underlying scientific basis of *Odor Mortis* analysis, the expert testimony based upon that analysis, and the use of an expert's sense of smell to identify *Odor Mortis*.

In addition, specific discussion of scientific evidence in this presentation will focus on the development of the decompositional odor analysis database and will include collection methodologies, experimental design, controls, and ramifications of air collection protocols at crime scenes. *Odor Mortis* will be discussed and how the chemical signature of death changes over time. This discussion will end with a summary of how these analytical procedures were used as circumstantial evidence in the Casey Anthony case to confirm the presence of human remains in the trunk of the defendant's car.

For those individuals who smell decomposing bodies on an almost daily basis, they know it is a pungent, unique, and for many, an objectionable odor. How unique is the odor? Most experienced people can say it smells nothing like rotting food, small animals, or fish; however, is that partly because of the quantity of the rotting material we smell? Medical examiners are routinely confronted by these issues. For example, two scenarios involving a medical examiner will be discussed where large quantities of rotting material were associated with a case. The first is where a closed thermal cooler was found by the side of a road with decomposed, liquidized tissue of approximately a foot deep in which bones had sunk to the bottom. Is the smell of the inside of this cooler enough to enable a medical examiner to tell whether this was a rotting deer and not a human? The second scenario involves a driver of a dump truck filled with mildly rotting cow entrails from a slaughterhouse that was in a collision with a freight train on a hot summer day in Texas. Both the driver and the train engine became covered with the entrails that continued to rot in the summer heat while investigators worked the train crash. The smell was pungent and objectionable, but was it unique based on human smell alone? It might be difficult to make an *Odor Mortis* determination in either situation without some sort of scientific determination.

Lastly, toxicological analysis of decomposed remains will be discussed. Such toxicological analysis is routinely performed by forensic toxicology laboratories as an essential component of the medicolegal death investigation process. The presence of drugs and drug metabolites can be used to support a toxicological cause of death. A wide range of specimens are typically available, but the type and condition of the specimen is dependent on the decedent's state of decomposition. The usual specimens include decomposition fluid, solid organ tissue, cranial wash, bone, bone marrow, hair and nails. Toxicological analysis of specimens can also be used to identify products of decomposition. While these findings are not typically reported to the medical examiner, the results may prove useful in investigation and be used to support an *Odor Mortis* finding.

Odor Mortis, Human Decomposition, Circumstantial Evidence

W1 High-Profile Cases: The Los Angeles Experience

Christopher B. Rogers, MD, Lakshmanan Sathyavagiswaran, MD*, and Edward Winter, BA*, Los Angeles County Department of Coroner, 1104 North Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will be familiar with techniques used in handling high-profile cases including media relations, office security, and preparation of the autopsy report.

This presentation will impact the forensic science community by providing practical techniques for handling high-profile cases.

Most medical examiners periodically handle high-profile cases. These cases can be especially challenging because of increased media attention and the need to maintain the security of the medical examiner's office. A thoughtfully prepared autopsy report may help to avoid unanswered questions in the future.

Los Angeles County has seen a number of prominent people become coroner's cases, as well as other cases that have attracted public attention such as officer-involved shootings, deaths in custody, and serial murders. Taking examples from these cases, this presentation will demonstrate methods of handling cases that generate high public interest.

Members of the media need accurate and current information about medical examiner's cases. In order to prepare for high-profile cases, the medical examiner should develop a media relations plan. In larger offices, there should be a few people responsible for media calls and public statements. Smaller offices may specify in advance the resources necessary to handle a large number of media calls. At times the number of calls is so great that it is a full-time job to deal with them. There should be an advance agreement about which section of government will be responsible for media releases in high-profile cases. This will avoid the confusion of having several officials announce different information.

Although there may be pressure to announce results, press releases and other documents should never be prepared in haste. Part of the media plan should give sample press releases for various situations. There is an increasing need to monitor social media, as internet sites can spread misinformation rapidly. The medical examiner's office may need to disseminate accurate information, starting as soon as possible, through social media outlets.

A media relations plan should include provisions for office security. In some cases a large number of news vehicles, grieving fans, or demonstrators block access for employees and others. The decedent must be protected from photographers and curious members of the staff and public. The medical examiner's office must, however, allow access to employees and those whose business is unrelated to the high-profile case. In the past, the police have assisted with security by limiting access to the parking lots.

During the autopsy, as in many forensic cases, details that seem small at first can assume great significance later. The autopsy surgeon should re-read and carefully follow office procedures. Any extraneous photographs (by surveillance cameras, cell phone cameras, etc.) should be prohibited. Photographs, x-rays, documents, and computer files should be secured. Toxicologists and other consultants need to be aware of questions that may come up concerning the case. The typed autopsy report should be proofread several times and checked against primary sources of data. It is possible to find flaws in even the most carefully prepared autopsy report, but they should be minimized to the fullest extent possible.

High-Profile Case, Media Relations, Security

W2 Postmortem Monocular Indirect Ophthalmoscopy Workshop

Patrick E. Lantz, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; Lezah P. McCarthy, MD*, Coastal Pathology Associates, Onslow Memorial Hospital, Western Boulevard, Jacksonville, NC 28546; Candace H. Schoppe, MD*, and Christina J. Tatum, MD*, Wake Forest University, Baptist Medical Center, Medical Center Boulevard, Winston Salem, NC 27157; Stephen Lenfest, MD*, Wake Forest University School of Medicine, Medical Center Boulevard, Department of Pathology, Winston-Salem, NC 27157; and Vivian M. Hathuc, DO*, Wake Forest Baptist Medical Center, Medical Center Boulevard, Winston Salem, NC 27157*

After attending this presentation, attendees will: (1) differentiate between direct and indirect ophthalmoscopy noting advantages and limitations of each technique for the postmortem detection of fundal hemorrhages; (2) discuss the fundal location of retinal hemorrhages relative to their projected aerial image during monocular indirect ophthalmoscopy; and, (3) on a fundal diagram, accurately draw retinal abnormalities observed during monocular indirect ophthalmoscopy with a simple ocular model.

This presentation will impact the forensic community by providing an overview of postmortem monocular indirect ophthalmoscopy, facilitating skill acquisition, and evaluating practical training.

Postmortem examination of the retina has relied on ocular evisceration. In most medical examiner/coroner jurisdictions, ocular enucleation is not a standard autopsy procedure unless child abuse is suspected, thus creating observational bias when citing the prevalence of postmortem fundal findings such as retinal hemorrhages (preretinal, flame-shaped or splinter, and dot/blot), perimacular retinal folds, retinoschisis, and postmortem artifactual retinal folds. Postmortem Monocular Indirect Ophthalmoscopy (PMIO) permits examination of the decedent's posterior fundus and portions of the peripheral retina. The required equipment necessary for PMIO is relatively inexpensive and when compared to direct ophthalmoscopy. This technique is less affected by corneal clouding, lens opacity, or vitreous hemorrhage. PMIO uses a focal light source and an aspheric, convex condensing lens. An excellent source of coaxial illumination is a halogen, xenon surgical, or procedural headlamp. This light source creates a collimated beam of light and permits the examiner to stabilize the condensing lens with both hands. Current aspheric lenses range from +14 to +40 diopters and come in different diameters permitting a field of view of 35°-55°. Postmortem corneal opacity may cause the fundus to appear hazy; however, by gently removing the epithelial layer of the cornea, the emergent image is usually of adequate quality to readily detect lesions such as fundal hemorrhages and retinal folds.

Learning how to perform and become proficient at PMIO can be perplexing and intimidating. Most pathology residents and forensic pathology fellows have limited exposure to indirect ophthalmoscopy. Because the projected aerial image is inverted and laterally reversed, precise descriptions or recording of fundal abnormalities can be challenging. Unlike binocular indirect ophthalmoscopy with a teaching mirror attachment, an instructor and the fellow or resident cannot view the projected aerial image simultaneously during PMIO. To address these learning obstacles, it is necessary to develop tools and models to facilitate skill acquisition. An hour or two with an inexpensive ocular model can shift the learning curve of the resident, fellow, or forensic pathologist substantially to the right demonstrating how to correctly position the light source and hold the indirect lens.

This workshop consists of three sessions. An initial discussion reviews the technique of PMIO, highlighting the optics, the equipment, and examples of abnormal fundal findings found at autopsy by PMIO. Next, attendees will have a realistic learning experience by practical hands-on training with a procedural headlamp, an aspheric indirect lens, and a simple ocular model containing a variety of retinal abnormalities observed at autopsy. The ocular models have variably sized "pupillary" openings and some will have clear acetate over the openings to simulate corneal glare. Facilitators will assist attendees in positioning the procedural headlamp, holding the indirect lens, viewing the projected aerial image, and accurately recording the retinal abnormalities. Following practice visualizing and diagramming numerous fundal images, attendees will be evaluated with a series of unknowns. Self-assessment of technical skill training and review of the unknown retinal findings concludes the workshop.

Forensic Science, Postmortem Monocular Indirect Ophthalmoscopy, Retinal Hemorrhages

W3 Advanced DNA Mixture Interpretation and Statistical Approaches

Debra E. Glidewell, MS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297-5205; Debra A. Figarelli, BS*, 7881 North 114th Avenue, North, Largo, FL 33773; Timothy S. Kalafut, PhD*, and Joel D. Sutton, MSFS*, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297-5205; and Robert I. Obrien, BS*, 7881 114th Avenue, North, Largo, FL 33773*

After attending this presentation, attendees will be able to: (1) describe the importance and use of statistics for DNA mixtures; (2) describe all mixture statistical formulas and mixture interpretation approaches outlined in the SWGDAM DNA Mixture Interpretation Guidelines (approved 1/14/10); (3) use multiple approaches to DNA mixture deconvolution and statistical applications; and, (4) be familiar with one software tool for DNA mixture deconvolution.

This presentation will impact the forensic science community by providing attendees with a better understanding of complex mixture deconvolution techniques, the United States Army Criminal Investigation Laboratory (USACIL) software tool, and the application of statistical formulae outlined in the SWGDAM DNA Mixture Interpretation Guidelines.

DNA mixture deconvolution and the application of statistical methods is one of the most challenging aspects of forensic DNA analysis. This mixture workshop will be a hands-on workshop using both qualitative and quantitative approaches to mixture deconvolution. This workshop will review the SWGDAM Guidelines to include the use of analytical and stochastic thresholds, heterozygous peak balance, percent contribution to assess mixture proportions, and stutter considerations.

The NFSTC DNA Services team has trained over 100 forensic DNA analysts in DNA mixture interpretation and statistical applications using the 2010 DNA Mixture Interpretation Guidelines. NFSTC will provide devices for computerized interactive participation by attendees which will allow attendee opinions to be recorded anonymously and seen on a screen. This on screen anonymous feedback allows attendees to see how other laboratories are approaching DNA mixture deconvolution. This information can then be taken back to their laboratories to share with the analytical staff.

Due to the nature of the cases routinely received, the USACIL has years of experience in complex mixture interpretation. USACIL presenters will discuss their methods and demonstrate a software program used by USACIL staff. ArmedXpert™ is a commercial DNA data analysis program developed by the U.S. Army Criminal Investigation Laboratory and licensed to NicheVision Forensics, LLC. The program uses data tables generated from data analysis tools. The user is able to quickly compare samples from multiple tables to one another in a case, between cases, to a laboratory staff database, QC databases, and create tables or cmf files for CODIS entry. In addition, the software uses a proportional allele method to deconvolute two and three contributor mixtures.

USACIL will provide real case examples of complex mixture data that will be worked through as interactive group activities. The panel of instructors will discuss and show how to apply all interpretation and statistical approaches outlined in the SWGDAM Guidelines for each case example. These case examples will then be deconvoluted using the software (ArmedXpert™) employed by USACIL in order to compare the manual versus automated deconvolution results.

When drafting the 2010 SWGDAM DNA Mixture Interpretation Guidelines, one of the goals of SWGDAM was to provide information that would enable greater consistency and accuracy among analysts within a laboratory. This workshop is designed to provide attendees with hands on applications of scientifically acceptable methods for mixture deconvolution. The interactive component is intended to encourage analysts and technical leaders to review their standard operating procedures and validation data in light of the training on these guidelines and to update their procedures as needed.

DNA, Mixture, Workshop

W4 Sex-Related Homicide and Death Investigation: Practical and Clinical Perspectives—Significance of Pornography, Sexual Deviance, Autoerotic Fatalities, Signature and MO, Serial Murder Investigation, as Well as the Increase in African American Serial Killers Involved in These Events

Vernon J. Geberth, MS, PO Box 197, Garnerville, NY 10923; Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, AB T6H 5R8, CANADA; and Barbara C. Wolf, MD*, District 5 Medical Examiner's Office, 809 Pine Street, Leesburg, FL 34748*

After attending this presentation, attendees will: (1) understand the role of fantasy in sex-related death; (2) collect and preserve physical and psychological evidence in sex-related incidents; (3) determine the MO and signature characteristics in crime scenes; (4) understand investigative and behavioral analysis in criminal profiling; and (5) understand serial murder trends.

This presentation will impact the forensic science community by informing the attendees of the dynamics and proper procedures in the investigation of sex-related homicides and death investigations.

Sex-related homicides and deaths occurring during sexual events have drastically increased over the years and claim victims from all walks-of-life (men or women, lovers or strangers, elders, or children). These fatalities may occur from recreational misadventures or sex-related crimes, which are perpetrated by sex offenders and represent the most horrific crimes imaginable. The internet has certainly provided society with technological advances but has also resulted in the proliferation of pornography and easy access to sex-related materials to anyone with a computer or computer access. It is significant that the sex industry, which consists of commercial enterprises providing adult entertainment, earns over $13 billion a year in the United States and how that may influence the increase in sex-related events.

Attendees of this presentation will better understand the significance of sexual deviancy, fantasy, and pornography in sex-related events as well as the investigative and behavioral analysis applied to these types of incidents. Attendees will understand the importance of the collection and preservation of evidence in sex-related events and the attendees will appreciate the impact of Signature characteristics and *modus operandi* as applied to sex-related homicides.

In the first segment, the presenters will provide examples of sexual deviance as well as the paraphiliac considerations in these type death investigations. There are over 35 Paraphilias described in the literature and a number of Paraphilias are cross-associated with sexual homicides. These will be explored at length in the presentation. The presenters with also explore the connection between Pedophilia and the sexual homicide of children with appropriate case studies provided for illustration. The attendees will then be apprised of the current knowledge regarding autoerotic fatalities.

Attendees will be apprised of the current knowledge regarding autoerotic fatalities including definitions, incidence, crime scene characteristics, typical and atypical methods, and victims. It will be demonstrated that the widely-cited incidence of 500 to 1,000 autoerotic deaths-per-year in the United States is no longer accurate. It will be explained that an incidence of 0.2 to 0.5 cases per million inhabitants per year is a better estimate of the incidence of autoerotic deaths. New epidemiological data have demonstrated that this incidence is higher in big cities compared to rural areas. There is no clear evidence of a preferential time-of-day for these deaths, but there appears to be slightly more incidences of autoerotic deaths during summer. Recently, the typical and atypical methods of autoerotic deaths have also been revisited based on the new standardized classification of asphyxia. New data on the crime scene characteristics will also be presented, along with a discussion of four types of atypical victims: non-white female, children, adolescent, and the elderly. This presentation will provide a comprehensive and practical illustration of specific examples and cases with a discussion of the investigative and clinical considerations, which will include pathology, pathophysiology, as well as the investigative and behavioral and forensic aspects of these events.

The second segment of the workshop will focus on the dynamics of sex-related homicides, which includes rape, lust murder, and serial killing. Using a case history format, the importance of "signature" and *"modus operandi"* will be demonstrated to illustrate the application of Investigative and Behavioral Analysis to the crime scene examination.

Current research regarding the frequency of sexual posing in homicide crime scenes and the phenomena of African-American sexual serial killers in the United States will be included. The myth that there are no African-American serial killers has been perpetuated based on media coverage on television and/or Hollywood movies such as: *The Red Dragon, Silence of the Lambs, and Hannibal* which exclusively focus on the white serial killers. However, there has been a drastic increase in the number of African-American serial killers since the 1980's. Only recently, with the arrest and conviction of Anthony Sowell in Cleveland, Ohio and the identification through the use of familial DNA of Lonnie Franklin, Jr. "The Grim Sleeper" that the media has acknowledged the fact that there are African-American serial killers reported on these cases. The current research indicates over 150 African-American sexual serial killers as of July, 2011.

The overall goal will be to provide comprehensive and practical information which will serve an investigative guide in sex-related homicide and death inquiries.

Sex-Related Homicide, Autoerotic Deaths, Serial Murder Trends

W5 Paper Fundamentals for Forensic Document Examiners

Elaine Wooton, MFS, Office of Investigations – Forensic Document Laboratory, Stop 5116, 8000 Westpark Drive, Suite 200, McLean, VA 20598-5116; David Wicker, MS*, Document Security Systems, 28 Main Street East, Suite 1525, Rochester, NY 14614; Kathleen E. Wyles, BS*, Appleton, 100 Paper Mill Road, Roaring Spring, PA 16673; and Peter V. Tytell, BA, Forensic Research, 116 Fulton Street, Suite 2W, New York, NY 10038-2712*

After attending this presentation, attendees will have a better understanding of ASTM training requirements. Individuals with little previous exposure to the subject area will have a comprehensive introduction, those with moderate exposure will have an updated refresher, and those with significant exposure will have had an opportunity to share their knowledge and case experiences with the other participants.

This presentation will impact the forensic science community by establishing and implementing standards for training and practice, and providing a more predictable skillset. The "questioned document" profession has established minimum training requirements which are documented as an ASTM standard; this includes training regarding paper. As both a supplemental initial training and continuing education opportunity, this workshop provides access to technical expertise that geographically dispersed individuals and groups could not realize.

Forensic document examiners are qualified through an apprenticeship process. The types of training required were determined by the profession and are described in the ASTM Standard *E2388-05 Standard Guide for Minimum Training Requirements for Forensic Document Examiners.*

In order to ensure that examiners are up-to-date regarding paper, the all-day workshop will be divided into four sessions: the first will include the history of paper and the paper manufacturing process. The second will cover techniques and casework that involve paper. The third will introduce security papers. The final session will include techniques for the examination of security papers, and casework examples in which security paper played a role.

History: Using extensive artwork and historical images, the "Paper History Timeline" will be shared with workshop participants. In Asia, the Middle East, and Europe, cultures were striving to have something on which to write! Fraud was soon to follow.

Manufacturing Process: Using extensive video, images, and marginally technical explanations, speakers will ensure the workshop participants comprehend the technical complexities that have radically changed the simple process that is papermaking.

Paper Properties and Basic Examinations: Various characteristics are inherent in a single piece of paper given the materials and process used. Knowing what they are, identifying differences, identifying reasonable variations, and deciding what they mean are the fundamental basis of paper examinations. In this session, how the characteristics are affected when paper is acted upon, and methods for assessing the condition of those characteristics will be described. Indented handwriting, fracture match, and paper fiber impressions will be discussed. Participants will be invited to share case summaries.

Security Papers: As the value of a paper document increases, the need to protect that document also increases. Over time, many elements have been changed or added to make documents more difficult to alter or counterfeit. These elements may be printed material, chemical additives, or other security materials (such as fibers or planchettes.) In this session, the entire range of security papers will be described.

Security Papers – Examination Techniques and Case Examples: Counterfeiters have only one job: to fool the person they need to fool. Typically, the person receiving a counterfeit item is not a forensic examiner and the counterfeiter knows this. Many efforts to duplicate security papers are amusing to the skilled document examiner; however, they are sufficient to be accepted as genuine. In this session, technical information regarding

examination techniques and equipment will be provided, as well as examples of cases in which security paper played a role. Some will be of the amusing variety and some of the nearly undetectable variety. In addition, as in the Paper Examination session above, participants will be invited to share case summaries.

Paper, Watermark, Security

W6 Practical Ethics in Forensic Science – A Multidisciplinary Call to Arms

J.C. Upshaw Downs, MD, Georgia Bureau of Investigations, 925A Mohawk Drive, Savannah, GA 31419; Anjali R. Swienton, JD*, SciLawForensics, Ldt., 12447 Great Park Circle, #210, Germantown, MD 20876; Kenneth E. Melson, JD*, Office of Legal Policy, U.S. Department of Justice, 950 Pennsylvania Avenue, NW, Washington, DC 20530; Max M. Houck, PhD*, Analytic Services, Incorporated, 2900 South Quincy Street, Suite 800, Arlington, VA 22206; Barry A.J. Fisher, MS*, 19854 Vintage Street, Chatsworth, CA 91311; Christine Funk, JD*, State of Minnesota, Office of the Public Defender, 919 Vermillion Street, Suite 200, Hastings, MN 55033; Haskell M. Pitluck, JD*, 573 Lake Avenue, Crystal Lake, IL 60014; Joseph P. Bono, MA*, PO Box 2509, Leesburg, VA 20177; Jennifer L.P. Downs, BA*, ForensX, Limited Liability Company, 11511 Abercorn Street Ext #182, Savannah, GA 31419; Jay A. Siegel, PhD*, Indiana University, Purdue University Indianapolis, Chemistry, School of Science, 402 North Blackford, LD 326 D, Indianapolis, IN 46202*

After attending this presentation, attendees will better understand the nature of practical applied ethics, including the history, practice, enforcement, and expectations from a multidisciplinary view. Attendees will understand potential dangers associated with unethical conduct.

This presentation will impact the forensic science community by providing a better understand of the history and nature of ethics as it relates to the practice of forensic science.

"Tainted Science and Testimony Leads to Re-opening of 120 Cases over Last 15 years," "Man Freed After Serving 21 years in Prison Due to Lab 'Oversight?", "State Crime Lab Employee Accused of Biased Analyses and Testimony"

All of these headlines can confront and scare legitimate practicing forensic scientists. At the heart of this fear is wondering how such events could ever occur, since inherent in the practice of forensic science is the requirement for each practitioner to be truthful and beyond reproach. A failure of forensic scientists to act ethically results in serious adverse outcomes. The word "ethical" can be defined merely as proper conduct – doing the right thing, the right way, for the right reason. While seemingly simple to define, the application of being "ethical" is somewhat more obscure. The 2009 National Academy of Sciences Report on the status of the forensic sciences argued for the need for enhanced ethics training within all forensic disciplines. Tacit within this commentary is that there is a significant problem related to practitioner behavior. As most involved in the day-to-day practice of forensic science would argue that they are complying with all extant codes of conduct, there seems to be a disconnect between theory and practice which needs to be addressed. Thus, the question becomes when is ethical, "ethical," and when is it not? As a non-partisan in the adversarial justice system, the scientist should have no stake in case outcomes.

Clearly, as part of the legal system, there must be room for differences of opinion in the forensic sciences. What is not clear, however, is when such differences are so divergent that individuals' ethics are drawn into question. In this workshop, the role of ethics in the forensic sciences from different perspectives will be addressed with the intent of approaching an understanding of when the proverbial ethical line is crossed.

The workshop will include a discussion of practical ethics in forensic disciplines from multiple points-of-view, including historians, theologians, educators, practitioners, law enforcement, witnesses, attorneys, and judges. Presentations will include comparisons to canons of ethics in the existing forensic organizations and in other fields, with possible mechanisms for enforcement of standards presented. The unrealistic expectations of the public may be at least partially responsible for the present intense interest in the field. Recognition of ethical concerns by those in the field and vehicles for whistle-blowing to bring unacceptable behaviors to an end are addressed. Potential outcomes of unethical behavior, especially in the forensic sciences, are presented in a series of case studies.

In the final analysis, all forensic practitioners should remain keenly aware of the inherent ethical dilemmas in the nature of the work and should maintain the highest standards of personal and professional conduct. Transgressions sully the entire field and should not be tolerated. The first step involves knowing the basics and where dangers might lie. This workshop intends to present such a primer.

Ethics, Whistle-Blower, Dilemmas

W7 Preparation and Strategic Planning for Accreditation of Forensic Laboratories Based on the ISO/IEC 17025 International Standard

Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Laurel J. Farrell, BA*, 2935 Spinnaker Place, Longmont, CO 80503; Terry Mills, MS*, 5360 Galberry Lane, Gulf Breeze, FL 32563; Sudhir K. Sinha, PhD*, InnoGenomics Technologies, LLC, 134 LaSalle Street, New Orleans, LA 70112; Marc A. LeBeau, PhD*, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Anja Einseln, MS*, American Society of Crime Directors Laboratory Accreditation Board, 139 J Technology Drive, Garner, NC 27529*

The goal of this workshop is to provide attendees with a general overview of the recourses to meet ISO/IEC 17025 requirements and explain how they may be applied in the context of forensic laboratories to include medical examiner laboratories. After attending the workshop the participants will understand the accreditation process as well as the general requirements to prepare for ISO/IEC 17025 accreditation of forensic laboratories.

This presentation will impact the forensic science community by providing an overview of the accreditation of a multi-discipline forensic laboratory based on ISO/IEC 17025. The workshop is geared towards managers and analysts of international forensic laboratories with little or no exposure to the accreditation process. This workshop will cover definitions of common quality assurance terms, the accreditation process, various accrediting bodies, and the general ISO/IEC 17025 and ILAC G-19 guidelines for forensic laboratories. The workshop will provide realistic expectations of what is required to achieve accreditation and provide an achievable roadmap. The workshop will allow international forensic laboratories to create a strategic plan and timetable to achieve accreditation based on the ISO/IEC 17025 Standard.

Laboratory accreditation is a tool used to evaluate the general competence of a laboratory, and as such, is increasingly expected by clients of forensic and medical examiner laboratories and by the courts. The number of states in the United States and countries internationally mandating laboratory accreditation is growing. The value of accreditation increases in the investigation of international crimes when the accreditation program is based on an internationally recognized standard. Often evidence analyzed by forensic laboratories is at the center of multi-country investigations involving drug trafficking, cyber-crime, identity theft, corruption, terrorism, human trafficking, and other transnational crimes. Multi-country investigations and prosecutions require that the criminal justice systems in one country can use and trust forensic laboratory reports issued by laboratories in other countries. The concept of and mechanism for international uniformity, consistency, and competence of laboratories

through Regional Multi-Lateral Recognition Arrangements and the International Laboratory Accreditation Cooperation (ILAC) Mutual Recognition Arrangements will be explained including many of the acronyms and buzz words in the accreditation world (ISO, ILAC, IAAC, APLAC, AB, CAB, regional cooperations, MRA, and MLA to name a few).

The International Organization for Standardization has thousands of standards that are used worldwide. The standard ISO/IEC 17025:2005 General requirements for the competence of testing and calibration laboratories is the ISO standard currently in wide use for forensic laboratories. How this standard is applied to the accreditation of forensic laboratories will be covered. The workshop will include a general overview of the Management and Technical Requirements sections of ISO/IEC 17025:2005 covering the main issues of each section.

ISO/IEC 17025:2005 covers general concepts that have been proven to provide a sound foundation for effective organizations performing testing and calibrations; however, ISO/IEC 17025:2005 is not specific to forensic science. ILAC's Guidelines for Forensic Science Laboratories (ILAC G19), is an example of an amplification document for forensic laboratories, and will be reviewed to demonstrate the relationship between an ISO standard and an amplification document.

Following the general overview, detailed presentations will be provided on Document Control, Traceability, Measurement Uncertainty, and Internal Audits.

Document Control: The requirements for document control are an excellent area to begin with if a laboratory is just beginning to prepare for accreditation. Specific requirements and strategies for compliance will be provided.

Traceability and Measurement Uncertainty: These topics are new to many in forensic science and specifically to the area of toxicology. Establishing traceability has a significant impact on the quality of laboratory results and measurement uncertainty provides a mechanism to compare test or calibration results between laboratories. Specific applications will be provided in the area of toxicology.

Internal audits are a requirement in ISO/IEC 17025:2005; however, internal audits are also a useful tool in preparing your laboratory for accreditation. How to plan and conduct global, vertical, and horizontal audits will be covered.

Months have been spent preparing for ISO/IEC based assessment and now it is time to submit the application to an accrediting body. Understanding the assessment process minimizes the fear associated with an external assessment. The workshop will step through the process from application through accreditation being granted. The development of the assessment plan will be covered. The methods used by assessors to document conformance with requirements will be presented. These will include document review, case record review, observation of testing or calibration activities, and interviews of laboratory personnel. The general process for remediation of findings of non-conformance will be provided. In addition, tips and techniques for making this process as easy as it can be will be provided.

The workshop will conclude with discussion of the most common deficiencies found during accreditation assessments of various forensic testing laboratories.

This workshop will provide valuable practical guidance to national and international forensic laboratories working towards and maintaining accreditation based on the ISO/IEC 17025:2005 standard.

ISO/IEC 17025, Accreditation, Requirements

W8 Examination and Analysis of Explosives and Device Construction/Components

Chris E. Taylor, BS, United States Army Criminal Investigation Lab, 4930 North 31st Street, Forest Park, GA 30297-5205; Thomas J. Hopen, MS*, Alcohol Tobacco Firearms Forensic Science Lab, 2600 Century Parkway, NE, Suite 400, Atlanta, GA 30345; Jesse Brown, BS*, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Melinda K. McPherson, PhD*, University of Missouri, Columbia, MO; Andrew M. Bowen, MS*, Stoney Forensic, Incorporated, 14101-G Willard Road, Chantilly, VA 20151; William B. Bodrey, Jr., BS*, Gerogia Bureau of Investigation, 3121 Pathersville Road, Decatur, GA 30034; Alan Higgins*, NEK Advanced Securities Group, 110 South Sierre Madre, Colorado Springs, CO 80903; and David A. Green, BS*, Lake County Crime Lab, 235 Fairgrounds Road, Painesville, OH 44077*

After attending this presentation, attendees will be familiar with forensic explosive analysis, microscopical analysis, instrumental analysis, and sample preparation techniques. The attendees will also become familiar with the investigative leads generated by the characteristics of and components used in a device, its container housing, and its firing train.

This presentation will impact the forensic science community by providing an understanding of the principles and practices of explosive material identification, explosive device construction, component characterization, and report writing. This training will provide exposure to a variety of experts and testing approaches that can be utilized in local, state, and federal laboratories.

The increase of domestic and foreign terrorist activities has brought awareness to explosive analysis in local, state, and federal forensic science service providers. From offering general awareness of materials to investigators and first responders to laboratory analysis of explosives, explosive residues, and device components, analysts in this specialized field continue to work together to share information and intelligence. This networking is valuable for sourcing materials and identifying domestic and foreign terrorists, potentially leading to their arrest or capture. Although national and international agencies are involved in this type of work, this workshop will focus on the forensic science practitioner and training in the forensic science testing of explosive materials and device construction/components.

The workshop will provide the foundational knowledge of explosive terms, types of explosions, specific types of explosive compounds and their characteristics. The workshop will present the attendees with an understanding of common approaches to the examination and analysis of explosive residues and materials. The ensuing presentations and activities over the two days will cover physical examinations and chemical analyses, tips on sample isolation and preparation, improvised explosive devices (IEDs), low explosives, high explosives, and homemade explosives (HME's). Microscopical examination and preparation techniques will be enhanced with hands-on exercises. Workshop attendees will have opportunities to reconstruct devices from found evidence and debris. Faculty presenters will discuss specific cases and offer their conclusions. The panel and participants will conclude this session with discussions on appropriate wording and report writing guidelines that will reflect an understanding in the criminal justice, forensic science, and judicial communities.

In addition to the foundational knowledge, the workshop will provide a short review of explosive blast physics (thermal effects, pressure wave, etc.), the types of explosions followed by the types of explosives (primary, high, and low). Individual compounds of each type will be reviewed including their brief history, development, and modern usage. Explosive materials such as black powder, black powder substitutes, flash powders, and smokeless powders will be examined and characterized as a part of a hands-on exercise. The high explosives will focus on commonly seen compounds such as TNT, C-4, and PETN. Plastic bonded explosives, emulsions and modern blasting agents will also be covered. Analytical

approaches will be discussed and the instrumental techniques utilized such as microscopy, FT-IR, GC/MS, and X-ray techniques.

Microscopical analyses have been intimately tied to forensic science since its inception. However, some modern trends have resulted in moving away from the microscope in explosives analysis. This session will focus on the extreme power the microscope can offer the examiner. From searching debris for small pieces of fragmentation and particles to microcrystalline techniques that can identify specific explosive compounds, the microscope is an invaluable tool in the examiner's toolbox.

In the last few years, new trends in explosives have resulted in an increase in the number of homemade explosives (HMEs). This session will familiarize attendees with the current analytical practices related to HMEs. How these devices are developed and used, the types of explosive materials in them, and the chemistry behind their devastating effects will be presented. Lastly, the workshop will offer a brief insight into potential future testing methods to include instrumentation and innovations in explosives detection and analysis that could impact this field.

At the conclusion of this workshop, the attendees will have the knowledge, understand techniques required to pursue the analysis of explosives, and understand of the importance of the materials used in the construction of explosive devices. Participants will be able to utilize the principles taught in the lectures and offered in the hands-on exercises to hone their skills and bring these resources back to their organizations thereby improving on their existing explosive analysis programs.

Explosives, HME, IED

W9 What Did You Just Step In?! Use of Forensic Soil Examinations to Find Out

Kim E. Mooney, PhD, United States Army Criminal Investigation Laboratory, Trace Evidence Branch, 4930 North 31st Street, Building 925, Forest Park, GA 30253; David B. Flohr, MSFS*, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Andrew M. Bowen, MS*, Stoney Forensic, Incorporated, 14101-G Willard Road, Chantilly, VA 20151; David A. Stoney, PhD*, Stoney Forensic, Incorporated, 6405 Woodland Run Court, Clifton, VA 20124; Maureen Bottrell, MS*, Federal Bureau of Investigation, Trace Evidence Unit, Quantico, VA; Thomas J. Hopen, MS*, Alcohol Tobacco Firearms Forensic Science Lab, 2600 Century Parkway, NE, Suite 400, Atlanta, GA 30345; Raymond C. Murray, PhD*, University of Montana, 106 Ironwood Place, Missoula, MT 59803; Christopher S. Palenik, PhD*, and Skip Palenik, BS*, Microtrace, 790 Fletcher Drive, Suite 106, Elgin, IL 60123-4755; William Schneck, MS*, Washington State Patrol, Crime Laboratory, 580 West 7th Street, Cheney, WA 99004; and Marianne Stam, MS*, California Department of Justice, Riverside Criminalistics Lab, 7425 Mission Boulevard, Riverside, CA 92509*

After attending this presentation, attendees will be equipped with sufficient knowledge of soil analysis to either initiate this type of service in their laboratory or suggest improvements to their existing methods for soil analysis. Situational awareness of the need to utilize the analytical services of an outside laboratory for select soil comparisons will also be gained.

This presentation will impact the forensic science community by providing education to those desiring training in forensic soil examinations, as well serving as a reminder about a service that more laboratories may wish to add to their suite of analytical services. This workshop will help to make soil analysis more accessible to the forensic community by demonstrating the limited instrumentation necessary to make this service available. Additionally, the workshop will provide a forum for examiners to discuss the differences in existing techniques, the need for standardization, and the impact of accreditation.

A quick search of the internet for "soil analysis laboratories in the United States" returns a long list of laboratories providing soil analysis for agricultural concerns. However, laboratories providing comparative soil examinations for forensic applications are rare. Though soil analysis is a well-established field of forensic examination, the air of mystery and difficulty has made the "forensic soil examiner" a rare breed.

Proficiency in the field is only maintained through constant practice and continuing education; however, training courses in the discipline are infrequently offered and often cancelled due to a lack of attendees. Laboratories often cite the lack of instrumentation, time, or personnel as the reasons for not providing this service. Much of this can be overcome with proper and efficient training; for the underpinning work in such examinations can be performed without high-end instrumentation. In fact, much of the comparative work can be performed with instrumentation that most forensic laboratories already have available (i.e., polarized light microscopes, automated scanning electron microscope/energy dispersive spectrometer, Fourier transform infrared spectrometers, and x-ray fluorescence spectrometers).

During this two-day workshop, attendees will gain insight into the geological and historical foundations for soil examinations and their practical applications in forensic science. They will gain experience in the application of a variety of laboratory techniques commonly used for forensic soil examinations. Lectures and "hands-on" sessions will include, but are not limited to, the following: the historical basis for forensic soil examinations; geology as related to the formation of soil; soil collection methods; comparative color and texture analyses; the preparation and separation of soil samples for the isolation of the botanical, anthropogenic (man-made), clay, and mineral components of soil; the application of x-ray diffraction and Fourier transform infrared spectroscopy for the identification and comparison of clays; fractionation of the heavy and light mineral components for identification purposes; mounting methods for identification of soil minerals by polarized light microscopy; methods for percent composition comparisons of the heavy and light mineral content; the utilization of automated scanning electron microscopy-energy dispersive x-ray analysis for automated mineral analysis; determination of provenance based upon the sum total of the components identified in soil; report writing verbiage; and significance evaluations.

Attendees will gain, at a minimum, a theoretical and practical foundation for incorporating soil analyses into their laboratory's suite of analytical services. They will also obtain the skills necessary to detect, collect, and preserve soil evidence and to perform minimal comparisons, thereby enabling preliminary evaluation of such evidence for use in their own cases.

Soil, Mineral Analysis, Microscopy

W10 Drug Enforcement Administration U.S. Customs and Border Protection Forensic Mobile Device Workshop

Rhesa G. Gilliland, MS, Drug Enforcement Administration, Digital Evidence Laboratory, 10555 Furnace Road, Lorton, VA 22079; Samuel I. Brothers, BBA*, United States Customs & Border Protection, 7501 Boston Boulevard, Room 113, Springfield, VA 20598; and Lam D. Nguyen, MS*, and Scott D. Roffman, MS*, Drug Enforcement Administration, Digital Evidence Laboratory, 10555 Furnace Road, Lorton, VA 22079*

The goal of the presentation is to assist attendees in the examination of mobile devices in a forensically sound manner through discussion of relevant topics: (1) handling and preservation of mobile devices: attendees will understand proper procedures for collecting and handling mobile devices so as to preserve data for forensic examination; (2) validation of mobile device examination methods: this discussion will present a proposed framework for validating mobile device examination methods and software tools in light of agency accreditation requirements; and, (3) by learning to leverage available resources against their limitations, attendees will be able to relate the *Daubert* standards to the challenges specific to codifying methodologies in an ever-evolving discipline.

This presentation will impact the forensic science community by providing sound strategies and methodologies that can be directly applied to the examination of mobile devices and further the development of the digital forensic discipline.

The following topics will be covered: handling and preservation of mobile devices from seizure to analysis and methods validation with a proposed framework for validating mobile forensic methods and tools.

Attendees will: (1) understand the importance and applicability of the *Daubert* Standards in mobile forensic methods; (2) develop and apply an organizational methodology for software tools validation within the framework of accreditation; and, (3) be able to leverage available resources while understanding their limitations and understand the challenges of codifying methodologies in an ever-evolving discipline.

A review of all cell phone forensic tools and the Cell Phone and GPS Forensic Tool Classification System will be covered in depth. Our world has become saturated with inexpensive digital devices. The ubiquity of these devices has changed the way we do everything, from staying in touch with friends on our smartphones to finding the nearest gas station with GPS technology. Criminals also use these devices to aid in the commission of crimes. GPS devices are used for human and narcotics smuggling, while cell phones are used to deliver text messages coordinating the next terrorist attack. Most electronic devices themselves contain a wealth of information and intelligence for investigators, though the field of digital device forensics is still in its infancy. There is a need for a common framework to classify the plethora of tools released into the commercial marketplace in the last five years. Given the exaggerated claims of software manufacturers, the field of mobile forensics has long since clamored for an understanding of not only how these tools work, but when they should be used. Attendees will be able to categorize any mobile device acquisition tool within a classification system. In addition, an overview of many commercial tools for cell phone data extraction currently available will be discussed. This presentation will provide a common framework for the digital device data extraction tool classification system for the entire digital forensics community.

The Apple iPhone®, utilizes SQLite Databases to store user data and applications that have been installed on the device. A digital forensic examiner trying to access this information through traditional means may miss large amounts of relevant data still present within the database. Because of the way inactive data is marked for deletion, it may be impossible to extract this data through typical database queries. Fragmented sections of these databases may also be found in unused space on the device. While the complete file is not readable by traditional methods, forensic recovery may still be possible. The key to gaining access to this information is to understand how the data is organized within the database structure and the manner in which it has been stored and encoded. Attendees will gain an understanding of how to obtain digital evidence from SQLite databases. Attendees will also gain an understanding of how this information is stored, how active and deleted content within these databases can be extracted, and how to decode the extracted information. An explanation of SQLite data storage structure, encoded data, the use of regular expressions to search for and identify records, and the ability to decode the stored values within the recovered records will also be presented. The storage of call history and text messages utilized by Apple's iOS® on the iPhone® will be specifically addressed and used as an example for how to identify and decode deleted records.

Mobile Forensicx, Apple iOS®, Validation

W11 Digital Photography for Forensic Document Examiners

David Witzke, BA, Foray Technologies, 3911 5th Avenue, Suite 300, San Diego, CA 92103; Ted M. Burkes, BS, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Room 2158, Quantico, VA 22135; and Joseph L. Parker, MSA, 518 Pinegate Road, Peachtree City, GA 30269*

After attending this presentation, attendees will be able to: (1) successfully demonstrate the effective documentation of forensic digital capture techniques as well as explain how digital technologies are used in evidentiary photography processes; (2) successfully complete a hands-on exercise demonstrating the comparison of image resolution and screen (display) resolution, demonstrating the artifacts caused by improper resolution settings and parameters; and (3) successfully complete a hands-on exercise demonstrating the artifacts caused by improper image processing techniques (such as rotating an image, compressing an image, printing an image, etc.). Participant achievement of the training objectives will be evaluated by observing participant behavior in the classroom and assessment of demonstrated practical skills by the instructor.

This presentation will impact the forensic science community by addressing the need for knowledge about the legal ramifications of digital evidentiary photography and best practices for digital evidentiary photography to include acceptable file formats and standards for capturing, storing, printing, transferring, and preserving digital/digitized evidence. It will also provide participants with the acceptable methods and techniques for comparing imaging technologies. The activities will include instructor-led demonstrations and hands-on exercises using image-editing software on the laptop computers participants bring for use in the course.

The Digital Photography for Forensic Document Examiners Training Program is intended for individuals working in a law enforcement field who have limited knowledge and experience using digital technologies in a forensic environment. Upon completion of this program, attendees will have a basic understanding of forensic digital imaging concepts and how various image capture techniques can aid in their investigative process.

It is recommended that attendees taking part in this course have a basic understanding of the Microsoft Windows XP operating system. In addition, it is recommended that all class participants be actively involved in a law enforcement discipline that uses digital imaging technologies.

This is a one-day training program that includes both lecture and hands-on training including note taking. Course instruction also includes a review of best practices and procedures as well as a comprehensive discussion and application of digital imaging techniques.

Digital Photography, Questioned Documents, Digital Imaging

W12 Humanitarian Forensic Science: The Forensic Investigation of Human Remains From Armed Conflicts and Catastrophes

Morris V. Tidball-Binz, MD, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND; Duarte N.P. Vieira, PhD, MD*, National Institute of Forensic Medicine, Lg. da Sé Nova Coimbra, Coimbra, 3000-213, PORTUGAL; Luis Fondebrider*, Argentine Forensic Anthropology Team (EAAF), Rivadavia 2443, 2do piso, dpto.3 y 4, (1034) Capital Federal, Buenos Aires, ARGENTINA; Ute Hofmeister, MA*, International Committee of the Red Cross, Calle 76 No 10-02, Bogota, COLOMBIA; Paul S. Sledzik, MS*, National Transportation Safety Board, Transportation Disaster Assistance Division, 490 L'Enfant Plaza East, SW, Washington, DC 20594; Mercedes Salado Puerto, PhD*, Argentine Forensic Anthropology Team, Av. Rivadavia 2443, Piso 2 Dep.4, Buenos Aire, 1034, ARGENTINA; William Goodwin, PhD*, School of Forensic Medicine and Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM; Shuala M. Drawdy, MA*, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND; Thomas D. Holland, PhD*, Department of Defense JPAC, Central ID Lab, 310 Worchester Avenue, Hickam AFB, HI 96853; Christophe Girod, BA*, Committee on Missing Persons in Cyprus, Karditsis 3, Ayios Andreas, Nicosia, 1100, CYPRUS; Nizam Peerwani, MD*, Office of the Chief Medical Examiner, Tarrant County, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919; and Michael S. Pollanen, MD*, Office of the Chief Coroner, 26 Grenville Street, Toronto, M7A 2G9, CANADA*

After attending this presentation, attendees will become familiar with the main practical considerations for large-scale forensic investigations for the search of missing persons from armed conflicts and catastrophes.

This presentation will impact the forensic science community by exploring the application of forensic science in humanitarian contexts and outlining some of the unique challenges posed to the wider forensic community by investigations into persons gone missing. It will also present some of the solutions identified for assisting forensic practitioners, institutions, and service providers involved in these investigations. A multidisciplinary panel of international experts will share their experiences, lessons learned and recommendations regarding practical considerations for large-scale forensic investigations in the search for missing persons from armed conflicts and catastrophes.

The humanitarian scope of forensic investigations applied in the search of missing persons world-wide requires awareness and consideration of factors rarely encountered in the domestic setting. International public law provisions must be well understood and socio-political factors impacting investigations must be taken into consideration. Forensic practitioners must be aware of the health and safety issues associated with working in foreign environments, as well as unique health and safety precautions necessary in potentially dangerous contexts. The psycho-social needs of the families related to the investigation of victims of conflict should be addressed, including the expectations of the bereaved. The selection and integration of identification methods should be planned with care and should be suitable to the specific requirements of the investigation, including the biological profile-related characteristics of the victims and the needs of the investigation. Resources for large-scale investigations, which are usually limited, should be appropriately managed and suitable for logistically-challenged settings while maintaining quality assurance and ethical conduct. Data gathered during investigative processes must be properly managed, taking into consideration chain-of-custody and confidentiality of the data. It must be decided in advance to whom the data will be shared with and under what circumstances. Utilization of local expertise and resources should be balanced against the needs for confidentiality, neutrality, and impartiality in the investigation at the same time recognizing that long-term investigation and identification processes require local involvement to ensure sustainability. Finally, specific ethical dilemmas related to forensic work and management of the dead in diverse contexts must be addressed, taking into consideration all other planning challenges and constraints. For example, political or prosecutorial pressures may place emphasis on investigative processes for judicial purposes leaving reduced resources for identification efforts. Likewise, reduced resources may force investigators to selectively target specific graves for investigation while leaving other known gravesites untouched, or necessitate the recovery of only a sample of remains within a grave.

As forensic practitioners increasingly become involved in international humanitarian operations, they must adapt their working methods to the specific needs of the investigation, which may differ from the domestic setting. In addition, they must integrate their technical skills into multi-disciplinary teams in order to address the various needs of the investigation and the victims to which the investigations relate. Therefore, it is imperative that practitioners working in large-scale forensic investigations for the search of missing persons from armed conflicts and catastrophes become familiar with the unique challenges that these operations may pose.

Humanitarian, Conflicts, Catastrophes

W13 Estimating Uncertainty in Weights: Hands-On Workshop Using SWGDRUG Document SD3

Suzanne Bell, PhD, West Virginia University, 1600 University Avenue, Oglebay Hall, Room 208, Morgantown, WV 26506-6121; Sandra E. Rodriguez-Cruz, PhD*, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081; Linda C. Jackson, MS*, Department of Forensic Science, 700 North 5th Street, Richmond, VA 23219; and Scott R. Oulton, BS*, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

After attending this presentation, attendees will be able to: (1) reference the SWGDRUG website and all associated resources; (2) understand the concept of uncertainty estimation in the seized drug context; (3) evaluate their weighing procedures and protocols using several different uncertainty estimation tools; (4) design a simple uncertainty budget using Excel; (5) design an uncertainty budget utilizing laboratory control charts; and (6) defend a reasonable uncertainty estimation before their peers and before triers of fact.

This presentation will impact the forensic science community by showing how estimation of uncertainty is a key element of any quantitative data and should be estimated when quantitative data is obtained. The 2009 National Academy of Sciences Report emphasized the need for estimation of uncertainty and accredited laboratories will soon face issues of uncertainty estimation and reporting. This workshop will assist forensic scientists in developing reasonable and defensible uncertainty estimations for an important category of quantitative data.

This workshop will include a hands-on tutorial designed to assist forensic analysts in estimating the uncertainty of weights obtained in a seized drug analysis. Although the target audience is drug analysts, anyone interested in uncertainty estimation will find this workshop useful and valuable. The workshop will be taught at an introductory level. No chemical knowledge is required or assumed. The workshop is built around the Scientific Working Group for Seized Drug Analysis (SWGDRUG, *www.swgdrug.org)* Supplemental Document SD-3, which presents several examples for making reasonable and defensible uncertainty estimates for weight measurements.

Uncertainty is a fundamental part of any quantitative measurement. Uncertainty is not the same thing as error, and recording data with an estimation of uncertainty does not imply that data is somehow suspect. The opposite is true; a quantitative value such as a weight of a drug exhibit, along with an uncertainty estimate, is more valuable in many cases, both to

the laboratory and to the customers it serves. The exercise of estimating the uncertainty associated with an instrument or procedure assists laboratories in improving practices and facilitating more effective and efficient method validation policies. The workshop will present examples of how these tasks can work together to improve laboratory operation.

The first part of the workshop program will include a general introduction to SWGDRUG Recommendations - Part IV C (Quality Assurance/Uncertainty) and Supplemental Document SD-3, followed by a discussion on the basic principles of uncertainty estimation. Statistical and metrological resources will be presented and key statistical concepts will be reviewed. Attendees will also receive useful information related to the selection, requirements, operation, calibration, and maintenance of laboratory balances.

The second part of the workshop will be dedicated to discussions of SWGDRUG Supplemental Document SD-3 (Measurement Uncertainty for Weight Determinations in Seized Drug Analysis). A copy of this document will be provided to all attendees and its purpose and background, within the scope of SWGDRUG's mission, will be discussed. This document contains specific examples of how to calculate the uncertainty associated with weight measurements performed in a laboratory. The basis, assumptions, and background behind each one of these examples will be presented in a format that provides for active discussion with the workshop audience. The workshop presenters will also provide assistance and suggestions on how to present and defend uncertainty estimates to peers as well as legal professionals.

The third part of the workshop will be dedicated to open discussions. Attendees are strongly encouraged to bring examples of specific laboratory models for presentation during this section of the workshop. Examples will be discussed and assistance provided on developing uncertainty budgets. Attendees are also welcomed to bring a laptop computer and data from their laboratory for use during the hands-on portion of the workshop.

Uncertainty Estimation, Seized Drugs, SWGDRUG

W14 Using Pharmacokinetics to Analyze Forensic Toxicology Cases

David M. Benjamin, PhD, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918; Dwain C. Fuller, BS*, Veterans Affairs North Texas Health Care System, Toxicology-B113, 4500 South Lancaster Road, Dallas, TX 75216; Graham R. Jones, PhD*, Medical Examiner's Office, 7007-116 Street, NW, Edmonton, AB T6H 5R8, CANADA; W. and Lee Hearn, PhD*, Miami-Dade County, Medical Examiner's Office, #1 on Bob Hope Road, Miami, FL 33136-1133*

After attending this presentation, attendees will: (1) summarize the basic physiology, pharmacology, and pharmacokinetics required to interpret drug blood and urine levels which have been obtained both before and after death; (2) present confounding issues that limit the interpretation of many quantitative blood test results such as postmortem redistribution, and pharmacokinetics in children; and (3) review approaches to analyzing the complicated Forensic Toxicology case.

This presentation will impact the forensic science community by showing how forensic toxicologists, pathologists, and criminalists are often presented with the results of a single blood test or a single urine test and asked, "Did it kill him/her?", "Was she/he impaired?", and/or "Did it injure him/her?" Such questions are very difficult to answer on the strength of one test result. The workshop begins with a review of the physiology, pharmacology, and pharmacokinetics of drugs, followed by presentations involving postmortem redistribution, postmortem pharmacokinetics, tissue distribution in the ante- and postmortem settings, and the significance of using various sampling sites for blood.

Pharmacokinetics is the study of the absorption, distribution, metabolism, and excretion of drugs. In many instances, determination of the cause and manner of death may be elucidated by analyzing the correlation of the drug's pharmacokinetics and the drug's effect (pharmacodynamics). Forensic toxicologists, pathologists, and criminalists are often presented with the results of a single blood test or a single urine test and asked, "Did it injure or kill him/her?", or "Was she/he impaired?" These questions are very difficult to answer on the strength of one test result. In many instances, the investigating forensic scientist would like to develop an adequate history regarding the time the last dose was taken, the amount, the route of administration, and whether the final dose was a single acute OD, a large OD, or an OD that occurred due to drug accumulation over time, but access to those data are unavailable. In addition, genetic factors regulating drug metabolism, drug interactions, and differences in a drug's pharmacokinetics during toxic dosing (toxicokinetics) impact the analysis of the drug's blood levels and toxic effects.

Though many cases involve the analysis of blood samples obtained from living subjects, in some cases, the blood samples are obtained after death. In the postmortem state, multiple samples obtained from different body sites (e.g., femoral, iliac, subclavian, and cardiac) often show different quantitative results. This may be due to partial absorption from the gastrointestinal tract, incomplete distribution of the drug after ingestion but prior to death, or postmortem redistribution. Cardiac blood is the least reliable. There are four chambers of the heart, and on analysis, all may give different results. Results of blood samples taken from the left side of the heart are less reliable than results obtained from blood samples taken from the right side of the heart because the left side fills from the pulmonary vein (and the lungs are known to accumulate drugs), thus causing the blood to contain higher levels of drug than found in the right heart, which fills from the systemic circulation (vena cavae).

When blood samples have been obtained after death or at autopsy, changes in postmortem redistribution, putrefaction, bacterial contamination, and postmortem production of ethanol may confound the interpretation of the results, unless blood sampling from various body sites and tissues was carried out. In the postmortem state, determining the cause and manner of death may be quite difficult. Moreover, in the postmortem setting, the pharmacokinetics of the drug is altered, as is the volume of distribution (Vd). Using PK and Vd data from antemortem studies and applying them to postmortem data, or using Vd data from adults and applying them to children may lead to major errors in the interpretation of the data and incorrect conclusions about the cause of impairment or death. Attendees will learn how to better apply the principles of PK in their cases, and raise the level of the application of the principles of PK in their practice of forensic toxicology.

Pharmacokinetics, Postmortem Redistribution, Forensic Toxicology

W15 Hell on Earth — Just Another Day at Work: An Overview of the Tri-State Crematory Catastrophe

Kris L. Sperry, MD, Georgia Bureau of Investigation, 3121 Panthersville Road, PO Box 370808, Decatur, GA 30037-0808; J.C. Upshaw Downs, MD*, Georgia Bureau of Investigation Medical Examiner's Office, 925 A Mohawk Drive, Savannah, GA 31419; Mark A. Koponen, MD, University of North Dakota, Department of Pathology, 501 North Columbia Road, Mailstop 9037, Grand Forks, ND 58282-9037; and Greg Ramey, MA*, Georgia Bureau of Investigation, 3121 Panthersville Road, Decatur, GA 30034*

After attending this presentation, attendees will be able to understand how to approach a mass disaster created when large numbers of bodies are not cremated in accordance with standard funeral practice. Participants will also gain an understanding of how multiple agencies interact in dealing with a complex mass disaster. Approaches to public and media involvement will also be discussed.

This presentation will impact the forensic science community by showing lessons learned from a unique incident which created social havoc

throughout Georgia, Tennessee, and Alabama. The impact was felt among thousands of individuals who had sent the bodies of their loved ones to be cremated. This incident also captured national and international attention in the forensic and non-forensic communities.

On the otherwise typical afternoon of February 15, 2002, during the course of the AAFS meeting in Atlanta, GA, a call came in that changed an otherwise beautiful and mild, deep-South winter's day into one of the singularly most macabre events ever imagined. A decade later, the memories are vivid.

Acting on an anonymous call, investigators responded to a scene in the Noble Community of rural Walker County, GA, just 100 miles from Atlanta, the heart of the "new south." A passerby had discovered what were believed to be human remains in a heavily wooded area, adjacent to several residences and the family-owned Tri-State Crematory, serving northeast Alabama, south central Tennessee, and northwest Georgia.

Investigators arrived to find a scene almost defying description – dozens of bodies, in various stages of decomposition, were laid out in a garage. As investigators recovered from the initial shock and continued exploring the property, dozens of bodies, then hundreds were discovered. Eventually, bodies were found strewn in the woods, comingled in pits, comingled in casket vaults, and within several buildings and vehicles on the property. The crematory owner had maintained essentially no records regarding his supposed cremation practices. A full-scale mass death scene investigation ensued, requiring the combined resources of local, state, and national agencies. The National Disaster Mortuary Response Team (D-MORT) was deployed to assist with the processing the unidentified bodies and partial sets of remains. It was eventually determined to represent remains of some 334 individuals. The recovery process alone lasted for three weeks. Eventually, this case became the largest criminal investigation in the history of the state of Georgia, involving over 500 individuals from more than 55 local, state, and federal agencies in the recovery and identification of these remains. Successful and continuous multi-jurisdictional agency interaction was essential to the resolution of the matter, particularly in handling a problem that literally grew with each passing day.

The scale of the recovery and identification process was hindered by multiple factors, including: location, multiple clusters of mini-scenes with varied conditions, lack of defined scene boundaries, unknown and varied postmortem interval of individual cases, and unknown numbers of remains. All of these factors, combined with the intense international interest in the case led to one of the most unusual death investigation cases in the annals of death investigation. This overview touches on the various aspects of the case including initial response, scene assessment and triage, body recovery, identification, family interaction, media interaction, and criminal investigation.

Families and media: The macabre nature of the event resulted in immediate and eventually world-wide interest in the case. Given the intense interest in the case, media interaction became an important factor. A balance had to be struck between the families' rights to be kept informed and public information. Daily interactions included meetings with grieving family members and the national and international press. Dignitaries concerned enough to visit the site included the state's Governor and both U.S. Senators. Superimposed was a criminal investigation, involving some 700 charges and three states. The balance was struck to inform families of progress first and to have one public face associated with the media. The importance of a "family-first" philosophy facilitated a rapid and successful resolution.

Initial response/scene: The challenging nature of the sheer volume (literally hundreds of bodies, including many co-mingled and partial remains) was compounded by the ill-defined crime scene area and the lack of any kind of tentative manifest to facilitate with recovering and processing of the remains. The key to a successful outcome in such a massive undertaking is effective assessment and planning.

Body recovery: The archaeology of body recovery from mass graves and pits, combined with the need for preservation of evidence for potential criminal prosecution, is a fortunately rare occurrence. The early recognition of the nature and scope of the case allowed strategic placement of sufficient resources in a timely manner. The latter, combined with a strong team concept, kept morale high and expedited the initial processing of remains.

Identification: The unique nature of such an aggregate of an unknown number of unidentified partial and complete remains raging from minimally decomposed to skeletonized was compounded by the lack of knowledge regarding numbers of bodies present. Identification concerns were paramount to the families, and as such, rapid protocols for body identification were required. A balance had to be struck between speed and science, with accuracy unquestioned. The identification techniques employed and success/concerns is summarized. The identification process included collection of thousands of DNA samples from family members and lasted almost two years, although an internet inventory of remains with possible identifiers still results in occasional requests for possible identification.

Investigation/Prosecution: The ultimate cost of this man-made disaster to the State of Georgia was approximately 10 million dollars and generated over 100,000 pages of documentation. The perpetrator was charged with 787 counts, including theft by deception, abuse of a corpse, fraud, and giving false statements. He allegedly faced the potential of over 8,000 years in prison if convicted. He eventually pled guilty and was sentenced to twelve years, with credit for time served. Approximately 1,700 family members whose loved ones' bodies had been abandoned joined a class action suit. Settlements reached totaled well over $100 million but were later significantly reduced to approximately $54 million

In the final analysis, this case was about hundreds of families whose loved ones' bodies were left to decompose in the foothills of North Georgia. The overall investigation and close teamwork between the law enforcement, medical examiner, anthropologist, and district attorney resulted in a guilty plea in one of the most bizarre criminal cases of all time and a rapid resolution to the ubiquitous civil litigations.

Motive: "To those of you who may have come here today looking for answers, I cannot give you." said by Ray Brent Marsh upon entering his guilty plea. His attorneys would later allege that the admitted perpetrator of the crime resulting in largest investigation in the history of the state was a victim of mercury poisoning, allegedly from exposure caused by the dental amalgams from cremated bodies.

Crematory, Media, Identification

W16 Applications of 2D and 3D Geometric Morphometrics in Forensic Comparisons

Victor W. Weedn, MD, JD, Maryland State, Office of the Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223; Howard A. Harris, PhD, JD, University of New Haven, Forensic Science Program, 300 Boston Post Road, West Haven, CT 06516; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Mary A. Bush, DDS*, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; H. David Sheets, PhD*, Canisius College, Department of Physics, 2001 Main Street, Buffalo, NY 14208; Alain Beauchamp, PhD*, Forensic Technology WAI Inc., 5757 Davendish Boulevard, Suite 200, Cote St – Luc, QC CANADA; William R. Oliver, MD*, Brody School of Medicine, East Carolina University, Brody Medical Sciences Building, Greenville, NC 27834; Jurrien Bijhold, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, 2497GB, NETHERLANDS; and Nicholas D. Petraco, PhD*, 899 10th Avenue, John Jay College of Criminal Justice, Department of Science, New York, NY 10019*

The goal of this workshop is to familiarize attendees with the possibilities for morphometric comparison in both 2D and 3D formats as well as limitations and possibilities for use in forensic science are discussed.

This presentation will impact the forensic science community by showing methods that are used for pattern recognition in forensic comparison with error rates.

Last spring, the Forensic Sciences Foundation's (FSF) Theoretical Forensic Science Committee sponsored a contest. Mary Bush, DDS from the State University of New York at Buffalo was the winner of this "New Science or Technology to Forensic Science" competition.

Based on the contest, this workshop has been developed to discuss and present different aspects of morphometric comparison in forensic science, with application to odontology, footwear impressions, bullets, fingerprints, facial comparison, wound analysis, and 3D reconstruction.

This workshop will: (1) provide an overview of geometric morphometric (GM) analysis; and, (2) demonstrate the methods for evaluation, measurement, and statistical comparison of shape change/distortion of an object in question. The generation of matching criteria and error rates based on a statistical model are discussed in relation to the work of Dr. Bush. Application of GM methods to bitemarks, fingerprints, shoeprints to 3D visualization of 3D bullet comparison, medical forensics, and facial comparison will be presented. Advantages and disadvantages of the different approaches on comparison of shapes based on pattern recognition in digital images will be discussed.

A well-developed method to describe shape variation between biological specimens is geometric morphometric analysis. GM analysis involves placement of landmark points, curves, or outlines on either two- or three-dimensional images. The landmark data can be extracted and analyzed statistically as a unit. GM methods allow for a quantitative examination of shape by capturing the geometry of morphological structures of interest and preserving this information through statistical analysis. Shape information can be visualized by plotting landmark positions in Procrustes superimposition, a method of optimally matching one shape to another. This can be performed with or without scale. Procrustes distances can be used to summarize variations in populations, to express the degree of similarity of individual specimens, means of populations, or to search for matches between specimens.

Amongst the tools available for statistical analysis is principal component analysis (PCA) with which the principal variations of shape can be plotted and visualized. This allows for determination of which shape aspect is responsible for the most variation. Canonical variates analysis (CVA) can also be used to determine if shape information can distinguish between different categories of data. A range of other standard multivariate statistical methods can also be applied to shape data, allowing applications to a wide range of research questions and practical problems.

There has been much recent discussion in forensic forums concerning what constitutes a match, or what defines two objects as being indistinguishable. It might be stated that two objects are identical when differences in measured attributes fall below measurement error levels, when the differences seen are no longer distinguishable from random effects. Error rates can be established by repeated measures studies, in which the same object is measured multiple times. The Procrustes distance derived from GM analysis can be used as a quantitative descriptor of error, and can be used as a threshold value below which objects might be said to match.

Clearly measurement resolution also depends on the scale of the object being measured, and the resolution (smallest object measurable) of the means used to image the object. For example, in crime scene or accident reconstruction, the resolution required might be fractions of a meter; in a shoeprint, individualizing detail might be separated by cm, in a bitemark the achievable measurement resolution might be on a mm scale, fingerprints on a micron scale, and tool marks potentially submicron.

With these examples in mind, careful attention to the issues of magnification (scale) and resolution is of the first importance. However, GM methods can be applied regardless of scale, as long as the nature of the data is understood. At each level of scale, error rates can be established and quantified.

Using GM methods, large datasets can be statistically compared to explore the issues stated above. Ideally, quantification of the range and types of distortion produced will provide forensic practitioners with quantifiable validations of the quality of example items in the pattern evidence disciplines.

Morphometric, Pattern Recognition, Comparison

W17 Advances in Asphyxia by Strangulation for Pathologists and Anthropologists

Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, T6H 5R8, CANADA; Steven A. Symes, PhD*, Mercyhurst Archaeological Institute, Mercyhurst College, 501 East 38th, Erie, PA 16546; Joao E.S. Pinheiro, MD*, Instituto Nacional de Medicina Legal, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; and Ericka N. L'Abbe, PhD*, PO Box 5023, Pretoria, 0001, SOUTH AFRICA*

After attending this presentation, attendees will have a better understanding and knowledge of the new standardized INFOR classification of asphyxia, best practices of autopsy dissections in strangulation cases, radiology aspect of these cases, anthropology best approach, and updates on the pathophysiology.

This presentation will impact the forensic science community by informing the forensic pathologists and anthropologists of the updates on strangulation and the best practices in these cases.

The classification of asphyxia and the definitions of subtypes are far from being uniform, varying widely from one textbook to another and from one paper to the next. Unfortunately, similar research designs can lead to totally different results depending on the definitions used. Closely comparable cases are called differently by equally competent forensic pathologists/medico-legal doctors. In response to this situation, a unified system of classification was recently proposed. This new standardized classification of asphyxia, called the INFOR classification, will be presented. In the INFOR classification, asphyxia in the forensic context is divided in suffocation (subdivided in choking, smothering, and confined spaces/entrapment/vitiated atmosphere), strangulation (subdivided in hanging, ligature strangulation, and manual strangulation), positional and traumatic asphyxia, and drowning. The controversies around the term mechanical asphyxia will be discussed. Asphyxial games will be presented in relation to this new classification.

The external and internal examination findings in strangulation will be discussed. A proper neck dissection is a key element in the investigation of strangulation deaths. Despite the usefulness of x-rays and computed tomography as ancillary techniques, manual dissection of the neck structures remains the most widely used technique to assess the integrity of neck structures. There are two ways to dissect the neck: *in situ* or *ex-situ*. The *ex-situ* method follows the removal of the neck structures by cutting the muscles insertions of the base of the mouth and gently removing this group of structures from the vertebral column. This *ex-situ* method is superior to the *in-situ* method and the reasons for this will be explained. The method will be described step-by-step, with images of external and internal injuries. The common pitfalls in the interpretation of autopsy findings will be discussed: anatomical variations (e.g., triticeal cartilage), normal mobility or bending of a cartilage or join (with considerations on the rate of ossification of the hyoid and thyroid horns and the sinostosis of the horn/body joint of the hyoid), and postmortem changes.

The incidence of bone fractures in suicidal versus homicidal hangings and manual strangulation will be presented, along with the explanations for these injuries. The accuracy of anthropologist/pathologist interpretations of evidence obtained during autopsy and analysis of bones will be discussed.

The modern understanding of the pathophysiology of hanging and strangulation was significantly changed by the creation of the Working Group on Human Asphyxia in 2006. The results from this ongoing study will be presented. The study of filmed hangings and strangulation has clearly established the agonal responses in these deaths: rapid loss of consciousness (10 s ± 3 s), mild generalized convulsions (14 s ± 3 s),

decerebrate rigidity (19 s ± 5 s), beginning of deep rhythmic abdominal respiratory movements (19 s ± 5 s), decorticate rigidity (38 s ± 15 s), loss of muscle tone (1 min 17 s ± 25 s), end of deep abdominal respiratory movements (1 min 51 s ± 30 s), and last muscle movement (4 min 12 s ± 2 min 29 s). The time to irreversible damages and death in hanging and strangulation will be discussed, based on the study of non-lethal filmed events. The implication of the advances from the Working Group on Human Asphyxia on the understanding of asphyxial games will be discussed.

Asphyxia, Strangulation, Forensic

W18 Deadly by Design: Forensic Toxicology, Adverse Effects of Synthetic Cannabinoids, and Novel Designer Drugs ("Bath Salts")

Barry K. Logan, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Brianna Peterson, PhD*, Washington State Patrol, 2203 Airport Way, South, Seattle, WA 98134; Wendy R. Adams, PhD*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Kurt C. Kleinschmidt, MD*, University of Southwestern Texas Medical Center, Deprtment of Surgery, Division of Emergency Medicine/Toxicology, 5323 Harry Hines Boulevard, Dallas, TX 75390; Jillian Yeakel, MSFS*, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; Christine Murphy, MD*, Carolinas Poison Center, PO Box 32861, Charlotte, NC 28232-2861; Gregory A. Schmunk, MD*, Polk County Medical Examiner's Office, 1914 Carpenter Avenue, Des Moines, IA 50314; and Amy Miles, BS*, Wisconsin Laboratory of Hygiene, 2601 Agriculture Drive, PO Box 7996, Madison, WI 53707*

The goals of this presentation are to: (1) make the forensic science community aware of the prevalence and toxicity of the products; (2) educate forensic professionals about the challenges involved in their analysis including sample preparation and analysis; (3) familiarize forensic pathologists and toxicologists with the adverse effects of the chemicals; (4) provide reference case details of circumstances surrounding impairment and criminal acts committed under the influence of the drugs; and, (5) present evidence that the drugs can cause death.

This presentation will impact the forensic science community by increasing awareness of the latest categories of abused drugs which will require changes in current forensic practice and by providing evidence to support the scheduling and control of these dangerous new chemicals, many of which are currently available without restriction.

This program will present information regarding the various classes of synthetic drugs which have recently become popular within the recreational drug using community. Exploration of the highs associated with these drugs has become known as the "research chemicals movement." Compounds used by these groups include synthetic cannabinoid agonists, cathinone derivatives, pyrovalerone derivatives, and many others. Use of these chemicals has significant adverse effects and forensic consequences.

The program builds on basic analytical information presented at the AAFS Annual Meeting in 2011, and will cover the latest developments in the availability, analysis, and forensic toxicology of these new illicit drugs. The scope will include information about the chemicals in circulation, how they are detected and measured, adverse event reports presented to Poison Control Centers, and the involvement of the drugs in impaired driving, suicide, assault, and homicide cases.

Specific presentations will cover the current scope of drugs present in these materials, their legal status, and how the analog and homolog aspects of the federal law should be interpreted. The remainder of the workshop will include a review of current analytical approaches to the identification of the chemicals in seized materials, blood, urine, and tissue, and will include pharmacokinetic data in blood, urine, and oral fluid from controlled administration of a range of the synthetic cannabinoid drugs. The focus of the remainder of the session will be on adverse effects associated with the various compound classes from various medical and forensic perspectives. This will include data from Poison Control Centers derived from calls from the public and medical professionals that have documented hypertension, agitation, paranoia, and seizures following use of synthetic cannabinoid and other legal high drugs. The program also includes case reports of suicides, assaults, and homicides following use of the unscheduled drugs mephedrone and MDPV sold as "Bath Salts" but intended for recreational use. Finally, a series of deaths in which either the synthetic cannabinoid or stimulant type drugs appear to have played a role will be discussed along with the difficulties in testing for use of the compounds and assessing their role in the causation of death.

At the conclusion of the workshop, attendees will be able to describe the various categories of drugs in the synthetic cannabinoid and designer drug categories; select or order appropriate analytical tests to ensure their detection; apply aids to the interpretation of designer drug findings in forensic casework; and recognize adverse effects of the drugs through evaluation of signs and symptoms of use.

Designer Drugs, Synthetic Cannabinoids, Forensic Toxicology

W19 The Anatomy of Error: Dissecting Adverse Events to Strengthen the Forensic Sciences

Susan M. Ballou, MS, and Melissa K. Taylor, BA*, National Institute of Standards & Technology, Law Enforcement Standards Office, 100 Bureau Drive, Mailstop 8102, Gaithersburg, MD 20899; Barbara Gregory, MPH*, Duke University, Duke University Medical Center, 104425, Durham, NC 27710; Deborah Boehm-Davis, PhD*, George Mason University, College of Humanities and Social Sciences, 4400 University Drive, Mailstop 3F5, Fairfax, VA 22030-4444; Scott A. Shappell, PhD*, Clemson University, Department of Industrial Engineering, 130B Freeman Hall, Clemson, SC 29634; and Christopher J. Plourd, JD*, Law Office of Christopher J. Plourd, 1168 Union Street, Suite 303, San Diego, CA 92101-3818*

After attending this presentation, attendees will: (1) learn the fundamentals of human error analysis; (2) define error, active error, and latent error; (3) discuss the origins of error in human and system perspectives; (4) understand human factors impacting performance; (5) describe and apply the different models of failure; and, (6) identify and initiate steps to resolve potential "error traps" in the work environment.

This presentation will impact the forensic science community by providing an overview of the field of human error, illuminate how human factors such as fatigue and bias can negatively impact performance, and educate the attendees on the application of human factor codes to items analyzed in a high profile murder case.

Reviewing the actions and accomplishments of other professions that have successfully dealt with human errors will assist attendees in understanding the fundamentals of error analysis. The medical and aviation professions have conducted extensive research on the subconscious to identify how human performance is helped or hindered by the design of equipment, work environment, and peer pressure. Making corrections or changes according to these revelations have improved performance and mitigated errors within these professions.

Fatigue has long been associated with decreases in human performance. While this is a problem that challenges most industries, those that are human-centric are at an even greater threat. The forensic sciences remain a field that heavily relies on the performance of its analysts and requires 100% accuracy. Unfortunately, crime scene technicians and analysts are just as susceptible to fatigue as other professionals. Operator fatigue has been shown to effect performance after just 18 hours of sustained wakefulness. While reductions in alertness and performance are a problem for workers in general, those who perform tasks, which demand high levels of cognition, are even more susceptible to the effects of fatigue. Fortunately, there are a number of management techniques, countermeasures, and interventions that will be discussed and defined to help mitigate these negative effects.

One aspect of the management technique is the education of staff on the difference between active errors, those events when individuals are in direct contact with physical evidence and latent errors, when the underlying support system comes into question. These topics have been part of the two year effort assigned to the Expert Working Group on Human Factors in Latent Print Analysis, an effort that has recently completed its task. Evaluating approaches to reducing errors in terms of their efficacy, appropriateness, cost, scientific basis, feasibility, associated risks, and quality of evidence have been documented and will be offered.

The class participation portion of the workshop provides an opportunity for the attendees to take the provided information and apply it to an actual criminal case. Applying lessons learned (when back at the crime scene, in the laboratory, or managing staff), work flow is increased when provided an opportunity to experience direct application. Part of the direct application will be segmenting levels of forensic work, using error coding techniques and assigning mitigation activities. A 1992 murder case, the conviction of Ray Krone and the associated bitemark evidence, will be used for this activity.

Therefore, this workshop has direct application to individuals who collect, handle, analyze, manage, and store forensic evidence. It introduces the concept of applying error mitigation techniques to the forensic science profession and provides established guidance learned in other professional fields. An actual criminal case will be presented allowing each attendee to gain experience in the actual error coding process and understand the underlying basis and resulting influence of errors.

Error, Cognitive Bias, Quality Assurance Quality Control

W20 Flawed Forensics: Recognizing and Challenging Misleading Forensic Evidence and Disingenuous Expert Testimony

Andrew Sulner, MSFS, JD, Forensic Document Examinations, LLC, 220 East 57th Street, Suite 200, New York, NY 10022; Joseph J. Maltese, JD*, New York Supreme Court, 130 Stuyvesant Place, 3rd Floor, Staten Island, NY 10301; Linda K. Baden, JD*, and Michael M. Baden, MD*, 15 West 53rd Street, #18B-C, New York, NY 10019; Jose A. Baez, JD*, 522 Simpson Road, Kissimmee, FL 34744; David M. Benjamin, PhD*, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of Pennsylvania, Erie County Court House, 140 West 6th Street, Room 223, Erie, PA 16501; Peter Neufeld, JD*, The Innocence Project, 40 Worth Street, Suite 701, New York, NY 10013; Michael Risinger, JD*, Seton Hall University, School of Law, One Newark Center, Newark, NJ 07102; and Marvin Schechter, JD*, 1790 Broadway, Suite 710, New York, NY 10019*

After attending this presentation, the attendees will be better acquainted with the current problems and challenges facing expert witnesses in various disciplines of forensic science. Attendees will learn how expert testimony or evidence is being challenged as unreliable, or misleading and disingenuous, what methods lawyers use to impeach such testimony or evidence, and the legal basis for excluding such evidence.

This presentation will impact the forensic science community by providing forensic scientists with examples of the problems and challenges they can face when testifying in court. All stakeholders in the administration of criminal or civil justice – experts, lawyers, and judges – will benefit from learning about scientific and evidentiary challenges to expert testimony, testimonial practices that experts should avoid, and the means by which lawyers challenge and judges exclude forensic expert testimony. This workshop will assist forensic scientists and lawyers in recognizing when the testimony of a particular expert witness is misleading and disingenuous and how to challenge and effectively impeach or preclude such testimony.

A multidisciplinary faculty will review actual testimony of forensic specialists in different disciplines. Discussion of cases and reported court decisions will illustrate the problems and ongoing challenges facing forensic scientists testifying in criminal and civil cases. Critical knowledge about when and under what circumstances, testimony or evidence introduced by forensic scientists will be challenged as being misleading or disingenuous, and how such challenges take place in the adversarial process of our judicial system will be discussed.

The uses and limits of cross-examination to reveal weaknesses in the testimony of forensic scientists will be explored, and examples involving misleading and disingenuous testimony by toxicologists, pathologists, and other forensic scientists will be examined and discussed from a scientific and legal standpoint, and from the perspective of the forensic scientist, the trial lawyer, and the judge. Actual cases in which deficiencies in report writing and incomplete or misleading testimony by forensic practitioners contributed to wrongful convictions will be reviewed and analyzed, and recommended solutions designed to correct this problem will be discussed.

Workshop attendees will learn about the true meaning of the different types of casework "peer review" occurring within the forensic community, the methods lawyers can use to impeach disingenuous testimony concerning such peer reviews, and the legal basis for excluding peer review testimony by the actual reviewer.

High profile criminal defense attorneys will discuss cases involving flawed and fabricated scientific evidence. The lead defense attorney in the recent, highly-publicized capital murder prosecution of Casey Anthony, which resulted in not guilty verdicts on all charges involving the death of the defendant's 2-year-old daughter, will discuss the challenges he faced before and during the lengthy jury trial, as well as the methods used to impeach the forensic evidence presented by the prosecution.

Attendees will become acquainted with the principles and pitfalls involving courtroom testimony in the wake of the National Academy of Sciences (NAS) Report and recent court decisions defining the parameters of forensic testimony. Specific examples of courtroom testimony will be utilized to illustrate problems in fingerprint comparison, tool mark identification, and bitemark analysis. Various aspects of testimonial evidence will be specifically targeted, such as the use of terminology in rendering a conclusion. The validity of subjective analysis and the intermingling of scientific principles will be addressed in the context of probability assertions. How the forensic practitioner handles the dual problems of explaining key forensic discipline definitions and producing appropriate back-up materials in buttressing validity will also be examined.

Finally, attendees will learn about the misleading use journal articles, treatises, and studies or experiments to substantiate or attack the basis for an expert opinion in the pre-trial and trial phases of a court proceeding, and the manner in which judges scrutinize and evaluate such evidence. Attendees will also learn about the ethical implications for a trial judge faced with disingenuous expert testimony and the nature of the ensuing judicial response.

Flawed Forensics, Misleading Evidence, Disingenuous Testimony

W21 Innovation in Forensic Image and Video Analysis

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Jurrien Bijhold, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, 2497GB, NETHERLANDS; Richard Vorder Bruegge, PhD*, Federal Bureau of Investigation, OTD-DES, Building 27958A, Pod E, Quantico, VA 22135; William R. Oliver, MD*, Brody School of Medicine, East Carolina University, Brody Medical Sciences Building, Greenville, NC 27834; and Leonid I. Rudin, PhD*, Cognitech, 283 S Lake Avenue, Suite 230, Pasadena, CA 91101*

After attending this presentation, attendees will understand how to validate forensic methods in image restoration and limitations and possibilities of forensic multimedia investigation.

This presentation will impact the forensic science community by providing an overview of the new developments and needs in forensic research.

During this workshop information will be provided on new developments of forensic investigation of (digital) images and video streams and the use of 3D computer modeling in forensic investigations. The workshop will be interactive and many examples of case material will be shown.

Traditional sources of images as evidence concern crime scene photography, and more specifically, photographs of fingerprints, tool marks, shoe prints, and other impressions. A short overview of image processing techniques is given. Special attention is given to the introduction of artifacts by image processing (e.g., FFT on fingerprints), quality assurance, and validation aspects. During the last decades, the use of CCTV-camera systems and digital cameras on phones has become widespread. Typical questions concern the quality and the selection of images from a specific camera in a multi-camera-recording, and combining the information. Digital processing of video streams for presentation and storage purposes, and the compression techniques that are applied in digital CCTV-systems, lead to questions about the integrity and authenticity of recordings. In addition, questions about image interpretation like facial recognition, body height, car speed (often in low resolution), time lapse, or compressed images have increased. A special discussion will be given on image analysis.

Since more images are being processed for forensic investigation, new methods have been developed for answering questions about the interpretation of images. Examples given: is it possible to read a license plate number? Is a suspect, or his car, the one depicted in the image? What is the body length of the robber or the speed of a car? Gait analysis, and, is it possible to do a reconstruction of an accident or a shooting incident from the information in these images? Methods for image comparison, facial comparison with non standardized images, image reconstruction, and measurement in images are presented and discussed. Special attention will be given to measurement uncertainties of the results and the impact on the conclusions from these investigations.

Common sources of video streams and images are video recordings from handy cams, digital photo cameras, the internet, and cellular phones. Typical questions about these recordings concern the integrity and authenticity of the recordings, the data compression techniques used, the synchronicity of sound and images, compensation for camera movement, and the conversion of a video stream to a higher resolution image. This session will focus on methods for state-of-the-art image enhancement techniques such as contrast, stretching, and deblurring, as well as super resolution, stabilizing, and automatic tracking methods. It will also cover the issue of erased video files, and how to recover these when they are partly erased.

The state-of-the-art methods for camera comparison will also be presented, examples of comparing Photo Response Non Uniformity with software. With this method a camera can be linked to a camera. Also the cautions of identification and limitations of the technique are discussed, and solved with likelihood ratios.

The methods are discussed also in relation to forensic medical image analysis and possibilities within pathology, with many practical examples. Computing speed for some of the image analysis methods (especially for high volume of data), and the possibilities of fast parallel computing with GPU's and CUDA for forensic video applications are discussed.

Finally, an overview on the use of 3D computer modeling in forensic investigations will be provided because these techniques have an impact on traditional crime scene photography. Computer models and animations have been recently used for analyzing video by superimposition of computer generated views of the model on the video images, for the visualization of complex scenarios in animations and for testing scenarios against video footage and evidence in crime scene photographs. Examples: the reconstruction of car accidents from photographs, analysis of blood spatter patterns from photographs using a computer model of the crime scene, the visualization of wound channels in computer models of human bodies, the reconstruction of bullet trajectories, the reconstruction of a burglary using the limited information in dark images from a multi-camera video recording, and the analysis of firework explosions from video recordings, photographs, and geographical data. Special attention is given to modeling techniques, the accuracy of the models, the methods for visualizing uncertainties, and possibly erroneous suggestions coming from these visualizations. 3D video fusion for use in casework is demonstrated.

Multimedia, Video, Medical

A1 Footprint Ridge Density — A New Attribute for Sexual Dimorphism

Tanuj Kanchan, MD, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; Kewal Krishnan, PhD, Panjab University, Department of Anthropology, Sector-14, Chandigarh, 160 014, INDIA; and K.R. Aparna, and S. Shyam Sundar, Kasturba Medical College, LHH Road, Mangalore, Karnataka 575 001, INDIA*

After attending this presentation, attendees will be able to recognize that the ridge density in footprints exhibit sexual dimorphism in Indian population.

This presentation will impact the forensic science community by recognizing the sexual dimorphism of the ridge density in footprints that may be used in identification of dismembered human remains in cases where an individual foot is recovered and brought for examination. It can give vital evidence in identification of the perpetrator of the crime in cases where the footprints are left behind at a crime scene.

Determination of sex has a vital role to play in forensic examinations. Footprints are often encountered at crime scenes especially belonging to murder and sexual assailants. From the available footprints at the crime scene, if the sex of the suspect is inferred, the burden of the investigating officer is reduced by half as the search of potential suspects will be restricted to a particular sex. Although researchers have attempted sex determination from fingerprint ridge density, the sex differences from the ridge density in footprints remain unreported. To the best of the authors' knowledge no systematic studies are available on the sex differences from ridge density in footprints worldwide. This preliminary study is done to evaluate the sex differences from ridge density in footprints and study its usefulness in discriminating sex in Indian population using statistical considerations.

The present prospective research was conducted on 106 young adults (56 males and 50 females) at the Department of Forensic Medicine, Kasturba Medical College, Mangalore, India. Healthy individuals aged 20 to 25 years were included in this study after taking informed consent. The subjects with any disease, deformity, injury, fracture, amputation, or history of any surgical procedures of the feet were excluded from the study. Each subject included in the study was asked to wash his/her foot clean with soap and water. A clean plain glass plate was uniformly smeared with black duplicating ink with the help of a roller. The subjects were asked to apply their feet on the smeared plate and then transfer them on to a white paper. Regular pressure was applied on the foot area to obtain the footprints. A 5mm x 5mm square was drawn on a transparent film and placed on the obtained footprint samples in the areas to be analyzed. In order to measure ridge density, the count was carried out diagonally on a square measuring 5mm x 5mm. The epidermal ridges were counted with the help of a hand lens. This count represents the number of ridges in 25mm square area and reflects the ridge density value. The ridge density value was similarly obtained individually from the four designated areas on the footprints that are commonly encountered at the crime scene. The four designated areas included: upper portion of the inner border of the great toe, the ball of the great toe, the ball of the 5th toe below the triradii point, and the central prominent part of the heel. The male female differences in ridge density were statistically analyzed individually for each of the designated areas from the footprints. Ridge density was compared between right and left sides for each of the designated areas. Statistical significance was defined at the standard 0.05 level.

Mean ridge density was significantly higher in females than males in the designated areas in both feet. No right-left differences were observed among males and females. Statistically significant differences exist in the footprint ridge density between different areas in males and females in right and left feet. The likelihood ratio (LR) was calculated to obtain the probability inferences of sex, based on ridge density values. Posterior probabilities was calculated using Bayes' theorem and information obtained from both LR computations and posterior probabilities were used to show favored odds. The present research reveals that footprints in females demonstrate a greater ridge density, hence, finer ridge details than males in Indian population. Thus, the mean ridge densities can be used as a presumptive indicator of sex of an unknown footprint left at a crime scene.

Forensic Science, Sexual Dimorphism, Foot Print Ridge Density

A2 Efficiency of Human DNA Isolation From Food Bitemarks

Sara C. Zapico, MSc, and Sofía T. Menéndez, MSc, HURLE, Pol Asipo C/A P3B N3, Llanera, Asturias 33428, SPAIN*

After attending this presentation, attendees will consider the possibility of isolating human DNA from bitten foods.

This presentation will impact the forensic science community with a better understanding of using bitten foods found at crime scene in a criminalistic approach due to the possibility of human DNA isolation and comparison.

Typically, bitemark analysis is used for physical comparison between bitemarks present on physical evidence (human skin or bitten object) and the reference sample (such as suspect's teeth). However, if it is not possible to correctly identify the suspect using this method, it is important to recover salivary DNA. This evidence has been recovered and analyzed from bitten inorganic substrates like cigarette butts and human skin.

On the other hand, there are few studies in which it was possible to isolate human DNA from bitten foods. These attempts have not been successful due to food characteristics. Thus, finding and isolating human DNA from food bitemarks is extremely challenging.

The goal of this research was to analyze the efficiency of human DNA isolation from bitemarks in three different types of foods. The isolated DNA was characterized using PCR for two human housekeeper genes to ensure recovering and isolation of human DNA.

Three volunteers bit into three different foods: cheese, donuts, and apples. The food was kept at room temperature. After 15 hours, the food was placed in a plastic bag and frozen at -15ºC. The day after, the food was submitted to the lab and saliva from each sample was collected using the double swab technique. The DNA was isolated using QIAamp DNA Mini Kit according to the manufacturer's protocol. The DNA was quantified using NanoDrop 2000c. PCR was performed to look for two human housekeeper genes, GAPDH (Glyceraldehide 3-phosphate dehydrogenase, enzyme implicated in glycolysis) and RPL22 (human gene codifies 60S ribosomal protein L22). As positive controls, epithelial cells from two of the volunteers were used.

The results showed the differences in the quantity and quality of DNA isolation between foods. Although the highest DNA concentration was found in the apple and cheese samples, the ratio 260/280, which is commonly used to assess the purity of nucleic acids since proteins absorb light at 280nm, was lowest in apple samples and highest in cheese samples. The DNA concentration from donut samples was the lowest and the ratio 260/280 had an intermediate value. Positive controls showed a high DNA concentration and ratio 260/280.

PCR results were showed in 2.5% agarose gel. In the two positive controls, DNA from cheese samples and donut samples, 1µl DNA was

enough to amplify the housekeeper genes. However, DNA from cheese samples demonstrated highest amplification efficiency compare with DNA from donut samples. DNA from apple samples failed to amplify even when using a 5µl sample. These differences were related to the 260/280 ratio because apple samples had the lowest ratio which indicated that the samples were contaminated with proteins. This issue affected PCR efficiency, compromising the appropriate samples amplification.

The findings from this research provide the evidence that it is possible to recover and isolate human DNA from food bitemarks, although the quality of DNA depends on the type of food. These results show the potential importance of bitten food recovered from crime scenes.

Food Bitemarks, DNA Isolation, PCR Efficiency

A3 Genetic Analyses on Bone Remains: The University of Rome "Sapienza" Laboratory of Forensic Genetics' Experience

Silvia Zoppis, MD, Manuela Rosini, MSc, and Carla Vecchiotti, PhD, Department of Legal Medicine, Viale Regina Elena 336, 00161, Rome, ITALY*

After attending this presentation, attendees will understand some principles of genetic analysis on bone remains. The challenges related to this kind of investigation, especially for what concerns criminal cases and the importance of the honesty of the forensic scientist when a certain and unequivocal interpretation of the DNA profile obtained cannot be provided.

This presentation will impact the forensic science community by highlighting the importance of bone remains as an evidentiary sample in forensic caseworks and the difficulties related to the genetic analysis of such samples due to degradation and/or inhibition factors. In these cases it is fundamental for the scientist to consider asserting that a complete and interpretable genetic profile not obtained from a sample (thus the sample cannot be considered useful for a comparison) does not mean a failure but, on the contrary, reveals scientific honesty and should stimulate the necessary progress in this field.

Genetic analyses on bone remains in the field of human identification represent one of the most stimulating and complex challenges for forensic geneticists. Unlike the analysis of biological materials such as blood, semen, saliva or urine that usually do not present any particular technical and operational difficulty so that personal identification can be achieved, the identification of bone remains forces the analysts to face multiple and complex variable factors (e.g., the degradation of genetic material and the environmental contamination of the samples) that can affect the success of obtaining a complete and interpretable STR profile. In such cases an accurate evaluation of the characteristics of the sample and the environmental conditions to which this finding has been exposed is extremely important.

This presentation describes the methods used in the Laboratory of Forensic Genetics of the Department S.A.I.M.L.A.L. of the University of Rome "Sapienza" for the analysis of bone remains for the purpose of either personal identification or the assessment of a parental relationship. A selection of twenty cases during the years 2007-2011 where genetic analyses were performed on different bone samples (femur, tibia, humerus, mandible) using different DNA extraction, amplification, and STR typing methods will be presented. The results obtained from each case will be compared in order to assess the specific role of three important variable factors: the age of the remains, the environmental conditions of storage/finding, and the cause of death.

Six out of the twenty cases showed interpretation problems related to the DNA degradation caused by environmental factors (for instance, the effects of high temperatures in case of charred remains and the acceleration of autolytic processes in case of hexumation of a corpse) and/or the presence of PCR inhibitors (e.g., calcium phosphate, humic acid) that likely were co-extracted with the DNA from the evidence sample. The results show that the possibility of obtaining a complete and interpretable genetic profile depends largely on the three variable factors mentioned above, particularly with regard to the environmental conditions of storage/finding of the remains, thus confirming the need to optimize the analytical methods to minimize the effects of environmental inhibitors.

Genetic Analyses, Personal Identification, Bone Remains

A4 Standardization of Spermatozoa Identification in Sexual Assault Cases Using a Fluorescence-Based Assay

Anick De Moors, MSc, Royal Canadian Mounted Police, Forensic Science and Identification Services, 1200 Vanier Parkway, Ottawa, ON K1G 3M8, CANADA*

After attending this presentation, attendees will have an understanding of how a fluorescence-based staining assay was optimized and validated at the Royal Canadian Mounted Police (RCMP) using a large number of sexual assault type specimens.

This presentation will impact the forensic science community by enhancing the search and standardizing the identification of spermatozoa in sexual assault exhibits.

The detection of spermatozoa on swabs and suspected seminal stains on fabric provide strong confirmatory evidence in sexual offence cases. Currently, the identification of spermatozoa by the RCMP Evidence Recovery Unit Search Technologists is carried out using phase contrast microscopy. In case of specimens with little spermatozoa, the search may become labor-intensive and time-consuming.

The high specificity of the fluorescence-based staining assay selected in this study lies on the unique mouse monoclonal antibody specific to human sperm heads incorporated in the staining protocol. The validation studies performed by initial users of the fluorescence-based staining assay provided strong positive feedback which prompted the RCMP's evaluation of this kit.

The optimization of the fluorescence-based staining assay involved testing different glass slides and coverslips, finding the optimal amount of 1M DTT pH 8.0 to use on vaginal and fecal slides for optimal staining, finding ways to preserve the fluorescence signals on slides, assessing the possibility of re-staining slides, finding optimal sample slide preparation (comparing a swab extract versus rolling a swab versus using a swab clipping), and performing some spermatozoa integrity tests.

The validation studies performed to evaluate the limitations of the fluorescence-based staining assay included: sensitivity, reproducibility, specificity and robustness using non-human semen, other human body fluids and contaminating yeasts, fibers and dyes, spermicides, sexual lubricants, condoms, medicated creams, and 24-year old semen stains. The practicality, sensitivity, and speed of the fluorescence-based protocol was compared to the current phase contrast protocol and examined in the context of an improved workflow in processing sexual assault cases.

Experiments carried out indicate that the fluorescence-based staining assay is: (1) highly specific and valid (no interference from semen obtained from various animals and absence of positive fluorescence signals in all control slides prepared from swabs with only blood, yeast, urine, vaginal epithelial cells, or fecal material); (2) sensitive and reliable (spermatozoa detected in vaginal swabs soaked in 1:1,000 and 1:10,000 semen dilutions; spermatozoa detected more effectively in real casework samples containing few spermatozoa compared to phase contrast microscopy); (3) fast (one minute versus an average of 10 minutes or more using phase contrast microscopy for <10 spermatozoa); (4) robust (spermatozoa detected from 24-year-old suspected semen stains, no interference from spermicides, lubricants, fluorescent and non-fluorescent condoms and antifungal creams); and, (5) simple to use for the detection of spermatozoa in a variety of sexual assault samples.

The swab clippings used to prepare the slides for spermatozoa identification produced very informative DNA profiles. The fluorescence-

based staining assay results were merged with duo female: male DNA quantification ratios and PCR amplification kits profiling outcomes. The following general correlations were found between the fluorescence-based staining assay results and STR male profile outcome: (1) vaginal swabs with 1:25 human semen dilution gave an average of 136 spermatozoa count from swab clippings (N=12), an average female:male DNA ratio of 0.24 and a major male profile using PCR amplification kit for which a match probability could be calculated; (2) vaginal swabs with 1:100 human semen dilution gave an average of 45 spermatozoa count, an average female:male DNA ratio of 1.3, a complete Yfiler profile and mixed profiles using PCR amplification kit with minor male components for which an inclusion probability estimate was calculated at 8-9 loci or a major male profile for which a match probability could be calculated; (3) vaginal swabs with 1:1000 human semen dilution gave an average of 4 spermatozoa count, an average female:male DNA ratio of 15.6, a complete Yfiler profile and mixed profiles with minor male components for which an inclusion probability estimate was calculated at 4, 5, or 8 loci. The optimized fluorescence-based staining assay combined with the use of 6mm circle slides could expedite and standardize the search for spermatozoa in specimens containing a limited number of spermatozoa.

Spermatozoa, Sexual Assault Cases, Fluorescence

A5 Katie's Law: A Threefold Increase in Database Samples Impacts a Team of Five

Megan Honderd, BS, and Carrie Thor, BS*, Colorado Bureau of Investigation, 690 Kipling Street, Suite 4000, Denver, CO 80215*

After attending this presentation, attendees will understand the effects of implementing an All Arrestee law/bill based on the state of Colorado's legislative rules and guidelines.

This presentation will impact the forensic science community by giving other labs an insight into the Colorado Bureau of Investigation's (CBI) Database procedures and how the increased numbers of samples are processed.

Colorado is one of several states to implement an All Arrestee law/bill. The collection and use of DNA by Law Enforcement agencies has been a useful tool in solving and preventing crime. This bill was implemented to help prevent a significant number of violent crimes and to help assist in developing leads that may solve cold cases in the State of Colorado.

As a result of the new law, buccal samples are collected along with fingerprints at the time of booking for an adult arrested for a felony in the state of Colorado. Samples are submitted to the Colorado Bureau of Investigation, entered into the laboratory information management system, and held until the individual is charged with a felony. Once the individual has been charged, the sample is processed; a profile is developed and uploaded into CODIS.

The CBI Database has experienced no negative impact to the backlog status despite a threefold increase in the number of sample submissions. This has been accomplished with minimal changes to the Database Unit. No changes were made to the current instrumentation which consists of two semiautomated punches, a laboratory information management system, a robot for extraction, six thermal cyclers, and two genetic analyzers. The staff increased by four when the bill went into place which included the addition of one DNA analyst to help process the samples, one database technician to enter the samples, and two crime data specialists to research the samples for charges and process expungement requests. Before the bill went into effect, the Database Unit consisted of two DNA analysts, one CODIS administrator/analyst, and two technicians. This presentation will outline the system employed by the CBI Database laboratory in more detail.

Some of the challenges that the Database Unit had to overcome were interpretation of the bill, where to store the increased number of samples, how CBI would be notified when the charges are filed and a docket number is assigned, integration of data using the Colorado Crime Information Center (CCIC), and handling of expungement procedures.

Analysis efficiency will be further improved with the implementation of an expert system and a twenty-four capillary genetic analyzer in the near future. Overall efficiency in the future may be increased by working with agencies to update criminal history information and automate the charge information.

Database or Databank, All Arrestee, Katie's Law

A6 Human Body Fluid Identification by Matrix-Assisted Laser Desorption Ionization-Time of Flight Mass Spectrometry

Joseph Donfack, PhD, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; Eunice Flores, PhD, and Christiane Honisch, PhD, Sequenom, Incorporated, 3595 John Hopkins Court, San Diego, CA 92121; Kathryn A. Harper, BS, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; Leah E. Willis, PhD, Federal Bureau of Investigation Laboratory Nuclear DNA Unit, 2501 Investigation Parkway, Quantico, VA 22135; and James M. Robertson, PhD, Federal Bureau of Investigation, Counterterrorism Forensic Science Research Unit, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will have a better understanding of how Matrix-Assisted Laser Desorption Ionization-Time of Flight mass spectrometry (MALDI-TOF MS) was used for messenger ribonucleic acid (mRNA) profiling of blood, saliva, and semen.

This presentation will impact the forensic science community by introducing a new multiplex approach of mRNA profiling of body fluids of forensic interest.

It is now well established that different tissues have different genetic expression patterns. The discovery of mRNA biomarkers that are differentially expressed in three body fluids commonly found at crime scenes (blood, saliva, and semen) has contributed to the prospect of using mRNA as a tool for forensic investigation. The validation of these tissue-specific mRNA biomarkers by several research groups has paved the way for mRNA profiling as a potential supplemental method for human body fluid identification.

This presentation will introduce a new multiplex approach of mRNA profiling of body fluids of forensic interest. The most comprehensive methods for mRNA profiling tested to-date all share a common start which is total RNA extraction and complementary DNA (cDNA) synthesis. Diverging from this initial step are two frequently described and standard methods of mRNA profiling for forensic-like stains. The first one is qualitative in nature and combines end-point PCR and capillary electrophoresis (CE); whereas the second includes quantitative PCR chemistries. However, the drawbacks of these existing mRNA profiling methods are (a) the limited multiplex capabilities per reaction mainly due to a limited availability of fluorescent dyes/tags for both CE and qPCR, and (b) the use of internal sizing standards (CE). Sequenom's iPLEX® biochemistry on MALDI-TOF MS, commonly used for single nucleotide polymorphisms (SNPs) genotyping, was adapted for qualitative mRNA profiling. Briefly, an initial end-point PCR phase followed by a primer extension step was used with cDNA. A positive extension reaction was indicative of the presence of cDNA in the sample. This approach on MALDI-TOF MS has the ability to simultaneously determine the molecular weight of DNA fragments without the use of size standards, and thus provides multiple data points per experiment to enable analysis of high-level multiplex PCR reactions.

In this study, total RNA was extracted from mock forensic stains: blood (N=15), saliva (N = 13) and semen (N = 17), and converted into cDNAs. Multiplex primers (19 plexes composed of five blood, six saliva, four semen, and four housekeeping-specific primer sets) and corresponding extension primers/probes, were designed from the sequences of 12 mRNA markers. In general, the body-fluid specific primer sets correctly identified

the targeted body fluid. The range of specificity of the primer sets was 93-100% for blood and semen samples and 88-100% for saliva samples. A multidimensional scaling (MDS) plot was constructed in which the gene expression data (obtained as genotypes and converted into numeric values) were projected onto two viewable dimensions representing linear combinations of markers that provide variation in the data set. MDS analysis of the samples based on expression of all 19 PCR assays demonstrated that the gene expression profiles of the three human body fluids clustered uniquely and were distinct from each other. The results of this study suggest that MALDI-TOF MS has potential for use as a method for the identification human body fluids of forensic interest.

mRNA Profiling, MALDI-TOF MS, Sequenom's iPLEX® Biochemistry

A7 Microwave Selective Heating in the Thermal Development of Latent Fingerprints on Porous Surfaces

Roberto Rosa, PhD, Paolo Veronesi, PhD, and Cristina Leonelli, PhD, University of Modena and Reggio Emilia, Department Materials and Environmental Engineering, via Vignolese 905, Modena, 41125, ITALY*

After attending this presentation, attendees will be informed about the potentialities of microwave heating technique as an innovative methodology in thermal development of latent fingerprints on porous surfaces.

This presentation will impact the forensic science community by providing application of microwave dielectric heating to the selective heat treatment of fingerprint residues on papers and other porous surfaces. Comparison with conventionally thermal developed fingerprints will be shown, highlighting the effects of peculiar characteristics of microwave dielectric heating on the visualization of fingerprints and on the obtained contrast with the surrounding porous surface.

Comparison with conventional thermal developed fingerprints will be shown, highlighting the effects of peculiar characteristics of microwave dielectric heating on the visualization of fingerprints and on the obtained contrast with the surrounding porous surface. There are several techniques which are currently used for the development of latent fingerprints on porous surfaces: optical methods and, more commonly, chemical treatment such as visualization with ninhydrin. However, there is always the need to develop new fingerprints detection techniques in order to increase the sensitivity, be readily deployed at crime scenes, be introduced in sequences of detection techniques, reduce the overall cost of fingerprint processing, and avoid the use of hazardous chemicals. Concerning all of these aspects, thermal development of latent fingerprint is of great potential since it is a simple, low-cost, and chemicals-free method. This is particularly true *in situ*ations where development might not otherwise be attempted for reasons of time and cost. It is widely recognized that thermal development of latent fingermarks on paper occurs following different stages. First, fluorescent marks are developed after rapid heating often resulting in the browning of marks which can become visible with longer heating times. Finally, fingermarks lose contrast as paper turns dark brown with further heating.

Several previous studies investigated different kinds of heating devices. Brown *et al.* performed experiments with a hot air gun, a direct contact heating method, a muffle furnace, and a GC oven. The results indicated that introducing the sample into a hot oven was the optimum technique for the thermal development of latent fingerprints on paper.[1] However, several impractical aspects of the method were evident. First, the introduction of the sample in the oven necessarily induced temperature fluctuations within the chamber that greatly influenced the degree of development of the sample. Moreover, the nature of most of the furnaces used dictated that the sample could not be monitored during treatment, making the technique difficult to execute optimally. More recently, Song *et al*. re-investigated the direct contact heating of the sample using less thermally conductive surfaces.[2] In particular, the devices investigated as a thermal developer of fingerprints on porous surfaces included a commercial hair straightener with ceramic coated surfaces, a non-stick surface sandwich toaster, and heated glass. It was determined that the hair straightener was superior to the other devices due to the high control of temperature, the high portability of the device and the speed with which samples could be treated. These advantages made it more favorable than the heated furnace. Moreover, with the hair straightener the operator could easily monitor and control the progress of the development thus reducing the risk of destroying the evidence due to overheating of the sample. However, the technique is mainly limited since it is not possible to conventionally heat the fingerprint residues and the surrounding surface to a different extent.

The goal of this presentation is to propose microwave dielectric heating as an alternative thermal treatment technique for the development of latent fingerprints on porous surfaces. As it is well known, microwave heating is fundamentally different from conventional heating since heat is generated internally by means of electromagnetic wave-material interaction. Direct coupling of microwaves with matter leads to a rapid, volumetric and selective heating of the material which is impossible to reproduce with conventional heating sources. Microwave or dielectric heating occurs by energy transfer from the electromagnetic field to the material, rather than relying on heat transfer. Dielectric and magnetic properties are the basis of the material response to the applied electromagnetic field. Particularly for dielectric materials (such as paper), the dipolar loss mechanism, due to the re-orientation of dielectric polarization, is the most prominent loss mechanism at the microwave frequencies.[3] For this reason, microwave power absorption and the consequent heating are more effective for those materials with higher water- or, better, dipoles-content. Since the main chemical constituents of the glandular secretions (both eccrine and sebaceous one) constituting the fingermarks are mostly water and minor amounts of inorganic and organic compounds, selective absorption of microwaves can lead to the thermal visualization of latent fingerprints, with the possibility of enhanced contrast with respect to conventional thermal treatments.

A specifically (for paper and wood treatment) designed microwave single mode applicator was experimentally used to develop differently aged latent fingerprints, deposited on recycled copy paper and cardboards, from different donors. Output power level of approximately 500 W was directed from the magnetron generator to the sample, which was positioned in the centre of the WR-340 waveguide resulting in visible fingerprints in less than 60 seconds. Contrast with the underlying porous surface was also obtained with the conventional thermal development techniques.

As a matter of fact, the browning of the overall substrate was greatly reduced since the latent fingerprint residues selectively absorbed microwaves. Moreover, the overall time necessary to the visible browning of marks was decreased due to the high heating rates typical of microwave heating. The use of microwave multi-mode applicators was investigated as well, although it greatly increased the time necessary to visually detect the fingermarks. The results of all the experiments will be fully presented and the advantages, compared to the conventionally thermal developed fingerprints, will be thoroughly explained. Critical considerations concerning comparison with other development methods will be addressed during the presentation as well as the design of a dedicated and portable device.

A8 Positive Human Identification of a Cold Case: Multidisciplinary Approach of Forensic Experts in Pathology, Anthropology, Odontology, and Genetics

Ciro Di Nunzio, PhD, Magna Graecia University, Institute of Forensic Medicine, Magna Graecia University of Catanzaro, Campus "Salvatore Venuta", Viale Europa, Germaneto, Catanzaro, 88100, ITALY; Matteo Borrini, PhD, University of Florence, Department of Ancient History, via del Mattone 17, Cadimare (SP), 19131, ITALY; Maurizio Saliva, MD, Magna Graecia University of Catanzaro, Institute of Forensic Medicine, Viale Europa, Località Germaneto, Catanzaro, 88100, ITALY; Emilio Nuzzolese, DDS, PhD, Magna Graecia University of Catanzaro, Institute of Forensic Medicine, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, 70124, ITALY; and Francesco Ausania, MD, Isabella Aquila, MD, and Pietrantonio Ricci, MD, Magna Graecia University of Catanzaro, Institute of Forensic Medicine, Viale Europa - Località Germaneto, Catanzaro, 88100, ITALY*

After attending this presentation, attendees will have an understanding of issues arising from Italian legislation on exhumation of unidentified bodies and how the collaboration of forensic experts can greatly speed up the identification process.

This presentation will impact the forensic science community by assisting in improving the cooperation of experts in pathology, anthropology, Odontology, and genetics.

In Italy, the Presidential Decree 285/90 stipulates that bodies must be buried enclosed in wooden coffins and ultimately exhumed after a period of 10 years and the remains transferred into zinc boxes. In some regions of Southern Italy it is common for close relatives to be present during this procedure. This presentation concerns a case of an eighty-six year old male whose remains were exhumed without the authorization of the family along with several other exhumations. The cemetery operators placed the skeletonized and disjointed remains in galvanized containers and stacked them with a multitude of similar containers. Since a clear identification system was not in place, relatives were not able to recognize the specific box containing the remains of their kinsman.

The judicial authority launched an investigation, its primary objective being to establish the integrity and completeness of the remains and also the correspondence of the morphological and morphometric skeletal remains. Thereafter, it commissioned DNA profiles which were compared to those of samples of believed living relatives. The approach taken was similar to the one used to identify corpses after a mass disaster (Disaster Victim Identification - DVI). An interview was conducted with family members to collect antemortem detail. This provided vital information, namely that the deceased had an upper and lower mobile dental prosthesis and had surgical implants in the femur following a fracture two months prior to his death.

A preliminary survey of the various zinc containers was carried out in order to narrow down the number of potential possibilities. In only one of these were artifacts found which corresponded with the antemortem data of the subject, namely a mobile dental prosthesis and a titanium intramedullary implant associated with a comminuted fracture of the femoral neck and proximal diaphysis. These findings were combined with other data, such as an intact skull which clearly indicated a male of advanced years. The dental and anthropological assessment allowed the exclusion of the presence of remains from different burials — except for one clavicle — and confirmed that the bones belonged to a single Caucasian male subject whose age and osteobiographic characteristics were totally compatible with the antemortem data collected.

After the generic identification based on morphometric traits, a genetic analysis was carried out by comparing the DNA profile obtained from a femur fragment of the deceased with those obtained from close relatives. The genetic analysis confirmed the relationship.

This case represents an example of the practical application of multidisciplinary teamwork that follows the DVI procedures for the identification of commingled human remains. The close collaboration between different disciplines such as anthropology, odontology, and genetics confirms that these individual areas of expertise should all be involved for the purpose of human identification following Interpol recommendations. More specifically, osteological and odontological assessment may assist the genetic analysis by narrowing the range of subjects for molecular comparison. This teamwork approach actively reduces both the time and costs of the investigation and raises the evidential value of the data obtained.

Forensic Science, Human Identification, Genetic Profile

A9 A Study of Sex Differences in Fingerprint Ridge Density in a North Indian Population

Kewal Krishan, PhD, Panjab University, Department of Anthropology, Sector-14, Panjab University, Chandigarh, 160 014, INDIA; Tanuj Kanchan, MD, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; and Chitrabala Ngangom, MSc, Panjab University, Department of Anthropology, Sector-14, Chandigarh 160 014, INDIA*

After attending this presentation, attendees will understand the usefulness, importance and variability of fingerprint ridge density in distinguishing sex in forensic examinations as this is a recently developed area of research and the literature on this aspect has been scanty.

This presentation will impact the forensic science community by presenting new information on variability of fingerprint ridge density in an Indian population and its use in distinguishing sex of latent fingerprints found at the crime scene.

In the past, fingerprints collected from the crime scene and from the items of evidence of crime have been successfully used to identify suspects, victims, or any other persons who touched the surface in question. The thickness of epidermal ridges varies between individuals; females are supposed to have finer ridges than males and therefore a greater ridge density within a given area. The goal of this research was to test this hypothesis and attempt to infer sex from the fingerprint ridge density in an Indian population. One hundred ninety-four (194) individuals (97 males and 97 females) aged 18 and 25 years were included in the study. The fingerprints were taken from all the fingers. Thus, a total of 1,940 fingerprints were obtained and epidermal ridges were counted in the three defined areas (radial, ulnar, and lower) of each fingerprint. The fingerprint ridge density in the three defined areas and between sexes was compared using one way ANOVA and t-testing, respectively.

The distribution of fingerprint ridge density in radial and ulnar areas is similar with fingerprint ridge density ranging from 12-20 and 13-20 among males and 15-21 and 14-21 among females in the radial and ulnar areas, respectively. A considerably lower fingerprint ridge density is observed in the lower area (9-14 in males and 10-14 in females) than that observed in the radial and ulnar areas. Extent of overlapping was maximum in the lower area; 63.91% males (n=62) and 68.03% females (n=66) had a fingerprint ridge density of either 11 or 12 in the lower area. In the radial area, maximum overlapping was observed for the fingerprint ridge density value of 17, with 20 males and 21 females having a fingerprint ridge density of 17. Extent of overlapping in the male and female values for fingerprint ridge density was minimal in the ulnar area. It is evident that the mean fingerprint ridge density is maximum in the radial area (males=15.84, females=17.94), followed by ulnar area (males=15.51, females=17.11) and minimum in the lower area (males=11.29, females=12.05). Significant sex differences ($p<0.001$) were observed between the fingerprint ridge density values observed in the three areas analyzed. The sex differences are observed to be maximum in the radial area ($t= -11.897$), followed by ulnar ($t= -9.776$) and lower areas ($t= -5.332$). Significant male-female differences ($p<0.001$) were observed in each of the three areas analyzed on each fingerprint.

When each finger was analyzed individually for sex differences in the fingerprint ridge density, it was observed that statistically significant sex differences ($p<0.001$) exist in the fingerprint ridge density of each individual finger in the three designated areas in both hands. It is further observed that fingerprint ridge density varies between different fingers in the three areas analyzed in the study. In the radial and ulnar areas, the fingerprint ridge density was minimum in the thumb and maximum in the ring finger followed by little finger in right and left hands among males and females. In the lower area, the fingerprint ridge density was maximal in the thumb in both hands among males and females whereas, minimum fingerprint ridge density was observed in the middle finger in the right hand and in the little finger in the left hand among males and females.

This study suggests that the fingerprint ridge density can be a relevant and useful parameter in estimating sex of a latent fingerprint of unknown origin from the scene of crime.

Personal Identification, Fingerprint Ridge Density, Sex Determination

A10 Forensic Signatures of Laboratory Grown Bacillus Spores Based on Cellular Lipid Composition: Implications for the Analysis and Attribution of Microbial Evidence Collected From a Bio-Crime

Devonie L. Murphy, MS, Ohio Bureau of Criminal Investigation and Identification, 1560 State Route 56 Southwest, London, OH 43140; Rogelio Alvillar, BS, Federal Bureau of Investigation, 2501 Investigation Parkway, Counterterrorism Forensic Science Research Unit, Building 12, Quantico, VA 22135; Christopher Ehrhardt, PhD, Virginia Commonwealth University, Department of Forensic Science, Grace E. Harris Hall South, Room 2014, 1015 Floyd Avenue, Richmond, VA 23284-3079; James M. Robertson, PhD, Federal Bureau of Investigation, Counterterrorism Forensic Science Research Unit, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Jason D. Bannan, PhD, Federal Bureau of Investigation, Laboratory Division, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will become familiar with lipid composition of Bacillus cells, the effect that laboratory growth recipes have on the relative abundance of lipid biomarkers in cells, and multivariate signatures that may help provide investigative leads in a microbial forensic investigation.

This presentation will impact the forensic science community by establishing new biochemical markers that potentially can be used to analyze evidence collected at the scene of a biocrime and, consequently, can assist an investigation.

Lipids are dynamic features of the bacterial cell membrane. Synthesis and incorporation of different lipid structures can reflect the nutritional substrates available to an organism during growth. Within the laboratory, the particular recipe of growth nutrients used during batch culturing is often unique to the host facility or an individual scientist conducting the research. Previous studies have demonstrated that biochemical signatures are associated with certain growth recipe constituents (e.g., brain-heart infusion), but no study to date has systematically examined a comprehensive complement of complex nutrient additives and its effect on the forensic signatures of *Bacillus* spores.

In this study, lipid composition was investigated as an informative phenotype for the types of nutrients that were used during batch growth of *Bacillus cereus* T-strain (BcT) spores. BcT was chosen as a forensic surrogate because of its genetic, structural, and biochemical similarity to pathogenic strains of *Bacillus anthracis*. Five protein sources were examined: tryptone (enzymatic digest of casein protein), peptone (enzymatic digest of meat protein), soy protein, brain-heart infusion, and gelatin. BcT spores were grown in media containing the same base formulation but supplemented with 8g/L of each of the five nutrient types. After growth, lipids were extracted from spore cultures using a saponification-hexane separation technique. Structural characterization and determination of 11 relative abundance for each lipid was determined with gas chromatography (GC). Composition was characterized by the relative abundances of the four structure classes of *Bacillus* fatty acids (iso-odd, iso-even, anteiso, and straight-chained) and the abundance of individual fatty acid methyl ester (FAME) biomarkers.

Results showed that spores grown on each of the nutrient sources possessed significant differences in the abundance of certain lipid markers. Specifically, spores grown on tryptone containing media were enriched in branched-odd (15:0 iso and 17:1 ω10c) and depleted in straight-chained lipids (14:0, 16:0, 16:1 ω7c). The converse was true for organisms grown on peptone-containing media. Spores grown on soy and gelatin additives showed lipid compositions intermediate between tryptone and peptone cultures. Spores harvested from brain-heart media showed proportions of branched-odd lipids that were similar to tryptone cultures, but were also enriched in one straight-chained lipid, 15:1 ω5c suggesting that it may be an informative biomarker for brain-heart additive. Discriminant function analysis (DFA) was used to model the variation among each nutrient type and to generate a mathematical framework for systematically discriminating each of the five spore cultures based on lipid composition. DFA results showed excellent discrimination with linear equations based on eight lipid biomarkers. In addition, examination of the canonical variable coefficients identified promising stand alone biomarkers (14:0, 17:1 ω10c) for nutrient source identification.

Historic research of bacterial fatty acids and spores led to the hypothesis that fatty acid content of bacterial spores could provide insight into the growth formulations and process by which the spores were produced. The results of the work reported here support the hypothesis. Thus, by comparing the fatty acid profiles of the evidence obtained at a bio-crime with those of collected evidence from facilities under investigation, meaningful inclusions and exclusions might be made. While FAME analysis alone cannot constitute a forensic investigation, it can provide useful information regarding the provenance of a threat agent.

Fame, Microbial Forensics, Sample Provenance

A11 Restoration of Partial Short Tandem Repeat Profiles Resulting From DNA Lesions Induced by Bleach and Hydrogen Peroxide Treatments

Maria Saeed, BS, 1201 Bon Air Crest Place, Richmond, VA 23235; Stephanie M. Rogers, PhD, Federal Bureau of Investigation, Counterterrorism Forensic Science Research Unit, 2501 Investigation Parkway, Building 12, Quantico, VA 22135; Shauna M. Dineen, MS, United States Army, 35 Apple Hill Lane, Lynnfield, MA 01940; Leah E. Willis, PhD, Federal Bureau of Investigation, Nuclear DNA Unit, 2501 Investigation Parkway, Quantico, VA 22135; and James M. Robertson, PhD, Federal Bureau of Investigation, Counterterrorism Forensic Science Research Unit, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will become familiar with the degradation of the Short Tandem Repeat (STR) profiles caused by treatment of DNA with either bleach or hydrogen peroxide (H_2O_2) and the improvement of the profiles after treatment of the extract with a commercial kit containing a suite of enzymes designed to restore PCR amplification of damaged DNA to its normal level.

This presentation will impact the forensic science community by providing the analyst with the awareness that DNA from evidence that is either refractory in PCR amplification or that yields partial STR profiles may be restored either to yield full profiles or to increase its value as probative evidence.

Biological evidence collected at a crime scene or clothing from a victim may yield probative information about an incident. However, the evidence may have been exposed to the environment, or stains may have intentionally been treated with cleansing agents which typically contain bleach or H_2O_2. The DNA present in the evidence may be adversely affected by such environmental or chemical influences. Ultraviolet light, heat, humidity and freeze/thaw cycling are familiar environmental effects that are known to produce double-strand breaks, single-strand nicks, modified bases, and loss of nucleotide bases. Similarly, DNA lesions may be produced by bleach and H_2O_2. The lesions may prevent procession of DNA polymerase during the polymerase chain reaction (PCR), inhibiting the amplification of STR regions, and lead to full or partial loss of the DNA profile.

Living cells possess several DNA repair mechanisms to correct lesions produced during growth and exposure to various endogenous events and exogenous agents. The repair pathways use enzymes such as glycosylase to excise modified or mismatched bases, endonucleases to remove abasic residues, DNA polymerase to fill in the gaps, and DNA ligase to seal nicks. However, since evidence is composed of dead cells, these repair pathways no longer function. To repair damaged DNA from skeletal remains, forensic anthropologists resorted to using in-house formulations of several enzymes, and this work finally led to the development of a DNA repair kit by suppliers of molecular biology products.

In the work reported here, a commercial DNA repair kit was evaluated for the repair of damaged DNA presenting partial STR profiles. Either bleach or H_2O_2 was applied to HL-60 cell line DNA, or blood and semen stains on cotton sheeting and non-porous surfaces using standard concentrations. The sterilization efficacy of the oxidizing agents on bacteria was examined in parallel experiments. Initially, DNA damage (oxidation) was assessed using a real-time PCR quantification assay. An increase in cycle threshold value for treated DNA compared to untreated DNA indicated DNA damage. Next, the DNA was amplified to obtain STR profiles. Samples with partial STR profiles were chosen to test the DNA repair kit and optimize the protocol with respect to reaction time, temperature, and enzyme mix volume.

Treatment with bleach or H_2O_2 led to full or partial STR profile loss, depending on the severity of the process. Incubation at 37° C with the repair enzymes resulted in allele recovery from the partially damaged DNA within three hours, but the best recovery often required an overnight time period. Generally, treatment with the enzyme mix resulted in increased peak heights for most all of the alleles, particularly for the larger STR loci that had peak heights below the detection (50 rfu) and/or stochastic thresholds (200 rfu) before repair. No allele drop-ins were observed. Currently, the emphasis is on optimizing the reaction conditions to reduce the time required to achieve full profile restoration from partially damaged DNA.

The use of the commercial repair kit may provide a means to obtain a full STR profile from environmentally exposed evidence or from evidence obtained after oxidizing treatments with bleach or H_2O_2 that would otherwise be refractory or result in partial profiles. The repair does not involve multiple, time-consuming steps. It can be easily incorporated into the current STR analysis procedure and should work on a liquid-handling robotic system.

Bleach and Peroxide, STR Analysis, DNA Repair

A12 Fire Debris Software

Mary R. Williams, MS, and Michael Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816-2367*

After attending this presentation, attendees will be introduced to newly developed software for the analysis of fire debris.

This presentation will impact the forensic science community by utilizing the newly developed software for the analysis of fire debris. The software combines current data analysis methods along with newer methodology. Features of the software include some data analysis methods described in ASTM E1618-10 and automated searching procedure based on the total ion spectrum from gas chromatography/mass spectrometry (GC/MS) of libraries of liquid residues and substrate materials.

In fire debris analysis, a residue is extracted from the fire debris and analyzed by GC/MS. Currently, data analysis methods include total ion chromatograph, extracted ion chromatograph and target compound chromatograph visual pattern recognition of the residue against a known reference liquid. One or all of these methods are used to characterize the liquid residue into one of seven major classes based on the chemical composition of the residue and then further sub-classified by its carbon range. An extracted fire debris residue can be compared to a reference liquid by visual comparison of their stacked total ion chromatograms within in the software. In cases where the analyses have been performed with different GC/MS methods, the total ion chromatogram plots can be aligned within the windows of the software for better visualization. Extracted ion chromatograms for the residue and the reference liquid based on characteristic ions of the same functional groups can be aligned and plotted. The relative contribution of the characteristic ion groups can be calculated and plotted within the software. These tools will support and facilitate current methodologies of fire debris data analysis.

A newer data analysis method is utilized in the software to automate searching a library or libraries of reference liquids and substrate materials. The search is performed on the total ion spectrum of the GC/MS data which is the sum of the intensity of each m/z across the chromatographic time range. A result from the search is a list of the reference liquids from the library in rank order from most similar to the least similar compared to the residue. The libraries are obtained from the Ignitable Liquids Reference Collection and Substrate Databases, which are joint projects between the National Center for Forensic Science and the Technical/Scientific Working Group for Fire and Explosions. A sample reference number, product name, and classification are given for the selected library reference liquid or substrate material. In a click of a button the software will connect the user (on an internet accessible computer) to the entry in the database for that selected reference liquid or substrate material to obtain more information. A subsequent result from the library search is a posterior probability of class assignment based on Bayesian Decision Theory.

The software developed for fire debris analysis will provide information in a suitable format for fire debris analysts to perform data analysis by current methods. New methods incorporated into the software will analyze the data in a complimentary fashion with the ability to rapidly search an extensive library of reference materials and provide a posterior probability for the assigning a classification.

This work was supported in part by the National Institute of Justice, Office of Justice Programs, award 2008-IJ-CX-K401. The content of this publication does not necessarily reflect the position or the policy of the Government, and no official endorsement should be inferred. Support is also acknowledged from the University of Central Florida, National Center for Forensic Science, a State of Florida Type II Research Center.

Fire Debris, Ignitable Liquids, Software

A13 Evaluation of Novel DNA Extraction Methods and Modifications to Existing Methods

Kelly M. Elkins, PhD, Metropolitan State College of Denver, Chemistry Department, PO Box 173362, CB 52, Denver, CO 80217*

After attending this presentation, attendees will learn about new methods for extracting DNA from biological samples containing cellular material.

This presentation will impact the forensic science community by providing systematic data that can be used by the analyst in selecting a method for extracting DNA from crime scene or reference samples especially when considering time and cost.

DNA extraction is a method of purifying DNA from other cell contents including proteins, enzymes, and membranes. DNA extraction is employed routinely by crime labs to recover DNA from biological samples containing cellular material. While a number of methods for extracting DNA from crime scene evidence are available to the practioner, research results are presented in which new methods have been evaluated and older methods have been modified to reduce the time needed to recover the DNA. The extracted DNA is used for modern DNA typing analyses including autosomal, Y-chromosome and mitochondrial DNA typing using STRs, SNPs, and sequence comparison. The DNA extraction methods used in crime laboratories including Chelex® 100, Phenol-Chloroform-Isoamyl Alcohol, dialysis, and commercial kits (e.g., Promega's DNA IQ™ and Qiagen's QIAamp™) vary widely in terms of cost and extraction time. The 5% Chelex® method is the cheapest method but it is time-consuming due to a recommended six to eight hour, 56 ºC incubation step performed prior to vortex mixing, boiling, and centrifugation steps. The Chelex® beads chelate metal ions, including magnesium, known to be essential for DNase nuclease activity. Inactivating nuclease enzymes that digest DNA reduces DNA degradation in the extraction process. In this study, modifications to the Chelex® method were evaluated including reducing the reagent concentration and incubation time in order to decrease the overall cost and time involved in using this method for casework and other samples. In addition, extractions with Silicycle®, EDTA, and citrate were performed to determine if these methods would also yield amplifiable DNA. Like Chelex®, Silicycle®, EDTA, and citrate reagents also chelate metal ions. The extraction efficiency with consideration to DNA yield, cost and time was tabulated for all of the methods.

In this study, the Chelex® method was evaluated for DNA recovery and amplifiability using reduced incubation times (thirty to ninety minutes) and overnight without Proteinase K. The results showed that any incubation time over sixty minutes and the procedure from which Proteinase K was omitted produced results similar to those produced using the standard method. Omitting the Proteinase K that digests proteins significantly reduces the cost of employing this method. In addition, the concentration of Chelex® was varied from 1% to 5% solutions. Reduced Chelex® concentrations yielded amplifiable DNA at a reduced cost. In addition, extractions with similar concentrations of Silicycle®, EDTA, and citrate were evaluated for use in DNA extraction using varying incubation times for comparison to the Chelex® method. The Silicycle® method was observed to extract successfully amplifiable DNA as evaluated by real time-PCR using TPOX primers validated for DNA quantitation and post-PCR agarose gel electrophoresis. EDTA and citrate are very inexpensive chelating compounds that could be useful to the forensic community as DNA extraction agents.

DNA Extraction, Real-Time PCR, Chelex

A14 Single Channel Simultaneous Analysis of DNA and MicroRNA

Graham Williams, MSc, University of Huddersfield, Forensic and Analytical Research Centre, School of Applied Sciences, Huddersfield, HD1 3DH, UNITED KINGDOM*

After attending this presentation, attendees will be aware of a new proposed protocol that will analyse DNA and miRNA simultaneously.

This presentation will impact the forensic science community by exhibiting a new protocol that will expand the capability of forensic science laboratories with minimal modifications and expenses.

It is often necessary to establish the identity of the body fluid from which a DNA profile was obtained. This issue is frequently encountered in sexual offences where it can be necessary to distinguish between saliva and vaginal material or where there is a very small amount of the body fluid present, such as trace amounts of blood on a dark surface. This issue is currently being resolved by the use of mRNA and microRNA (miRNA) analysis utilising a co-isolation technique to separate out the DNA and the miRNA phases for subsequent analysis.

This study presents an alternative protocol in that the DNA and miRNA are co-isolated without physical separation. All downstream processes are carried out simultaneously through a single channel process resulting in a single electropherogram indicating both the DNA profile obtained from the body fluid stain and the identity of the body fluid.

A number of blood and saliva samples were collected from volunteers (with informed consent). Blood was collected using the finger prick method and depositing blood onto a filter paper. Saliva was collected using buccal swabs. Dual extraction was carried out using the QIAamp DNA Mini Kit with no modifications. miRNA was present in the eluents due to their small size and abundance within each cell. The DNA/miRNA sample then underwent cDNA synthesis by carrying out stem-loop reverse transcription PCR, which reverse transcribes and lengthens the miRNA marker prior to amplification.

Amplification was carried out using a modified version of the Amp*f*STR NGMSElect kit (ABI). The modification was the incorporation of labelled miRNA primers. The primers used are complementary to miR-205 and miR-451 markers which are specific to saliva and blood, respectively. No other modifications to the amplification protocol were made.

Following capillary electrophoretic separation on the ABI Prism 310 genetic analyser, full DNA profiles were obtained matching the volunteer DNA profiles. In all blood samples, a peak indicating the presence of miR-451 was generated and in all saliva samples, a peak indicating the presence of miR-205 was generated indicating a 100% correct identification rate (n=15). Small peaks were observed in the miR-205 bins for blood and vice versa; however, such peaks were considerably smaller than the expected peaks and in many cases were less than 150 rfu.

Reverse transcription negative controls were carried out by using sterile water in place of the MMLV reverse transcriptase. In all cases, no discernable peaks were obtained within the miRNA bin sets. The DNA profiles were unaffected.

In all cases, the correct DNA profiles and the correct body fluid identity were obtained, thus demonstrating the proof of principle in that a single stream simultaneous analysis of DNA and miRNA is possible and robust. The advantages of this technique are that only minor modifications are required to install the BFID capability into a forensic science laboratory. The single work stream element means that there are reduced opportunities for contamination, and it is cost-effective. Finally, this single stream simultaneous process means that it may be possible to definitively associate a DNA profile with a particular body fluid.

Future work will involve the identification and characterization of further body fluid markers with a view to developing a full BFID panel multiplexed with a DNA profiling system.

DNA, miRNA, Co-isolation

A15 Internal Validation of AmpFISTR® Identifiler® Plus Amplification Chemistry on Applied Biosystems' ABI PRISM® 310 Genetic Analyzer

Tiffany D. Bard, BS, 611 22nd Street, Apartment 322B, Huntington, WV 25703; and Cara E. Lupino, MS, Rhode Island Department of Health, 50 Orms Street, Providence, RI 02904*

After attending this presentation, attendees will have acquired a deeper understanding of how well Identifiler® Plus amplification kit advances the interpretation process. Nine studies reveal the superiority of this amplification kit when run on a 310 genetic analyzer.

This presentation will impact the forensic science community with a greater understanding of the results Identifiler® Plus can bring to the

laboratory. Identifiler® Plus achieves greater sensitivity, faster amplification time, and increased interpretation of mixtures.

An internal validation of the Identifiler® Plus amplification kit was conducted to assist the Rhode Island Department of Health Forensic Science Laboratory's transition from a two kit amplification system (Profiler® Plus /COfiler®) to a one kit system increasing turnaround time and decreasing consumable usage. Since this is a small laboratory with strict budgeting, transitioning to Identifiler® Plus will increase throughput, save money by reducing consumable usage, and assist in relieving the backlog of cases.

The Identifiler® Plus amplification kit includes the 13 core CODIS markers, Amelogenin, and an additional two markers to increase the level of discrimination of the final profile as compared to Profiler® Plus/COfiler®. The new chemistry of this kit combines the Ampli®Taq Gold DNA Polymerase with a Master Mix reagent and reduces the overall kit package by two tubes and one box. Identifiler® Plus also provides this laboratory with a 5-dye amplification system and faster amplification time. The new improvements to the PCR thermal protocol remove about an hour of the amplification time. The combination of a one kit system paired with the new PCR protocol increases the laboratory's turn-around time and allows cases to be processed faster and more efficiently.

Samples were amplified with Identifiler® Plus on a GeneAmp® PCR System 9700 Thermal Cycler using a 29 cycle thermal protocol. Nine studies including sensitivity, precision/reproducibility, concordance, mixture, known and non-probative evidence samples, match criteria, contamination, denature, and stutter percentage were performed on two Applied Biosystems PRISM® 310 Genetic Analyzers and generated data was analyzed using GeneMapper *ID* v3.1.0.

The sensitivity study assessed the range of DNA concentrations that could produce reliable typing results. A precision/reproducibility study was performed to determine if accurate and reliable genotypes could be reproduced over consecutive days. All alleles were evaluated to determine if they fell within the recommended ±0.5bp window. The concordance study assessed the ability of Identifiler® Plus to accurately reproduce the NIST SRM 2391b reference samples. A mixture study was performed to examine the behavior of a sample containing two contributors comparing the resulting profiles to previous ones typed in Profiler® Plus/COfiler®. Match criteria and contamination studies were completed to determine if the positive and negative controls were working properly; positive controls had expected profiles and negative controls contained no contamination. A denature study was evaluated to determine if there was a significant difference between denaturing/chilling the samples before placement on a genetic analyzer and not denaturing/chilling. Lastly, an intra-laboratory stutter study was performed to evaluate if stutter remained under the 15% - 20% threshold.

Sensitivity study results indicated 0.5ng was the ideal input of target DNA to amplify at 29 PCR cycles with Identifiler® Plus. The sizing precision for each allele demonstrated the accuracy and reliability of sizing the Identifiler® Plus amplicons, even when several maximum/minimum values exceeded the recommended ±0.5bp window. Results obtained during the concordance study demonstrated intra-laboratory concordance when NIST SRM samples are amplified with Identifiler® Plus on multiple genetic analyzers. Mixture results showed a major contributor could be extracted at every marker with Identifiler® Plus when amplifying a target input of 0.3ng in samples containing a mixture of two individuals' DNA at ratios 10:1 and 1:10.

The methods utilized in the known and non-probative casework samples study were successful in the recovery of at least a partial DNA profile in concordance with Profiler® Plus/COfiler®. With proper lab technique and appropriate DNA target amount, extraction positives and amplification positives produced the correct profile with few extraneous peaks, and no contamination of any negative sample occurred during the validation. For the denature study, the step of 95°C denaturation and a snap-cooling step on an ice block prior to placing the samples on the instrument for separation caused the reduction of peak heights as compared to samples that were not denatured and snap-cooled prior to run.

Internal Validation, AmpFISTR® Identifiler® Plus Amplfication Kit, ABI PRISM® 310 Genetic Analyzer

A16 Validation of the PowerPlex®18D Direct Amplification System

Kelly M. Borycki, BS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701; Jennifer Bas, MFS, Las Vegas Metro Police Department Crime Lab, 5605 West Badura Avenue, Suite 120B, Las Vegas, NV 89118; and Justin Godby, MFS, and Pamela J. Staton, PhD, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand the capabilities of direct PCR amplification for processing forensic DNA profiles.

This presentation will impact the forensic science community by showing the reliability of a new technology that can potentially save a significant amount of time and money during the production of forensic DNA profiles. It will also provide other laboratories that are considering adopting direct amplification with a general internal validation scheme.

As the role of forensic DNA analysis has grown, there has been a significant increase in the number of samples that forensic DNA laboratories receive for analysis. Many states are moving toward, or have already adopted, legislation that would require a DNA sample to be collected from all arrestees, drastically increasing the throughput requirements of many laboratories. In order to maintain efficiency and prevent a sample backlog, it is imperative to reduce the time and cost associated with forensic DNA testing.

Direct PCR amplification significantly reduces the time required for DNA analysis by eliminating both DNA extraction and quantification on single source blood or buccal stain samples. Promega's direct PCR amplification chemistry, PowerPlex® 18D (PP18D), further decreases the time required to produce a final profile by using shorter thermal cycling - approximately one-half required by traditional amplification chemistries. With this kit, database or reference samples can be processed, reviewed, and uploaded into CODIS in as little as one day.

Due to the lack of a purification step when using PP18D with FTA® punches, the chemistry has been designed to overcome most types of inhibition that would commonly be encountered with this sample type. An additional advantage to the PP18D kit is the amplification of two non-CODIS, highly discriminating penta-nucleotide repeat unit markers that can increase the level of discrimination associated with profiles generated using this amplification system.

This study sought to validate the PowerPlex® 18D direct amplification kit for use with single-source FTA® card samples. Samples were collected on the Whatman® EasiCollect™ device. One 1.2mm punch was taken using a Harris manual punch and amplified for 27 cycles on an Applied Biosystems GeneAmp® PCR System 9700 thermal cycler. Half reaction volumes (7.5µL water, 2.5µL 5X Master Mix, 2.5µL 5X Primer Pair Mix) were used to further reduce the cost associated per sample. Fragment separation was performed using Applied Biosystems 3130xl Genetic Analyzers. Data generated was analyzed using the Applied Biosystems GeneMapper® ID-*X* software v1.1.1. When applicable, quantification was performed using the Quantifiler® Human DNA Quantification kit and the Applied Biosystems 7500 Real-Time PCR System.

PP18D was determined to yield full profiles from samples with concentrations as low as 0.4ng/µL. The kit was shown to be precise at all 18 loci with 99.7% certainty. Known/non-probative samples that were collected from employees were compared to known profiles, and all samples (85 of 85) were concordant. Seven samples were amplified and

run on different instruments and different days to test reproducibility and were found to be concordant. Other common sample types (cotton swabs, Omni® swabs, and extracted DNA) were also tested and yielded full profiles.

Based on the findings of this study, PP18D for processing database samples, as well as troubleshooting single-source casework samples, will be incorporated. Future studies will be done to determine the feasibility and reliability of performing direct PCR amplification on non-FTA® card samples once the lysis buffer from Promega is released for commercial use.

Direct Amplification, Validation, Efficiency

A17 Volume Reduction Solid Phase Extraction of Forensic Samples on a Plastic Microfluidic Device

Briony C. Strachan, MSci, 409 McCormick Road, Chemistry Building, Charlottesville, VA 22904; and James P. Landers, PhD, McCormick Road, Charlottesville, VA 22904*

After attending this presentation, attendees will gain an understanding of progress towards disposable plastic microdevices that can facilitate the volume reduction of large volume, dilute biological samples for downstream processing in human identification via STR analysis.

This presentation will impact the forensic science community by introducing a disposable plastic microdevice applicable for DNA extraction and purification from dilute biological evidence collected in forensic investigations, enabling higher throughput of samples than previous glass devices. This work is a step towards the use of a micro-total analysis system for forensic genetic analysis.

Microfluidic devices present numerous advantages to current forensic analyses, including low reagent consumption and reduction in analysis time, combined with the ability to deliver a closed sample in-answer out multi-process system within a single device.[1] Additionally, these devices require less sample template, enabling preservation of sample for further analysis when there is limited quantity during forensic casework.

Successful utilization of solid phase extraction (SPE) within microfluidic devices has been established through numerous publications from our lab, demonstrating silica-based phases capable of highly efficient and reproducible DNA purification.[2] Although successful, a challenging forensic sample type for microfluidic platforms are those collected from surfaces or stains, which may involve large volume (milliliters) of a dilute sample for processing. The challenge of macro-to-micro interfacing has been previously addressed by the development of volume reduction solid phase extraction (vrSPE), where a large SPE phase was designed to accept sample volumes 10-fold larger than traditional SPE devices.[3,4] Such microdevices have been fabricated in glass: an expensive, time-consuming process that utilizes hazardous chemicals (e.g., HF), however, the use of plastic substrates (like poly (methyl methacrylate); PMMA) circumvents these issues. Volume reduction SPE microdevices can be created from PMMA by micromilling processes for pennies per chip using laser ablation, with an 8-fold reduction in fabrication time. The presented research adapts the vrSPE technology to a plastic device, allowing for simple, inexpensive extraction and concentration of DNA from dilute biological samples, ready for PCR and subsequent STR analysis.

The ease of design and fabrication of vrSPE PMMA devices enables creation of multiple geometries to tailor a device to a specific purpose. Several new designs will be presented including those that allow for a 4-fold increase in the sample volume (from 500µL to 2mL) to be accepted onto the device, or conversely, a 4-fold reduction in time (from 30 minutes to ~8 minutes) to load a 0.5mL sample. Furthermore, multiplexing the vrSPE method will be shown for the simultaneous tetraplex extraction of four whole blood samples from four different individuals, with each 16-plex STR profile reported. Each design provides a significant improvement for both analysis time and throughput compared to traditional glass vrSPE.

A18 Do You Really Know What Your Robot is Doing?: The Importance of Paying Attention to Liquid Handling Details

Mark Pietras, BA, John T. Bradshaw, PhD, and Keith J. Albert, PhD, Artel, 25 Bradley Drive, Westbrook, ME 04092*

After attending this presentation, attendees will understand that liquid handler performance, and behavior, can and will affect assay work. Uncovering liquid handler errors can help optimize and/or troubleshoot assay work.

This presentation will impact the forensics science community by exposing the importance of really understanding liquid handling devices, specifically, automated robots. As more forensic bench work turns to automation, it is extremely important that the automated volume transfer steps are known (verified) so the methods can be tweaked and optimized for the automated assays.

The introduction of automation into forensic science, biology, and chemistry labs has arguably led to significant advances in testing capabilities over the past 20+ years. Automation has certainly led to increased numbers of experiments, as compared to manual testing, particularly for pipetting operations. Because of this advantage, liquid handling robots have become commonplace even in small laboratories. However, in spite of all the advantages that a liquid handling robot brings to a laboratory, it also brings a different set of commonly overlooked challenges such as ensuring quality.

The focus of this presentation is to highlight the need of ensuring quality in important assays performed with automated liquid handlers. Nearly all assays performed within a laboratory are volume-dependent. In turn, all concentrations of biological and chemical components in these assays, as well as the associated dilution protocols, are volume-dependent. Because analyte concentration is volume-dependent, an assay's results might be falsely interpreted if liquid handler variability and inaccuracies are unknown or if the system(s) goes unchecked for a long period. If liquid handlers are properly employed (with the right methods/materials for the specific assay), and they are regularly assessed for performance, they can be powerful systems for lowering costs, increasing throughput and avoiding errors associated with manually-pipetted methods. It is imperative, therefore, to quantify the volumes transferred with an automated liquid handler, especially for the specific automated methods that are used to perform assays. Measuring and knowing the exact volumes transferred for specific and/or routine methods will inherently lead to confidence in the

experiment. Knowing an assay's exact volume and component concentrations is critical to properly interpreting the results.

It may be argued that the largest challenge presented by using a liquid handling robot is the potentially incorrect assumption that the robot is doing what it is should be doing. The robot may in fact be doing exactly what the user told it to do, but is that really what the user wanted? One might say that the real question is, do you *really* know how your robot is behaving, and particularly, do you *really* know how your robot is performing for your assay work?

This presentation discusses real case studies of how liquid handlers were performing, or rather misperforming, for certain test procedures. Herein, examples of the importance of monitoring various commonly employed tasks will be presented which are likely considered mundane and often assumed to have little bearing on overall robot performance. Specific examples showing how liquid handler performance can be altered based on: (1) pre-wetting disposable pipette tips; (2) running identical methods on identical robots; (3) protocol differences between high volume and low volume dispenses; and (4) effect of volume transfer mode (reverse or waste mode vs. forward mode). The examples presented will help users to think more about the specific tasks they are asking their robots to perform, and hopefully uncover certain steps that, if observed and controlled, will result in optimized liquid handler performance to ensure the highest quality work possible.

Automated Liquid Handlers, Liquid Handler Behavior, Optimizing Liquid Delivery

A19 Evaluation of Lyophilized Reagents for STR Analysis

Alexis M. Meeker, MFS and Jamia Fillinger, BS, George Washington University, 2100 Foxhall Road, NW, Washington, DC 20007; and Daniele S. Podini, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road Northwest, Washington, DC 20007

The goal of this presentation is to demonstrate a proof of concept experiment in which PCR reagents were prepared in and subjected to non-ideal temperature conditions.

This presentation will impact the forensic science community by providing a springboard for further exploration of lyophilized reagents designed for use in non-ideal forensic environments.

Recent literature indicates growing interest in the use of DNA as a biometric tool for applications in both the lab and the field. A factor which must be considered for field applications is the ability to maintain reagents in non-ideal conditions. Commonly used typing kits recommend storage of primers and reaction mix at 2 to 8°C and polymerase at -15 to -25°C. This would be problematic, for example, in a situation where a battlefield lab is deployed in a location such as Afghanistan. Suppliers may have difficulty reaching such locations and reagents would be exposed to a non-ideal, high temperature environment during shipping and at the field laboratory. An understanding of how PCR reagents will be affected by their environment is therefore necessary.

The purpose of this study was to evaluate the use of dried primers and stored at various non-ideal temperatures, along with commercially available lyophilized polymerases for use in STR analysis. Five temperatures were chosen for evaluation: room temperature, 4°C, 37°C, 50°C, 65°C, and 80°C. Several commercially available lyophilized polymerases already containing reaction mix were evaluated as well. Primers were dried down utilizing a speed vac and stored at their respective temperature for one week along with the lyophilized polymerase/reaction mix. A PCR amplification protocol was employed followed by capillary electrophoresis analysis. In addition, the effect of the high temperature environment on the dried primers was tested by using polymerase and reaction mix which had not been exposed to the non-ideal conditions. The latter reagents were stored according to manufacturer recommendations until amplification.

Full or partial profiles were obtained for temperatures closest to recommended storage conditions and some amplification was observed for several loci at temperatures up to 65°C. Artifacts such as incomplete adenylation and peak imbalance were observed and suggest that protocol improvements are necessary. Full profiles could be obtained with primers stored at temperatures up to 80°C when polymerase and reaction mix which had not been exposed to the non-ideal, high temperature environment were used for the PCR amplification. This suggests that the reagents which were most affected by the higher temperatures were the polymerase and reaction mix (in particular dNTPs). It is important to note that the polymerases which were chosen, although lyophilized, were not specifically designed for STR analysis in mind. Some reagents were tailored towards real time PCR applications, which likely contain non-ideal amounts of components such as $MgCl_2$ for end point PCR applications. This is suggested in these experiments by the presence of artifacts such as incomplete adenylation and non-specific PCR products even when reagents were stored in the conditions which were recommended by the manufacturer.

Results observed at higher temperatures believed to be incompatible with PCR reagents indicate that with optimization, there is potential for future development of lyophilized reagents for use in PCR field kits. If a product could be designed and tailored to STR analysis and the forensic practitioner's objectives, it is likely that the results obtained here could be improved in terms of profile quality.

Battlefield Forensics, STR Analysis, PCR

A20 Who's on Your Shoes? Investigating DNA Profiles From New and Worn Shoes

Jessica Byram, BA, 8743 Malaga Drive, 2D, Indianapolis, IN 46250; Meredith Reid, BA*, 3245 Rue Channel, Apartment 185, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Biology Department, 1400 East Hanna Avenue, Indianapolis, IN 46227; and Cynthia Cale, BS, and Gay L. Bush, PhD, Strand Analytical Laboratories, 5770 Decatur Boulevard, Suite A, Indianapolis, IN 46241*

The goal of this presentation is to demonstrate to the forensic community that multiple DNA profiles can be recovered from the soles of three types of shoes before being worn outside of the store and for some shoe types, the wearer can become the primary DNA contributor after just several hours of wear.

This presentation will impact the forensic science community by presenting a pilot study which successfully recovered DNA from the soles of all three shoe types. It will demonstrate that all three varieties of shoes produced mixed profiles when initially purchased, and will document at which point a major profile, consistent with the wearer, could be generated.

The recovery of DNA that can generate a DNA profile from crime scene evidence is an important aspect of forensic investigations. Shoes represent an item that could potentially be recovered from a crime scene and provide valuable information about the suspect or victim. Shoe impressions may be used to link a suspect with a crime scene and the shoes themselves can later be seized for additional laboratory analyses. Such additional investigations often involve the collection of DNA from the soles and heels of the shoes. A potentially complicating factor to the generation of a DNA profile is the possibility that DNA is deposited on the shoe when being tried on in the store. This could be a possible form of contamination and contribute to the generation of a mixed DNA profile. To date, no previous research has been discovered that investigates whether DNA is present on shoes when they are purchased. The goal of this research is to conduct a pilot study to determine if DNA is present on the soles of three types of new shoes before being worn outside of the store, if DNA is present before being worn, and at what time does the wearer become the primary contributor on the sole.

Three shoe types: flip-flops, close-toed casual shoes (commonly referred to as "flats"), and sneakers were chosen for this study because each

has a different level of exposure to the environment and different levels of contact with the sole of the foot. The bare foot comes in direct contact with the flip-flops and the flats; however, sneakers are commonly worn with socks which could potentially reduce the chance of epithelial cells being deposited from the foot onto the sole of the shoe. In addition, the flats and sneakers represent a more closed environment while the flipflops expose the epithelial cell DNA to environmental factors. The sole of each shoe was swabbed before being tried on by the wearer after purchase. Then, the shoes were worn and swabbed again at four, eight, and twelve hour intervals of wear. Because suspects may throw their shoes away after a crime, or dispose of the shoes from their victims, the investigators were also interested in testing whether the placement of the shoes in an outdoor garbage receptacle would influence the ability to generate a DNA profile. Therefore, after the twelve hour wear interval, the shoes were placed in the garbage for six days and the soles were swabbed again after removal. All sampling was conducted using sterile swabs and the DNA was extracted using a common commercial DNA extraction kit. The DNA was quantified via quantitative PCR, and DNA profiles were generated to establish whether the DNA samples represented a mixture of multiple donors or if a major contributor could be established.

DNA of high enough quantity for subsequent DNA typing was recovered from 67% of the samples collected from the flip-flops, 67% of the samples collected from the flats, and 33% of the samples collected from the sneakers worn with socks. The quantification data suggests that some shoe types are better reservoirs for DNA than others. In addition, all three varieties of shoes produced mixed DNA profiles when initially purchased. Samples typed from both the flats and the sneakers suggest the wearer can become the primary DNA contributor after just several hours of wear, while samples taken from the flip-flops consistently generated mixed or incomplete profiles. The DNA typing data suggest that some shoe types will better reflect the actual wearer of the shoe, which may be a crucial link in a forensic investigation.

DNA Profile, Shoes, Forensic Investigation

A21 A Systematic Approach to the Analysis of DNA From Earrings in Varying Conditions

Caitlin C.M. Vogelsberg, BA, University of Indianapolis, Archeology and Forensics Laboratory, 1400 East Hanna Avenue, Indianapolis, IN 46227; Neva H. Williamson, BS*, Sefanie M. Percival, BS; Anna K. Wesseler, BS, University of Indianapolis, 1400 East Hanna Avenue, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Biology Department, 1400 East Hanna Avenue, Indianapolis, IN 46227; Cynthia Cale, BS, and Gay L. Bush, PhD, Strand Analytical Laboratories, 5770 Decatur Boulevard, Suite A, Indianapolis, IN 46241*

The goal of this presentation is to demonstrate the possibility of generating a usable DNA profile from samples collected from stud earrings, to investigate whether or not the raw material used to construct the stud earrings can influence the quantity of DNA recovered from the jewelry surface, and to examine the effects of outdoor environmental conditions on both DNA quality and quantity.

This presentation will impact the forensic science community by investigating a DNA-bearing source that could produce a DNA profile when more commonly used sources, such as body fluids or tissue, are not left at the crime scene, or are not in an analyzable condition.

A variety of evidence can be collected from crime scenes and includes items such as hair, fingerprints, bodily fluids, personal effects, and weapons. From these materials, investigators attempt to isolate information pertinent to both victim and perpetrator identification. Although new research is constantly being conducted to maximize the amount of trace DNA that can be collected from evidence and to incorporate new DNA-bearing sources, it is still lacking in several areas. Specifically, there are no discovered studies, to date, that systematically investigate the potential for jewelry and other personal effects commonly found at crime scenes to be acknowledged as options of items bearing viable DNA. Because earrings are commonly worn by both sexes in our society, they represent good potential sources for the collection of DNA samples when more commonly analyzed sources are not available. Personal effects found in association with the crime scene may serve as circumstantial evidence to link a victim or suspect to that location. DNA collected from such items may also be useful when known comparison samples are available to assist in identifying missing persons or other unknown decedents. This presentation will benefit the forensic community by investigating a DNA-bearing source that could produce a DNA profile when more commonly used sources, such as body fluids or tissue, are not left at the crime scene, or are not in an analyzable condition. For example, jewelry can be accidentally removed from the body during a struggle, or taken by a perpetrator as a trophy during a robbery or assault. The ability to link a potential suspect or victim to an area where an assault previously occurred would be beneficial to crime scene investigators. In addition, a body may be discovered in a condition that is not conducive to positive identification via more traditional means such as fingerprint, dental, or DNA typing of the body itself. In such a situation, the ability to generate a DNA profile from associated personal effects would be valuable to the investigation.

The goal of this project is to determine whether amplifiable DNA can be collected from epithelial cells deposited on earrings composed of three common metals: gold, silver, and surgical steel, and whether environmental exposure could compromise the ability to generate a DNA profile. The gold, silver, and surgical steel studs were worn by participants for varying amounts of time ranging from one to five hours. The earrings were then removed from the participants' ears and immediately swabbed along the posts and earring backs with sterile cotton swabs. The earrings were returned to the participants and worn again for at least one hour. The studs were once again removed from the participants' ears, placed in mesh containers, and positioned in an outside location where they were exposed to the ambient environment. The earrings remained outside for four days and were exposed to rainstorms, high winds, and ultraviolet radiation from the sun. The studs were removed from the mesh containers and swabbed once again on the posts and earring backer.

The DNA collected from the swabs was extracted using a common commercial kit and all samples were quantified using real-time PCR. All earring materials yielded quantifiable DNA of varying amounts suggesting earrings made from gold, silver, and surgical steel are potentially valuable personal effects for the generation of a DNA profile. In addition, DNA typing of the samples suggests that forensically significant profiles can be generated from earrings made of common metals, even when exposed to adverse weather conditions.

DNA, Suboptimal, Earrings

A22 Analysis of Synthetic Polymers Using MALDI-TOF

Shana L. Kilgore, BA, 658 Ridge Road, Templeton, PA; and Stephanie J. Wetzel, PhD, and Sara Johnson, MS, Duquesne University, Department of Chemistry and Biochemistry, 600 Forbes Avenue, Pittsburgh, PA 15282*

The goal of this presentation is to demonstrate the need for objective identification of synthetic polymers in the trace evidence realm of forensic science and to propose the analysis of the fragmentation patterns of these polymers obtained from MALDI-TOF mass spectra to be used for fiber identification.

This presentation will impact the forensic science community by providing an objective method for trace evidence analysis and identification of synthetic fibers.

Synthetic fibers, or polymers, are created through addition or condensation reactions that combine monomers. Each manufacturer may introduce various chemical additives, which affect the chemical and physical properties of the material. Such additive categories include: flame retardance; dyes, pigments; UV absorbers and antioxidants; plasticizers;

surfactants; and lubricants. Each manufacturer is at liberty to distinguish their product with various additive combinations. However, these additive combinations are not able to be used for identification purposes with the current analysis techniques for synthetic fibers. Current methods of analysis include: visual comparison and microscopy, which are both subjective identification techniques, and Fourier transform infrared spectroscopy (FTIR), which identifies the polymer into a general type. Fiber evidence collected from a crime scene can provide valuable information in the investigation of the crime. However, it is often not a critical piece of evidence due to the lack of objective identification of fiber source. Trace fiber evidence can come from many different sources that often appear identical through the above mentioned analyses. This makes it nearly impossible to determine a source of origin. A synthetic fiber database classified by polymer type and manufacturer additives could objectify fiber analysis by narrowing and confirming the fiber's source of origin. This creates a need for an analytical technique that can ultimately identify the fiber type and manufacturer source. Matrix-assisted laser desorption ionization (MALDI) is a mass spectrometry analytical technique that utilizes a laser beam to ionize the analyte, in this case the fiber. The absorbing matrix is mixed with the sample, allowing the analyte and the matrix to co-crystallize on the target plate. The matrix uses the energy provided from the laser to desorb itself from the target, pulling analyte particles with it into the gas phase as ions. In ion form, the analyte particles are then carried to the mass spectrometer detector, the time-of-flight (TOF) mass spectrometer. The TOF works by accelerating the ions toward the drift region where all ions have the same kinetic energy but different masses, thereby separating based solely on particle size. The goal of this research is to provide an objective identification procedure through the use of MALDI-TOF analysis that can distinguish various synthetic polymers based on the individual manufacturers' additives. MALDI-TOF was used to determine the polymer additive composition for comparison of similar polymer types. Optimized MALDI parameters were obtained for nylon, olefin, and polypropylene to produce mass spectra with high resolution and complete peak separation. This was obtained by spotting the target with a salt solution comprised of trifluoroacetic, sodium salt in tetrahydrofuran (THF) followed by a matrix solution, comprised of α-cyano-4-hydroxy-cinnamic acid (CHCA) in THF. The optimized parameters were then used to obtain two sets of mass spectra for four differently manufactured nylon fibers using the matrices, CHCA and trans-2-[3-(4-tert-Butylphenyl)-2-methyl-2-propenylidene] malononitrile (DCTB). These same fibers were also analyzed using FTIR as a comparison. The FTIR results confirmed the fiber identity as nylon, but could not distinguish any differences between the different manufactured nylon fibers. The MALDI-TOF mass spectra were analyzed to distinguish between matrix peaks, polymer peaks, and chemical additive peaks. When comparing spectra obtained for nylon against the spectra for the matrices CHCA and DCTB, there were similar peaks present that were not attributed to the matrix. Further analysis is required to detect spectral differences due to additive composition of differently manufactured polymers. However, when compared to FTIR analysis, this method provides a possible successful objective method for synthetic fiber analysis and identification.

Synthetic Polymer, Matrix-Assisted Laser Desorption Ionization, Manufacturer Additives of Synthetic Polymers

A23 Quality Control: How Sterile Are Your Laboratory Examination Gloves?

Krista E. Latham, PhD, Emily Zepp, BA, Rana Jan, BA, and Kelsey Labens, BS, University of Indianapolis, Biology Department, 1400 East Hanna Ave, Indianapolis, IN 46227; and Cynthia Cale, BS, and Gay L. Bush, PhD, Strand Analytical Laboratories, 5770 Decatur Boulevard, Suite A, Indianapolis, IN 46241*

The goal of this presentation is to inform participants of the potential for cross-contamination of DNA from nitrile examination gloves used in the DNA laboratory setting by investigating potential manufacturer contamination and potential contamination by analysts, and the possible implications for such cross-contamination in interpreting forensic DNA casework.

This presentation will impact the forensic science community by demonstrating the difficulty of depositing contaminating DNA on nitrile examination gloves by the brief and casual contact required to remove gloves from their boxes. However, it also demonstrates the possibility of obtaining DNA of a high enough quantity to potentially complicate forensic DNA analyses.

Quality control is an essential component of the forensic laboratory as it is crucial in obtaining accurate analytical results and maintaining the integrity of the testing. The use of latex or nitrile examination gloves is an essential quality control measure against cross-contamination from a DNA analyst's hands to the sample they are processing in a forensic DNA laboratory. The gloves create a barrier between the epithelial cells that can potentially be shed from the analyst's hands and the sterile laboratory environment. However, opened boxes of gloves are often left in arbitrary spaces until the supply is depleted and analysts often retrieve gloves from the boxes with their bare hands. The objective of this research is to systematically test whether such laboratory procedures could potentially introduce contaminating DNA into the laboratory setting.

Sterile swabs were used to collect samples from nitrile examination gloves and the boxes in which they were housed. Both previously opened and previously unopened boxes of gloves were tested. The previously opened boxes of gloves were randomly chosen from a university laboratory in which a genetics course was being conducted. The internal box surface, rim of the box, and the exposed surface of the top glove were swabbed for possible epithelial cells deposited by an individual reaching into the box to retrieve a pair of gloves. In addition, one glove was removed from the box by a gloved researcher and the exposed surface of the next glove was swabbed. This procedure was repeated with the removal of a second glove. Previously unopened boxes of nitrile examination gloves were opened by an ungloved analyst. The internal box surface, rim of the box, and the exposed surface of the top glove were swabbed for possible DNA deposited by the analyst. The analyst removed three gloves with bare hands and the exposed surface of the next glove was swabbed. This procedure was repeated with the removal of another three gloves. In addition, previously unopened boxes of nitrile examination gloves were opened by a gloved analyst. The internal box surface, rim of the box, and the exposed surface of the top glove were swabbed for any DNA that may have been deposited in the box during packaging by the manufacturer. The gloved analyst removed ten gloves and the exposed surface of the next glove was swabbed. This procedure was repeated an additional two times with the removal of twenty additional gloves.

The DNA was extracted from the swabs using a common commercial kit and quantified via quantitative PCR. One sample taken from a previously opened box of gloves contained DNA that was of high enough quantity for further analysis. All other samples produced a no DNA after quantitative PCR. The sample containing DNA was amplified and did not generate a successful DNA profile.

DNA Cross-Contamination, Nitrile Examination Gloves, Forensic DNA

A24 Ricin Bioavailability: Poor Binding to Human Serum Proteins and Toxicity Facilitation

Oluseyi A. Vanderpuye, PhD, Albany State University, Forensic Science, 504 College Drive, Room 118, Hartnett Building, Albany, GA 31705; Samuel O. Oladimaji, PhD, Lagos State University, Department of Biochemistry, PMB 1001 LASU Ojo Lagos, Lagos State 234-1, NIGERIA; and Robert D. Simmons, BS, Ansley A. Williams, BS*, and Roman Casterline, BS, Albany State University, Department of Criminal Justice & Forensic Science, 504 College Drive, Albany, GA 31705*

The goal of this presentation is to review how glycoproteins in human blood and serum are able to bind to ricin which is a highly toxic carbohydrate-binding protein. It was also an objective to show the capabilities of lectin blotting of electrophoresis gels in providing information on the characteristics of proteins found in human blood.

This presentation will impact the forensic science community by providing some insight into the extent of binding of serum glycoproteins by the toxin ricin. The poor binding of serum glycoproteins by ricin suggests that the glycoproteins in this body fluid may not effectively compete with cell surface proteins for ricin binding. This suggests that serum may not ameliorate ricin toxicity as might have been predicted because it contains glycoproteins that bind to the lectin RCA–I which has similar carbohydrate binding specificity to that of ricin.

It has been proposed that binding of ricin to proteins in human blood may affect its bioavailability, and, hence, its capacity to kill cells. Ricin binds to galactose residues in terminal beta glycosidic linkages on glycoproteins. Its binding to cell surface proteins and lipids which bear these structures allows ricin uptake by cells subsequently causing cell death.

Samples of 1mg/ml of the purified serum proteins, alpha 2 HS glycoprotein, transferring, and immunoglobulin G were mixed with an equal volume of SDS gel electrophoresis buffer which contained 10mM dithiothreitol and denatured by boiling. Six different human serum samples were diluted 20-fold in SDS gel electrophoresis buffer which contained the reducing agent dithiothreitol and the proteins were also denatured by boiling. Sample volumes of 20ul were electrophoresed in 4-20% gradient polyacrylamide gels and electrotransferred to nitrocellulose. Blots were probed with the following biotinylated lectins: ricin; ricinus communis agglutinin-II; sambucus nigra agglutinin; and, concanavalin A. The blots were developed by using streptavidin-alkaline phosphatase which was followed by the chromogenic blot substrate combination of 5-bromo-4 chloro-3 indolyl phosphate and nitroblue tetrazolium.

Six serum samples and the purified human proteins, transferrin, immunoglobulin G and alpha2 HS glycoprotein were separated by SDS gel electrophoresis. Total protein staining of the electrophoresis gel with Coomassie Brilliant Blue dye revealed the typical pattern of protein bands for the serum samples. A predominant protein band of approximately 66,000 Daltons corresponding to serum albumin was present in all serum samples. Strong protein bands at 50,000 and 25,000 Daltons (immunoglobulin G) and 75,000 Daltons (transferrin) were also present in the serum samples by comparison with the purified proteins which were electrophoresed on the same gel. Alpha2 HS glycoprotein is heavily glycosylated and does not stain well with Coomassie Blue but was detected in the sample of the purified protein as bands at a position of 50,000 Daltons. The carbohydrate structures present on the purified proteins have been studied in detail by other investigators and those on transferrin and immunoglobulin G would be expected to be able to bind to ricin by blotting electrophoresis gels. Other lectins of known carbohydrate-binding specificity were used in this study as controls to show that the lectin blotting technique was working properly. Concanavalin A (Con A), sambucus nigra agglutinin (SNA), and ricinus communis agglutinin have binding specificities that allowed prediction of their binding to the purified proteins and could be used to help interpret the results with ricin.

As expected, Con A bound to purified transferrin and the 50,000 Dalton polypeptide of immunoglobulin G which contains high mannose and biantennary structures but poorly to alpha2 HS glycoprotein. SNA binds to carbohydrates that contain alpha 2-6 linked sialic acid and to purified transferrin and alpha2 HS glycoprotein but not to immunoglobulin G which usually contains little or no sialic acid. Sialic acid molecules are sometimes linked to galactose on proteins and would prevent binding of ricin to such glycoproteins. From these results, it will be possible to later perform experiments involving enzymatic removal of sialic acid to see how ricin binding is affected and to use SNA as a control. RCA-I is a lectin that binds terminal beta-linked galactose on glycoproteins and might be expected to bind the same glycoproteins as ricin. RCA-I bound strongly to many serum proteins and also to transferrin and to the 50,000 Dalton polypeptide of immunoglobulin G, both of which have been characterized as containing terminal beta-linked galactose. RCA-I did not bind to alpha2 HS glycoprotein which instead is known to contain large amounts of sialic acid. Surprisingly, ricin exhibited comparatively weak binding to immunoglobulin G and transferrin and serum proteins and no binding to alpha2 HS glycoprotein.

From these results it was concluded that ricin showed poor binding to serum proteins whereas the related protein RCA-I, which comes from the same plant, bound strongly to serum proteins. The poor serum protein binding by ricin could help explain its extreme toxicity because proteins in blood would compete poorly with ricin for binding to cells.

Ricin, Serum, Blood

A25 How Does Sampling Strategy and Phone Type Influence the Generation of a DNA Profile Collected From Cell Phones?

Megan E. Madonna, BS, and Elizabeth M. DeVisser, BSc*, 1216 East Castle Avenue, Indianapolis, IN 46227; Sara Berger, and Haydee Lara, University of Indianapolis, 1400 East Hanna Avenue, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Biology Department, 1400 East Hanna Avenue, Indianapolis, IN 46227; and Cynthia Cale, BS, and Gay L. Bush, PhD, Strand Analytical Laboratories, 5770 Decatur Boulevard, Suite A, Indianapolis, IN 46241*

The goal of this presentation is to demonstrate the differences in DNA quantity and quality collected from different areas of cell phones and the influence of environmental exposure on the generation of a DNA profile by collecting samples from cell phones recovered after an extended period of time in an outdoor context.

This presentation will impact the forensic science community by demonstrating effective sampling strategies when cell phones are found at crime scenes.

DNA analysis represents an important investigative tool for crime scene investigations. DNA can be collected from a variety of objects and analyzed in order to aid in human identification or link an individual to a crime scene. For example, published case reports have demonstrated that DNA profiles can be recovered from items such as steering wheels, pens, contact lenses, and even food products. Cell phones represent a common item that is used by a large portion of society and thus likely to be recovered as evidence from crime scenes. Cell phones are objects that are extensively handled due to frequent use by an individual and therefore represent a good surface for collecting a DNA sample. A 2007 study investigated the ability to obtain DNA profiles from flip phones; however, no studies have been conducted that systematically investigate the ability to obtain DNA profiles from other types of cell phones.

Different areas of cell phones are subject to different types of contact with the human body. For example, the keyboard mostly comes in contact with the human fingers, the backplate mostly comes in contact with the palm of the hand, and the screen mostly comes in contact with the ear, cheek, and mouth regions of the face. Different degrees of handling and different avenues of DNA deposit, namely sloughed skin cells, sweat, or

saliva, suggest that there may be an optimal location for collecting DNA samples from a cell phone. Furthermore, different areas of the cell phone are subject to different types of environmental exposures with some areas being more vulnerable to environmental variables or contamination from extraneous DNA.

This pilot study investigates the best sampling strategy for obtaining analyzable DNA from several locations on three types of cell phones and explores the possibility of obtaining amplifiable DNA from cell phones that have been exposed to the environment for an extended period. The three cell phone types chosen for this study include handheld, flip phone, and touch screen cell phone models. Samples were taken from the keypad, backplate, and screen of each cell phone after 24-hours of use and again after placing the cell phones in an outdoor location that left them vulnerable to temperature fluctuations, rainfall, and sunlight (UV light). The samples were collected using sterile swabs. DNA was extracted using a common commercial DNA extraction kit, and quantified via quantitative PCR. DNA profiles were generated to establish whether the DNA samples represented a mixture of multiple donors or if a major contributor could be established and whether environmental exposure interfered with the DNA typing process.

DNA was collected from all samples taken from the handheld and flip phones, and 67% of the samples collected from the touch screen phones contained DNA of high enough quantity for DNA typing. The data suggest that optimal sampling locations vary by cell phone type and that samples collected from cell phones can produce complete profiles although exposure to environmental elements resulted in some loss of alleles. Single contributor profiles consistent with the user were produced from samples collected after 24-hours of use from the keyboard of the touch screen and flip phone models, and from the backplate of the handheld model. After seven days of environmental exposure, all DNA profiles consisted of a mixture or partial profile in which some of the user's alleles were detected, suggesting that environmental exposure for even a short amount of time can negatively influence DNA typing results.

DNA, Cell Phones, Sampling

A26 Assessing the Degree of Similarity Between Accidental Patterns on Shoeprints Associated With Wearers That Participate in Shared and Independent Activities

Manal R. Khalil, BS, 1063 Mosser Road, Breinigsville, PA 18031; Jacqueline A. Speir, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Nicholas D. Petraco, PhD, John Jay College of Criminal Justice, Department of Science, 899 10th Avenue, New York, NY 10019*

After attending this presentation, attendees will understand the degree of similarity between accidental characteristics based on the context in which footwear is used, how accidental characteristics change with wear over time, and how imaging science and semi-automated numerical methods can assist with comparisons.

This presentation will impact the forensic science community in three ways. First, it will comment on how rapidly, and to what extent, wear-derived random accidental characteristics develop on the outsoles of individuals that participate in shared versus independent activities. Second, it will assess the divergence of an accidental pattern with continued wear, taking into account the fact that new accidental characteristics may randomly develop, while existing accidental characteristics may randomly erode. Third, this research illustrates the utility and reliability of using imaging science and semi-automated numerical methods to quantify the similarity in accidental patterns that vary with continued use and wearer-context.

The goal of this research is to address the similarity and rate at which wear-derived random accidental characteristics develop on the outsoles of individuals that participate in shared versus independent activities. To carry out this research, two groups of volunteers were solicited and provided with new, approved footwear. The first group was asked to wear the footwear while repeatedly participating in shared group activities over a three-month period of time; the second group was permitted to wear the approved footwear while carrying out daily independent activities. At predetermined step-intervals, participants submitted their footwear for analysis which consisted of data: (a.) acquisition; (b.) registration; (c.) segmentation; (d.) processing; and finally, (e.) comparison.

The actual data in this experiment consisted of 600 pixel-per-inch (PPI) scans of footwear outsoles and impressions acquired using an established Magna brush method. Once acquired, the digital scans were registered to a common two-dimensional coordinate system, removing translational and rotational variations from the footwear impressions that cannot be avoided during the data acquisition step. Once registered, the digital images were examined for the presence of individualizing characteristics that represent the accidental pattern associated with the footwear. Once identified, these individualizing characteristics were segmented from the background invariant class characteristics that are shared by all footwear in this study. Next, each image was divided into small pixel blocks to generate a one-dimensional feature vector. Using the position and area associated with each identified accidental characteristic in the segmentation image, a feature vector representative of each shoe was automatically populated. The resulting accidental pattern was then compared to itself, thereby generating a known-match distribution. Each accidental pattern was also compared to all other impressions generating a known non-match distribution. The known-match and known non-match distributions generated by wearers that participated in shared versus independent activities were compared to determine how wearer-context impacts the degree of similarity in accidental patterns. The within and between group known-match and known non-match distributions associated with a given step-interval were also compared with each other and over time to investigate the rate at which the similarity in accidental patterns diverge with continued wear, including an assessment of the rate at which accidental characteristics randomly develop and erode.

Footwear, Correlation, Semi-Automated

A27 A Geometric Morphometric Approach to Fingerprint Analysis

Sara C. Hidalgo, BS, and Bryan E. Dutton, PhD, Western Oregon University, Department of Biology, 345 North Monmouth Avenue, Monmouth, OR 97361; Emma K. Dutton, PhD, Oregon State Police, Forensic Services Division, Oregon State Police General Headquarters, 255 Capitol Street NE, Salem, OR 97310; Stephen B. Taylor, PhD, Western Oregon University, Division of Natural Science and Mathematics, 345 North Monmouth Avenue, Monmouth, OR 97361; Patrick Aldrich, MS, Western Oregon University, Department of Biology, 345 North Monmouth Avenue, Monmouth, OR 97361; and Ryan J. Stanley, BS, Western Oregon University, 345 North Monmouth Avenue, Monmouth, OR 97361*

After attending this presentation, attendees will learn about efforts utilizing geometric morphometric tools for the spatial analysis of fingerprints to determine fingerprint uniqueness.

This presentation will impact the forensic science community by adding an assessment of this spatial analytical approach and the establishment of a statistical basis for determining fingerprint uniqueness.

Geometric morphometrics, a spatial statistical modeling method, is useful for quantitatively studying biological shape variation. Geometric morphometric analyses include methods from multivariate statistics, non-Euclidean geometry, biometrics, and digital graphics that preserve biomathematical aspects of the objects being analyzed. Furthermore, morphometrics includes a collection of readily available statistical tools (e.g., NTSYSpc and R). Within the forensic science community, forensic anthropology has led the way in exploring the applicability of geometric

morphometric techniques. Examples include analyzing mandibular morphology and craniofacial landmarks, performing a three-dimensional virtual reconstruction of a fragmented cranium, and estimating pediatric skeletal age.

For this study, a sample of fingerprints taken from the Oregon population have been utilized for geometric morphometric analyses including characterization, pattern recognition, and probabilistic modeling (i.e., determining the areas where differences are concentrated among friction ridge contours) in an effort to fully ascertain the relevance and efficacy of this spatial approach to resolving fingerprint uniqueness. Procedures for the selection of landmarks (e.g., specific minutiae primarily associated with deltas and cores), the superimposition of fingerprint images (i.e., Procrustes), the visualization of shape change (i.e., thin-plate spline), the ordination of superimposition data (i.e., principle components analysis), and the application of multivariate statistics were established.

A comparison of typical approaches for conducting geometric morphometrics with employment of a geographic information system (GIS) to emulate morphometric techniques is also presented. GIS is a collection of hardware and software components that integrate digital map elements with relational database functionality. The strength of GIS lies in its inherent ability to integrate, store, edit, and analyze spatial features and relationships, as well as the query and display of spatial information. These systems include traditional mapping capabilities (e.g., land surveying and aerial photography) and provide users with tools to interactively search and analyze any spatial information, including fingerprint space. GIS is increasingly being applied to the analysis of the positions, patterns, and relationships between objects located in a defined space. These objects include discrete entities expressed as points, lines, or polygons. Collections of objects in a defined space may be linked or associated with one another geometrically or by functional associations. GIS-based spatial analysis is very similar in concept and scope to graph theory in discrete mathematics. Techniques in spatial analyses include data modeling, image processing, grid algebra, surface analysis, and network analysis and visualization. The GIS-based tools available for spatial analysis have grown exponentially in recent years, all driven by the practical need to understand, predict, and model relationships between objects located in space. Our geometric morphometric procedures were emulated in GIS which was initially developed for meeting other objectives associated with ongoing fingerprint research being conducted in our laboratory. The impetus for this comparison of geometric morphometric techniques using a GIS platform included minimizing data handling and increasing overall efficiency in spatial analysis.

This project was supported by Award No. 2009-DN-BX-K228 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication/program/exhibition are those of the author(s) and do not necessarily reflect those of the Department of Justice.

Fingerprints, Geomorphic Morphometrics, GIS

A28 Forensic Science Ethics and Criminal Prosecutions: Missing Pieces

Barry A.J. Fisher, MS, MBA, 19854 Vintage Street, Chatsworth, CA 91311*

After attending this presentation, attendees will better understand the interconnection between professional conduct and the "Brady" obligation of prosecutors.

This presentation will impact the forensic science community by discussing the importance of communication between government laboratories and prosecutors.

This presentation will examine the role of ethics in forensic science. First-rate Codes of Ethics already exist in a variety of sources: scientific societies; accreditation bodies; certification associations; and within parent organizations that house forensic science laboratories. Codes of ethics serve to help practitioners understand their obligations to the criminal justice system and to their profession. However, failure to abide by codes of ethics and even sanctions resulting from breaches of ethics, may not affect a trial in which an expert is a witness.

The situation is complicated because there is no clear legal mandate for an employer to turn over information of ethical misconduct to the prosecution. In addition, it is uncertain whether a government body employing an individual sanctioned for ethical wrongdoing by a professional organization would even know of such that sanctions were imposed. Ethical sanctions are often considered confidential matters. Further, there is no requirement for government experts to be members of professional associations having Codes of Ethics. Thus, an expert who engages in unethical practices, but who is not a member of a professional society, is not bound by that society's code.

Under Brady, prosecutors have a legal duty to disclose information and to inform the defendant of information deemed to be material that could influence the outcome of a trial or could impeach the integrity of an expert witness. Impeachable information would likely include ethical sanctions. Presumably, ethical misconduct, and especially sanctions from a professional society, would be considered Brady material. But how would a prosecutor become aware of an ethical breach of ethics?

Here is a hypothetical: A member of a professional association, e.g., the American Academy of Forensic Sciences, violates ethical standards and is censured for that conduct. Let's say he or she is removed from the organization. Would such information be routinely provided to the individual's employer that the person was censured? If a censured individual worked for a public forensic science laboratory, that information may be considered "Brady material" by the prosecution. But how does the prosecutor who calls that individual know of the censure? It could be argued that the information should be turned over to the defense. As it stands, the public lab administrator may or may not be unaware of the ethical breach. If the results of a professional society's ethics investigation are turned over to the individual's employer, does the lab have a legal duty to advise the prosecution? Does the professional association have a responsibility to advise the employer, the courts, the public, or the prosecution of such matters?

A solution to this problem is likely some form of government oversight of forensic science to establish rules of ethical conduct within the profession. Simply establishing a uniform Code of Ethics as the National Academy of Sciences report on forensic science recommends does not fully address the current situation. In addition, courts at some point need to define what the Brady obligation means, not only for the prosecution but to the Government's forensic science delivery system.

Forensic Science Ethics, Brady Material, Discovery

A29 Legal vs. Scientific Proof: And Never the Twain Shall Meet?

Jay A. Siegel, PhD, Indiana University-Purdue University Indianapolis, Department of Chemistry, School of Science, 402 North Blackford, LD 326 D, Indianapolis, IN 46202; Barry A.J. Fisher, MS*, 19854 Vintage Street, Chatsworth, CA 91311; Betty Layne DesPortes, JD*, Benjamin & DesPortes, PC, PO Box 2464, Richmond, VA 23218; John J. Lentini, BA*, Scientific Fire Analysis, Limited Liability Company;, 32836 Bimini Lane, Big Pine Key, FL 33043; Robert E. Barsley, DDS, JD*, Louisiana State University Health Science Center School of Dentistry, Oral Health Resources, Room 2115, 1100 Florida Avenue, New Orleans, LA 70119; John Collins, MS*, Michigan State Police, Forensic Science Division, 7320 North Canal Road, Lansing, MI 48913; Matthew F. Redel, JD*, Sheridan County Prosecuting Attorney, 148 South Brooks Street, Sheridan, WY 82801; and Paul C. Giannelli, JD, LLM, MSFS*, Case Western Reserve University School of Law, 11075 East Boulevard, Cleveland, OH 44106*

After attending this presentation, attendees will: (1) understand the definition of legal proof and scientific proof; (2) understand the difference

between the two kinds of proof; (3) understand the critieria for proof that forensic scientists need in court; and, (4) understand the criteria for proof that attorneys need to establish in court.

This presentation will impact the forensic science community by providing an opportunity for dialogue between the forensic science and legal communities so that they can have a better understanding of each other's criteria for proof in court.

In a criminal case, the goal of the prosecutor is to prove that the accused is guilty of the crime(s) charged, including all of the elements of each crime. The prosecutor must prove his case "*beyond a reasonable doubt*." If, in a murder trial, a gun possessed by the accused was suspected of firing the fatal bullet, the prosecutor's task is to prove that the fatal bullet was fired from the weapon. If the accused deposited blood at the scene of the murder, the prosecutor must try to prove that the blood came from him. This trial is going on in real time and the evidentiary questions must be answered with today's knowledge, now. Naturally, this begs the question: what constitutes proof beyond a reasonable doubt?

Science, including forensic science, doesn't see things in the same way as the law. Science is a constantly moving target. As scientists do research, more data is collected and conclusions may change. As science advances, so does the ability of forensic scientists to associate items of evidence with people or objects. What was true 25 years ago may not be true now. For example, back then, there was no way to reliably associate blood evidence with one particular individual. Today, DNA typing has made that possible. What will happen 25 years hence? For many years, it has been accepted, almost without question, that a bullet can be traced to a particular rifled weapon. Now, these conclusions are being questioned. All of this means that the concept of scientific proof changes as advances in science change, but the concept of legal proof doesn't change. All of the elements of a crime must still be proven beyond a reasonable doubt. Obviously, the particular elements that must be proven are unique to each case.

This program will examine the issues of legal and scientific proof. Is there a clear understanding of the two types of proof among the actors in the adjudicative process including the scientists? What are the best ways of reconciling the problem of legal proof being an immediate, static set of requirements, whereas the elements of scientific proof of a given concept change with time? How does this impact the appeal of adjudicated cases?

To get at these and related questions, we are convening a panel of distinguished experts in the legal field and in forensic science. They will be given a series of questions that will hopefully get at the issues of proof. Time permitting, questions will also be accepted from the audience.

Legal Proof, Scientific Proof, Attorney

A30 A Philosophical View of Forensic Science: Native and Non-Native Principles That Form the Foundation of the Discipline

Max M. Houck, PhD, Analytic Services, Incorporated, 2900 South Quincy Street, Suite 800, Arlington, VA 22206*

After attending this presentation, attendees will gain insights into the philosophical foundations of forensic science and enhance their perspectives on the basic theories and principles that may guide this discipline.

This presentation will impact the forensic science community by influencing how forensic scientists think about their discipline and profession and may guide thinking on basic research that is needed and has been called for by the forensic community, national groups, and critics.

This presentation offers a philosophical view of forensic science that provides at least some of the necessary underpinnings to conduct its work and research. In this view, forensic science is seen to have three native principles that form a philosophical basis: other principles or concepts; borrowed from related historical disciplines; and fill in necessary working modes.

The first native principle is classification. Any collection of objects, real or imagined, is a set; set theory is the branch of mathematics that studies these collections. Basic set theory involves categorization and organization of objects and involves operations such as set union and set intersection. Advanced topics, including cardinality, are standard in undergraduate mathematics courses. The notion of set is undefined; the objects constituting (its members or elements) the set define it. The members of a set may be real or imagined but membership criteria for a set should be definite and accountable. Forensic science's taxonomies are additive to the taxonomies of nature and the manufacturers, although are initially based on them. Forensic science has developed an enhanced appreciation for discernment between otherwise similar objects but hasn't exploited them to their benefit. Thus, although classification is an inextricable part of forensic science, forensic science does not necessarily truck in fixed taxonomies.

The second native principle is uniqueness. Uniqueness comes with assumptions that affect the resolution of analyses. The first assumption is that all things are unique in space and, thus, their properties are non-overlapping. The second assumption is that properties are constant with time. The assumption of uniqueness of space is considered axiomatic and, therefore, an inherently non-provable proposition: The population size of "all things that might be evidence" is simply too large to account. A statistical analysis is therefore warranted when uncertainty, either of accounting or veracity, exists.

The third native principle that guides forensic science is the exchange principle, which posits that when two items come into contact, information may be exchanged; the results of such a transfer would be proxy data. Because forensic science demonstrates associations between people, places, and things through the analysis of proxy data, essentially all evidence is transfer evidence.

Principles from other sciences, mainly geology, apply to forensic science. The first is Uniformitarianism, which states that natural phenomena do not change in scope, intensity, or effect with time. Paraphrased as "the present is the key to the past," the principle implies that a volcano that erupts today acts like volcanoes did thousands or millions of years ago; geologists can interpret proxy data from past events through current effects. Likewise, in forensic science, bullets test-fired in the laboratory today are comparable to bullets fired during the commission of a past crime. The same is true of any analysis in forensic science that requires a replication or reconstruction of processes in play during the crime's commission.

Three additional principles from geology applicable to forensic science are of

- Superposition, in a physical distribution, older materials are below younger materials unless a subsequent action alters this arrangement;
- Lateral Continuity, disassociated but similar strata (layers) can be assumed to be from the same depositional period; and
- Chronology, the notion of absolute dates in a quantitative mode and relative dates in a relational mode, that is, older or younger.

A forensic example of the principle of superposition would be the packing of different soils in a tire tread, the most recent being the outermost. A good case of lateral continuity would be the cross-transfer of fibers in an assault, given that the chances of independent transfer and persistence prior to the time of the incident would be improbable. An example of absolute chronology in forensic science would be the simple example of a purchase receipt from a retail store with a time-date stamp on it; examples of relative chronology abound but can be thought of as a layer cake, with the older layers at the bottom.

Philosophy, Foundations, Principles

A31 Alternative Models Promote the Self-Regulation of the Forensic Enterprise

Richard Tontarski, MFS, United States Army, Criminal Investigation Laboratoy, 4930 North 31st Street, Forest Park, GA 30297-5205; Wesley P. Grose, MFS, Los Angeles Sheriff's Department, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032; Max M. Houck, PhD, Analytic Services, Incorporated, 2900 South Quincy Street, Suite 800, Arlington, VA 22206; and Dean M. Gialamas, MS, Los Angeles County Sheriff, Scientific Services Bureau, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032*

The goal of this presentation is to identify alternatives for integrating key organizations and stakeholders into coordinating, guiding, and regulating aspects of the forensic science profession to enhance its effectiveness, reputation, and professionalism.

This presentation will impact the forensic science community by stimulating a discussion and debate among its stakeholders about oversight and compliance alternatives for forensic science based on critical precepts needed to strengthen the profession.

There is little fundamental disagreement about the areas of forensic science needing improvement and standardization when forensic services are considered globally. Studies conducted periodically over the last 25 years by government-funded working groups, committees, and organizations, have identified similar concerns about shortcomings in forensic science, from fundamental education to consistent standardization in analysis methods to continuing need for research. The National Academies of Science National Research Council's *Strengthening Forensic Science in the United States: A Path Forward* is only the latest study to echo these needs and enjoys the greatest current visibility.

As the *NAS Report* reminds us, forensic science has no overarching structure or unifying entity able to provide direction, guidance, or oversight to the profession. The solution proposed by the *NAS Report* is the creation of a federally operated regulatory body, the National Institute of Forensic Science. This is not the only viable model to fill this gap.

Many laudable organizations originated to improve distinct aspects of forensic science, including accreditation, certification, sharing professional information and research results, and educational curricula. All have contributed significantly to advancing the profession. Much of the work is voluntary because most of the organizations have little to no professional staff, or their staff function is limited to operations that focus on the organization. These aggregate organizations represent the main professional aspects of the forensic enterprise and their activities need to shape the forensic profession. What is lacking is a strategic architecture and processes to coordinate and synchronize these aspects, and more, of the forensic science profession. Without such a strategic approach, professional progress will continue to lag behind expectations and need.

A National Forensic Science Board (NFSB) could coordinate forensic programs and activities nationwide. The US forensic science industry has many of the resources in place needed to lead and significantly advance all aspects the profession. What we are lacking are consistent coordinated efforts. The NFSB concept proposes to fill that gap.

Several models are available for forensic science to use as a starting point to build this strategic architecture. They include the National Safety Transportation Board (NTSB), a government entity, and the National Fire Protection Association (NFPA), a private, nonprofit. What both organizations have in common is that they have no regulatory authority and yet, both are the undisputed authoritative voice and promulgator of standards in their respective areas. Through proven deliverables meeting public need, each organization has gained respect and built trust. This has given them the authority they need to positively guide, impact, and strengthen their industries.

The NFSB model takes a similar approach. It proposes to integrate and synchronize the on-going efforts leveraging the subject matter expertise that has been developed by each of the recognized forensic professional organizations. It would also ensure that all the stakeholders that have labored so diligently to identify needs and propose solutions are heard, including the legal community, victim advocates, wrongfully accused, community needs, laboratory management, and individual examiners. With non-regulatory oversight, a collaborative, holistic approach can be developed to gain an accurate understanding of capabilities, resource gaps, and profession requirements and to address the profession's needs.

Some key concepts for how such a Board might be organized and operate include:

- Serving as an independent advisory body for the Executive, Legislative, and Judicial Branches;
- Providing consistent leadership and oversight in the furtherance of excellence and reliability in the forensic sciences by issuing recommendations on topics that include, but are not limited to:
  - Proper analytical procedures and processes,
  - Appropriate formal education,
  - Initial and ongoing training requirements for forensic practitioners to prepare for and maintain analytical competency,
  - Appropriate training for forensic laboratory managers,
  - Methods for ensuring competency;
- Acting as an investigative body for and issuing recommendations on acute forensic science issues, including:
  - Receiving, investigating, and addressing stakeholder concerns and complaints,
  - Evaluation of laboratory failures,
  - Appropriate use and limitations of forensic analyses or procedures,
  - Current research needs for forensic disciplines;
- Providing consistent direction and support to forensic science discipline groups, that includes:
  - Recommending certification and accreditation changes,
  - Defining the purpose, responsibilities, and expectations of practitioners,
  - Coordinating, defining, and prioritizing the research needs,
  - Reviewing and promulgating work product as authoritative forensic guidance,
  - Supporting professional staff.

There are several significant barriers to creating and operating a model like a NFSB, all of which can be overcome. Financial resources are not the primary hurdle; the costs to start and sustain such a Board with professional staff are anticipated to be modest. Three major challenges to launching this concept are:

1. Territoriality: Forensic science has demonstrated a tremendous capacity for volunteerism. Until the profession can move beyond immediate, operationally-discrete functions (with their perceived political threats, concerns, and challenges) and trust in a larger process that will encompasses, recognizes, and addresses our collective concerns, significant collective progress will continue to be stymied and limited to individual initiative and its necessarily limited scope of success.
2. Inertia: Any undertaking of this magnitude and scope requires managing expectations and building relationships that will transcend the individual needs of any one forensic organization.
3. Fear: Any proposal to accomplish a model like what is outlined for the Council will have naysayers; no plan will be quite right for all parties. Leadership will be required to stem inevitable territoriality, to lead people to act on their better natures, and to provide a consistent vision of goals and outcomes.

The forensic community needs to decide its fate actively, rather than respond to sniping, attacks, and political pressures; however, this includes considering and possibly embracing stakeholders' and critics' perspectives. Failure to coordinate and synchronize the forensic profession's collaborative efforts will result in continued misunderstandings among stakeholders and critics, resulting in an increasing loss of faith in forensic science and, ultimately, the criminal justice system.

This presentation will address alternatives to implementing and operating a National Forensic Science Board.

Forensic Science Management, Operational Policy Oversight, Forensic Science Board

A32 A Market History of the United Kingdom's Forensic Science Service

Chris Maguire, PhD, Northumbria University, Ellison Place, Newcastle Upon Tyne, NE1 8ST, UNITED KINGDOM; Max M. Houck, PhD, Analytic Services, Incorporated, 2900 South Quincy Street, Suite 800, Arlington, VA 22206; and Paul Speaker, PhD, West Virginia University, College of Business & Economics, Morgantown, WV 26506*

After attending this presentation, attendees will provide the audience with a historical review of the origins of the UK's Forensic Science Service, its development from regional laboratories into a centralized national agency to its scheduled demise as a government-owned company in 2012. The participants will gain a better understanding of the internal and external forces that created, shaped, and debilitated this internationally-recognized forensic leader.

This presentation will impact the forensic science community by presenting the "lessons learned" aspect of one of the core issues facing forensic science: how to provision, allocate, and manage scarce resources. The Forensic Science Service has become an unintended case study in the on-going discussion of the best methods of providing forensic services to a criminal justice system. This review will help inform the community of the base facts that led to the current situation and provide insights for future forensic policy worldwide.

"You know why there are so many whitefish in the Yellowstone River? Because the Fish and Game people have never done anything to help them." —Russell Chatham, Silent Seasons, 1978

The Forensic Science Service had a long and distinguished history. Originating from proposals to the Home Office in 1929 for the establishment of a national police college with scientific laboratories to support police investigations and to undertake research, it coalesced in the 1930s and 1940s with the combining, relocating, and creation of laboratories for casework and research around the UK. Throughout the 1970s, the Home Office Forensic Science Service (FSS) created six purpose-built regional laboratories to replace the pre-war facilities. The Metropolitan Police (London) laboratory was merged with the FSS in 1996.

Up to 1990, the FSS was the only significant forensic provider in England and Wales. Funded by government grants and proportional fees paid by regional police agencies, the FSS was a wholly-governmental entity. Between 1979 and 1987, the staffing levels in the FSS remained fairly constant and all of the staff were civil servants. The fee structure system was not transparent and the true costs of the forensic support was hidden amongst the myriad of other government services the police 'bought'; additionally, large forces that were only occasional users of forensic services paid dearly. Nevertheless, through 1987, the demands on laboratory services grew rapidly as the number of operational police officers deployed increased, recorded crime increased, significant changes in the forensic science 'toolkit' (such as DNA) were introduced, and quality assurance and standardization across the regional laboratories increased their administrative burden. This led to a growing dissatisfaction amongst the police users about the FSS's timeliness; from the FSS's point of view, police were unable to forecast their demand accurately.

The Thatcher government sought mechanisms that identified elements of the civil service which would benefit from being given more autonomy and managerial and budgetary control. These "Executive Agencies" emerged from civil service reforms and were reorganized as discrete 'business units' within central government departments to deliver their services directly. Executive Agency was seen as the appropriate vehicle for change in the FSS to regulate the demand and supply of its service. In this mode, the FSS would become more flexible, responsive, and provide "value for money." In 1991, the FSS became an Executive Agency of the Home Office. At the same time, the FSS introduced a "product-based" charging model for services, each product having a unit charge or a time charge. All of the FSS costs had to be supported by earned revenue but, as an Executive Agency, the FSS was a non-profit making organization. Monies earned over and above costs were returned to the police; any shortfall was supported by the Government as a short-term loan and had to be repaid in the following year.

While the FSS had 100% share of the available forensic market, other entities had seen the opportunity to enter this potentially lucrative field: Executive Agency had opened the market. Client police forces shared FSS price lists with competitors and asked for quotes, particularly in "commodity" market sectors, where the police were buying "tests" rather than "services." For the police, the increasing competition to FSS meant they began to have choices in forensic science supplier and the provision of some services, like DNA profiling, became very price sensitive.

In 1999, the legal position of the FSS changed from that of Executive Agency to that of Trading Fund status. The FSS remained part of the Home Office, its parent government department, but the advantage of this changed legal status was that it could retain its income from operating activities and use this to meet it expenditure. In effect, the FSS had to operate like any other commercial business and the organization was required to recover its full costs and earn the appropriate return on capital employed. However, the Local Government Act (1999) required public bodies, including Police Authorities, to obtain "Best Value" in procuring their services. This required Police Authorities to challenge suppliers and to competitively tender request for services, including the procurement of forensic services; this policy directly affected the FSS's market share. The legislative aim was to encourage a more competitive market and no single supplier would win the entire contract regardless of how competitive a bid was made. No matter how competitive FSS made their bids they could only lose work to the competitor organizations.

Increased competition led to the FSS faltering and it was recommended that a new structure, that of a Government-owned company (GovCo), would help the FSS adapt; the goal was to eventually change the FSS into a Public Private Partnership (PPP or fully privatized) with the transition lasting no more than 12-18 months. The FSS became a GovCo in October 2005; however the staff, Unions, and clients for the FSS were fiercely opposed to the goal of a fully privatized company. The Government dithered and the momentum to create a PPP was lost. In 2005, the House of Commons Select Committee on Science and Technology (7th Report) was highly critical of the government delay in moving FSS Ltd from GovCo to PPP status. New police procurement legislation in 2008 split operational forensic science into a series of work packages and, for each work package, specified the services to be delivered, the quality standards to be met, and created a standard user specification. Under this procurement scheme, the forensic suppliers could only compete on price; innovation and improved customer service levels counted little. Financially on the ropes, the FSS closed three laboratories by March 2011, letting go 500 operational scientists in the process.

Forensic Science Service, Market, Economics

A33 Does the "Scientific Method" Apply to Forensic Science? Should It?

Walter F. Rowe, PhD, George Washington University, Department of Forensic Science, 2100 Foxhall Road Northwest, Washington, DC 20007*

The purpose of this presentation is to dispel claims that there is a unitary scientific method and that this scientific method should apply to forensic science. The presentation will demonstrate that different sciences have their own methods for formulating problem to investigate and for gathering evidence. The presentation will also show that forensic science

is properly classified as a historical science like archaeology rather than an experimental science like chemistry. Finally, the presentation will explore the implications of such a classification for forensic science education.

This presentation will impact the forensic science community by understanding the distinction between "experimental" sciences and "historical" sciences and will also understand the differences in the methodologies employed by these two categories of science. They will also understand why forensic science is properly classified as a 'historical' science rather than an experimental science.

The National Research Council's recent report *Strengthening Forensic Science in the United States: A Path Forward* (National Academies Press: 2009) in discussing forensic science education stated: "Forensic examiners must understand the principles, practices, and contexts of science, including the scientific method." Many scientists and philosophers of science maintain that there is a unitary 'scientific method' that is applicable to all sciences. Some of these scholars believe that all science can be reduced to physics and that the research methods of physics should be applied across-the-board to all sciences. On the other hand, other scholars in the field of science studies (most notably Dean Henry Bauer in his *Scientific Literacy and the Myth of the Scientific Method* (University of Illinois Press: 1994) have argued that there is no unitary scientific method that is applicable to all sciences. For many of these commentators, this view is primarily a pragmatic recognition that different sciences deal with different subject matter and make use of different standards for selection of research problems and for the evaluation of evidence. Psychologists Hilary Putnam and Jerry Fodor have argued that there are logical grounds for dismissing the claim that all science can be reduced to physics. If such is the case, the different branches of science should have distinct logical structures and would have their own "scientific methods."

Professor Carol Cleland has stressed the critical distinction between "experimental" sciences such as physics and chemistry and "'historical" sciences such as astronomy, geology, paleontology, archaeology and evolutionary biology. "Experimental" sciences seek to formulate laws that predict the outcomes of future experiments, while "historical" sciences seek to reconstruct past events from traces left behind. "Experimental" sciences infer effects from causes; "historical" sciences infer causes from effects. While "historical" sciences may conduct experiments that superficially resemble those of "experimental" science, these experiments seek to find traces of past events predicted by specific reconstructions of those events.

Forensic science clearly belongs to the "historical" sciences rather than the "experimental" sciences. All the evidence examined in forensic science laboratories is the result of past events. Forensic examinations are conducted so that investigators can infer what crimes have been committed, who committed them, and how they were committed. In order to accomplish these goals, forensic scientists must sift through the myriad pieces of evidence found at the typical crime scene and determine the forensically relevant items of evidence and the appropriate examinations to perform on them. Such choices are guided by the forensic scientist's understanding of the capability of specific items of evidence to distinguish between various possible reconstructions of the crime.

The classification of forensic science as a 'historical' science has important implications for forensic science education programs. While some forensic scientists (such as forensic anthropologists) have been educated in fields where reconstruction of the past is the norm, most forensic chemists and many forensic biologists come from educational backgrounds that stress the 'experimental' sciences. Consequently, forensic science education programs should place stronger emphasis on historical, reconstructive reasoning. This should be done through the use of simulated or mock crimes which students are called upon to investigate. The mock crime scenarios should include relevant as well as irrelevant evidence and the students should be required to identify the relevant items of evidence, select the most forensically useful methods of analysis, carry out examinations of the evidence, and weigh the likelihoods of different crime reconstructions.

Forensic Science, Scientific Method, Historical Science

A34 The Forensic Science Laboratory in Kosovo

Xhemajl Ademaj, PhD, Ministry of Internal Affairs, Ulpiana D1 Hyrja 7, #9, Prishtina, 10000, KOSOVO*

After attending this presentation, attendees will be introduced to the facilities and operation of the forensic laboratory in Kosovo.

This presentation will impact the forensic science community by describing the current capabilities of the Kosovo forensic science laboratory as well as future initiatives.

Kosovo is located in Southeast Europe with a population of 2.2 million people. A forensic science laboratory in Kosovo has never been organized at the level of most modern forensic science laboratories. This was made possible after the war of 1999 with the help and support from the United States. The United States Government/ICITAP provided 9.5 million dollars to support this project. Ideas and supporting materials for the construction of the forensic laboratory in Kosovo by the United States have greatly benefitted law enforcement in Kosovo. This poster presentation is an elaboration of areas of expertise that the laboratory offers as well as the current status and need for expansion. In particular, future areas of expertise are needed in order to achieve accreditation under ISO 17025 international standards.

The laboratory is 1000 square meters and employs 38 experts. Forensic laboratories in Kosovo are crucial to criminal justice system. Forensic scientists in Kosovo laboratories provide valuable information that aids in the investigation and prosecution of crime through the scientific examination of physical evidence. Their efforts carried out to the highest standards of scientific objectivity, integrity, and quality, give voice to the silent witnesses of physical evidence and contribute to the cause of justice. The addition of a LIMS (Laboratory Information Management System) has improved the laboratory's ability to track the internal flow of evidence and case analysis. This system is used to track cases, analytical results, and evidence as it is processed through the laboratory. The LIMS system assists with the assignment of cases, case flow, and backlog control. LIMS can also generate and maintain case reports and allow for statistical analysis of the types of cases, number of cases, turnaround times, and other management data.

The Kosovo forensic laboratory also has an intensive quality assurance program which covers the following areas: staff qualifications, training, proficiency testing, administrative policies, technical procedures, security and evidence integrity, chemical reagent quality control, equipment maintenance and performance verification, documentation of laboratory analysis, and the review of casework, reports, and testimony.

The forensic laboratory in Kosovo is a full service laboratory offering a wide variety of services. Included is the analysis of controlled substances, toxicology, latent prints comparisons, firearms and tool mark identification, trace evidence examination, DNA analysis, and questioned document examination.

Technological equipment of all sectors and photos from the Automated Biometric Identification and Automated Fingerprint Identification Systems will be presented in order to stimulate a discussion and engourage the exchange of information. The forensic laboratory in Kosovo has significant needs that must be met in order for forensic services to continue to improve and meet the demands of ISO 17025. The forensic laboratory scientific staff is encouraged to participate in seminars and scientific conferences in the United States and in Europe in order to adopt techniques and newer methods in various forensic disciplines. Each sector in the forensic laboratory already has staff who are Associate Members in organizations such as European Network of Forensic Science Institutes and the International Association of Identification, and has members who participate in working groups within these organizations.

Laboratory, Forensic, ISO17025

A35 Development of Optimized Recovery and DNA Typing Methodologies for the Analysis of "Touch and Contact DNA" Samples

Erin K. Hanson, PhD, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; Kirsten T. Kelley-Primozic, BS, McCrone Associates, Incorporated, 850 Pasquinelli Drive, Westmont, IL 60559; Bianca N. Vigil, MS, McCrone Microscopes and Accessories, 850 Pasquinelli Drive, Westmont, IL 60559; and John Ballantyne, PhD, University Central Florida, Department of Chemistry, 4000 Central Florida Boulevard, Orlando, FL 32816-2366*

The goal of this presentation is to provide an understanding of new methodology for the collection and DNA typing of epithelial cells collected from touch and contact DNA samples.

This presentation will impact the forensic science community by providing a characterization of the biological material in touch or contact DNA evidence and providing strategies for DNA recovery and analysis from isolated cells.

In forensic casework analysis, it is sometimes necessary to obtain genetic profiles from increasingly smaller amounts of biological material left behind by persons involved in criminal offenses. The ability to obtain DNA profiles from trace biological evidence is routinely demonstrated with so-called "touch DNA evidence" (generally perceived to be the result of DNA obtained from shed skin cells transferred from donor to an object or person during physical contact). While these studies clearly demonstrate the ability to obtain genetic profiles from trace biological evidence (e.g., paper and documents, keyboards, bedding and fabrics, shoe insoles, firearms and cartridge cases and drinking containers), they often employ a "blind-swabbing" approach and therefore fail to include an evaluation of the type of cellular or genetic material that may be present in such samples. This often results in the presumption that the DNA profiles are obtained from shed skin cells as opposed to, for example, saliva traces without any scientific basis for this assertion. This possible misrepresentation of the source of biological evidence could place undue weight to a given piece of evidence. It is therefore essential that methodologies for the analysis of biological material from touch and contact DNA samples allow for a skin vs. non-skin tissue source identification and allow for a demonstration of a direct link between the biological material and recovery of DNA profiles from it.

The goal of this work was focused on the development of collection strategies for the recovery of biological "particles" from contact DNA samples and also the recovery of DNA profiles from the collected particles. For initial method development, buccal epithelial cells were used as they would be expected to be more stable than shed biological "particles." Buccal smears were prepared directly on a low retention polymer material. Individual or multiple buccal cells (five and ten cells) were then collected using a water soluble adhesive and immediately placed into a tube containing reagents for direct cellular lysis. Amplification of the lysates was then performed using LTDNA protocols. Using the developed collection and typing methodologies, STR profiles were obtained from as little as one buccal epithelial cell. No inhibitory effects from varying cell staining reagents were observed. With the success of the developed collection and typing methodologies developed, these methods were applied to the analysis of contact and touch samples. Contact samples were prepared by placing the low retention polymer material in direct contact with worn clothing items (shirts, pants, and hats) or human skin. The structural nature and quantity of the biological material presence was then determined with the aid of various staining techniques, with a possible nucleus observed in only a few particles within each sample. In order to obtain STR profiles from the contact samples, increased numbers of "particles" needed to be collected (e.g., 100 "particles" in some cases). The collection of only "nucleated" particles, if identified, may result in improved recovery of genetic profiles. Therefore, additional work will be needed in order to further characterize the nature of the biological "particles" present in contact and touch samples in order to determine the most suitable type and quantity of "particles" needed for analysis. Despite the need for additional work, the results of this initial work provide an indication that it will be possible to perform a more comprehensive molecular-based approach to the characterization, analysis, and interpretation of trace biological material recovered from touch and contact samples.

Touch/Contact DNA, Epithelial Cells, DNA Analysis

A36 Internal Validation of GeneMapper®ID-X for Use in Forensic Casework

Emily M. Fete, BS, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701; Angela D. Spessard, MFS, and Karin A. Crenshaw, MS, Palm Beach County Sheriff's Office, 3228 Gun Club Road, West Palm Beach, FL 33406; and Amy McGuckian, MSFS, and Cecelia A. Crouse, PhD, Palm Beach County Sherrif's Office, Crime Laboratory, 3228 Gun Club Road, West Palm Beach, FL 33406-3001*

After attending this presentation, attendees will understand the need for an efficient software system to help streamline data analysis in laboratories experiencing a bottleneck of forensic DNA interpretation.

This presentation will impact the forensic community by demonstrating the effectiveness of GeneMapper®*ID-X* for analysis of both casework samples as well as an expert system for casework standards. Moreover, mixture analysis tools from GeneMapper®*ID-X* and ArmedXpert™ will be presented and compared.

Due to the implementation of robotic equipment to extract, quantitate, amplify, and detect forensic DNA samples, the bottleneck of forensic DNA analysis has shifted to data interpretation. There is now a need for computer software that maximizes efficiency and encompasses the resources needed for DNA analysis. Applied Biosystems' GeneMapper®*ID-X* is one of the software systems capable of reducing this bottleneck and providing a suite of tools to assist in single source and DNA mixture interpretation.

The Palm Beach County Sheriff's Office Forensic Biology Unit (FBU) DNA validation data was originally created, collected, and analyzed using Promega's PowerPlex®16 amplification kit, two AB®3130*xl* platforms, and GeneMapper®ID v3.2.1 (GMID). The FBU recently purchased GeneMapper®*ID-X* v1.2 (GM*ID-X*) for use with questioned casework samples and plans to utilize the expert system capabilities for streamlining the interpretation and review of known casework samples. The validation of GM*ID-X* for use with casework included the following studies: known samples and stutter, NIST, non-probative, reproducibility, precision, contamination and analytical threshold, sensitivity and stochastic thresholds, and mixtures. The studies were completed according to the Scientific Working Group for DNA Analysis (SWGDAM) guidelines. Original GMID data was analyzed with GM*ID-X* and the results were compared.

The GM*ID-X* software was able to produce accurate, reliable, reproducible, and concordant results between data obtained with GMID. Concordant allele calls, basepair, and RFUs were obtained between GM*ID-X* and the originally analyzed data using GMID. The validation data demonstrates that GM*ID-X* is suitable for use with forensic casework using PowerPlex®16 and the FBU's two AB®3130*xl* platforms.

Upon completion of the validation of GM*ID-X* for typical forensic samples, the validation of GM*ID-X* as an expert system was initiated. GM*ID-X* can automatically review allelic ladders, controls, and samples using user defined thresholds, and with color-coded process quality value flags (PQVs), it can assist in the manual review of single source samples. For the validation of GM*ID-X* as an expert system, known single source samples were run through the software to determine the applicable peak quality values for the FBU laboratory. A workflow with different analysis methods and table settings distinct from those used by the FBU to analyze and interpret unknown casework samples was created.

GM*ID-X* also contains a new Mixture Analysis Tool that is meant to assist analysts in deconvoluting two-person mixtures by performing

mixture calculations and helping provide analysts with a common platform from which to interpret DNA mixtures. Another mixture analysis tool that can be used in conjunction with GM*ID-X* is ArmedXpert™. A mixture study was conducted with two mixture sets on both software systems in order to determine ease of use and establish a workflow for each mixture analysis tool. ArmedXpert™ requires GMID or GM*ID-X* to correctly size and generate DNA profiles prior to importing them into ArmedXpert™ for analysis. Once a profile is imported, it can be compared to staff profiles, compared to other samples run in the same batch, compared to known standards, or sent to the mixture interpretation section of the software for up to three-person DNA mixture deconvolution. ArmedXpert™ and GM*ID-X* can also perform random match probability, combined probability of inclusion/exclusion, and likelihood ratio statistics.

Overall, GM*ID-X* is one of several software systems available to reduce the forensic data review bottleneck. The implementation of an expert system into a laboratory's workflow will reduce the need for manual review of known samples by streamlining the analysis of typical forensic casework samples. GM*ID-X* has been validated for use with casework samples and the foundation for its validation for use as an expert system for known single source samples has been established. GM*ID-X* and ArmedXpert™ are important tools available for DNA analysts to assist with the often time-consuming and complicated data interpretation of single source and mixture profiles. The generation of statistically appropriate calculations is another important advantage of these programs.

GeneMapper®ID-X, ArmedXpert™, Validation

A37 Evaluation of SampleMatrix® for DNA Storage

Susanne E. Howlett, MS, Fredericksburg, VA 22407; Lora J. Gioeni, MS, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Joseph Donfack, PhD, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; and James M. Robertson, PhD, Federal Bureau of Investigation, Counterterrorism Forensic Science Research Unit, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the benefits of using a non-freezing alternative for long term storage and transportation of DNA samples. Freezing is currently the most commonly used method for storing extracted DNA in many laboratories. Preserving good quality DNA for perpetuity is obligatory and mandatory by many forensic laboratory protocols in order to facilitate prospective and retrospective analyses. Storage requires a large number of freezers, maintenance and power costs, and back-up generators. An alternative to low temperature storage is the SampleMatrix®, commercially available as a synthetic polymer. Storage technology using SampleMatrix® mimics the natural molecular principles of anhydrobiosis by forming a thermo-stable barrier around the biological sample to protect it from degradation. The SampleMatrix® is widely used in academic institutions and is gaining acceptance by forensic laboratories.

This presentation will impact the forensic science community as the results of this study may provide a more environmental friendly and cost effective solution for storing aliquots of DNA samples. Previous studies that evaluated the efficacy of the SampleMatrix® to protect DNA extracts have utilized standard Combined DNA Index System (CODIS) Short Tandem Repeat polymorphisms (STR) primer sets to monitor DNA degradation. The original commercial multiplex CODIS STR kits amplified amplicon sizes ranging from 97-464 base pairs (bp).

Newer CODIS STR kits target even smaller amplicons (<300bp). Since DNA degradation is characterized by the fragmentation of larger DNA regions into smaller ones, it was hypothesized that monitoring for a decrease in the number of larger DNA fragments would be more informative while being easier than examining STRs. To test the hypothesis, DNA degradation was induced by storage of extracts in sealed tubes at high temperature and DNA decay was monitored by SYBR Green qPCR utilizing four primer sets designed to amplify amplicons of 92, 250, 500 and 970 base pairs in size. The samples were tested from day one through 135 at a weekly interval for the first month and every three weeks for the remainder of the time period. The DNA samples (1, 5, and 20ng/µL) with and without the SampleMatrix® were heated to 37ºC (equivalent to 1.046 years at room temperature for 135 days) or 50ºC (equivalent to 2.575 years at room temperature for 135 days) for fast aging of the DNA and to determine the efficacy of the SampleMatrix®. This experimental procedure is designed to mimic exposure of the purified DNA samples to high temperatures such as during transportation, which according to according to FedEx shipping guidelines can occur at temperatures as high as 60ºC, depending on the time of the year. Controls were maintained at -20 ºC for an accurate comparison.

Preliminary results indicate that the SampleMatrix® is useful in preventing the degradation of DNA at low concentrations (1 ng/µL). When using the 1ng/µL DNA samples, significant differences in the qPCR cycle threshold (Ct) values between the control and experimental samples were seen (F-Statistics, $p < 0.009$, for all primer sets and both temperatures). Even when held at 50ºC for 30 days, there were no significant (F-Statistics, $p > 0.05$) differences in the Ct values of the control versus the experimental samples at 5 and 20 ng/µL for all primer sets in this study.

Additional experiments include another high-heat study using lower concentrations of DNA (<1 ng/uL), similar to what is expected to be recovered as "touch DNA" evidence. In summary, the SampleMatrix® may be useful in forensic laboratories, since it may guarantee good quality DNA for cold cases by eliminating DNA degradation caused by repeated freeze thaw cycles and the need to handle DNA on ice during processing.

Long-Term DNA Storage, SampleMatrix®, DNAstable®

A38 The Role of DNA Stained Currency in the 2008 Lancashire Gang Robbery

Breanna Mead, MS, James Hayward, PhD, Benjamin Liang, PhD, Lawrence Jung, BS, Stephane Shu Kin So, PhD, Dominick Avento III, BS, and MeiLin Wan, MS, Applied DNA Sciences, Incorporated, 25 Health Sciences Drive, Stony Brook, NY 11790; and Simon Scott, and Paul Broxson, Blackburn Police Station, Whitebirk Drive, Accrington, Lancashire BB1 3, UNITED KINGDOM*

After attending this presentation, attendees will better understand the frequency of armed robbery of Cashand-Valuables-In-Transit (CViT) as well as the problems that these types of robberies are posing to the global economy. The history of the case solved by the Lancashire Police Department (United Kingdom) in 2008 dealing with a gang robbery will also be presented. This particular robbery resulted in over 70,000 British Pounds being stolen, and a cash transport guard being shot and wounded. Attendees will also learn about the role that DNA stained currency played in assisting detectives solve this particular case.

This presentation will impact the forensic community and/or humanity in demonstrating that CViT robberies have become a costly problem. Over £19.4million were stolen in 2008 in the United Kingdom alone. The transportation of cash and valuable items between financial institutions has long been a target of robberies in the UK. Regulations in the UK dictate that security guards protecting the cash and valuables are not allowed to carry weapons. Furthermore, vehicles utilized to transport valuable goods are also manufactured to be smaller than their US counterparts in order to fit onto much more narrow streets making them an easy target for thieves.

This has posed a great problem in the CViT field requiring an unconventional approach that can help in linking stolen cash to criminal activities. Conventional staining ink systems could not provide the information necessary for establishing traceability of the recovered evidence to the crime as they did not have an acceptable forensic tagging method. A taskforce was established that involved the Metropolitan Police Service (Scotland Yard), security companies, and experts in the field to

utilize forensic level tagging in cash staining dyes for the purpose of apprehending suspects and collecting forensic evidence. In order to face this issue, botanically derived DNA is combined into an exploding ink cartridge (also called a degradation unit) then placed into a cash transportation box. This cash box is then filled with cash or valuables that are to be transported. Should the box be tampered with in any way, the exploding ink cartridge will deploy and spray all of the items within the box with a botanical DNA-marked ink mixture.

In the Lancashire case, police apprehended a suspect as he was trying to use stained currency. The evidence was screened using gel electrophoresis for the presence of specific inks that are utilized in cash-in-transit boxes. After the initial screening process demonstrated that the essential inks were present, any DNA present on the currency was extracted. Primers specific for the botanically derived DNA utilized in cash-in-transit boxes were used to amplify any DNA present on the evidence. Once amplified, DNA was separated using capillary electrophoresis and analyzed using genetic software. Once the specific genetic combination was discovered from the stained notes, the combination was tracked back to the cash transportation box that the DNA was issued to which, in turn, had been reported as being stolen. With the help of cash-staining ink marked with botanically derived DNA, robberies dropped by 50% from 2009-2010, and as a result, the number of convictions from this novel technology is currently on the rise.

Cash-and-Valuables in Transit, Armed Robbery, Botanically Derived DNA

A39 Comparison of Genetic Markers and Developmental Validation of the Multicopy LINE-1 Marker for Use in a Sensitive Real -Time Quantification Method

Jaclyn B. Kenline, BS, 44 Doe Run Drive, The Woodlands, TX 77380; Lauren G. Bouse, MSFS, 12934 East SH-21, Bryan, TX 77808; Pablo A. Noseda, BS, 14723 TC Jester Boulevard, Houston, TX 77068; and David A. Gangitano, PhD, 14723 TC Jester Boulevard, Apartment 1118, Houston, TX 77068*

After attending this presentation, attendees will understand how to apply the Scientific Working Group on DNA Analysis Methods (SWGDAM) criteria in a developmental validation of a new marker for forensic DNA quantitation of low copy number and degraded samples and the comparison with different genetic markers in use.

This presentation will impact the forensic science community by giving information on a new marker that can be used as an alternative tool for the quantification of degraded and low copy number samples.

Three different genetic markers were studied for use in a sensitive real-time PCR quantification method using a SYBR® Green detection system. The markers studied were: a long interspersed nuclear element (LINE-1), a multi-copy short interspersed nuclear element (*Alu*), and a reduced size short tandem repeat marker (mini TH01). The markers were compared on target specificity, sensitivity, linearity, accuracy, and precision. The LINE-1 and *Alu* methods were the most sensitive systems with the ability to detect down to approximately 1pg/µl. However, the LINE-1 method was able to remain linear up to 50ng/µl compared to *Alu* which experienced a loss in linearity at 10ng/µl. The LINE-1 method displayed more accuracy and precision than the other methods at three different concentrations of a known DNA standard (10, 5 and 1ng/µl). LINE-1 displayed the following values (mean ± standard deviation) for each sample: 8.6±0.23 for 10ng/µl, 2.7±0.06 for 5ng/µl, and 0.42±0.03 for 1ng/µl. Although the LINE-1 method consistently estimated values lower than expected, the system performed similar to Quantifiler® human DNA quantitation kit for the same samples. The LINE-1 and mini TH01 primers displayed better target specificity than *Alu* according to the melt curves generated by each.

In addition to these comparative studies, the LINE-1 method was tested on species specificity, population, stability, inhibition, and mock case work samples. The LINE-1 method performance met all the SWGDAM criteria. With the exception of primates, the LINE-1 primers do not amplify other species. The samples tested from individuals of known ethnic origin were all positive. The stability of the system was tested by analyzing DNA that was artificially degraded with the DNase I enzyme. As expected, the system indicated that the amount of quantifiable DNA present in the samples decreases as the amount of degradation increases. The system was also tested in the presence of common PCR inhibitors with and without the addition of bovine serum albumin (BSA) to the system. Finally, the system was tested on several common mock case work type samples including touch DNA samples and samples that are considered to be low copy number or degraded. Utilizing the LINE-1 marker appears to provide an adequate screening and quantification method for the analysis of forensic case work samples, specifically low copy number or degraded samples.

It is recommended that forensic DNA analysts become familiar with the developmental validation SWGDAM criteria and its application.

Real-Time PCR, Low Copy Number, LINE-1

A40 Differential Extraction of Mixtures in Sexual Assault Casework Using Pressure Cycling Technology (PCT)

Deepthi Nori, MFS, Florida International University, 1340 Southwest 102 Court, Miami, FL 33174; and Bruce R. McCord, PhD, Florida International University, Department of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the principles of pressure cycling technology and its applicability in analyzing mixtures from sexual assault casework.

This presentation will impact the forensic science community by providing a better understanding of how this novel technology can be used to perform selective lysis of a specific type of cells and decrease the analysis time by simplifying the extraction procedure.

Forensic DNA analysis has elevated the degree of confidence in the analysis and interpretation of evidence but the bottle neck that plagues the crime labs across the country is the tedious, time consuming protocols that require practice and expertise in analyzing mixtures. Organic differential extraction is the most commonly used method to isolate sperm DNA from sexual assault evidence. This two-step extraction procedure involves selective digestion of epithelial cells in the first step followed by isolation and digestion of the sperm cell pellet. The major disadvantages of this technique are incomplete separation of sperm and non-sperm fractions, particularly in samples that are overwhelmed by large numbers of female epithelial cells relative to sperm cells and the time-consuming nature of the process.

Pressure cycling technology sample preparation system (PCT SPS) involves the use of pressure pulses to disrupt tissues, cells, and cellular structures enabling the recovery of their components. Barocycler® NEP2320, a commercially available instrument from Pressure Biosciences Inc, is equipped with a hydrostatic pressure chamber that generates alternating cycles of ambient and high pressure up to 45000 psi resulting in the lysis of cells. A working pressure range of 5- 45 kpsi, number of programmable cycles (1-99), duration of holding time at ambient pressure and at high pressure are the four parameters that can be controlled to achieve this objective. This can be used in conjunction with mechanical homogenization, temperature control by an external water bath, or commercially available extraction kits.

The current study involves the application of pressure cycling technology in the selective digestion of sperm cells from evidence mixtures collected from different substrates with an emphasis on the role of buffer

composition on sperm DNA yields. The cells were extracted in 1X PBS buffer (pH 7.4) with varying buffer compositions and subjected to 45000 psi pressure for 60 cycles. Samples were placed in specially designed PULSE™ tubes and introduced into the pressure chamber. This pressure treatment was followed by phenol/chloroform/isoamyl alcohol purification to obtain a clean DNA sample devoid of salts and proteins for successful downstream analysis. The purified DNA was quantified with Promega Plexor® HY system.

According to previous studies, high selectivity and improved recovery with the reducing agent, Tris (2-carboxyethyl) phosphine (TCEP) indicated the potential for highly selective detection of sperm cells in comparison to the addition of detergents or changes in temperature. These observations were applied to mixture studies of evidence obtained from various substrates such as swab and fabric. Preliminary data indicates that pressure cycling technology has application in differential extractions indicating improved extraction of sperm DNA at high pressures when compared to epithelial cells in the presence of appropriate buffers.

Pressure, Sexual Assault, Differential Extraction

A41 Increasing Efficiency in a DNA Unit Using Lean Six Sigma

Joanie B. Wilson, PHD, Jeremy Dubois, BS, Layne Barnum, BS, Erica Sparacino, MS, Myles Robichaux, BS, Alyson E. Saadi, MS, and Melinda Richard, BS, Louisiana State Police Crime Laboratory, 376 East Airport, Baton Rouge, LA 70806; Timothy D. Kupferschmid, MFS, Sorenson Forensics, 2495 Southwest Temple, Salt Lake City, UT 84115; and Glenn Fahrig, MS, and Adam Becnel, MNS, Louisiana State Police Crime Lab, 376 East Airport Road, Baton Rouge, LA 70806*

The goal of the presentation is to show how implementation of Lean Six Sigma can lead to a decrease in backlog and a better working environment for analysts.

This presentation will impact the forensic science community by showing how the use of Lean Six Sigma can dramatically impact the workflow and throughput of forensic cases.

The number of DNA requests received in many public crime laboratories has increased such that backlogs exist and turnaround-times are extended. The Louisiana State Police Crime Laboratory (LSPCL) saw a 22% increase from 2006 to 2007 in the number of DNA requests submitted. The completion rate was not increasing at a rate to compensate for the increased submittals nor could the completion rate eliminate the backlog of requests that had accumulated. Turn-around-times exceeded a calendar year.

The Efficiency Improvement Grant provided the tools needed for LSPCL to change the technical workflow of DNA forensic analysis which allowed the backlog to be greatly reduced, case turn-around-time to be reduced, and productivity increased such that LSPCL can complete 100% of the DNA requests that are received each month. Management of the administrative work within the DNA Unit has also been changed to ensure that the capacity of the laboratory is maintained and no new backlogs are created.

LSPCL hired external consultants and engaged in several projects aimed at solving the current state problems and changing processes to ensure continued success. Through the development of Lean Six Sigma (LSS) methodology, these projects achieved all goals set forth and has led to a culture that is client driven, quality focused, and efficiency minded. LSS is the unique combination of Lean thinking and Six Sigma process improvement to form a thorough and comprehensive approach to quality improvement, process improvement, and the elimination of waste to produce a remarkably efficient and quality driven product. The combination of Lean thinking and Six Sigma variation reduction, when merged together, forms seven guiding principles. The principles are: (1) focus on the customer; (2) identify and understand how the work gets done; (3) manage, improve, and smooth the process flow; (4) remove non-value added steps and waste; (5) manage by fact and reduce variation; (6) involve and equip the people in the process; and, (7) undertake improvement activity in a systematic way. DMAIC is the acronym that describes the seventh principal. It is a systematic improvement framework, and it is the framework that the LSPCL and consulting teams follow to make dramatic efficiency improvements. DMAIC stands for Define, Measure, Analyze, Improve, and Control. During the define phase of this project, a process map of the standard operating procedure was developed in which the twelve major steps of the process and the major functions under each step were identified. Additionally, a Value Stream Map (VSM) was developed that depicted the flow of cases and information through the laboratory. During the measure phase, current processes were measured to establish a baseline performance. Current state of cases and data for concepts such as turnaround time, total queue time (waiting to be worked), total process time, value added time (amount of time spent performing actual tasks), non-value added time, and the number of cases in progress (WIP) were measured. State spaghetti charts were created to graphically illustrate the physical movement of people and evidence throughout the laboratory. Next, the analyze phase focused on analyzing the data collected during the measure phase and investigating the causes of the problems, bottlenecks, backlogs, and defects uncovered during the previous two phases. Daily production meetings were implemented to discuss daily progress and workflow. Construction of a Level Load Chart was developed to help create flow throughout the laboratory. The improve phase involved three distinct segments: (a) generate ideas about possible solutions; (b) select the most appropriate solution; and, (c) plan and test the solution.

Laboratory processes and equipment were relocated to reduce motion waste, and standards of work were implemented. Unnecessary procedural steps were removed and a master hour-by-hour schedule was implemented along with a three week schedule of a proposed casework cycle. Teams of three DNA analysts performing DNA analysis on batches of 8-10 cases in a five day production cycle were created. The final phase, control, enabled the laboratory to put in place a Management System to continually monitor its output and adjust operations when the data indicated or when the customer's requirements changed. Visualization of current process and performance measurements were displayed. Data such as samples processed, cases received and completed, backlog, turnaround time, and status of unassigned priority cases are tracked visually on a daily, weekly, and monthly basis and analyzed for a constant, smooth output. LSS can be applied to any process or any industry. LSPCL used this methodology to enhance the technical scientific process.

As of June 2011, LSPCL has decreased its turnaround time from an average of 291 days in May 2008 to an average of 31 days with 95% of DNA requests completed within 30 days. LSPCL has tripled the productivity from 50 cases per month to 160 cases per month. The backlog has decreased from approximately 1,400 cases in May 2009 to 120. Total queue time decreased from 181 days in May 2010 to five days. Additionally, the number of samples completed per month has increased from 312 to 979 with an average number of cases completed per analyst per month increasing from 1.9 to 11.5 cases.

LSS methodology gives the user the necessary tools and a process that provides rapid and sustained improvements for technical or administrative processes. LSS was, and continues to be, a powerful management tool in the DNA forensic operations of the LSPCL. With turn-around-times of <30 days, a workflow that allows a DNA forensic request to be completed within 6 days, the capacity to work all cases submitted each month, and a backlog that is eliminated each month, LSS has proven its ability in the forensic laboratory. The methodology allowed LSPCL to meet all project goals and has afforded increased operational efficiency and increased quality and service to the agencies served. The real-time support provided to investigations is helping solve crimes and is thereby making the citizens of Louisiana safer.

Increasing, Laboratory, Efficiency

A42 DNAgard®Tissue as a Room Temperature Microbial Preservation System for Forensic Soil Samples

Tiffany A. Vickman, BS, Pamela J. Staton, PhD, and Dishari Mukherjee, MSFS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701; and G. Michele Yezzo, BS, PO Box 244, West Jefferson, OH 43162*

After attending this presentation, attendees will become aware of the different storage techniques used for soil evidence; DNAgard®Tissue (Biomatrica) as a biological soil sample preservation system; and microbial community profiling (MCP) as a forensic tool.

This presentation will impact the forensic science community by evaluating a novel use for DNAgard®Tissue as an in-lab or on-scene forensic sample storage/preservation medium.

DNAgard® consists of a specialized liquid solution that allows for the immediate stabilization of the DNA from cells and tissues. According to Biomatrica, this method allows for samples to be stored at room temperature for up to six months. In addition, this presentation will compare commonly used and novel storage techniques, e.g., length in storage per storage condition, as well as its impact on DNA quality and quantity. This will provide a basis for future research in microbial community profiling as a forensic tool and, in particular, how microbial DNA profiles may be used for evaluation of soil as evidence. The soil environment is dominated mainly by prokaryotes whose diversity can vary greatly. Bacteria are the most dominant form of these microbial communities found in soil whereby bacterial DNA profiling may provide an opportunity for linking soil samples with one another. MCP can easily be performed in forensic laboratories as many, if not all, crime laboratories have the required capillary electrophoresis genetic analyzers and PCR equipment to perform this analysis. Collection and storage of soil samples is a critical aspect in preparation for microbial DNA analysis. Traditional storage techniques used by forensic laboratories include either storing soil samples at -20°C or at room temperature. Traditional soil analysis often involves drying and sieving of samples prior to evaluation. While this may be essential for chemical and microscopic analysis of soil components and profiles, such procedures may have lethal and destructive effects on microbial communities.

The goal of this study was to determine the best method for storing soil samples for microbial DNA analysis. Seven storage conditions were compared: (1) room temperature; (2) -20°C freezer; (3) DNAgard®Tissue at room temperature; (4) -20°C freezer then air-dried; (5) -20°C freezer then oven-dried; (6) room temperature then air-dried; and, (7) room temperature then oven-dried. Each week, for a total of 5 weeks, soil samples were removed from storage and tested in triplicate. Microbial DNA was extracted using PowerLyzer™ PowerSoil® DNA Isolation Kit (MO BIO Laboratories, Inc.), a commercial kit chosen for its reported ability to extract good quality DNA from difficult environmental samples. This method is also reported to remove all humic substances and other PCR inhibitors. Following extraction, the microbial DNA was analyzed using a Nanodrop 2000c Spectrophotometer (Thermo Scientific) where the A260/280 ratio and sample concentration were determined. Preliminary testing revealed that storing soil samples in DNAgard®Tissue for up to five weeks resulted in extracted DNA of higher quality and yielded more consistent results when compared to other storage conditions. This study provides fundamental information to proceed to the next phase of testing which is microbial community profiling performed on an Applied Biosystems (AB) GeneAmp® PCR System 9700 with amplified products separated on the AB 3130xl Genetic Analyzer. The data generated will be analyzed using AB GeneMapper® ID Software v3.2.1.

Soil, Microbial, DNAgard

A43 Developing an Empirically Based Ranking Order for Bone Sampling: Examining the Differential DNA Yield Rates Between Human Skeletal Elements — Phase I

Amy Z. Mundorff, PhD, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996; Edwin F. Huffine, MS, Bode Technology, 10430 Furnace Road, Suite 107, Lorton, VA 22079; Emilie Frank, BS, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996; and Sarah L. Bettinger, MSFS, Shannon Weitz, BS, and Amy M. Jeanguenat, MFS, Bode Technology, 10430 Furnace Road, Suite 107, Lorton, VA*

After attending this presentation, attendees will learn the order in which skeletal elements, from a relatively short post mortem interval, are most likely to produce DNA profiles suitable for identification.

This project will impact the forensic science community by replacing intuition with empirical data to establish a comprehensive ranking according to each bone's potential to provide usable genetic material for DNA identification, thus providing investigators with a clear bone sampling strategy. These results are particularly applicable for identification projects following mass fatality events with high fragmentation, which often rely heavily on DNA to identify and reassociate disparate fragments.

DNA may be the only method available for positive identification when access to ante-mortem information is limited; when readily identifiable features, such as fingerprints, have been compromised; or when elements are fragmented as in a plane crash. Large-scale identification efforts focused primarily on osseous material including the World Trade Center disaster and the post-conflict identifications conducted in the former Yugoslavia have led to major advances in understanding genetic material used for individual DNA identifications. It has been noted that bones and teeth yield higher levels of DNA than muscle and are often the only surviving tissue available to establish identification. However, bones differ in their structure, function, and composition leading to possible differences in DNA yield. Existing research into specific bone selection for DNA identification is inadequate.

Current selection of skeletal elements for DNA testing is based on the collective wisdom of forensic practitioners who typically request dense cortical bone such as the femoral shaft. This preference is bolstered by retrospective studies measuring success rates between skeletal elements, focusing on both mitochondrial (Edson et al. 2004, Leney 2006) and nuclear DNA (Milos et al. 2007). These studies found weight bearing long bones to be most successful, however, smaller elements such as patellae or phalanges were often not tested. A more recent examination of DNA success rates by skeletal element found that several smaller elements not typically sampled, such as the patellae and foot phalanges, were more successful than dense cortical bones (Mundorff et al. 2009).

Phase 1 of this project involved DNA testing each skeletal element and tooth type from three recently skeletonized individuals from the donated collection at the University of Tennessee Forensic Anthropology Center. The same bones (n=56), from each of three skeletons were tested (total n=168). To minimize destruction during sampling, a 3/8-inch circular hole was drilled in the bone instead of cutting out a window or wedge. This sampling approach resulted in the collection of ~0.20g of bone powder from both small and large bones. Following extraction and quantification, samples were normalized to 2ng when possible, and amplified with AmpliF/STR Identifiler™.

Both the quantity and quality of the DNA from each sample was analyzed to determine which bone types consistently yielded complete DNA profiles, defined as 15 loci and Amelogenin, from all three skeletons. Triplicate data from each bone type was combined to determine the average relative fluorescent unit per locus by element type. The quantification value along with the quality of the resulting profile provides a guide to establishing a comprehensive ranking according to the potential of each element type to yield a complete DNA profile.

Results demonstrate that the quantity and quality of DNA obtained from different skeletal elements is highly variable. Many atypical DNA sample choices, such as cancellous tarsal bones (ankle), the patella (knee-cap) and the distal hand phalanx (finger tip), outperformed more traditionally sampled dense cortical bone such as the femur, tibia, and humerus.

These results supplement traditional DNA sampling protocols by ranking skeletal elements according to their ability to produce high quality DNA profiles. Topping the list are smaller elements that can be removed intact, reducing potential contamination, and can also be removed with a disposable scalpel, reducing the need for a bone saw (and electricity, labor, and expensive equipment), allowing for easier and more efficient sampling in the field.

Phase 2 of this project (in progress) will determine whether these results hold true for skeletonized remains from longer post mortem intervals (0-3 years, 4-10 years, 11-20 years, and 21-50 years) and will document DNA degradation over time.

The opinions, findings, and conclusions or recommendations expressed in this publication are those of the author(s) and do not necessarily reflect those of the Department of Justice.

Human Identification, DNA Sampling, Skeletal Element

A44 Epigenetic Markers: A Forensic Tool for the Determination of Biofluids Present at Sexual Assaults and Other Crime Scenes

Tania Madi, BSc, 90 Southwest 3rd Street, Apartment 1414, Miami, FL 33130*

The goal of this presentation is to demonstrate to attendees a new method to identify the originating tissue source of DNA.
This presentation will impact the forensic science community by providing a novel tool that may be useful in the differentiation of biofluids and cell types such as saliva, blood, sperm, and epithelial cells.

Often in forensic cases, knowledge of the originating source of the DNA found at crime scenes is required. Although certain chemical and microscopic tests exist in tissue type identification, they are mainly presumptive with varying sensitivity and specificity. Therefore, the development of a method to identify the source of DNA found at crime scenes is imperative. This study explores the possible use of epigenetic markers in identifying DNA sources.

Epigenetic modification of mammalian DNA is a naturally occurring mechanism crucial for the function of the genome and its transcriptional regulation. Although the DNA sequence in each individual cell is identical, its epigenetic profile is not. Epigenetic modifications include methylation at CpG islands and histone deacetylation. These modifications play a role in regulating the transcription and expression of genes allowing cells to differentiate into functionally and metabolically specialized cell types. The study of epigenetics as a useful tool in forensic tissue identification has proven to be promising. In the current study, researchers present a set of epigenetic markers found to be differentially methylated in four common bio-fluids found at crime scenes: saliva, blood, sperm, and epithelial cells.

After PCR amplification, any methylation information is lost. It is therefore necessary to subject DNA to bisulfite conversion, a chemical treatment that converts all unmethylated cytosine bases in the DNA to uracil and subsequently to thymine bases during PCR. These base changes are then detected in downstream analysis such as PCR or sequencing. The detection of a thymine base at a CpG site indicates that the modification process was successful in converting the cytosine base and that the site was not methylated. In contrast, if a cytosine base persists during the modification process and a thymine base is not detected, the CpG site is likely methylated.

Samples of each tested biofluid were first taken from ten individuals. The DNA was extracted and the entire genome subjected to bisulfite conversion. Modified DNA was PCR amplified at several specific loci that are believed to be differentially expressed in these biofluids. Loci chosen contain a minimum of five CpG sites. The resulting PCR products were then sequenced using a Pyromark (Qiagen) pyrosequencer. Pyrogram peaks displaying the sequence and the percent methylation level at each CpG site were then analyzed and compared between the four cell types for methylation pattern differences. These profiles showed hyper or hypomethylation of one cell type relative to the other cell types. Using this method, epigenetic markers were identified to differentiate saliva, blood, sperm, and epithelial skin cells. The results of this study indicate the potential of a novel tool in identifying biofluids found at crime scenes.

Epigenetic, Pyrosequencing, DNA

A45 Optimizing Human Semen Stain Detection Using Fluorescence

Kelly Conroy, BS, San Jose State University, Forensic Science Program, 1 Washington Square, 508 MacQuarrie Hall, San Jose, CA 95192; and Steven B. Lee, PhD, San Jose State University, 1 Washington Square, MacQuarrie Hall 521, San Jose, CA 95192*

After attending this presentation, attendees will become more familiar with the abilities and limitations of current forensic alternate light source methods and filter glasses currently used to screen sexual assault evidence samples as a presumptive test for semen stains. The attendees will then gain additional knowledge on the fluorescent excitation and emission wavelength combinations that have been newly developed that have shown potential in enhancing visual detection of semen stains on different fabrics.

This presentation will impact the forensic science community by increasing viewer's knowledge of semen stain detection. In addition, the results of the study indicate the need to conduct further research in semen stain detection. The combinations of new excitation wavelengths with emission and blocking filters may impact the forensic community by enhancing the detection of semen stains and thus increasing the ability to process sexual assault evidence.

Human semen fluorescence has been observed for many years and is currently used as a presumptive screening test in forensic laboratories. The purpose of this project is to improve the visual detection of semen stains on different types and colors of fabrics with new combinations of different wavelengths of fluorescence using a standard forensic alternate light source (ALS), coupled with new fluorescence filters. As the detection of semen stains is one of the first steps in sexual assault evidence processing, the ability to locate these stains is important in order to obtain more probative evidence.

To establish a baseline for the project, a four year old positive control sample of semen deposited on a white tissue was examined under the Spectrum 9000, a forensic ALS, at six different discrete excitation filter settings. The stain was then viewed through various long pass, short pass, and band pass filters covering a range of wavelengths as well as yellow and orange goggles (480nm long pass, 545nm long pass respectively). The samples were photographed and observations were made on the visibility of the stain, taking into account amount of stain visible, relative brightness of the stain, contrast of the stain with the background, and the ability of the camera to record the stain.

Photographic documentation and visible qualitative evaluation of preliminary results indicate excitation wavelengths include 570nm, whereas previous reports listed the excitation range of semen as being from 300-500nm. Fluorescence emission filters in the 510-590nm range allow the stain to be easily detected by the eye of the observer. Since there was fluorescence observable at lower wavelengths that are blocked by the orange goggles commonly used in forensic laboratories, there is potential for capturing more of the visible fluorescence by the use of unique band pass filters. The results establish a baseline for a white substrate for the project, and the photos taken of the stain through the various filters will be analyzed using image analysis software to determine quantitatively if the

unique combination of fluorescence and discrete filters selected increase the ability to detect semen stains as compared to methods currently employed in forensic biology laboratories.

Future areas for research include utilizing the band pass filters that have been identified during the baseline tests to evaluate semen stains of various amounts deposited on various substrates after varying time intervals of storage to determine the effectiveness of the newly identified filters with relatively fresh stains versus those stored over time. Preliminary work highlights the appearance of a broader than previously thought excitation range for human semen.

Semen Stains, Alternate Light Source, Fluorescence

A46 Evaluation of Automated Systems in a Mitochondrial DNA Unit

Andrea C. Phares, BS, 13126 Ashford Park Drive, Raleigh, NC 27613; Katie M. Horsman-Hall, PhD, 700 North 5th Street, Richmond, VA 23219; Stephen E. Rodgers, MS, and Brian Shannon, MS, Virginia Department of Forensic Science, 2nd Floor, Mitochondrial DNA, 700 North 5th Street, Richmond, VA 23219; and Brad Jenkins, MS, Virginia Department of Forensic Science, 700 North 5th Street, Richmond, VA 23219*

After attending this presentation, attendees will learn how implementation of two automated systems, the Qiagen EZ1® Advanced and Agilent 2100 Bioanalyzer, will benefit forensic mitochondrial DNA units by limiting user handling, decreasing lab time, and allowing for prediction of length heteroplasmy prior to sequencing.

This presentation will impact the forensic science community by understanding how implementing these automated systems into a mitochondrial DNA unit allows for faster analysis by the analyst. Limited user handling of these systems results in decreased risk of contamination, while elimination of analyst interpretation of agarose gel bands allows for more accurate quantitation. Contamination thresholds were set and heteroplasmy may be screened to better prepare for downstream data.

Mitochondrial DNA (mtDNA) analysis is a prominent tool in forensic laboratories for missing persons, unidentified remains, and analysis of samples from which nuclear DNA (nuDNA) is difficult. mtDNA analysis is both time consuming and sensitive to contamination and would therefore benefit greatly from automated systems. The goal of this research was to evaluate two automated robotic platforms, the Qiagen EZ1® Advanced and the Agilent 2100 Bioanalyzer for their suitability for implementation into a mitochondrial DNA unit. The Qiagen EZ1® Advanced would allow for faster DNA extraction with no detectable contamination with limited analyst intervention. The Agilent 2100 Bioanalyzer would allow for more accurate quantitation than currently implemented gel electrophoretic methods as well as indication of heteroplasmy and contamination.

The Qiagen EZ1® Advanced robotic platform allows for the automated extraction and purification of six samples simultaneously. This system was evaluated for concordance by comparison to known mtDNA profiles from both buccal swabs and blood cards as well as resistance to cross-contamination between samples and runs. The ability for the Qiagen EZ1® Advanced to sufficiently extract mtDNA for sequencing from alternate knowns (toothbrush bristles and razors) and nuDNA from all samples used above was demonstrated. The Qiagen EZ1® Advanced DNA extracts were concordant with known mtDNA profiles. Cross-contamination was not observed in studies running alternating samples and blanks. The Qiagen EZ1® Advanced was able to produce full mtDNA and nuDNA profiles from all samples.

The Agilent 2100 Bioanalyzer allows for automated DNA quantitation through separation of nucleic acids into microfabricated channels with fluorescent detection of post-PCR products. This system was evaluated for detection sensitivity with a dilution series of a 200bp fragment, known buccal swabs, and HL60 DNA. Data was compared to determine the optimal amount of DNA required for sequencing. Reproducibility was also shown with these dilution series by running the samples in triplicate on three chips. The 200bp fragment was quantitated with agarose gel electrophoresis to evaluate accuracy between the two methods. The Agilent 2100 Bioanalyzer was also run with known samples containing length heteroplasmy, to determine whether these length variants could be detected prior to sequencing. A contamination threshold, similar to that set by local FBI laboratories, was also determined by examining low concentration samples where DNA was detected but did not sequence. The Agilent 2100 Bioanalyzer has been shown to accurately quantitate samples below 20ng/µl. The Agilent 2100 Bioanalyzer was able to reproduce quantitation values on three separate chips. The instrument was able to correctly predict length heteroplasmy before sequencing by observance of split peaks within the electropherogram.

Qiagen EZ1® Advanced, Agilent 2100 Bioanalyzer, Mitochondrial DNA

A47 Towards a Multi-Chamber Plastic Microdevice for Simultaneous Amplification of Multiple DNA Samples

Jenny A. Lounsbury, MSFS, Daniel C. Miranian, and James P. Landers, PhD, University of Virginia, Department of Chemistry, 409 McCormick Road, Charlottesville, VA 22904*

After attending this presentation, attendees will have gained an understanding of the progress being made towards the development of a multi-sample microfluidic PCR platform for the simultaneous amplification of multiple DNA samples.

This presentation will impact the forensic science community by demonstrating a multi-chamber microdevice capable of amplifying up to seven DNA samples simultaneously, increasing sample throughput as compared to other PCR microdevices and demonstrating the applicability of a microfluidic platform for forensic analyses.

The polymerase chain reaction (PCR) is a key step in the processing of forensic biological samples. Typically, it is the most lengthy step (typically 2.5-3.5 hours) contributing to a time-consuming analytical process on the order of eight to ten hours. However, it has the advantage of high sample throughput, amplifying up to 96 samples at one time with conventional thermal cyclers. Microfluidic platforms for PCR have demonstrated numerous advantages over conventional PCR, including reducing the time required to complete the reaction as well as reducing sample and reagent consumption. Although PCR has been successfully adapted to a microdevice,[1] the majority of devices are limited in that they can only amplify one to two samples at a time. In order for a PCR microchip to be a generally accepted platform, the development of a device capable of amplifying multiple samples at once is clearly important.

Concurrently, the trend in microfluidics is to move towards alternative substrates for microchip fabrication to reduce fabrication and device costs. Typically, microdevices are made from glass, but are time-consuming and laborious to fabricate, often requiring the use of hazardous chemicals. Microdevices from polymeric substrates, such as poly(methyl methacrylate) (PMMA), can be fabricated using simpler techniques, including laser ablation and hot embossing.[2] In addition, PMMA is inexpensive, so devices can be disposed of after a single use and, as a result, this eliminates the risk of contamination between samples.

Previous work has demonstrated the use of infrared-mediated PCR (IR-PCR)[3] which utilizes a halogen lamp and a fan to heat and cool a sample in a PCR microdevice, respectively. IR-PCR provides increased heating and cooling rates compared to conventional block thermal cyclers, therefore reducing the time required for PCR. IR-PCR amplification of short tandem repeat (STR) regions of the human genome in a single chamber PMMA microdevice has been demonstrated using a combination of commercially-available fast polymerases, yielding a full STR profile (16 of 16 loci) in 33 minutes[4] – a ~5-fold reduction from average conventional amplification times.

Multi-chamber PCR microdevices were fabricated in PMMA using a CO_2 laser system, with eight PCR chambers arranged in a circular pattern within a 1cm diameter focal spot of the halogen lamp. The temperature in each chamber was monitored using miniature type-T thermocouples and the inter-chamber temperatures were found to vary up to 4°C, likely due to variation in the emitted radiation from the halogen lamp. Results show that, even though there were significant differences in the peak height of the amplified products (due to the temperature variation), suggesting slight differences in the power delivered to each chamber, STR amplification was successfully performed in the multi-chamber device, yielding full STR profiles (seven of seven loci) in all seven chambers in 42 minutes. With modifications to provide a more homogenous delivery of power from the lamp (i.e., the use of a diffuser), the temperature variations will be minimized, which, in turn, will minimize peak height variations. Furthermore, these results indicate that a polymeric multi-chamber microdevice for simultaneous sample amplification has the potential to increase throughput on a microfluidic platform while reducing overall analysis time as well as cost-per analysis.

A48 Strategies for the Enrichment of Low Copy Number DNA Templates

Ashley Hall, PhD, Mong-Kuen Sun, BS, and Derek Cutler, BS, University of Nebraska-Lincoln, 103 Entomology Hall, Lincoln, NE 68583*

After attending this presentation, attendees will understand a novel genome amplification protocol, useful with forensic-type samples. They will be presented with the steps taken that were necessary to optimize the reaction, minimizing typical low coy number artifacts.

This presentation will impact the forensic science community by introducing a novel technique useful in the analysis of limited DNA samples and describing the experimental steps taken for its optimization.

In recent years, whole genome amplification (WGA) techniques have been used to enrich the genomic material in a sample so that low-level DNA can be successfully amplified. Using a WGA protocol, the entire genome is pre-amplified using multiple random start points for the molecular xeroxing process, providing an enriched full-genomic template for a second polymerase chain reaction in which the specific DNA fragments of interest can be amplified. Therefore, as it has been applied in human forensics, WGA is essentially the first step in a genome-wide nested PCR protocol. Due to the particulars of the forensic sample, (e.g., the use of loci containing repetitive DNA, the possibility of heterozygote imbalance, stutter and other PCR artifacts) no currently available WGA protocol completely addresses the needs of the forensic scientist.

In recent years, whole genome amplification (WGA) techniques have been used to enrich the genomic material in a sample so that low-level DNA can be successfully amplified. Using a WGA protocol, the entire genome is pre-amplified using multiple random start points for the molecular xeroxing process, providing an enriched full genomic template for a second polymerase chain reaction in which the specific DNA fragments of interest can be amplified. Therefore, as it has been applied in human forensics, WGA is essentially the first step in a genome-wide nested PCR protocol. Due to the particulars of the forensic sample, (e.g., the use of loci containing repetitive DNA, the possibility of heterozygote imbalance, stutter and other PCR artifacts), no currently available WGA protocol completely addresses the needs of the forensic scientist.

The premise for an improved WGA technique is simple. Standard WGA unnecessarily complicates a sample by enriching for total DNA when, in fact, there are a limited number of well-defined loci of interest for forensic profiling. A more judicious strategy would be to target only the regions of interest for pre-amplification, providing them as an enriched template for the follow-on profiling of the specific loci of interest. This modified WGA has been termed Targeted Genome Amplification (TGA).

Briefly, TGA primers are designed to contain 5' and 3' invariable tails that are noncomplementary to, and therefore do not bind, any site in the human genome. Rather than enriching the sample for total DNA, only the regions containing the loci of interest, i.e., regions about 400 base pairs in length surrounding each STR locus are pre-amplified. In the same TGA reaction, primers complementary to these invariable TGA primer tails are included. They bind the tails and amplify the intervening sequences. The goal of this step is a balanced amplification of all loci maintaining the relative ratios of mixtures.

The technique has been optimized as a 3µl TGA reaction requiring no sample transfer between tubes. A fast PCR protocol is employed for the TGA. The reaction can be completed in less than 30 minutes. Subsequently, the STR multiplex PCR mix is added directly to the completed TGA reaction. Using this technique, PCR artifacts commonly observed with low copy number profiling such as peak height imbalance and stutter have been reduced to permit correct genotyping. This study successfully generated six-locus STR profiles from as little as 25pg DNA and three locus profiles from as little as 15pg DNA. The technique has been applied with some success to forensic-type samples. Results of the experiments will be presented and the course of future studies will be discussed.

Whole Genome Amplification, DNA Damage, DNA Repair

A49 Human Autosomal SNP Profiling Using Fully-Automated Electrospray Ionization Time of Flight Mass Spectrometry

Christine V. Marzan, PhD, Ibis Biosciences, 2251 Faraday Avenue, Suite 150, Carlsbad, CA 92008; Sandy D. Kirkpatrick, MS, and John V. Planz, PhD, University of North Texas, Health Science Center, 3500 Camp Bowie Boulevard, EAD 310E, Fort Worth, TX 76107; and Steven A. Hofstadler, PhD, and Thomas A. Hall, PhD, Ibis Biosciences Incorporated, 2251 Faraday Avenue, Suite 150, Carlsbad, CA 92008*

The goal of this presentation is to demonstrate the use of electrospray-ionization mass spectrometry (ESI-MS) system in the automated analysis of forensically-relevant human autosomal SNP markers.

This presentation will impact the forensic science community by using an automated assay with sensitivity, reliability, convenience, and ease of use/analysis suitable for forensics applications has been developed for the Ibis PLEX-IDTM and developmentally validated.

Single nucleotide polymorphisms (SNPs) represent a simple yet powerful tool for individual identification. Efforts by Pakstis and Kidd[1] to produce an ideal panel of genetically unlinked binary SNPs with high heterozygosity, low population bias, and uniform distribution over global populations have resulted in a 40-SNP panel analyzed across 40 global populations. A fully-automated PCR/electrospray ionization mass spectrometry (ESI-MS) assay capable of genotyping these 40 SNP markers has been developed for the Ibis PLEX-ID™ platform and has been developmentally validated.

The 40-SNP assay consists of a pre-fabricated kit containing all components necessary to analyze a sample except for template DNA. Eight five-plex PCR reactions per sample are arranged in columns of a 96-well assay plate such that up to 12 samples may be analyzed on a single assay plate. After adding DNA template to the appropriate wells of an assay plate

and thermal cycling, all downstream analytical steps through data processing are fully automated. A novel ESI-MS deconvolution algorithm deconvolves multiplexed PCR product charge state distributions into individual masses while retaining relative output signal amplitude estimates in proportion to relative input DNA concentrations, allowing evaluation of inter- and intra-locus product balance to aid interpretation of potential mixtures/contaminated profiles. Forward and reverse strands of each PCR product are measured with high mass accuracy, such that base compositions (A, G, C and T nucleotide counts) can be directly calculated for each product, allowing accurate assignment of nucleotide identity at the SNP position. The average mass measurement deviation for 31,030 independent DNA strand assignments was 12.4 ± 11.4 parts per million (ppm), corresponding to ~0.2 Da for PCR products of the average size amplified in the assay.

The 40-SNP assay has been characterized for concordance to existing methodology, sensitivity, reproducibility, species specificity, and the ability to detect when genotyping results indicate a pure sample or a mixture/contaminated sample. Concordance has been demonstrated for all loci using individual TaqMan® assays for each locus for 20 samples and comparing results to those obtained with the Ibis SNP assay. All loci displayed 100% concordance to TaqMan® results. Dilution studies suggest that reliable genotyping results can be obtained at template input levels close to 125pg of DNA per reaction.

Species specificity analysis indicated no interference using a 10-fold excess of exogenous cat, dog, *E. coli*, *S. aureus*, *C. albicans* or *A. oryzae* genomic DNA. Non-primate DNA did not produce PCR products recognizable as SNP locus products, and did not interfere with correct typing results when in excess in the presence of human DNA. Bacterial DNA at a 100-fold excess over human DNA did not interfere with correct genotyping results. Primate DNA (African green monkey, squirrel monkey, rhesus macaque, and marmoset monkey) did produce products and interfered with genotyping results to different degrees.

Fully-automated data analysis produced 5998/6000 correct genotype assignments (99.97%) in reproducibility studies utilizing three samples each analyzed 50 consecutive times at a constant DNA template input. A convenient software interface has been developed for visual review of data analyses. The Ibis PLEX-ID™ ESI-MS platform is capable of typing the full spectrum of forensically-relevant markers, Y-STR, autosomal STR, mitochondrial DNA, and SNPs on a single instrument within the same automated run.

A50 DNA Preservation in Partially Decomposed Soft Muscle Tissue Samples Using Different Preservative Solutions

Muhammad S. Nazir, MSc, School of Forensic & Investigative Sciences, University of Central Lancashire, Preston, Lancashire PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will better understand how to choose different preservative solutions for better preservation of DNA in partially decomposed soft muscle tissues under field conditions where no cold storage is available.

This presentation will impact the forensic science community by providing new ideas to preserve DNA under field conditions for successful profiling. The solutions mentioned in presentation are easy to handle under field conditions, and DNA can be preserved for a period of six months successfully at room temperature using these preservatives.

Following mass fatality incidents, DNA profiling is essential for identification and reassociation of fragmented, burnt, or decomposed corpses that would be very difficult or impossible by traditional means such as fingerprinting and odontology. However, successful DNA recovery depends on the collection and preservation of biological material obtained from deceased individuals and the availability of reference samples (Graham et al., 2008).[1] Inefficient preservation methods can cause destruction of intact DNA to such an extent that data is not always available for victim identification (Bing and Bieber, 2001).[2]

In order to assess the efficiency of different preservative solutions (10% buffered formalin, 96% ethanol and cell lysis solution - with and without sodium azide), partially decomposed soft muscle tissue samples were collected at different accumulated degree-days (ADD) from pig (0, 70 and 150 ADD) and rabbit (0 and 70 ADD) carcasses and were placed in preservative solutions.

DNA extraction was performed using DNeasy® Blood and Tissue kit according to the manufacturer's instructions at different time points (1 month and 6 months). DNA quantification was performed using agarose gel electrophoresis (2%) and Quant-iT™ PicoGreen® dsDNA Reagent from Invitrogen™, UK. DNA fragment analysis was performed using Applied Biosystems™ 310 and 3500 genetic analyzers.

In order to perform DNA fragment analysis from postmortem soft muscle tissue samples of the model organisms chosen, two nuclear genes, Connexin 43 and RAG-1, were aligned to identify conserved regions. Primers were designed to amplify 70 bp, 194 bp, 305 bp, and 384 bp amplicons. The primers were also designed to amplify human DNA which allowed the use of commercially purchased DNA standards to be used as controls. Following DNA extraction, PCR analysis was performed using the four primers sets in a multiplex (4-plex) and was optimized so that it worked over a wide range of template amounts (0.1ng to 75.83ng). The multiplex (4-plex) PCR was found to work efficiently in triplicate samples of all three species down to 0.3ng of DNA template.

The results showed that the 96% ethanol and cell lysis solution, with and without 1% sodium azide, are better solutions for DNA preservation in both fresh (0 ADD) and partially decomposed tissues (0, 70 and 150 ADD) for a period of six months, whereas 10% buffered formalin is a poor source of DNA preservation causing high DNA degradation.

Future work will include: DNA extraction from preserved samples after one year, development of real-time PCR quantification assays, DNA fragment analysis using ABI 310 and 3500 genetic analysers, and analysis of results using appropriate methods such as ANOVA, ANCOVA, and regression analysis.

A51 The Effect of a Harsh Environment and Indirect Human Activity on the Perseverance of DNA

Sarah Cavanaugh, MSFS, Bode Technology, Incorporated, 10430 Furnace Road, Suite 107, Lorton, VA 22079*

After attending this presentation, attendees will have gained insight into the possibilities for recovering DNA from evidentiary samples subjected to human and environmental exposure. They will be made aware of the current theories for locating reliable evidence for DNA and given quantitative data regarding those theories.

This presentation will impact the forensic science community by demonstrating that low template DNA samples can be collected and

analyzed after eighteen months by first considering the ambient environment and substrate on which the sample may have been deposited. This presentation will provide scientists with information to evaluate the currently implemented methods and adopt or modify their current protocols.

Locating reliable evidentiary samples for DNA analysis becomes more complicated as time between deposition of a biological sample and collection of sample increases. Exposure to environmental factors can also decrease the chances of obtaining a DNA profile. Certain factors such as temperature, humidity, and substrate are known to negatively affect DNA recovery, and a number of theories have been used by forensic scientists to help locate areas from which the best possible biological sample can be collected. However, a comprehensive and quantitative study regarding environmental impact and the effect of contaminating human traffic and activity on DNA profile recovery has not yet been published.

The research presented will show a comprehensive longitudinal study to determine the optimum locations at a crime scene that is best suited for biological evidence collection and to assess sample reliability for DNA analysis after eighteen months. This effort consisted of two concurrent studies: Study 1 examined DNA sample recovery by taking into account biological sample type, human traffic flow through a room, evidence placement within the room, substrate, and time; Study 2 examined DNA recovery by taking into account biological sample type, ambient environment (hot and humid or room temperature), substrate, and time.

For both studies, six replicate sets of mock evidence fluid samples: blood, semen, saliva, urine, oily fingerprints, and regular fingerprints were deposited on substrates and exposed to the environment in question for 18 months time. Study 1 had two different substrates available, and Study 2 used nine different substrates. Sample sets were collected, extracted, and analyzed after 0, 3, 6, 9, 12, and 18 months. Any DNA profile obtained was compared to the sample's known profile to calculate percent profile recovery and contamination (designated by the number of additional, unassociated alleles).

JMP®, a powerful Design of Experiments (DOE) statistics program, was used to create the test plan of both studies as well as analyze all the data and make correlations between the ability to recover the correct profile and the various factors (time, environment, and substrate) being evaluated. The JMP® software is able to analyze a response based on the effects of multiple factors. This type of experimental design and statistics capability is novel for the forensic field and allows the user to interpret a smaller data set with fewer replicates while still determining strong correlations.

After 18 months, the majority of samples were highly degraded and/or contaminated, as would be expected. However, more partial profiles were recovered from blood and oily fingerprints after the extended time period than thel other sample types. This study also provides quantitative data for the best substrates from which to recover evidentiary samples, the environments most likely to maintain viable DNA sources, and relative contamination amounts for both. Lastly, this presentation demonstrates the power of JMP® Design of Experiments software, a novel tool for large scale studies within forensic-based research.

DNA Recovery, Environmental Effects, Time Study

A52 Improved Isolation of DNA From Forensic Dental Specimens

Allison E. Reklaitis, MS, and Chenique Sanders, BS, Office of the Chief Medical Examiner, Department of Forensic Biology New York City Office, 421 East 26th Street, New York, NY 10016; My K. Tran, DDS, and Amir M. Moursi, DDS, PhD, New York University College of Dentistry, Department of Pediatric Dentistry, 345 East 24th Street, New York, NY 10010; and Sheila E. Dennis, MS, Office of the Chief Medical Examiner, Department of Forensic Biology New York City, 421 East 26th Street, New York, NY 10016*

After attending this presentation, attendees will learn a different less destructive technique to obtain DNA from from forensic dental specimens versus the more traditional crush and grind method of obtaining DNA from the pulp.

This presentation will impact the forensic science community by giving forensic biologists and those that also work on mass disasters, a technique of obtaining DNA from a dental specimen while preserving it for possible return to family members especially if it is the only sample that remains from an individual.

The DNA Missing Persons Unit within the Department of Forensic Biology at the New York City Office of Chief Medical Examiner performs nuclear and mitochondrial DNA testing for the purposes of identification, re-association of body parts, and upload into the Combined DNA Index System (CODIS). While success rates for postmortem samples such as blood, tissue, and bone were as expected, dental specimens failed to give consistent results. This may have been caused by exposure to detrimental environmental conditions. These environments may vary from bodies found in water, to remains buried in soil, or encased in cement. The goals of this study are to evaluate how exposure to the following conditions - water, soil, and cement - affects the ability to extract nuclear DNA from dental samples and to determine what improvements can be made to the examination and extraction protocols.

One hundred-twenty (120) adult teeth collected as dental waste from private dental offices were examined and categorized by a dentist according to tooth type (molars, incisors, premolars, and canines) and any abnormalities such as dental caries (cavities), open apices, calcification, and discoloration were noted. The teeth were incubated in soil, cement, and water from the East River in New York City, or physiological saline from 1 to 48 weeks. Two specimens from each environmental condition had the pulp tissue extracted at weeks one, two, three and four and every four weeks thereafter using a dental pulpectomy procedure. The pulpectomy involved removing tissue from the pulp chambers using nerve broaches utilized by dentists when performing a root canal. A phenol:chloroform:isoamyl alcohol (PCIA) extraction was performed on the pulp tissue. Each DNA sample was quantified, amplified with the Applied Biosystems (ABI) Identifiler[a] kit (28 cycles), and alleles detected using the ABI PRISM 3130xl Genetic Analyzer.

The current method used to extract DNA from teeth involved grinding the entire tooth using a freezer mill. This destroyed the morphology of the tooth and successful DNA results fluctuated and were unpredictable. Results from this study greatly improved examination procedures; the morphology of the tooth structure was maintained while examination efficiency increased by accessing the DNA in the tooth through pulpectomies.

By week 40, 30.8% generated full profiles and 16.7% generated high partial profiles all eligible for entry into CODIS. Overall by week 40, the number of identified loci decreased over time in most conditions but DNA extracted from dental specimens buried in soil showed the strongest reduction in identifiable loci.

Prior caries status of a tooth was not a factor in DNA extraction as those teeth yielded sufficient amounts of DNA. Conversely, teeth with open apices, that were calcified, or had no visible pulp tissue did not yield DNA or yield sufficient amounts of DNA for concentration or amplification.

Overall, the goals of this study thus far have been met. Improvements to the examination of dental specimens through pulpectomies require less examination and hands-on time compared to the conventional freezer mill method. Pulpectomies preserve the morphology of the tooth and yield similar DNA results. The dental specimens exposed to cement, soil, water, and even physiological saline show degradation over time as evidenced by the decrease in DNA concentration and quality of DNA profiles obtained.

DNA, Teeth, Extraction

A53 Low-Level Variant Detection in Mitochondrial DNA Using the Illumina® GA IIx Next-Generation Sequencing (NGS) Platform

Brandon Smith, BS, and Brittania J. Bintz, MS, Western Carolina University, 111 Memorial Drive, NSB #231, Cullowhee, NC 28723; and Mark R. Wilson, PhD, Western Carolina University, Forensic Science, Department of Chemistry/Physics, Cullowhee, NC 28723*

After attending this presentation, attendees will be more familiar with the concept of heteroplasmy and interpretation bias drawn from mitochondrial DNA sequence data using current sequencing methodologies. An overview of the Illumina® Next-Generation Sequencing (NGS) chemistry and workflow will be presented. Data elucidating depth of coverage required for variant detection at or below a 1% threshold will be shown. Per sample cost, training issues and implementation strategies will also be mentioned.

This presentation will affect the forensic science community by suggesting an alternative method for mtDNA sequence analysis, one that is able to reliably detect low-level variants in mtDNA down to the single molecule level.

Heteroplasmy is defined as the presence of more than one mitochondrial DNA (mtDNA) type within an individual (Melton 2004).[1] These differing mtDNA types may occur between populations within an individual, within a single cell, or within a single mitochondrion. Furthermore, heteroplasmy has been observed in two distinct forms including sequence and length heteroplasmy. Sequence heteroplasmy occurs when two nucleotides are present at a single nucleotide position, while length heteroplasmy occurs when two different lengths of a homopolymeric C-stretch are present within the mtDNA sequence. Higher mutation rates (Bogenhagen 1999)[2] and fewer DNA repair mechanisms than nuclear DNA (Kunkel 1981)[3] lend credence to the idea that millions of mtDNA molecules within an individual are not likely to have a single, uniform mtDNA type. As a result, it is presumed that all individuals are heteroplasmic at some level and therefore, mtDNA sequences from single source samples are a mixture of mtDNA types. Heteroplasmy may go unnoticed given the limits of detection of traditional Sanger sequencing methods, whereby a single sequence is generated from amplified mtDNA products. Failing to detect heteroplasmy gives bias to interpretation of mtDNA sequence data. With the advent of sequencing-by-synthesis technologies, it is possible to resolve and quantify mixtures of mtDNA at much lower levels than current technologies (Andréasson *et al.* 2006).[4] These findings suggest that sequencing-by-synthesis methods may be an attractive alternative to current methods used in Forensic laboratories by allowing for the detection heteroplasmy below a threshold of 1%. The Illumina® GA_{IIx} is a massively-parallel sequencing platform which utilizes a unique chemistry that is unlike most pyrosequencing technologies currently on the market. The Illumina® GA_{IIx} utilizes a proprietary flow cell that is covered with a dense lawn of primers which will bind to flanking adapters incorporated into amplified DNA products (Illumina® 2010).[5] Clonal amplification of captured products results in tens of millions of clusters per square centimeter of the flow cell. Each cluster is then sequenced and analyzed independently of one another. This allows for the generation of sequence data on a single molecule scale.

In this effort, the Illumina® GA_{IIx} was evaluated for mixture analysis of mtDNA. Initially, DNA was extracted from forensically relevant sample types including donated hair, buccal, and blood samples. The DNA was amplified using a novel amplification strategy described by Bintz *et al.*, and reference sequences were obtained from the mtDNA HV region of all 20 donors using Sanger sequencing methods. Artificial mixtures were then prepared using distinct templates from the samples described above in ratios of 99%/1%, 98%/2%, and 95%/5%. Multiplex assays were designed using the resulting mixtures. Resulting data shows the reliable detection of variants at a target level of 1%, which is significantly lower than the 10% threshold of current methods. Additionally, we were able to quantify the depth of coverage needed to detect variants at a level of 1% at an average of 250X coverage from approximately 50 individuals per Roche GS-Junior run.

Next Generation Sequencing, Mitochondrial DNA, Heteroplasmy

A54 Development of Streptavidin-Biotin Binding of DNA Amplicons Methods for the Typing and Re-Typing of Forensically Relevant Short Tandem Repeats

Jessica A. Shea, BS, and Amy N. Brodeur, MFS, Boston University School of Medicine, Program in Biomedical Forensic Sciences, 72 East Concord Street, Room 806, Boston, MA 02118; and Catherine M. Grgicak, PhD, Boston University School of Medicine, Program in Biomeical Forensic Sciences, 72 East Concord Street, Room 806B, Boston, MA 02118*

After attending this presentation, attendees will be informed of a method which would allow the re-amplification of a DNA target that has already undergone the Polymerase Chain Reaction (PCR) and is a now a constituent of the amplified work product. This will be accomplished by removing the amplicons and other PCR components such primers, dNTP's, etc, to sequester the original target DNA such that it is available for re-amplification with additional human identification chemistry. This would allow DNA crime laboratories and their analysts to genotype limited or exhaustive samples using a variety of kits/chemistries without the need for additional extraction or evidence processing.

This presentation will impact the forensic science community by demonstrating an approach that would allow for: (1) testing of both autosomal- and Y- STRs for limited sexual assault samples; (2) the ability of the analyst to re-amplify with mini-STR's or an enhanced amplification scheme (i.e., more Taq Polymerase, repair enzymes, more BSA) if it is realized that the DNA was degraded, damaged, and/or PCR inhibited: and, (3) the re-amplification of an exhaustive sample due to an amplification failure.

The first stage of development concentrates on maximizing PCR efficiency with primers that have been functionalized with biotin. In this study, the TPOX locus was used to test this optimization. Amplification of the TPOX locus was optimized by varying the concentrations of magnesium chloride ($MgCl_2$) and primers. The amplified products were then electrophoresed and stained with GelStar® Nucleic Acid Gel Stain

(Lonza Inc, Walkersville, MD). The resulting bands were analyzed using ImageJ - a public domain open source image processing software.[1] The optimal concentrations were determined to be those used with Sample 3-5 (i.e. 2.25 mM $MgCl_2$ and 0.06 µM primers) (Figure 1).

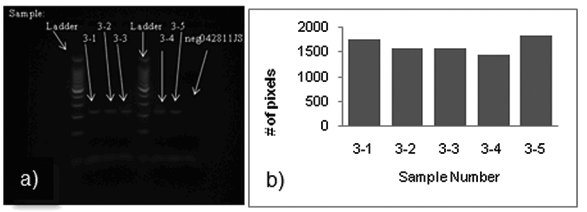

Figure 1: a) Agarose gel electrophoresis of the amplified product with non-biotinylated primer and varying concentrations of $MgCl_2$ and primer; b) Number of pixels (signifying signal intensity) of the amplified product analyzed with ImageJ.

Once optimized conditions for the amplification of TPOX were determined, it was of interest to confirm whether modification of the forward primer with biotin had a significant impact on amplification. As a result, new forward primers of the same sequence which were functionalized with biotin were used during amplification and the reagent concentrations once again varied. Agarose gel electrophoresis was performed as with the amplicons originating from the PCR using the non-biotinylated primer and the gel analyzed using ImageJ as previously described. In contrast to the aforementioned results, the optimal reagent concentrations were determined to be those used with Sample 4-4 (2 mM $MgCl_2$ and 0.04 µM primers) (Figure 2). This indicates that functionalization of the forward primer had an impact on the PCR, suggesting that optimization of the amplification for methods which use modified primers must be performed with the specific primer of interest.

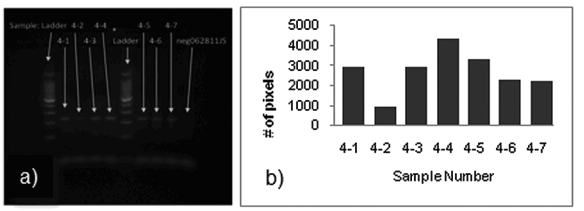

Figure 2: a) Agarose gel electrophoresis of the amplified product with biotinylated primer and varying concentrations of $MgCl_2$ and primer; b) Number of pixels (signifying signal intensity) of the amplified product analyzed with ImageJ.

Once the reaction is optimized, the clean-up procedure can be used on 1ng of DNA. First, the amplified DNA product is run on the 3130 Genetic Analyzer. Then the remaining sample is cleaned using post PCR purification to remove salts and any unincorporated primers. The amplicons can then be removed from the sample using Streptavidin coated magnetic beads. More specifically, the beads bind to the biotin on the primer (now hybridized to the amplicon) leaving the original DNA in the supernatant for subsequent re-amplification.

A55 Rapid and Direct CODIS STR Screening Using Short Microchip Capillary Electrophoresis

Maurice J. Aboud, MS, FL International University, 11200 Southwest 8th Street, Chemistry & Biochemistry CP304, Miami, FL 33199*

After attending this presentation, attendees will understand the development of a fast and portable DNA screening method that uses microchip electrophoresis for the rapid detection of a set of seven CODIS STR markers. They will gain an understanding of how this system works, the limitations of the system, and how these limitations were surmounted to achieve the desired resolution and capability to genotype on the microfluidic chip.

This presentation will impact the forensic science community by addressing the problems and limitations encountered with the current commercial microfluidic systems for DNA separation, such as poor resolution, and provide a useful tool for quick CODIS screening of DNA samples.

There are situations in which it is very important to quickly and positively identify an individual. Examples include suspects detained in the neighborhood of a bombing or terrorist incident, individuals detained attempting to enter or leave the country, and victims of mass disasters. Systems utilized for these purposes must be fast, portable, and easy to maintain. Current DNA typing methods provide the best biometric information yielding identity, kinship and geographical origin, but they are not portable. Currently DNA typing is performed by large-scale sequencers using multichannel fluorescent capillary array electrophoresis. Complex robotic extraction and PCR processing creates economies of scale and time, permitting large numbers of samples to be efficiently processed. Unfortunately this process is not flexible enough for many applications in the field and is not quick on a per sample basis.

The proposed alternative, microfluidic DNA typing, holds great promise but constraints on resolution and problems with coupling inline extraction, inline PCR, and multicapillary analysis make these systems highly complex. These systems require complicated integration of engineered components making them highly vulnerable to clogging, misalignment, and voltage leakage. The issues with large-scale integration of extraction, amplification, and DNA electrophoresis also make these systems less than portable. While there is no doubt that the technological issues may someday be solved, there are alternative modular approaches to perform this task that do not require extensive engineering and do not require complete system integration. Such modular systems are easily repaired in the field and can be quickly switched if problems occur. Furthermore, new advances in the field of DNA typing involving direct PCR make it possible to eliminate complex extraction steps and simply amplify DNA directly from a paper punch. This has the potential to greatly simplify analysis. Other advances such as commercially available high speed PCR and disposable short channel microchips provide off the shelf solutions to the problem of portable high-speed DNA detection. This approach is simple and does not require major engineering or retooling of equipment.

This project was designed to optimize and combine off the shelf components (direct PCR, high speed thermal cycling, and short channel microfluidics) to produce a high-speed genotyping system. In this project, we are utilizing known biological principles to accelerate the amplification rate of direct PCR and couple this fast amplification to a beta version of an Agilent 2100 Bioanalyzer that has been upgraded to permit ssDNA typing. The microfluidic chip separation channel is 1.5cm, placing unique restraints on resolution and sizing that have been solved using a specialized polymer matrix and multichannel fluorescence detection. Per sample run times are 80 seconds and fast and direct PCR was utilized to minimize sample-processing times. The efforts of this study demonstrate a simple, highly portable DNA typing procedure that should prove valuable for applications involving a need for a robust and rapid analysis.

Microchip, DNA Screening, CODIS Markers

A56 Separation of Semen From Superabsorbent Polymers for Forensic Analysis

Bailey Glasscock, BS, and Nicolle Hardell, BS, Virginia Commonwealth University Department of Forensic Science, 1020 West Main Street, Box 843079, Richmond, VA 23284-3079; Marybeth J. Sciarretta, MS, 4370 1/2 Kansas Street, San Diego, CA 92104; and Sarah J. Seashols, MS, Virginia Commonwealth University, Department of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will gain an understanding of the challenges in separating cellular material from the superabsorbent polymer (SAP) materials and the fibrous matrices found in evidence such as diapers, sanitary napkins, absorbent medical pads, and other related forensic evidence, and will learn a protocol that can successfully separate the cellular material from the substrate will be presented.

This presentation will impact the forensic community by describing best practices for isolating semen from evidence containing absorbent and superabsorbent materials, and the impact that SAPS have on downstream DNA analysis.

The presence of super absorbent polymers in forensic evidence has been found to complicate spermatozoa isolation for body fluid identification and inhibit organic DNA extractions. In certain cases, primarily involving women, small children, and infants, the successful isolation of cellular materials, and subsequently DNA, from SAP-containing materials such as feminine pads, diapers, and absorbent medical pads, is a difficult task, and failures of body fluid identification tests and DNA isolation have been observed. These super absorbent polymers are designed to absorb and retain large volumes of water or organic liquids, but when they are submitted as forensic evidence, they impede testing by sequestering the cellular material in the process. The purpose of this research was to develop a method to separate semen from SAPs found in materials such as diapers and feminine pads, with the ultimate goal of maximum yield from the evidence, and minimal inhibition of downstream forensic molecular testing.

Multiple centrifugal methods using size filtration were investigated to separate the SAP gel and fibrous material from the rest of the liquid sample containing the desired spermatozoa and other cellular material. Factors for a successful separation required determination of an optimal filter pore size, centrifugal speed and time that would allow cellular materials and liquid to flow through the filter, while preventing the polymers and cellulose fiber from flowing through. After a successful separation protocol was developed, sperm counts were used to compare percent yield and success of the protocol. Percent yield between isolation from just the top fabric layer of the item and a "core" of all layers of the item were also compared. DNA isolations and STR analysis were conducted on filtered SAP samples to determine levels of inhibition.

Finally, direct DNA isolation of the biological fluids on evidence with SAPs was evaluated using two silica-based DNA isolation methods. Since the silica methods have a direct affinity for DNA, samples were isolated using silica-based differential extraction methods to determine if direct DNA isolation is possible in the presence of SAPs, and if so, how those isolations are impacted. If the isolation methods are not affected by SAPs, laboratories may have the option to directly isolate DNA and determine presence of seminal fluid using molecular biology methods.

In conclusion, difficult samples such as evidence containing superabsorbent polymers can impact both body fluid identification and DNA analysis, and a modified approach was developed that can directly impact casework. This method uses standard materials and reagents found in most laboratories, and thus could be implemented quickly for significant impact.

Seminal Fluid, Semen, Diapers

A57 High-Throughput Human Mitochondrial DNA Database Development Using Automated Electrospray-Ionization Mass Spectrometry

Thomas A. Hall, PhD, Kristin A. Sannes-Lowery, PhD, Jessica E. Paulsen, MFS, Jenna Cromwell, MFS, Chantel M. Giamanco, MFS, and Steven A. Hofstadler, PhD, Ibis Biosciences Incorporated, 2251 Faraday Avenue, Suite 150, Carlsbad, CA 92008*

The goal of this presentation is to demonstrate the use of a fully-automated electrospray-ionization mass spectrometry (ESI-MS) system in the high-throughput development of a human mitochondrial DNA profile database.

This presentation will impact the forensic science community by revealing how, over the course of five years, the Ibis platform was used to develop a database of one hundred thousand human mitochondrial DNA profiles at a single site, allowing an unprecedented ability to interrogate the prevalence and extent of genetic variation in the non-coding region, including length and point heteroplasmy.

Forensic mitochondrial DNA (mtDNA) analysis is performed when DNA quantity/quality is insufficient for nuclear DNA analysis, or maternal-lineage DNA is required. Analysis involves sequencing mtDNA segments, a lengthy and labor intensive technique. Ibis Biosciences has developed a high-throughput mass spectrometry-based mitochondrial DNA profiling assay suitable for automated analysis of mtDNA control region segments that retains approximately 94% of the individually-discriminating information of sequencing the same regions. The assay amplifies HVI 15924-16428 and HVII 31-576 and provides more discriminating information than sequencing the minimum HVI and HVII regions of 16024-16356 and 73-34, respectively. Twenty four (24) overlapping PCR primer pairs are used to amplify 1051 bases of mtDNA hypervariable regions HVI and HVII in eight triplexed PCR reactions. Pre-fabricated 96-well kit plates are configured such that one sample occupies one column of an assay plate and 12 samples may be run on a single plate. All reaction components are supplied in frozen kit plates such that only DNA extract (5ul per well) needs to be added prior to thermal cycling. After thermal cycling, assay plates are placed directly onto an Ibis T5000™ or PLEX-ID™ instrument and all analytical steps through mass spectrometry data processing are automated. Amplified PCR products are desalted using an anion-exchange matrix coupled to paramagnetic beads and analyzed by ESI-MS in a time-of-flight (TOF) mass spectrometer. Forward and reverse strands of each PCR product are weighed with sufficient accuracy to calculate the base composition (A, G, C, and T count) of each amplicon in multiplexed PCR reactions. Base composition indexed by rCRS coordinates of amplified regions define 24-module mtDNA profiles that can be compared directly to each other or used to search a lookup or population database derived from mass spectrometry, sequence data, or both. Likewise, sequence data can be used to search a base composition-based database by converting the sequence(s) to base compositions corresponding to the primer pairs employed in the assay. Base composition profile comparisons to a population database are amenable to the same counting and confidence interval (upper bound frequency) estimates used for sequence comparisons.

The Ibis platform was used over the course of five years at a single laboratory to generate a searchable database of 117,278 human mitochondrial profiles. Profiles were developed as a list of PCR product base compositions referenced by revised Cambridge Reference (rCRS) coordinates. Profiles may be directly compared to each other, compared to a database of base compositions, or compared to a population database of sequence profile by converting sequence profiles to base compositions prior to comparisons. Frequency statistics for profile matches within a population database may be calculated in a manner identical to sequence database comparisons. The assay is not hindered by the presence of sequence length heteroplasmy, is capable of resolving mixtures, and can be

used to quantify the relative contributions of both length and point heteroplasmic variants. Statistics will be presented detailing the development of an mtDNA profiling system, sample processing rates over time using two Ibis instruments in parallel, rates of profile completion, heteroplasmic variants, and precision and reliability of assay controls.

mtDNA, Mass Spectrometry, Base Composition Analysis

A58 Concurrent Internal Validation of Four Forensic STR DNA Profiling Kits Using a Single Genetic Analyzer

Valerie M. Fuller, PhD, Tulsa Police Department Forensic Lab, 600 Civic Center, Tulsa, OK 74103; Rebecca E. Bucht, PhD, ReBuCo, Maurinkatu 16 A 18, 00170, Helsinki, 00170, FINLAND; and Abdernasser Agoune, MS, Hani Chaker Boubidi, MS, Ahmed Boussoufi, MS, Kaddour Daho, MS, Samir Lazreg, MS, and Amine Abdeli, MS, Institut National de Criminalistique et Criminologie, Gendarmerie Nationale, Bouchaoui, Algiers, ALGERIA*

After attending this presentation, attendees will be familiar with the validation study performed and how the results were used to set mixture interpretation guidelines and policy for the Department of Biology of the National Institute for Criminalistics and Criminology of the Algerian Gendarmerie Nationale (INCC).

This presentation will impact the forensic science community by presenting the results of a single combined internal validation of four STR kits: AmpFlSTR® Identifiler™, PowerPlex 16™, AmpFlSTR® SGM Plus™, and PowerPlex® ESI 16™ using the same analysis conditions and a single instrument throughout the entire study. With these concurrent validations, relative kit sensitivities, precision, analytical, and stochastic thresholds were determined. This study has allowed the authors to determine a hierarchy of kit use during analysis and has allowed us to create fixed interpretation guidelines for interpretation of DNA profiles in forensic casework at the biology department INCC-Algeria.

Forensic casework very often involves samples that may not produce DNA results. When results are obtained, the DNA profile information may not be interpretable. This may be due to the variable quality of biological material that can be obtained from forensic evidence exhibits, but this also may be due to the inherent variability of current STR DNA profiling technology. Every technology has a limit at which usable or reliable data can be obtained or cannot be interpreted for conclusive analysis. Forensic DNA profiling technology has two such limits.

Currently, forensic DNA profiling technology is centered upon the use of a very finite number of commercially available forensic human identity (HID) kits which produce amplified products via the polymerase chain reaction (PCR). PCR can fall prey to stochastic effects. An even more finite set of commercially available genetic analyzers are currently used in forensic DNA laboratories. The genetic analyzer is merely an analytical instrument used to observe the amplification products. These analytical instruments individually have their own limits of linearity and detection. A thorough comparative assessment of HID kit performance has not been truly executed, in the author's opinion, because the performance of these kits has been assessed under greatly varying analytical conditions, differing analysis equipment, and analysis conditions. Widely differing DNA interpretation methods are also used to evaluate the data generated, greatly exacerbating the already highly variable results that may have been obtained during the kit performance assessments.

Laboratory interpretation variability has been highlighted in recent years by inter-laboratory studies and surveys that have been performed. This interpretation variability appears to be the result of an oversimplification of observations on an analytical device without taking into account its limits and the disregard for an HID kit to produce non-stochastic DNA amplification during PCR depending upon input template concentration in PCR. In an effort to minimize the use of non-reliable PCR amplification results, several oversight committees have suggested new DNA interpretation guidelines which incorporate methods for determining and handling analytical and stochastic limits within DNA profiled data to ensure it is accurate analytically and reproducibly amplified.

These newly revised interpretation guidelines have recently been adopted by many accrediting bodies internationally in the last few years. In preparation for accreditation, the INCC was in the unique position to carry out validation studies on the four commercial STR HID kits currently in use using the new interpretation guidelines as part of the assessment of performance of each kit. To this end, a single combined internal validation of four HID STR kits (AmpFlSTR® Identifiler and AmpFlSTR® SGM Plus from Applied Biosystems and PowerPlex 16 and PowerPlex® ESI 16 from Promega) was designed specifically to observe and compare the performance abilities of these HID kits using a single dilution series of template DNA for amplification, the same post-amplification analysis conditions, and using the same multicapillary electrophoresis instrument throughout the entire study.

With the concurrent data generated by this validation study, it was determined that the relative sensitivities, precisions, and analytical/stochastic thresholds did not vary significantly among these four kits. However, due to the varying size of reporting amplicons within each kit, it was found that certain kits are able to complement each other to allow more complete results. The author's believe the use of new fixed interpretation guidelines for the interpretation of the DNA profiles in their validation study was key in determining that no single kit was able to out-perform the others. This allowed consolidation of methods for profiling forensic casework at the biology department of the INCC-Algeria.

DNA STR Kit Validation, DNA STR Kit Sensitivity, Analytical and Stochastic Thresholds of STR Kits

A59 Comparing Wearer DNA Sample Collection Methods for Determining the Best Method for the Recovery of Single Source Profiles

Corissa J. Harris, Forensic Science Program and Santa Clara County DA Crime Lab, San Jose State University, One Washington Square, MacQuarrie Hall 521, San Jose, CA 95192; Steven B. Lee, PhD*, Forensic Science Program Justice Studies Department, San Jose State University, One Washington Square, MacQuarrie Hall 521, San Jose, CA 95192; and Amanda J. Cardenas, BS, and Brooke A. Barloewen, MPH, Santa Clara County District Attorney Crime Lab, 250 West Hedding Street, San Jose, CA 95110*

After attending this presentation, attendees will have a better understanding on how to most effectively collect wearer DNA. Attendees will also see how the currently used collection methods compare to a new gel film method.

This presentation will impact the forensic science community by demonstrating which collection method best collects DNA from the last wearer of an item. This may allow for a reduction of mixtures that are not interpretable, often associated with wearer DNA.

Wearer DNA is the deposit of epithelial cells on clothing worn by an individual. Detection of the last individual to handle or wear an item is often an important determination in forensic science.

The most commonly used collection methods for wearer DNA include swabbing and scraping. These often result in mixture profiles. The detection of a single individual who last wore or came in contact with an item is desirable. Recently, adhesives have been introduced as a possible reliable method for the collection of biological evidence. Adhesives have a tendency to recover less, but more recently deposited particulate than the current methods because they are less invasive. The ability to observe the collected cells with the aid of a microscope is another advantage of using adhesives.

The goal of the research was to compare the current collection methods of swabbing and scraping with a gel film called Gel-Pak '0' which shares similar properties with adhesives. Gel-Pak '0' has been previously studied in comparison to other adhesives for the collection of epithelial cells, and was shown to recover the top layer of loose particulate. The particulate was deposited by the individual who last came in contact with an item. Therefore, in comparison to the other two collection methods, Gel-Pak '0' was hypothesized to recover single source profiles on clothing items from the most recent wearer.

DNA analysis was performed on samples collected by the three methods from various clothing items including baseball hats, t-shirts, sweatpants, socks, and other items commonly submitted to crime labs for DNA analysis. The habitual wearer and second/last wearer wore each item for a predetermined amount of time.

Research findings revealed that Gel-Pak '0' collected less DNA compared to the other two methods for the majority of items sampled but did not recover single source profiles from the last wearer. Instead, all three methods resulted in DNA mixtures. Low levels of DNA associated with wearer DNA often resulted in peak height imbalance and stochastic effects. This prevented the determination of major and minor contributors for the majority of items sampled. Even with mixed profiles, the last wearers' profiles were more discernable with Gel-Pak '0' and swabbing, while scraping had a tendency to recover more DNA from the habitual wearers. There was no significant difference in which swabbing or Gel-Pak '0' most frequently collected more of the last wearer's DNA. However, swabbing resulted in slightly more interpretable profiles from the last wearer and an increase in overall CODIS eligible profiles compared to Gel-Pak '0'.

This research may reveal how best to collect wearer DNA. Swabbing and the use of a gel film or adhesive preliminarily shows to be more effective in detecting who last wore a piece of clothing while scraping best determines the habitual wearer. Revealing individuals who last wore an item can be of great importance in forensic science, and therefore, further research with various adhesives and gel films could be vital for solving forensic investigations.

DNA Collection, Wearer DNA, Gel-Pak '0'

A60 Combined Chemical and Biometric Field Analysis of Human Fingerprints

Jessica L. Staymates, MFS, and Julie Flanagan, MFS, National Institute of Standards and Technology, 100 Bureau Drive, Mailstop 8731, Gaithersburg, MD 20899; Shahram Orandi, MS, National Institute of Standards and Technology, 100 Bureau Drive, Mailstop 8940, Gaithersburg, MD 20899; and Greg Gillen, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mailstop 8371, Gaithersburg, MD 20899*

After attending this presentation, the attendees will learn of a novel approach to combine quick field-deployable chemical trace detection analysis and a unique latent fingerprint collection method in a single sample.

This presentation will impact the forensic science community by offering a unique latent fingerprint collection method that is compatible with field-deployable chemical analysis techniques that are currently in use around the globe.

There are currently several existing methods to collect and analyze latent fingerprints for human identification with forensic applications. There are also numerous techniques to collect and detect trace levels of contraband materials from various surfaces within a few seconds. However, there is not yet a field deployable technique to collect a latent fingerprint and investigate that print for trace explosives or narcotics contamination in the field within a single sample. This presentation will describe a method to collect latent fingerprints and analyze them with a common trace contraband detection technique, ion mobility spectrometry (IMS).

IMS is a rapid screening technique commonly used in airports, prisons, and border control checkpoints to examine various surfaces for trace levels of explosives or narcotics. Surfaces are typically swiped with a collection material to collect microscopic particles, and the swab is then heated to temperatures exceeding 200°C for analysis. Adding a heat-sensitive and low out-gassing silicone adhesive to the collection swabs has been shown to improve the particle collection efficiency by a factor of 12.[1] This adhesive can also be applied to a surface for collecting a latent print, and, due to its heat resistance, is compatible with trace detection techniques such as IMS.

Collection swabs for lifting fingerprints were made by applying a heat-resistant silicone adhesive to opaque smooth Teflon swabs. Latent fingerprints containing trace levels of C-4 explosive were created by a volunteer on glass slides, and forensic magnetic fingerprint dust was brushed over the fingerprint for development. The adhesive swab was used to pull the latent fingerprint off the glass surface, similar to collection of a forensic tape pull. In addition to the latent fingerprint, a full set of ink-rolled exemplar fingerprints were also captured from the same volunteer. The latent print on the adhesive swab was analyzed directly with IMS. All fingerprints including both the exemplar and the latent were then scanned to digital form using an FBI Appendix-F certified scanning station. All images were cropped of most white-space, and the latent fingerprints were inverted across the vertical axis to correct for inversion resulting from the lift-capture. The digital fingerprints were measured for relative quality using the NFIQ algorithm[2], processed through the MINDTCT minutiae detector[3] and the resulting minutiae templates matched using the BOZORTH matcher[3] to verify that a match can be made between the latent and the matching exemplar finger. Preliminary results show that the fingerprint swabs were capable of producing an IMS response for the explosive, and the lifted prints had enough fingerprint detail to make a positive match using the algorithm, even after thermal desorption.

This presentation will introduce this novel approach of combining trace contraband detection with biometrics for field applications. Having the ability to collect a latent print and heat it for chemical analysis while keeping the print intact could be extremely useful for law enforcement and military operations. It could potentially reduce the cost and delay of sending fingerprint samples to a lab for chemical analysis. Chemical analysis in the laboratory may also affect the ability to analyze the fingerprint for biometric purposes. This work is beneficial to the forensic community by offering a unique latent fingerprint collection method that is compatible with quick field-deployable chemical analysis techniques that are currently in use around the globe.

A61 Shape Measurement Tools in Fingerprint Analysis: A Statistical Investigation of Distortion

Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; Anne Torres, BS, King County Regional AFIS Program, 513 3rd Avenue, Seattle, WA 98104; Glenn M. Langenburg, MS, and Susan Gross, MSFS, Minnesota Bureau of Criminal Apprehension, 1430 Maryland Avenue East, Saint Paul, MN 55106; Peter J. Bush, BS, SUNY at Buffalo, Laboratory for Forensic Odontology Research, School of Dental Medicine, B1 Squire Hall, South Campus, Buffalo, NY 14214; and H. David Sheets, PhD, Canisius College, Department of Physics, 2001 Main Street, Buffalo, NY 14208*

The goal of this presentation is to examine one of the concerns stated in the 2009 National Academy of Sciences Report (NAS), that of shape change (distortion) of a print as it is impressed on various substances with different mechanics of touch (i.e., pressure).

This presentation will impact the forensic science community by describing statistically the changes that occur when a print is impressed on different substances under varying pressures. This will allow for a quantifiable means to describe shape change of a fingerprint relative to these variables.

In the 2009 NAS report summary assessment on friction ridge analysis, it was stated that the impression left by a finger would invariably change each time due to degree of pressure used and impression medium touched. As per the NAS report, "None of these variabilities – of features across a population of fingers or of repeated impressions left by the same finger – has been characterized, quantified, or compared." It was the goal of this project to investigate the latter portion of this statement.

A well-developed method to study shape change is that of geometric morphometric analysis (GM). This involves the placement of landmark points on digital images. The data from the images is extracted and compared statistically, allowing for multivariate quantitative comparison.

Shape information can be visualized by plotting landmark positions in Procrustes superimposition. Procrustes distances can be used to summarize variations in populations, to express the degree of similarity of individual specimens, means of populations, or to search for matches between specimens.

The tools available for statistical analysis include Principal Component Analysis (PCA) with which the principal variations of shape can be plotted and visualized. This allows for determination of which shape aspect is responsible for the most variation and reveals patterns of covariance or related structure in data. Canonical Variates Analysis (CVA) can also be used to determine if shape information is distinguishable between different categories of data. CVA is a multi-axis discriminant function and it attempts to sort individuals into groups based on multivariate measurements.

It was the goal of this project to determine if these methods would translate to fingerprints describing changes in a print relative to pressure and substrate. A series of fingerprints were acquired from a volunteer who is also a fingerprint examiner. These prints were impressed on 10 print cards, computer paper, soft gloss photographic paper, and retabs. Each series was impressed with heavy pressure, normal pressure and light pressure. Ten prints were obtained in each series for a total of 114 prints of the same finger under the varying conditions of substrate and pressure.

The prints were then scanned on a flatbed scanner with a calibrated ruler in place and digital images created (1000dpi). Eighteen (18) landmarks were placed on the print and two on the scale for reference with tpsDig freeware. The landmarks were chosen at points of minutia that maximized the area of the entire print. The data was then extracted and the prints compared statistically with IMP freeware. Repeated measures were used to determine the variance, which was described by Root Mean Square (RMS) as the data was multivariate and not normally distributed.

Results indicated that there was a high degree of reproducibility of the prints at the varying substrates and pressures as the variance was very low at 0.000886 with an RMS of 0.029. PCA analysis determined that 56% of the variance in the prints can be seen in movement of the ridge structure in the fingertip portion of the print while the bottom portion remains almost stationary.

CVA plots of scores can separate specimens into groups (i.e. by pressure+ substrate). Cross-validation estimates of assignment tell how effectively the measurements are in performing this task of assigning specimens to groups. There was a high correct assignment to pressure based on substrate in all groups except the 10 print cards where the results were not pronounced, indicating that 10 print cards are relatively immune to pressure affects. Substrate differences were always detectable, an effect which increased with increasing pressure.

As per the NAS report, "Formal research could provide examiners with additional tools to support or refute distortion explanations." This study is a beginning attempt to understand affects of substrate and pressure on distortion of a fingerprint.

Forensic Science, Fingerprints, Geometric Morphometric Analysis

A62 Geographic Information Systems and Spatial Analysis – Part 1: Quantifying Fingerprint Patterns and Minutiae Distributions

Ryan J. Stanley, BS, Western Oregon University, 345 North Monmouth Avenue, Monmouth, OR 97361; Emma K. Dutton, PhD, Oregon State Police, Forensic Services Division, Oregon State Police General Headquarters, 255 Capitol Street NEt, Salem, OR 97310; Stephen B. Taylor, PhD, Western Oregon University, Division of Natural Science and Mathematics, 345 North Monmouth Avenue, Monmouth, OR 97361; and Patrick R. Aldrich, MS, and Bryan E. Dutton, PhD, Western Oregon University, Department of Biology, 345 North Monmouth Avenue, Monmouth, OR 97361*

After attending this presentation, attendees will understand how Geographic Information Systems can be used to quantify spatial relationships in fingerprints. Furthermore, attendees will learn how custom GIS tools can be used to run fingerprint matching simulations and calculate false match probabilities.

This presentation will impact the forensic science community by making a significant contribution toward forensic practice in the laboratory by establishing a degree of certainty for fingerprint uniqueness and by defining the limits for latent print identifications.

A Geographic Information System (GIS) is a collection of hardware and software components that integrate digital map elements with relational database functionality. GIS data is typically captured in the form of either raster grids (i.e., pixels) or vector features (i.e., points, lines, and polygons) with points in space using x, y and sometimes z coordinate values. While GIS is widely used for crime pattern analysis and emergency management applications, its spatial analysis capabilities have not been applied to fingerprint characterization and pattern recognition. The methodologies presented herein provide a framework for cataloging, characterizing, and quantifying fingerprint patterns and minutiae using custom and standard GIS tools. The power of a GIS is in its ability to allow users to integrate, store, edit, and analyze spatial features and relationships, as well as query and display spatial information. Such systems include traditional mapping capabilities (e.g., land surveying and aerial photography) and provide users with tools to interactively search and analyze spatial information. GIS is increasingly being applied to a field of study referred to as spatial analysis, which involves analyzing the positions, patterns, and relationships between objects located in a defined space. Collections of objects in a defined space may be linked or associated with one another geometrically or by functional associations. Given that fingerprint analysis and latent print identification is based on spatial associations between minutiae and ridge lines (e.g., ridge counts and minutiae locations, directions, and distributions), GIS-based tools for spatial analysis are a natural extension. Utilization of GIS in conducting dactylographic research is particularly appealing given that

fingerprint minutiae and ridge patterns are very analogous to geometries reflected in Earth surface topography, a traditional focus of GIS.

The Python programming language was used in conjunction with GIS software to create custom tools and automate complex project workflows. Python tools designed for fingerprint data collection, pattern characterization, and statistical analysis were created and deployed within a GIS toolbox. Initial minutiae detection was conducted using latent fingerprint processing software, with results exported as ANSI/NIST Type-9 records. A tool was created to parse finger and minutiae information from a Type-9 text file and transpose the data into Cartesian coordinate graph space. Coordinate referencing places the image and minutiae in quadrant I (+,+) of a Cartesian coordinate system. The Type-9 ULW summary output file was georeferenced to adjust the X-axis and Y-axis origins -100mm from the fingerprint core. Thus, all cores of each fingerprint image were positioned at (100,100mm) within Cartesian coordinate space. Once imported and registered in GIS, minutiae were subjected to an additional level of quality control and secondary processing. Minutiae were re-positioned to more accurately mark their placement and falsely marked minutiae were corrected. Minutiae files were aggregated within a GIS geodatabase for querying and spatial analysis. Custom GIS tools were built and implemented for extracting specific fingerprint metrics. A ridge counting tool provides the capacity to count fingerprint ridges between all minutia, and a ridge skeletonizing tool converts ridges into vector polylines, which allows for additional levels of analysis compared to raster grids. Pattern characterization tools were created to analyze point density and percent minutiae frequency by spatially intersecting minutiae with pre-established templates, such as a 2mm grid overlay and a core-centered "dart board" diagram. Distance and azimuth (0-360 degrees) from the finger core were calculated for all minutiae within the database. Using these values, minutiae were combined by print type and summarized in rose diagrams, which provide succinct figures for displaying minutiae distributions relative to the core. In addition, a Monte Carlo simulator was built to randomly sample n minutiae from a given fingerprint and iteratively match said minutiae against a database of fingerprints. This statistical analysis tool creates data suitable for building false match probabilities. Impacts of this work include making a significant contribution toward forensic practice in the laboratory by establishing a degree of certainty for fingerprint uniqueness and by defining the limits for latent print identifications.

GIS, Fingerprint, Analysis

A63 Geographic Information Systems and Spatial Analysis – Part 2: A Monte Carlo Approach to Estimating Probabilities for Latent Print Identification

Emma K. Dutton, PhD, Oregon State Police, Forensic Services Division, General Headquarters, 255 Capitol Street NE, Salem, OR 97310; Stephen B. Taylor, PhD, Western Oregon University, Division of Natural Science and Mathematics, 345 North Monmouth Avenue, Monmouth, OR 97361; Patrick R. Aldrich, MS, and Bryan E. Dutton, PhD, Western Oregon University, Department of Biology, 345 North Monmouth Avenue, Monmouth, OR 97361; and Ryan J. Stanley, BS, Western Oregon University, 345 North Monmouth Avenue, Monmouth, OR 97361*

After attending this presentation, attendees will understand the use of Geographic Information Systems as a means to quantify fingerprints and evaluate fingerprints.

This presentation will impact the forensic science community by addressing issues raised by the NAS report to apply a scientific approach to fingerprint analysis. The probabilities being produced are addressing the uniqueness of fingerprints.

A Geographic Information System (GIS) is a collection of hardware and software components that integrate digital map elements with relational database functionality. GIS data are typically captured in the form of either raster grids (e.g., pixels) or vector features (e.g., points, lines, and polygons) with points in space using x, y and sometimes z coordinate values. GIS allows for the placement of spatially rich objects, such as fingerprints, in a shared spatial environment, and allows for comparisons among the objects. For this study, approximately 950 fingerprint images from digits one, two, six, and seven were geo-referenced by placing the core at 100mm in Cartesian coordinate graph space consequently positioning every print in positive graph space. Fingerprint parameters including minutiae type placement, direction, and the spatial relationship of minutiae were quantified and were used to evaluate the uniqueness of fingerprint regions. The distances and directions between minutiae and between core and minutiae were calculated. In addition, a Monte Carlo simulation, more specifically a bootstrapping simulation, was used to estimate the probabilities of occurrence of different spatial configurations of minutiae within print types. These probabilities were created first for a reduced model of position only (x,y) with a margin of error (±0.32 mm) placed around each minutiae position, and then for models of increased information and complexity. The simulations consisted of *n* minutiae randomly selected from a specific fingerprint region. The selected minutiae were then used to query our database for fingerprints with the same minutiae configuration. This procedure was iterated 1,000 times to obtain a distribution of false matches. This procedure was performed on nine predefined, overlapping regions of a fingerprint that represent the entirety of a fingerprint. These regions were defined in such a manner as to reduce any artificial boundary effects created by the boxes. For every fingerprint used in this procedure, nine separate probabilities were obtained. The simulations were run on 50 randomly chosen fingerprint images per pattern type (right slant loops, left slant loops, whorls, arches) for a total of 300 fingerprint images sampled and 50,000 iterations performed per region within a pattern type and for the number of minutiae chosen. These results were then used to analyze whether different regions have a lower chance of false matching. Simulations were performed with three, five, seven, and nine minutiae chosen. As anticipated, as the number of minutiae selected increases, the chance of obtaining a false positive decreases. The overall means for all regions and print types were x-bar_3=0.16, x-bar_5= 0.000714, x-bar_7= 0.000005, x-bar_9=0.00. In addition, our simulations showed that the area above the core has a lower probability of matching anything not itself. The probability of false positives drastically decreased as more information, such as minutiae type and direction, was added to the model. Model simulations were performed both within print type and among all print types, and the findings for both approaches are similar. The research described addresses issues raised by the NAS report by applying a scientific approach to fingerprint analysis. The probabilities being produced are addressing the uniqueness of fingerprints.

This project was supported by Award No. 2009-DN-BX-K228 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. Fingerprints, Statistics, GIS

A64 Novel Nanoparticle Polymer Applications in Lifting or Preserving Imaged Latent Fingerprints

Charles R. Cornett, PhD,and Lindsey Sprangers, BS, University of Wisconsin-Platteville, Department of Chemistry, Platteville, WI 53818; Thea Somers, BS, and James Hamilton, PhD, University of Wisconsin-Platteville, Department of Chemistry, Platteville, WI 53818*

After attending this presentation, attendees will be introduced to a novel application of a polymer embedded with nanoparticles in the lifting and preservation of imaged latent fingerprints.

This presentation will impact the forensic science community by being aware of the research that has developed a clear polymer capable of lifting positive imaged latent prints from a wide variety of irregular surfaces as well as a nanoparticle-doped polymer capable of preserving imaged latents on a wide scope of paper documents. These constitute significant advances in the latent print discipline.

The 2005 on-going application investigation for a novel polymer began to focus on the lifting of imaged latent fingerprints from irregular and highly irregular surfaces such as plastic beverage containers, automobile dash boards, bank countertops, and mottled appliance surfaces including handles. Additional research demonstrated that the polymer provided a mechanism for preserving imaged latent prints on virtually any paper surface. Furthermore, accelerated aging tests involving heat and humidity sufficient to simulate ten years of aging were conducted. Experiments then focused on refinement of aerosol delivery of the polymer and solvent system.

Fingerprint samples were collected from these surfaces and the ridge detail assessed by five students who completed a three-credit course in fingerprint identification. Results demonstrated that the polymer spray provided an outstanding means of preserving imaged latent prints as well as lifting positive images of dusted latent prints from the aforementioned irregular surfaces with minimal stretching, distortion, or loss of ridge detail. Additional experimentation utilized latent prints collected from six volunteers on index cards at the same time of day, each day, for one week. The collected latents were dusted using magnetic black powder. One-half of the prints were sprayed with the polymer while the remaining prints are treated with a silicone-based product producing a negative image. Statistical results comparing the two lifts are presented. A semi-quantitative rubric was developed to compare ridge detail of the positive print images generated by this clear polymer and the negative print images generated by commercial available, silicone-based products for the index card experiment. Together, these studies demonstrate the viability of this polymer in the lifting of positive images of latent prints from nearly all surfaces.

In the preservation studies, simulated aging tests with heat and humidity demonstrated that the paper substrate yellowed prior to polymer degradation during tests designed to mimic ten years of aging. This led to the incorporation of zinc oxide (ZnO) nanoparticles into the polymer solution. The addition of the ZnO nanoparticles resulted in a clear solution given the nanochemistry of ZnO and filtration. The presence of the ZnO nanoparticles was confirmed by UV spectrometry scans ranging from 200nm to 400nm. Experiments demonstrated an increased resistance in simulated aging including UV light tests. In these experiments, newsprint, various cotton bonds, and copier paper were printed, dusted with magnetic black, and treated with the ZnO embedded polymer. The latent print was over-sprayed by a radius of approximately three centimeters. This enabled a comparison of the paper and the polymer coated paper outside of the latent print to assess the general effects of the polymer system on preventing paper oxidation. With regards to the effects of the embedding of the ZnO nanoparticles on the small potential of stretching distortion of ridge detail with the polymer-only application, the results indicate further reductions of distortion may be possible by this incorporation of the ZnO nanoparticles.

Nanoparticle, Latent, Fingerprint

A65 Assessing the Quantity of Friction Ridge Characteristics as a Function of Human Perception

Henry Swofford, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Shauna M. Steffan, MS, United States Army Criminal Investigation Laboratory, Latent Print Branch, 4930 North 31st Street, Forest Park, GA 30297; Garold C. Warner, BA, and Candice Bridge, PhD, United States Army Criminal Investigation Lab, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will understand the degree of variation in the perception and interpretation of friction ridge skin characteristics by Ten-Print and Latent Print Examiners.

This presentation will impact the forensic science community by discussing the variation in the quantity of friction ridge skin characteristics as perceived and interpreted by practicing Ten-Print and Latent Print Examiners.

Friction ridge skin characteristics (bifurcations, ridge endings, dots) and their unique arrangements are the primary information content evaluated by Ten-Print and Latent Print Examiners when comparing unknown friction ridge skin impressions to known (record) impressions. During the comparison process, the information content (characteristics) of these friction ridge skin impressions are perceived and interpreted by the human examiner. This study seeks to understand the variability associated with the human perception of friction ridge skin characteristics.

Fifty (50) high quality friction ridge skin impressions were evaluated and the quantity of friction ridge skin characteristics (bifurcations, ridge endings, dots) were reported by eight practicing Ten-Print Examiners and fifteen practicing Latent Print Examiners (total n=23). Each impression was prepared by the same individual recording the impressions under controlled conditions from nine different donors using standard black printers ink and a standard fingerprint card. Each impression was scanned into a digital format at 1,200 dpi and image samples used in the evaluation were cropped from various areas in the fingerprints at a set size of 6x6mm^2. Of the fifty impressions, two pairs of impressions were duplicate images to assess any variation in perception from the beginning of the study to the end of the study. Each of the fifty impressions was presented to the study participants in a digital format for evaluation. Examiners were asked to count and record how many bifurcations, ridge endings, and dots are perceived and interpreted by them for each impression.

Preliminary results from these twenty-three participants reveal more variation than expected in the perception and interpretation of friction ridge skin characteristics. Statistical analyses found no significant difference in the perception of friction ridge skin characteristics due to gender, age (<40yrs vs >40yrs), experience (<10yrs vs >10yrs), and specialty (Ten-Print Examiner vs. Latent Print Examiner). A slight variation was observed in the quantity of friction ridge characteristics perceived in the two pairs of duplicate images; however these variations were not statistically significant.

Preliminary results suggest the information content relied upon by Ten-Print and Latent Print Examiners may vary due to perception and interpretation differences by the human examiner. These preliminary results warrant further research to compare with computer based interpretations using the automated fingerprint identification system, to better understand the inter-examiner variability, and to determine whether these results have any impact on the conclusions generated during the comparison process.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Forensic Science, Fingerprint Characteristics, Fingerprint Perception

A66 Importance of Third Level Details in the Analysis of Fingerprints

Mukesh K. Thakar, PhD, and Haroon N. Khan, MS, Punjabi University, Department of Forensic Science, Patiala, Punjab, 147002, INDIA*

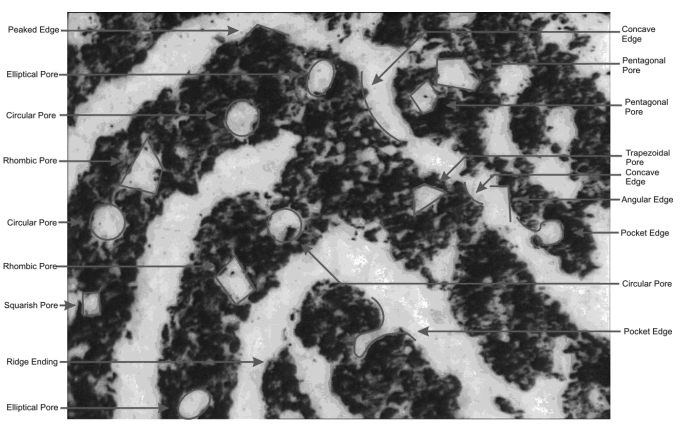
After attending this presentation, attendees will have exposure to the international community of forensic science which will help in exploring other areas of research.

This presentation will impact the forensic science community by being aware of lesser known characteristics that can produce very good results through innovation (i.e., measuring third level details which will provide an alternate method for identification of partial, smudged, or fragmented fingerprints).

The influence of cinema, television, and detective fictions has projected fingerprints as one of the most important types of evidence. The public has become most familiar with fingerprints as the best means to prove the identity of a criminal. These familiarities with fingerprints tend to provide them a greater importance in the field of criminal investigation. Fingerprints are most commonly available at the crime scene; their permanence and uniqueness leads to absolute identification of the person.

Prints recovered from the scene of crime are identified for their pattern types and compared with specimens obtained from suspects. During the process of comparison, 8-21 ridge characteristics are required to give a positive or negative opinion in the court of law (the number of characteristics varies from one country to another). If a sufficient number of characteristics is not available, the fingerprints cannot be used for identification. In many cases, the recovered fingerprints are partial, smudged, or fragmentary where the required numbers of ridge characteristics are not available. In such cases it becomes a great handicap for experts to give an opinion. In this situations, there is the need to include third level details (besides first and second level) such as the number, shape, and measurements of relative position of sweat pores and shapes of the edges of ridges which can be used to supplement the shortfall in the number of ridge characteristics to establish identity.

In the present study, an attempt has been made to collect 100 samples of partial, smudged, or fragmentary fingerprints along with complete prints from 53 males and 47 females on different types of papers. Second and third level characteristics (edgeoscopy and poroscopy) for each compromised print were marked at their correlative position to prove identity. After this, a further attempt was made to measure the distance between them. The results obtained were analyzed statistically and found significant. The range of ridge and edge characteristics (including pores) varies from 2-8/ridge; an example is given below in the photomicrograph (40X magnification).



Photomicrograph at 40x Magnification showing Second and Third Level details (ridge characteristics, shape of pores and edges)

Although the edge characteristics on fingerprints can be affected by a number of factors such as pressure applied, type of ink used, surface on which the prints are taken, and donor, the results obtained from this study are very encouraging and will be of great use to fingerprint examiners, particularly those who identify individuals from smudged or partial/fragmentary fingerprints, or any fingerprints in which only few ridges are available for comparison.

Fingerprints, Poroscopy, Edgeoscopy

A67 LIMS: Getting What You Want

Elizabeth D. Johnson, MS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Nicole R. Frazier, MS, 278 Tufts Court, Fayetteville, GA 30260; Michael L. Mann, MS, 2151 Cumberland Parkway, Apartment 612, Atlanta, GA 30339; Diana D. Wallace, BS, United States Army Criminal Investigation Laboartory, 4930 North 31st Street, Forest Park, GA 30297; Edmund D. Tamburini, MFS, 95 Vesta Court, McDonough, GA 30252; Jessica K. Linner, MSFS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Building 925, Forest Park, GA 30297; Ashley L. McClellan, BS, United States Army Criminal Investigation Laboratory, CODIS Lab, 4930 North 31st Street, Forest Park, GA 30297; and Stephen K. Gicale, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will know a minimum of ten concepts necessary for success when planning an information management project. The focus of the presentation is on project management ideas.

This presentation will impact the forensic science community by providing clear project management guidance to laboratories planning to implement a LIMS in the future or working to improve an existing LIMS. It will be beneficial to all laboratories with LIMS design or implementation aspirations.

Transitioning a laboratory from a traditional paper-based record keeping system to an automated information management system is a process that presents multiple challenges. Many crime laboratories either have faced this challenge already or will in the near future. Some are facing it for a second or third time due to dissatisfaction with initial attempts. The most common experience of this type is with the implementation of a laboratory information management system (LIMS).

During the three year period 2009-2011, the DNA database unit at the United States Army Criminal Investigation Laboratory contracted for, customized, and implemented an information tracking system. In the process, a number of key project management elements that proved important to the success of the system were discovered. Some elements were discovered because they were done well. Others were found because they could have been done better. The lessons learned are presented so that other laboratories may take advantage of them and avoid common pitfalls.

During the contracting phase, the goal must be to articulate and document detailed requirements for the system. No assumptions whatsoever can be made. The requirements document (or statement of work) will become the foundation of the development process. Items that are vague or left open to interpretation may become points of contention in the future and the system may not perform as expected. It was found to be highly beneficial to obtain statements of work from other laboratories as well as to visit other laboratories and observe similar systems in action. A contract officer representative who is not a member of the group writing the requirements should become involved in this phase. Where possible, it is advisable to engage an information technology specialist in order to ensure the system will work as planned on the laboratory's information services platform.

In the second phase of the project, design, or customization, laboratory management make a number of strategic decisions that determine the level of success. The composition of the design team is crucial. The most productive team was determined to be one which included someone who had performed every task the system would be expected to perform.

Perspectives of different users ensure that no critical functions were overlooked. It was found to be imperative to establish a documentation system for recording all interactions with the vendor early is the design/customization process. Phone conversations and emails on a multitude of minute details can quickly become difficult to manage. Reliable documentation can prevent misunderstandings and help to ensure the final product is satisfactory.

Once the system is designed/customized, the work is by no means over. Implementation is a very involved process. Many issues must be considered including entry of static data, conversion of legacy data, and interactions with other databases. Finally, the implementation phase must include a formal user training program with carefully constructed training exercises designed to cover every routine function.

LIMS, Information, Management

A68 Turn a Box of Case Files Into One Click on Your Screen Using a Specialized Laboratory Information Management System (LIMS) to Improve the Efficiency and Quality of Serology in a Forensic DNA Laboratory

Tian Liang, BS, Stephanie Masters, BS, Kari Killian, BA, Daniel Hellwig, MSFS, and Martyna Shallenberg, BS, Sorenson Genomics, 2495 Southwest Temple Street, Salt Lake City, UT 84115*

After attending this presentation, attendees will be shown how a specialized form of LIMS system can significantly reduce the process time and human errors of serology in a DNA laboratory. They also will learn the principles of how to design a more efficient LIMS system for different types of crime laboratories.

This presentation will give the forensic science community a different aspect of how to manage and track laboratory information in a superior way. It will compare the specialized form of LIMS to the traditional paper trials.

DNA analysis has become one of the most important criminal investigation tools. Serology, the first step of the DNA process, cannot be automated as other parts of this procedure due to the variation and complexity of the work and consequently more human errors could occur. *Sorenson Forensics, LLC* has improved both efficiency and quality of serology by utilizing a LIMS system with a software program, UNIFlow, developed by *UNIConnect*. UNIFlow is a software program that consists of different modules which are easily programmed by end users. After modification, it electronically tracks and manages every step of evidence and DNA sample handling, including case log-in, serology, DNA extraction, DNA analysis, and report generation.

This specialized LIMS system has significantly reduced the time of serology, averaging 20 minutes per case, by eliminating unnecessary work including filling out six handwritten forms (e.g., case evidence list, stain cutting list, reagent log, serology notes, case notes, and case management database). Uniflow also accesses four software programs (word processing, spreadsheet, database, and portable document software) to automatically input the same information repeatedly. Every detail of a case such as chain of custody (COC), case notes, serology notes and results, are entered real-time in LIMS. Hence, the COC can be recorded more precisely which protects the integrity of the evidence. In addition, backdating case notes is impossible which provides a truer representation of the evidence and DNA samples. All information can be corrected or changed if a mistake ever occurs; the changes are also tracked by LIMS and displayed on the final report. Moreover, by tracking information electronically, it largely prevents human errors such as misspellings, errors due to poor handwriting, and mislabeling tubes. By eliminating such human errors, LIMS largely reduces the possibility of sample handling errors. After serology is finished on each piece of evidence, the portion sent for DNA analysis is stored in an extraction tube with a unique barcode. The barcode is linked with all the information of the evidence and tracked in LIMS through every step of the DNA process. Therefore, sample swapping is almost impossible.

One of the most significant advantages of UNIFlow LIMS system is that it is highly flexible and can be programmed to meet the specific needs and preferences of various types of forensic and non-forensic laboratories. Sorenson Forensics, *LLC* had researched many different LIMS systems available on the market (e.g., Beast and Justice Trax) before establishing UNIFlow. There was no other forensic LIMS software that could be tailored to coordinate the laboratory work flow in extensive detail. Therefore, the company utilized UNIFlow software and literally built a specialized LIMS system from the ground up. However, certain laboratory personnel needed to be trained to program UNIFlow software, which may increase the initial input time and cost of this LIMS system.

Overall, by implementing the specialized LIMS system in a forensic DNA laboratory both the efficiency and quality of serology and the DNA process have significantly improved and human errors have been reduced practically or totally eliminated. This system is easily adjusted to various types of forensic laboratories which can enjoy the same benefits.

LIMS, Efficiency, Serology

A69 A Sample Tracking System to Automate and Increase Workflow in a Forensic DNA Casework Lab

Cindi L. Hricko, MS, 1020 Brand Lane, Apartment 1538, Stafford, TX 77477; and Michael A. Donley, MS, and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX*

After attending this presentation, attendees will understand the steps needed to create and use barcodes with a sample tracking system in a high-throughput, automated forensic DNA lab. The audience will be led through casework examples using the HCIFS Forensic Biology Laboratory system as a model and be shown that this type of system used with barcode-labeled samples will increase efficiency, limit human error, and help ensure the integrity of each sample.

This presentation will impact the forensic science community by demonstrating how barcode labeled samples and a sample tracking system can increase laboratory efficiency and decrease human error during DNA processing. This type of system will benefit the criminal justice community by demonstrating a way to ensure the integrity of casework samples while providing a step by step snapshot of the automated verifications performed throughout our DNA testing process.

Tracking samples correctly and efficiently is a critical priority that becomes increasingly difficult with increases in caseload. In a batch-testing system, quality concerns increase as batch sizes increase. Verifications are required for each tube change and each time a plate is moved to a new station. Manual verification (i.e., by a second analyst) of casework samples tends to be time consuming and requires second analysts to be available to verify that paperwork and labels match. This is inefficient as well as a source of potential error. Barcode labeled samples, in conjunction with a sample tracking system, help reduce labeling errors and provide automated verification.

The HCIFS Forensic Genetics Laboratory currently utilizes an electronic LIMS to track the chain of custody of evidence *items*. However, the LIMS does not track evidence *samples* throughout the DNA process. To overcome this limitation, the HCIFS Forensic Genetics Laboratory designed and implemented a sample tracking system that generates a barcode for each sample and utilizes a SQL database to maintain the sample information. The system reduced the number of second analyst verifications from approximately twenty to one.

Within the laboratory, twelve barcode stations are set up to quickly and efficiently label samples. Each station consists of a barcode printer, a scanner with 1D and 2D capabilities, and either a desktop computer or a mobile tablet with sample tracking software installed. The software was

written to allow us to alter and customize it to accommodate evolving manual or robotic procedures. The sample tracking system generates a 1D and a 2D barcode label for each sample that enters DNA processing. The barcode label is scanned and tracked electronically from that point forward. The system allows samples to be prioritized (e.g., stat. rush, normal) and then orders them by the date they were entered into the database. Batches are compiled by the analyst based on these criteria. Manual, second-analyst verifications have been replaced by automatic verification as the analyst scans the source tube and then the destination tube to ensure that labels match before transferring a sample. The system has numerous safeguards to prevent bypassing mandatory verifications or incorrectly scanning a sample. For example, if an analyst tries to scan the same tube for both the source and the destination tubes on a tube transfer verification, or the analyst scans the top label twice on a label verification, an error message will appear alerting the analyst that the verification failed and won't allow the process to continue until the verification is successful. Database management procedures are also included with the sample tracking system so that cases can be closed and stored in a separate database to prevent the program from running slowly.

To further automate the barcoding and sample tracking, the software is used with liquid handling robot with an integrated barcode scanner. This allows the robot to identify the position of each sample on the deck according to its barcode; the user does not prepare a fixed-order list of samples to begin the process. A full description of the sample tracking system and how it integrates into an automated lab will be presented.

Sample Tracking, Barcodes, Automation

A70 Investigative DNA Databases That Preserve Identification Information

Mark W. Perlin, PhD, MD, Cybergenetics, 160 North Craig Street, Suite 210, Pittsburgh, PA 15213*

After attending this presentation, attendees will understand how investigative DNA databases can be improved to better preserve DNA identification information. When databases store and match probabilistic genotypes, instead of allele lists, all the biological evidence information can be preserved.

The presentation will impact the forensic science community by enabling DNA databases to make better use of biological evidence for investigations. By moving to a more informative probabilistic genotype representation, databases like CODIS can become far more sensitive and specific. This sharpened information capability makes DNA databases more successful in connecting the right criminal to DNA mixture evidence.

A DNA database can link crime scenes to suspects, providing investigative leads. These DNA associations can solve cold cases, track terrorists, and stop criminals before they inflict further harm. However, current government databases do not fully preserve DNA identification information and cannot maximize public safety.

DNA data is summarized in a genotype. The genotype can be stored on a database, and compared with other genotypes to form a likelihood ratio (LR) match statistic. Data uncertainty, present in most evidence, particularly DNA mixtures, translates into genotype probability.

Highly informative DNA mixture interpretation uses all the quantitative data, placing higher probability on more likely genotype values. Most evidence, though, is currently interpreted by a qualitative human review that diffuses probability across infeasible solutions. Since the LR is proportional to the true genotype probability, weaker interpretation methods lead to weaker (or nonexistent) DNA matches.

The weakest DNA mixture interpretation method is the Combined Probability of Inclusion (CPI), also known as Random Man Not Excluded (RMNE). CPI uses thresholds to truncate quantitative data into all-or-none qualitative "allele" events. The current DNA databases (including CODIS) use a CPI allele representation that discards considerable genotype information, losing sensitivity and specificity.

The "probabilistic genotype" representation described by SWGDAM[1] is part of the new ANSI/NIST-ITL data exchange standard.[2] Unlike allele lists, a probability representation can preserve all DNA evidence identification information on a forensic database and calculates accurate LR statistics as it matches across the database.

ISFG's 2006 mixture guidelines[3] recommend the more informative LR over CPI. Unfortunately, current databases transform hard won LR genotypes into less informative CPI alleles. This presentation will explain how genotype probability can preserve identification information for DNA investigation.

Forensic DNA is an information science with DNA databases having the potential for considerable identification power. However, current database implementations discard most of the information in DNA mixture evidence. This presentation will help practitioners understand how to build and use investigative DNA databases that preserve all of the identification information present in their biological evidence.

DNA Database, DNA Mixture, Likelihood Ratio

A71 The Imperial Avenue Strangler: Issues in Crime Scene Documentation and Evidence Collection

Curtiss L. Jones, MS, and James T. Wentzel*, Cuyahoga County Medical Examiner's Office, 11001 Cedar Avenue, Cleveland, OH 44106*

After attending this presentation, attendees will understand challenges to documenting a complex homicide scene involving multiple victims killed at various times and will -become acquainted with existing and emerging technology for crime scene processing and documentation.

This presentation will impact the forensic science community by serving as a key aspect of crime and/or death scene documentation by augmenting traditional still photography with full spherical images, scene diagrams, and other pertinent information relevant to the ongoing investigation, presenting viewers with an ability to have unrestricted views of crime and death settings as if they were on-site.

The Imperial Avenue Strangler case presented the challenges of documenting the locations of 11 fatalities within the same crime scene area, the collection of evidence pertaining to the 11 fatalities from both inside and outside of a three story residence, and the recognition and collection of evidence from inside of the residence from an unknown number of non-fatal sexual assaults. Of the 11 fatalities, six were located within the residence and five were buried in shallow graves in the rear yard. Recognition and collection of probative evidence linking the suspect to the 11 fatalities, regardless of the location from which each body was recovered, was also a major consideration. Recovery and documentation of the buried remains located in the rear yard proceeded in typical fashion. The overburden covering the shallow graves was removed mechanically. Recovery of bodies and foreign material was performed by shovel, trowel,

and hand. Each of the victims recovered from the rear yard was wrapped in plastic, cloth, or a combination of both. The wrappings were robust enough to keep each victim's remains encapsulated. Had the victims not been wrapped, it would have necessitated an "archeological" style dig to recover all of the victim's clothing, property, and remains.

Inside the residence, an in-depth multi-format photographic documentation scheme was employed. Still photography combined with 360 degree panoramic high dynamic range image capture ensured a complete digital image recording of each room within the scene. Using software, the photographic narrative was then overlaid onto detailed drawings allowing for "virtual" navigation within the resultant digital scene. Any documentation and evidence collection had to be exhaustive because there was a real possibility that the residence would be completely destroyed once the scene was released. Once the scene documentation was complete, each room was subjected to evidence collection focused on obtaining probative items pertaining to the known fatalities and/or suspected non-fatal sexual assaults. It was decided that any items with potential probative value would be collected from the residence. The broad spectrum collection scheme would ensure that a high percentage of useful evidence items would be collected, even if the probative value of a specific item wouldn't be realized until a later date or at all. Specific attention was applied to the collection of known samples from the residence which could at a later date be compared to evidence items collected from the wrappings received with the victims' bodies. Examples of reference samples collected from the residence included tape, plastic bags, carpet fibers, and carpet pad. The experience of the Imperial Avenue Strangler case has shown that to be effective in scene documentation and evidence collection for a complex multi-victim crime scene, a strategic plan incorporating input from investigative agencies is necessary. Also, a comprehensive image capture scheme beyond typical still images is desirable to ensure that the condition of the crime scene is recorded and can be accessed at will even if the physical scene is ultimately destroyed.

Crime Scene Documentation, Evidence Collection, Serial Homicide

A72 Cold Case Criminalistics: An Anthropological Approach to Cold Homicide Casework at the Boston Police Department Crime Laboratory

Sarah A. Kiley, MS, University of Florida, C.A. Pound Human Identification Laboratory, 2033 Mowry Road, Room G-17, Gainesville, FL; and Donald R. Hayes, MS, Boston Police Crime Laboratory, 1 Schroeder Plaza, Boston, MA 02120*

After attending this presentation, attendees will be briefed on the complexities of cold case criminalistics and how collaboration between investigators, anthropologists, and criminalists has contributed to the successful evaluation and examination of cold case evidence at the Boston Police Department Crime Laboratory.

This presentation will impact the forensic science community by discussing the value of an interdisciplinary approach to cold case analysis to overcome the inherent challenges of missing documentation and degraded biological samples in an effort to expeditiously identify an aging suspect population in a modern crime laboratory; the implications of which contributes significantly to resolving investigations and successful prosecution.

In the United States, the definition of a backlogged case varies by jurisdiction, but has been defined by the National Institute of Justice as any case that has not been tested within 30 days of submission to a crime laboratory. Currently there is a considerable backlog of cold case homicides in the United States from the pre-DNA era. Federal grants, such as those offered by the National Institute of Justice DNA Backlog Reduction Program - Cold Case Initiative, provide eligible state and local authorities with additional funds to re-examine cold cases. Selection criteria for re-examination of cold cases include violent crimes where there is close contact and a significant potential for Locard's exchange of trace and biological material, e.g., homicide, rape/homicide, stabbing, strangulation and blunt force trauma.

Forensic anthropologists trained in taphonomy, trauma analysis, and human anatomy are particularly well-equipped to sequence events, distinguish between extraneous environmental modifications of human remains, and interpret patterns of evidence and biological materials associated with cold cases. In most areas of the country, forensic anthropologists work as consultants to local law enforcement as well as medical examiners' and coroners' offices to assist with the identification and/or recovery of skeletonized human remains. Forensic anthropologists are often asked to examine evidence without being present at the time of recovery or during transportation, autopsy, or testing. Careful examination of the condition and pattern of evidence is synthesized by the anthropologist along with photographs, case files, police reports, newspapers, and climate data to recreate the circumstances surrounding the time of death. Additionally, training in human gross anatomy and an understanding of biomechanics and trauma analysis are valuable in identifying and collecting aberrant biological materials from cold case evidence such as blood, semen, and other bodily fluids from a victim's clothing, especially when coupled with an autopsy report's description of the type, nature, location, and size of injuries sustained by the victim.

Criminalists investigating cold cases are similarly responsible for recreating the circumstances surrounding the time of death as well as understanding the taphonomic history of the forensic evidence since collection. This often involves researching internal institutional forensic documentation standards for collection, modalities for the retention and storage of evidence, documentation, testing practices, and understanding how these have changed over time. Additional information gathered from supporting agencies such as medical examiners' offices, hospitals and outside investigative service organizations can help locate evidence and reference samples and guide investigations. Another agency's commonplace practices - particularly practices in place prior to the field's understanding of and ability to use DNA evidence - may provide biological comparative or reference samples (e.g., slides, swabs, evidence, or blood) that were retained without extensive documentation. Finally, consideration of the type of biological material, as well as the medium, size, and estimated robusticity (given the taphonomic history) of the sample, should be considered prior to collection. A review of the literature and consultation with a DNA analyst should be part of the evaluation of the collection and retention of small samples from evidentiary items. Traditional criminalist screening methods for evaluating evidence should be amended to reflect the quality and quantity of a cold case sample.

The successful prosecution of cold cases is dependent on the ability to evaluate evidence and select the case specific DNA test that is most appropriate to conduct in light of the documentation available. A case series history from the Boston Police Department Crime Laboratory will be provided to illustrate some of these challenges.

Criminalistics, Cold Cases, Forensic Anthropology

A73 Quality Control on Crime Scene for First Response and "On the Spot Activities"

Donatella Curtotti, PhD, University of Foggia, Via Smaldone 21, Foggia, 71100, ITALY; and Luigi Saravo, PhD*, RACIS, Viale Tor di Quinto, Rome, 00123, ITALY*

After attending this presentation, attendees will understand that the lack of Standardized Operation Procedures (SOPs) for the management of crime scene evidence in the judiciary system commonly leads to acquittal decisions due to the unreliable nature of the scientific investigations of the police.

This presentation will impact the forensic science community by highlighting the importance of Standardized Operation Procedures (SOP)

in the first response and "on the spot activities" at the crime scene. It is intended to be a call to action to the scientific community to become involved and proactive in the creation of such procedures in the countries where a void still exists in this area.

Introduction: Crime scenes that involve offenses of a violent nature are worthy of special note for two reasons. Such crime scenes very often involve the distribution of blood, body tissue, and several types of traces from the offender. For this reason, they can provide excellent contact trace material and potential evidence. But the investigation of these violent crime scenes can be quite complex both in the first response and in the crime scene investigation. There are a variety of techniques and tools that can be used to visualize and collect all types of evidence. Mistakes or oversights made during the management of crime scene can have a great impact on the final outcome of the case. For a crime involving scientific evidence, it needs to be processed with Standardized Operation Procedures (SOP) which detail the sequential steps of the investigation.

Objective: Standardized Operation Procedures (SOP) for the management of forensic evidence at the crime scene are missing in many countries, including a large part of the European nations. The study presents a statistical analysis of several Italian and other European countries' decisions in which, despite the large amount of scientific evidence collected at the crime scene, the supreme criminal courts were unable to condemn the accused. The forensic investigations were not considered reliable enough to determine the standard of proof required by the law because the management of the process of the evidence in the first response and "on the spot activities" (such as initial assessment, identification of key evidence areas, preservation of the scene, crime scene documentation and recording, packaging and removal of traces) were conducted by the police without complying with Standardized Operation Procedures (SOP). Commonly, the practices introduced by the police for the processes of recovery, packaging, and storage of scientific material have been considered inadequate by the court to avoid contamination.

Goal: The goal of the study is to underline the importance of incorporating an accreditation process into crime scene investigations and to highlight the role played by SOP in ensuring both the quality of scientific investigations at the crime scene and the fairness of the judicial outcome.

Result: As a result of the efforts described in this study, a committee was recently formed in Italy to create the first Italian SOP for the activities of first response and crime scene investigations. This multidisciplinary working group is composed of members of police forces, magistrates, lawyers, forensic sciences experts, and academics. At the moment, it has drafted standardized guidelines on each step of crime scene investigation (such as observation, pre-examination, multi-communication, preservation, initial report, initial strategy, choice of methods and techniques, collection, packaging, chain of custody from crime scene to office/lab, storage items, and final report).

The procedures have been submitted to a large group of crime scene investigators attending training courses at the high schools of the police departments. At the end of the training courses, investigators have been asked to highlight the advantages of the introduced procedures, to focus on possible points of weakness of the procedures, and to strictly apply them when investigations are in progress.

Crime Scene, Forensic Investigation, SOP

A74 Obtaining DNA From Spent Bullet Casings: A Review

Lisa R. Ludvico, PhD, and Ronald Freeman, BA, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15282*

After attending this presentation, attendees will understand the many research approaches and techniques employed in trying to recover DNA from fired bullet casings.

The presentation will impact the forensic science community in that often the only physical evidence linking a murderer to the crime scene are spent bullet casings. Maximizing DNA recovery from such a comprised source (spent bullet casings) will aid law enforcement in identification of suspects.

Law enforcement officers have found in many cases that the sole evidence recovered at a firearm-related crime scene is spent bullet casings. Obtaining even a partial DNA profile from spent bullet casings would be of utility in eliminating possible suspects. It was previously believed that the high firing temperatures would destroy any touch DNA (tDNA) that transferred to the bullet. As reported at the 2009 American Academy of Forensic Sciences meeting, Nase *et al.* found that the time the bullet is in the firing chamber is not sufficient to destroy tDNA. The second great hypothesized obstacle was the quantity and quality of the DNA left on the casing. The Dawson-Cruz laboratory (2008) demonstrated that DNA concentration can be enhanced using both pre- and post- amplification techniques. Partial profiles can be generated using both pre and post amplification modifications.

The research scope of this talk includes demonstrating that tDNA can withstand the high firing temperatures with single shots as well as firings from an entire handgun magazine. Swabbing techniques using different swabbing matrices and a variety of surfactants (1, 2%, and 20% SDS) and alcohols, ethanol and 2-propanol, have been examined. Moreover, "target swabbing" was conductednon both spent and unfired (though handled) casings with hyper-imaging technology and locate areas believed DNA to be present. However, target swabbing via imaging instrumentation had little effect on total DNA recovered in this study. Partial profiles were generated using both pre and post amplification modifications.

Another study followed the Dawson-Cruz pre-amplification and post-amplification procedures, but used shotgun shells. The shells were used in place of hand gun casings to determine if a profile could be generated for a Pennsylvania Game and Wildlife open case involving a shotgun.

The effect of "pooling" DNA from all casings found at a crime scene is also being studied. The pooled findings from the various studies show that loading order has an effect on DNA deposition, with the first and last loaded bullets having the highest DNA concentrations. No significant difference in DNA recovery exists from firing one shot vs. an entire clip.

Currently, the determination of which of the major components of primers (antimony, barium, and lead) may be contributing to downstream inhibition in DNA processing and how much DNA is lost in the packaging of spent bullet casings.

A review of all in-house DNA recovery research spanning three years, seven interconnected studies and the published literature, will demonstrate the status of the research on obtaining DNA from used casings is currently and what techniques have been most promising.

DNA Recovery, Spent Bullet Casings, Low Template DNA

A75 Trace DNA From Fingernails: Increasing the Success Rate of Widely Collected Forensic Evidence

Lisa M. Hebda, BS, and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will appreciate the need for standardization in collecting and processing fingernail evidence and will be informed about best practices for recovering foreign DNA from fingernails and which DNA analysis methods are most successful for producing a DNA profile.

This presentation will impact the forensic science community by disseminating an optimized method of collecting and processing fingernail evidence which currently does not exist. The research has the potential to have a substantial impact on the way forensic pathologists, forensic nurses,

and forensic biologists conduct their work. The experiments were specifically designed to quickly and directly benefit practitioners so they will know how to best collect and process nail evidence.

Direct contact between an assailant and victim occurs during sexual assault and many other violent acts. As the victim attempts self defense, biological material from the assailant may be left, particularly under fingernails. Forensic nurses, emergency personnel, and pathologists often collect fingernails or material beneath fingernails from surviving or deceased assault victims for DNA testing. Unfortunately, very little is known about the utility of such collections, including if the existing methods for obtaining and testing fingernail/DNA evidence are optimal for producing probative evidence. Procedures for fingernail evidence collection and examination have never been standardized or optimized, nor has their subsequent genetic testing. In different jurisdictions nails can be clipped, scraped, swabbed, or simply not collected at all. A new set of clippers might be used for each hand, for each case, or the same set used for all cases. Rarely are nails treated individually, but instead are collected and processed for the right and left hand, raising the possibility of cross contamination or dilution of an assailant's DNA if it resides under only one nail.

Given the thousands of nail samples collected following sexual assault or upon autopsy each day in the United States, a surprisingly small amount of actual research has been conducted on nail evidence. In consultation with several forensic practitioners, the research to be presented was designed to address these questions in an objective and statistically reliable manner. First, the general level of foreign DNA found under nails was examined. Next, volunteers scratched one-another's forearm under a constant level of pressure, using the middle three fingers of each hand. A buccal swab was also provided. Multiple methods for collecting nail evidence were tested, including swabbing the underside of a nail with a wet swab moistened with an SDS solution, a wet swab followed by dry swab, scraping beneath the nail, and clipping and analyzing an entire nail. Likewise, the utility of processing nails individually or combining all nails from a hand together was examined. DNAs were quantified from each collection method and various DNA analysis procedures widely used in crime laboratories (STRs, miniSTRs, YSTRs) were evaluated using commercially available kits. Finally, experiments were conducted to examine if the results could be enhanced by increasing the DNA injection time (30 sec), injection voltage (3 kV), post-PCR purification, and increasing the volume of amplified DNA loaded for electrophoresis.

The recovery of exogenous DNA from under the fingernails of average individuals was uncommon using standard collection techniques. In general, a major profile matching the nail donor was seen, and any alleles foreign to the nail were weak and small in number (one or two loci). Likewise, standard STR analysis of post-scratching nail debris produced few alleles from the person being scratched, and occasionally produced a complete profile of the scratcher. In contrast, YSTR analysis tended to lead to more callable alleles from the person being scratched (when females scratched males, as would be most common in a forensic situation). Increased DNA injection time (30 sec), injection voltage (3 kV), or post-PCR purification resulted in an approximate doubling of peak heights, along with some new callable alleles, and in some instances, a complete YSTR profile was obtained. Combining the increased injection time and voltage raised peak heights even more. In contrast, loading a higher volume of amplified DNA did not appear to increase peak heights nor increase the number of callable alleles.

The fact that foreign DNA is relatively uncommon under fingernails accents the significance of those instances wherein a foreign DNA profile is obtained from fingernail evidence. In this regard, utilizing YSTRs when a female is assaulted by a male may be preferable as more data may be obtained than when utilizing standard STRs. Finally, the ability to generate callable alleles can be enhanced by post-PCR purification or by modifying the injection parameters of the genetic analyzer.

DNA, Fingernail, Sexual Assault

A76 Sex Determination Assay for Degraded or Low Quality DNA

Amanda Buszek, BS, and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will learn about a highly sensitive, pyrosequencing based sex determination assay for degraded or low quality DNA.

This presentation will impact the forensic science community by detailing a more sensitive technique for sexing challenging samples, such as aged skeletal remains or tissue with little or poor quality DNA, than is currently available. The pyrosequencing based method will better allow sexing of samples when the standard amelogenin method is not effective.

Current molecular based human sexing techniques target a region of the single copy amelogenin gene, which exists on both the X and Y chromosomes, with the X chromosome having a six base-pair deletion. When this region is amplified and sized, female samples result in a single allele (peak), while males produce two products. However, this method relies on a sufficient quantity of deoxyribonucleic acid (DNA) being present to produce a strong enough signal for detection, usually 0.5 – 1 ng. Unfortunately, many forensic samples, such as hair shafts, aged bone, or handled objects, have much lower quantities and/or quality of DNA, and traditional molecular sexing methods are unsuccessful.

In order to overcome shortcomings with targeting amelogenin in degraded or low copy DNA, multicopy loci can be assayed which increases the probability of amplification. For instance, X chromosome specific DXZ4 repetitive satellite sequences have successfully been used to help sex skeletal remains. Other sexing techniques utilize an autosomal multicopy Alu sequence and Y-specific multicopy DYZ5 sequence, with sensitivity as low as 4 pg. Different regions of the Y chromosome with even more copies have the potential to be utilized in this manner, including DYZ1, a family of repeats similar to but more prevalent than DYZ5, made up of a 3.4 kb repeat with 2000 to 4000 copies per cell.

In this study, a PCR multiplex for DYZ1 and Alu was created which was assayed using pyrosequencing technology. Pyrosequencing was particularly beneficial in these experiments because it is extremely effective for assaying small DNA fragments, consisting of as little as two primers flanking one or more internal bases. This technique differs from standard Sanger (dideoxy) sequencing as it is based on detection of pyrophosphate release upon nucleotide incorporation, which is converted to adenosine triphosphate (ATP) by ATP sulfurylase. A luciferase, in the presences of ATP, gives off light, while any unincorporated dNTPs are degraded by apyrase. Sequences can be generated beginning at the base directly beyond the primer, which are not possible using standard sequencing methods.

Small DYZ1 and Alu regions (<150 bp) were targeted and PCR primers were optimized and tested for specificity on male and female DNAs. Internal pyrosequencing primers were then developed for both regions which further increased the specificity of the reactions. Once the method was optimized on high molecular weight DNA, the sensitivity and accuracy were compared to traditional amelogenin amplification by analyzing artificially degraded DNA as well as low quality DNA extracted from forensic samples such as hair shafts, fingernails, aged skeletal remains, and touch DNA.

Modifications of standard pyrosequencing methods were also examined with a goal of increasing ease and throughput. Pyrosequencing generally utilizes biotinylated primers for post-PCR clean up, immobilizing single stranded products by strong noncovalent affinity to streptavidin. However, this process is time-consuming and requires a vacuum workstation and multiple costly reagents. Given this, the biotinylated primer technique was compared to an enzymatic purification utilizing the hydrolytic enzymes exonuclease I and shrimp alkaline phosphatase, thereby allowing for direct pyrosequencing of double stranded PCR products.

Ultimately, the DYZ1/Alu assay is far more sensitive and potentially less ambiguous sexing technique than the standard amelogenin method on low quality/quantity DNA, proving successful even with less than 1 pg of DNA. Pyrosequencing of multicopy sex-specific loci, along with autosomal controls, is a straightforward and fast molecular technique that could be highly useful to the forensic community.

DNA, Sex Determination, Pyrosequencing

A77 Comparison of Methods to Collect Contact DNA From Fabrics

Sarah M. Thomasma, BA, and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will learn about the different collection techniques utilized and preferred in acquiring contact DNA evidence from fabric items.

This presentation will impact the forensic science community by increasing knowledge about optimization of different collection methods for use on fabric based evidence. This improvement will assist investigators in choosing a collection technique that best fits the evidence in question and the background of the case. In particular, for clothing or other fabric based items that may have come into contact with multiple individuals, the methods described may improve the chances of identifying the victim or the perpetrator of a crime.

The tremendous sensitivity of current forensic techniques makes it possible, but not certain, to obtain a DNA profile from a small number of cells, including those collected from items that have come into contact with one or more individuals. Given this, it is important to collect as many cells as possible, and hence as much DNA, from the item in order to increase the chance of making an identification. Limited comparative research has been conducted on the common techniques used in forensic laboratories to collect DNA from fabric evidence, some of which may be suboptimal—failing to collect the maximum amount of DNA or cells present. Further, in the case of fabric items that may harbor DNA from more than one source, certain collection methods might be advantageous in helping to avoid retrieving mixed DNA samples while still recovering as much DNA as possible.

Common crime laboratory methods for collecting DNA from fabrics include swabbing, tape-lifts, or cutting out an area likely to have come into contact with an individual. The general effectiveness of swabbing has been studied in some detail, usually examining the type of swab used and how best to apply it to a surface. Direct comparisons of tape-lifts and swabs have been made, but generally only utilized saliva as the DNA source. Finally, objective comparison of either swabbing or tape-lifts to cuttings has not been conducted, even though forensic scientists often use the latter technique.

In this study, the three standard methods for collecting contact DNA from clothing were compared. Volunteers wore items such as t-shirts for a prescribed amount of time, and contact DNA was collected from selected areas of the item (e.g., collar or shoulder seams) using swabbing, tape-lifts, or cuttings. Next, separately swabbing or tape lifting the inside and outside of clothing was compared to see if DNA yields varied substantially. Finally, the t-shirts were purposely contacted by more than one volunteer to simulate evidentiary samples that may contain mixed DNA; for example, the inside and outside of a shirt where the arm/sleeve of the wearer had been grabbed. For comparative DNA isolation effectiveness, equally sized segments of fabric were tested using cotton swabs wetted with digestion buffer (containing 0.1% SDS) and rolled over an area of the fabric, tape-lifts applied until the tape was saturated with fabric and/or no longer adhered, or cuttings placed directly into digestion buffer. A standard organic extraction was used to purify the DNA, and yields were quantified using real time PCR, followed by STR analysis.

In general, significantly more cells/DNA were retrieved via cutting and soaking the fabrics than from swabbing or tape-lifts, although the cutting and soaking method tended to result in additional mixed profiles. More DNA was obtained when swabbing the inside versus the outside of the fabric, while there was no difference in DNA yields when tape-lifts were taken from inside or outside of the item. In spite of this, the frequency of mixtures between swabs and tape lifts was similar. All STR profiles generated from fabric samples that contained 200 pg/ml or more of DNA (optimal DNA input) resulted in callable alleles at least 13 loci. Over 80% of the samples that produced 100 pg/ml or more of DNA showed allelic activity at each locus, although approximately 60% of those contained alleles foreign to the wearer (one or more loci with three alleles). Close to 80% of the samples that contained 30 pg/ml or more of DNA (minimum input of 135 pg of DNA) had allelic activity at each locus, but approximately 50% contained alleles foreign to the wearer. Finally, samples with less that 30 pg/ml provided little information, with few or no loci containing callable alleles. The results indicate that although increased DNA yield enhances allelic activity, it may hinder the ability to identify individuals owing to the presence of additional alleles in the STR profile. Considering the totality of the results, careful consideration needs to taken when deciding on a method for cell retrieval from fabric based items.

DNA, Collection Methods, Fabric Items

A78 Optimizing Extraction Techniques for the Retrieval of DNA From Evidence Swabs

Michael S. Adamowicz, PhD, University of New Haven, Department of Forensic Science, 300 Boston Post Road, West Haven, CT 06516; Dominique M. Stasulli, and Emily M. Sobestanovich, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; and Todd W. Bille, MS, Bureau of Alcohol Tobacco Firearms and Explosives, National Laboratory Center, 6000 Ammendale Road, Ammendale, MD 20705*

After attending this presentation, attendees will have a better understanding of the possible benefits of potential modifications to the QIAamp® DNA Investigator Kit protocol when used to extract DNA from cells collected on cotton swabs. The methods evaluated include a variety of simple modifications to the manufacturer's "Surface and Buccal Swab" protocol.

This presentation will impact the forensic science community by providing experimental evidence demonstrating that some alterations to the manufacturer's extraction protocol can yield enhanced recovery of DNA from cotton swabs, while others provided no increase in yield or show decreased yield as compared to the published kit protocol. This study may suggest potential changes to extraction protocols that laboratories may implement in order to increase the yield of their DNA samples collected on cotton swabs.

Samples for DNA analysis are often collected from a wide variety of objects using cotton tipped swabs. However, the question remains: are all of the collected cells being released from the cotton fibers of the swab? With the advent of increasingly sensitive STR kits, more and more samples are being submitted for DNA analysis which have small quantities of DNA present, degraded DNA present, or both. Samples such as firearms and other handled objects fall into this category and have become items commonly submitted to forensic DNA laboratories. When processing these types of samples the recovery of the maximum amount of available DNA becomes critical, potentially dictating whether or not a usable profile can be derived for a piece of evidence.

The QIAamp® DNA Investigator Kit is a rapid and effective extraction tool for forensic samples. It can be used to process a wide variety of evidentiary materials and requires relatively little handling of the samples as compared to a phenol/chloroform/isoamyl alcohol DNA extraction. Using the standard protocol as a baseline, the following parameters were altered: incubation time, incubation temperature, stationary incubation,

physical disruption of the swab tip during incubation, and periodic re-suspension of the swab tip during incubation. Each of these conditions was performed as single variable experiments, as well as following up with extractions performed with a combination of conditions. All of the experiments were performed on cotton swabs which had either 10µl of liquid blood or 20µl of a buccal cell suspension dried onto them. All of the experiments were, at a minimum, performed in duplicate with both blood and buccal cells. Blank control swabs were also extracted for all conditions. Equivalent volumes of liquid blood and buccal cell suspension were also extracted in order to assess the retention of DNA on the cotton swabs. The concentration of DNA in each extract was quantified using the Applied Biosystems Quantifiler® Human DNA kit, and approximately one ng of extracted DNA was amplified with the Applied Biosystems AmpFl STR® Identifiler® Kit in order to assess the quality of the extracted DNA. Results indicate that up to 50% of the recoverable DNA may be retained on the cotton swab tip for both blood and buccal cells when using the standard extraction protocol. Stationary incubations performed poorly, with DNA yields falling significantly from those samples that were processed in a thermomixer. Incubation times of 18 or 24 hours showed no gain in the recovered quantities of DNA, and more often yielded less DNA that was of poorer quality. Some modest gains in yield were achieved with a three hour incubation coupled with an increase in temperature to 65°C with buccal cells. Physical disruption of the swabs was also no more effective than the standard protocol done with mixing. However, significant increases in DNA yields were observed using the swab re-suspension method for both blood and buccal cells, bringing the amount of recovered DNA close to the values observed for liquid samples.

In summary, while many alterations to the manufacturer's protocol were examined, only the swab re-suspension technique has shown significant gains in DNA yield to this point. These gains do appear to be substantial though, and further experiments will refine this technique to better enable forensic analysts to maximize the recovery of DNA from evidentiary swabs.

DNA, Cotton Swab, Extraction

A79 An Investigation of Trace DNA in Binding Materials and Clothing on Decedents in Simulated Crime Scenes

Michael A. Donley, MS, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Jonathan Lai, BSc, 1400 Washington Avenue, Albany, NY 12222-0100; and Roger Kahn, PhD, and Rhonda C. Williams, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to provide a comparison of different methods used for the collection of trace DNA from a perpetrator left on a decedent at a crime scene.

This presentation will impact the forensic science community by increasing the recovery of trace DNA from a perpetrator from a variety of materials encountered on a decedent at a crime scene.

A low level of skin cells is transferred to an object by contact with skin. This is useful in criminal cases when a perpetrator touches an object. Small numbers of cells containing DNA are transferred to the objects that can be collected as evidence. In death investigations, such items are routinely removed in the morgue and then submitted to the DNA laboratory for analysis.

The transportation of the decedent from the crime scene to the morgue may cause loss of trace DNA. In death investigations when the decedent is bound or the body has been moved, or if there is evidence of blunt force or multiple sharp force traumas, the Harris County Institute of Forensic Sciences will dispatch a Trace Evidence Collection Team to collect DNA or other trace evidence from the decedent at the crime scene. The Team will collect samples directly from the body and from materials binding or otherwise on the body. In this study, volunteers simulated crime scene scenarios where DNA was transferred onto a variety of materials that might be found on a decedent such as clothing, rope, duct tape and zip ties. Each material has different properties that might require different methods of collection to obtain the highest yield of perpetrator DNA from the item. The goal of this investigation was to determine and establish the best way to collect the perpetrator's trace DNA from various materials on deceased individuals at a crime scene.

The initial study focused on testing several solvents and techniques to collect trace DNA from binding materials such as rope, duct tape, and zip ties, and also to collect exogenous DNA from the victim's sleeve and arm. A single swab method and a double swabbing method were tested. The solvents tested were sterile water and 1% Sodium Dodecyl Sulfate (SDS) detergent.

The average yield of DNA was determined for each collection technique. The double swabbing technique with SDS detergent yielded 1.40ng of total DNA compared to the double swabbing technique with water which yielded 1.21ng of total DNA. The single swab technique with water yielded 0.59ng of total DNA. On average, single swabbing techniques yielded less DNA than double swab techniques.

The second phase in this study was to compare different techniques to the swabbing method for the collection of trace DNA. The techniques consisted of using tape lifts, dissolvable tape lifts, and taking cuttings from the items for recovering trace DNA. The study indicates that for zip-ties and duct tape, taking a cutting from the item obtained the highest yield of DNA. Double swabbing yielded the highest amount of perpetrator's DNA from sleeves. Tape lifts obtain the highest yield of DNA from skin and rope. Further data concerning each method, the quality of the profiles obtained, and recommendations for the collection of trace DNA on decedents will be provided.

Trace DNA, Binding Materials, Crime Scene Collection

A80 Comparison DNA Preservation Buffers for Low Quantity DNA 4°C Storage

Yuexun Liu, MD, Office of the Chief Medical Examiner of New York City, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016; Tatiana L. Gallardo, BS, 59-21 Cooper Avenue, Glendale, NY 11385; Adele A. Mitchell, PhD, Office of Chief Medical Examiner of New York City, 421 East 26th Street, Box 13-69, New York, NY 10016; and Mechthild K. Prinz, PhD, and Theresa A. Caragine, PhD, Office of the Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016*

After attending this presentation, attendees will have a better understanding of the DNA preservation capability of several commonly used buffers for DNA storage at 4°C.

This presentation will impact the forensic science community by assisting other laboratories in selecting the optimal DNA preservation buffer for short term storage at 4°C.

The amount of DNA recovered from some forensic evidence samples such as those from handled items is usually very low. Following extraction, DNA samples are typically stored at 4°C for a few days and sometimes a few weeks until completion of the testing process, and then transferred to a -80°C freezer for long term storage. Protecting DNA from potential loss or degradation during this period is critically important in order to obtain as much information as possible for genetic profiling. For this reason, it is necessary to evaluate the DNA preservation performance of buffers commonly used for 4°C wet storage.

Historically, forensic DNA has been suspended or eluted in water, 0.1xTE or 1xTE with or without additional reagents. For this study, two reagents, trehalose and fish sperm DNA, were considered. Trehalose is considered a very effective DNA protection agent in the dry condition. Fish sperm DNA is sometimes used as carrier DNA to enhance DNA recovery from a Microcon™ purification column. The following ten different DNA

buffers were evaluated: water, 0.1xTE, 1xTE; 15ng/µl fish sperm DNA in water, 0.1xTE or 1xTE; 10% trehalose in water, 0.1xTE, or 1xTE, and 15ng/µl fish sperm DNA in 10% trehalose with 0.1xTE. Human blood was extracted with the Qiagen MagAttract kit and diluted with each of the ten different buffers to a final concentration of 10pg/µl or less. Six replicates for each condition for six different time points were stored for up to 15 weeks at 4°C. Six replicates of DNA stored in 0.1xTE buffer alone were also stored at -80°C for each of six time points as a control. For each time point, DNA was measured with an in-house Alu based qPCR system.

Results from this study show a significant difference in the amount of DNA recovered from the various buffers used. Un-buffered DNA in water degraded quickly; however, the addition of fish sperm DNA increased the yield. Fish sperm also enhanced the performance of 0.1X TE buffer alone. Similarly, 10% trehalose was not effective when dissolved in water, but DNA was preserved better when trehalose was dissolved in 0.1xTE and 1xTE. With both fish sperm DNA and trehalose, 0.1xTE outperformed 1xTE. In order to investigate the difference between 0.1xTE and 1xTE, the affect of extra EDTA on qPCR was explored. Although qPCR was slightly inhibited with 1xTE, this effect cannot account for the dramatic difference between the two stored buffers.

Interestingly, there was no significant difference among the top performing buffers, 0.1xTE with 10% trehalose and/or 15ng/µl fish sperm DNA. More DNA was recovered from all of these buffers than from the controls stored in 0.1xTE alone at -80°C. This study proved that DNA preservation buffers have significant impact on the DNA recovery of low amounts of DNA stored at 4°C for even only a few weeks. Since it is critical to select optimal DNA preservation buffers to ensure the robust downstream genotyping, additional studies are in progress to examine the effect of these buffers on long term storage in both the wet and dry conditions.

DNA Preservation, Trehalose, TE

A81 Renewed Efforts to Identify the Victims of the World Trade Center Disaster via DNA Testing

Taylor M. Dickerson, MS, Carl Gajewski, MS, Asako Ishii, MS, Mark A. Desire, MS, JD, and Mechthild K. Prinz, PhD, Office Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016*

After attending this presentation, attendees will summarize the DNA testing efforts used to identify the victims of the World Trade Center disaster with a focus on the work that has been performed since 2006. Anyone attending this presentation will learn about the more recent techniques in DNA analysis used in the identification effort.

This presentation will impact the forensic science community by explaining how DNA testing is used to identify the victims of a large scale mass fatality event.

On September 11, 2001, 2,753 people died in the attack on the World Trade Center (WTC). Approximately 20,000 separate human remains were recovered initially from the site dubbed "Ground Zero," indicating an extreme level of remains fragmentation. New York City's Office of Chief Medical Examiner (OCME) was responsible for not only identifying each victim, but identifying every human remain that was recovered. DNA testing was crucial in the identification effort. Three DNA technologies, short tandem repeat (STR), mitochondrial, and single nucleotide polymorphisms (SNPs), were employed to aid in the identifications. As of October 2005, 1,597 victims and 10,904 remains were positively identified. Ninety percent of the remains were identified with DNA testing alone which suggested any future identifications would likely result from improved DNA technologies. By the end of 2005, such improvements began to take shape. The Bode Technology Group offered its optimized bone extraction method which proved to be successful on the WTC samples. Also around this time, more human remains were discovered on the roof of the Deutsche Bank building adjacent to Ground Zero. New phases in both the recovery and identification of the victims had begun. The renewed recovery effort included searching of additional roof tops in the Ground Zero vicinity and systematic excavation underneath previously paved over access roads. The excavated material was searched for biological remains by using large sifting platforms. The resulting samples varied in size but were generally small and severely compromised. In order to maximize the success rate for this sample type, the OCME Department of Forensic Biology validated the Applied Biosystems' MiniFiler™ kit and adopted the optimized bone extraction method. Overall, a number of methods have been employed to help identify more of the WTC missing persons. Aside from STR testing with the MiniFiler™ kit, there was also retesting of victims' reference samples, and enhanced data interpretation with Cybergenetics' TrueAllele® system. Also, the OCME has incorporated the optimized bone extraction into a high throughput sample flow for retesting of previously collected remains. Most of the new DNA results lead to piece to piece associations rather than finding new identifications. As of July 2011, 1,631 victims and 12,810 remains have been identified; 9,007 remains are still unidentified.

World Trade Center, Mass Fatality, Victim Identification

A82 Pyrosequencing Analysis of DNA Labeled Security Ink

Marie Allen, PhD, Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, 751 85, SWEDEN; and Martina Nilsson, PhD, Stockholm County Police, Forensic Unit, Stockholm, 106 75, SWEDEN*

After attending this presentation, attendees will have learned about the possibilities to analyze DNA from bank notes stained with ink and DNA using a rapid extraction method, a PCR, and then a pyrosequenicng assay. The pyrosequencing will reveal the unique DNA tag connected to a specific lot of bank notes or cassette. The analysis procedure, results, deciphering for control samples, and case work samples will be discussed. The use of DNA labeling for other items of value as art, perfume, clothing, and documents will also be discussed.

This presentation will impact the forensic science community by providing information regarding security labeling and the required DNA analysis to identify labeled items. This is of great value for labeling of cash-in-transit by incorporation of a unique DNA tag into the ink. As robberies of cash-in-transit are common in Sweden, this system will impact the handling of these cases and potentially prevent robberies. These issues will be discussed in more detail.

It is important to have systems and methods for security marking and protection of valuable property regardless of the material. Security marking is especially interesting when it comes to cash in transit and ATM machines where vast amounts of money are often handled. One method is to stain the money with either ink dye or dye and smoke. A further step is to add unique synthetic DNA tags that are invisible to the eye. DNA-tagged stolen money can then be traced back to its original location. This system is well developed and is already used in many countries in Europe.

Trace Tag, Inc. has developed the unique tags as well as an assay for analysis of the tags. The DNA tags consist of short synthetic oligonucleotides with a specific section for analysis purpose, and a variable section providing the unique tag sequence. Since there are billions of codes available it enables a unique link between a stained item and a security box, owner, or ATM machine. Moreover, the tags are totally invisible, cannot be replicated or counterfeited and can only be analyzed in authorized laboratories. These features allow analysis of individual bank notes that can be performed rapidly to assist the law enforcement in robbery investigations.

The analysis procedure is robust and user friendly. In short, the DNA tag is extracted from the note, the extract is amplified using PCR, and the

short DNA sequences are determined by pyrosequencing technology. Pyrosequencing is a fast and easy to use sequencing by synthesis method that can run up to 96-samples in less than an hour. The method was first developed for high throughput SNP analysis, but is also suitable for medium throughput SNP typing or sequencing of shorter stretches of DNA. Pyrosequencing technology has previously been utilized successfully for mtDNA sequencing and autosomal STR- and Y-STR analysis of forensic samples in our laboratory. The pyrosequencing data from the DNA-tagged material from each bank note is sent to Trace Tag International (TTI) in UK, where a database is used for identification of the unique code and the serial number of the sequence. The code is thereafter submitted to 3SI security systems, in Belgium, which identifies the customer (bank, security company, or others), the location, and the installation of the unique DNA tag.

Successful analyses of unique DNA tags by pyrosequencing analysis, and the subsequent identification through TTI and 3SI, show that tracing bank notes back to specific cash in transit boxes or ATM machines and their staining device is an efficient way to conquer crime. This labeling system and identification assay will thus provide an asset to overall security and has the potential to be applicable on a larger scale in a near future. The system can also be applied for invisible labeling of a large variety of additional items of value such as paintings, brand clothing, passports, documents, perfume, and much more. This will allow increased security in general and possibly prevent crimes. In addition to the possibility to actively trace valuable items or cash back to owners or banks, the information about DNA labeling can deter attacks, e.g., cash in transit vehicles.

Security Research, DNA Analysis, Pyrosequencing

A83 Who Needs Gold?

Kaylie M. Slaughter, BS, Pennsylvania State University, 632A Oakwood Avenue, State College, PA 16803*

The goal of this presentation is to explore the capabilities of various polymerases to overcome inhibition and generate short tandem repeat (STR) profiles from degraded, low template DNA samples encountered in forensic cases. Nuclear DNA extracted from evidence, which has been exposed to adverse environment conditions, may be degraded and the amount obtained may be lower than necessary for obtaining complete STR profiles. This research investigates a combination of extraction methods, various enzymes, and amplification protocols which can overcome the difficulties associated with amplification of low amounts of degraded DNA which may also contain inhibitors.

This presentation will impact the forensic science community by offering other options regarding enzymes used in polymerase chain reaction (PCR). Use of these enzymes and optimal amplification conditions can yield high quality human DNA profiles from low amounts of degraded DNA which may also contain inhibitors.

Forensic scientists are constantly looking for ways to attain complete human DNA profiles from less than ideal biological samples, particularly from low template DNA. DNA extracted from items of evidence which have been subjected to adverse environmental conditions can be degraded or inhibited in a way that could negatively impact the PCR reactions. Scientists in the past have changed amplification conditions in order to increase PCR efficiency which is crucial to the success of DNA analysis.

Cigarette butts retrieved from crime scenes are sometimes less than ideal forensic evidence. Temperature, humidity, and soil are some of the factors which can cause degradation of biological fluid deposited on cigarette butts. Tar and nicotine, a few of the components of cigarettes, can also act as inhibitors, as can humic acid in soil. The concentrations of these ingredients can adversely affect the amplification process. In addition, saliva deposited on cigarette butts that have been exposed to detrimental environmental conditions may yield lower than optimal amounts of DNA. DNA extracted from these items is also often degraded and contains inhibitors. Amplification of low template, degraded DNA can result in allelic dropouts, peak imbalance, and low intensity peaks.

This research explores the use of various polymerases during the amplification process of low template, degraded DNA samples which may also contain inhibitors. Although AmpliTaq Gold® is the polymerase of choice for obtaining human DNA STR profiles from forensic samples; there are other enzymes available in the scientific community. This study uses various polymerases and optimal amplification conditions to increase the efficiency and specificity of the PCR reaction, which in turn can yield better quality DNA profiles from low amounts of degraded or inhibited evidence samples.

The first part of this study focuses on amplification with polymerases other than the commonly used AmpliTaq Gold® polymerase to determine if other enzymes can yield similar or better STR profiles from an optimal amount of DNA which is neither degraded nor contains possible inhibitors. The second part of the study is conducted with DNA extracted from environmentally insulted cigarettes butts. This includes depositing known amounts of saliva from various donors on cigarette butts, exposing them to a range of temperatures, submerging the cigarette butts in water and burying them in soil. These conditions are carried out over varying lengths of time. Various extraction procedures are used and the amplification conditions, including the amount of enzymes, are optimized to obtain high quality STR profiles.

Complete DNA profiles were obtained using 0.1ng of uncompromised DNA and AmpliTaq Gold®, Ex Taq™, and Diamond Taq™ polymerases. Although all alleles were present, some of the alleles were below threshold parameters when 0.1ng of DNA was amplified with DFS Taq polymerase. Attempts to amplify 1.0ng or lower amounts of uncompromised DNA with Titanium® Taq and PrimeSTAR® HS DNA polymerases yielded either partial profiles or no profiles. Amplification parameters for these reactions were as recommended by the manufacturer of the kit used in this research.

While some of the compromised cigarette butts yielded full STR profiles, most extracts gave partial profiles when the recommended parameters of the amplification kit and the AmpliTaq Gold®, Ex Taq™, and Diamond Taq™ polymerases were used. When extraction procedures and amplification parameters, including the enzyme concentration, were optimized, more of the compromised DNA extracts yielded complete STR profiles.

This study indicates that by employing polymerases not commonly used in analyzing forensic evidence, analysts could potentially produce human STR profiles from low template, degraded DNA which may also contain inhibitors.

Polymerase, Inhibition, Degradation

A84 Multiplex Amplification of Deletion/Insertion Polymorphisms: A New Kit on the Block

Kaylie M. Slaughter, BS, Pennsylvania State University, 632A Oakwood Avenue, State College, PA 16803*

The goal of this presentation is to detect deletion/insertion polymorphisms from evidence samples which have been subjected to various adverse environmental conditions. Nuclear DNA extracted from these compromised body fluids can often be degraded and low in amount. Extracted DNA samples may also contain substances that inhibit polymerase chain reaction (PCR) used for the amplification of genomic DNA. Short tandem repeats (STRs), due to their high discriminatory power, is currently the method of choice for human identification. However, detection of STR loci requires large fragments of nuclear DNA, and commercially available kits used to detect STR loci from forensic samples do not always yield complete profile from degraded or inhibited samples. This research discusses a combination of the extraction methods and short deletion/ insertion polymorphisms (DIPS or Indels) which can help analysts acquire additional information from body fluids different from that obtained with only the STR amplification kits.

This presentation will impact the forensic science community by introducing deletion and insertion polymorphisms that can be derived from

degraded and inhibited evidence samples. Currently, forensic community uses STR profile from genomic DNA for identity. Addition of the deletion and insertion polymorphisms along with the sex determining locus, Amelogenin, would greatly enhance the capabilities of the scientists and help them obtain more genetic information from compromised samples.

Forensic scientists are constantly looking for ways to obtain complete DNA profiles from less than ideal biological samples. Some of the procedures to achieve this are to use different types of extraction techniques and more sensitive amplification kits. Saliva samples deposited on cigarette butts easily become less than ideal biological samples due to the environment where cigarette butts are often discarded during the commission of a crime. Temperature, humidity, and soil are only some of the factors which can hasten the process of degradation. Amplification of these types of samples may show allelic dropouts, peak imbalance, and low intensity peaks.

Tar and nicotine, some of the components of cigarettes themselves, can act as inhibitors. The concentrations of these ingredients can also adversely affect the amplification process. In addition, saliva samples deposited on cigarette butts that are exposed to detrimental environmental conditions may yield lower than optimal amounts of DNA, and the DNA in these extracts may be degraded and/or contain inhibitors.

One of the ways to improve DNA amplification when faced with degraded and inhibited samples is to change the size of the desired amplicons. The Investigator DIPplex kit takes advantage of short amplicons which are more likely to be amplified in degraded DNA samples. The short amplicons in this kit makes the DIPplex kit an ideal vehicle for analyzing degraded forensic samples such as body fluids deposited on cigarettes and then exposed to various adverse environmental conditions.

DNA from cigarettes butts, exposed to unfavorable environmental conditions, was extracted with various techniques and subjected to amplification using commercially available kits for detection of short tandem repeat polymorphisms. The same extracts were also amplified using the DIPplex kit in order to detect deletions/insertions in the genomic DNA.

Although the STR polymorphism and deletion/insertion polymorphisms cannot be directly compared, an assessment of the profiles can be easily made. It is concluded that the DIPplex kit is a highly sensitive and useful tool when amplifying degraded DNA samples. This assay can yield more identifying information from degraded samples than using only STR amplification. A combination of STR amplification and the deletion/insertion polymorphisms would give the forensic analysts more capabilities to analyze compromised samples.

STR, Insertion/Deletion, Polymorphisms

A85 Identification and Secondary Structure Analysis of a Region Affecting Electrophoretic Mobility of the STR Locus SE33

Julio J. Mulero, PhD, Dennis Wang, PhD, and Robert Lagace, BS, Life Technologies, 850 Lincoln Centre Drive, Mail Stop 404-1, Foster City, CA 94404; Nicola Oldroyd, BS, Life Technologies, Applied Biosystems, 850 Lincoln Centre Drive, Foster City, CA 94404; and Lori K. Hennessy, PhD, Life Technologies, 850 Lincoln Centre Drive, MS404-1, Foster City, CA 94404*

After attending this presentation, attendees will understand the difficulties in designing suitable primer binding sequences to amplify the SE33 locus due to a highly polymorphic region outside of the repeat region which, if amplified, affects the electrophoretic mobility of the amplification product.

This presentation will impact the forensic science community because the SE33 locus is listed among the highly recommended loci to be included as part of the expanded CODIS core loci and because of the expectation that this locus will increase international compatibility to assist law enforcement data sharing efforts.[1]

Concordance between new and existing STR kits is of paramount importance when querying historical data stored on National DNA Databases or when sharing information across international borders. As such, one of the most important aspects of any multiplex STR development project is a comprehensive investigation into the impact any changes to existing primer sequences may have on comparison of new and existing results. SE33 is one of the most informative markers in forensic use due to its high power of discrimination. During the course of developing a multiplex STR kit several SE33 primer designs were screened with one primer pair yielding a high frequency of discordant alleles when compared to the AmpFlSTR® SEfiler Plus™ PCR Amplification Kit. This discordance was mostly specific to samples of African descent with an estimated frequency of 5.1% and was a result of a mobility shift of approximately +0.84nt. The sequence analysis of the affected alleles revealed that the only difference from the wild type sequence was a SNP outside of the SE33 repeat but within the amplicon of this particular set of experimental primers. In total, three different SNPs were all within 9nt of each other, each of which could cause the mobility shift individually. A computer model generated with the Mfold software predicted a region of secondary structure that encompassed the SNPs. This secondary structure was a stem-loop structure and the SNPs affecting the electrophoretic mobility of the amplicon fell within the stem portion of the structure. In order to characterize this region further the wild type SE33 sequence region was cloned into plasmid DNA. Site directed mutagenesis on this DNA revealed that mutations within the stem portion affected the mobility of the amplicon whereas mutations introduced immediately outside or within the loop portion of the stem-loop structure did not affect the mobility of the amplicon. Thermostability measurements using an oligonucleotide containing either the wild type sequence or sequences containing each one of the three SNPs demonstrated that the oligonucleotides containing the SNPs had significantly lower Tms when compared to the wild type sequence. These experiments strongly suggest that the polymorphic region contains a secondary structure that, when disrupted due to the presence of a variant SNP, results in mobility shift relative to the wild type sequence. To overcome this problem, the SE33 primers used in the final configuration of the multiplex STR kit avoided the amplification of this polymorphic region yielding in turn results highly concordant with the SEfiler Plus™ Kit.

SE33, Stem-Loop, STR

A86 Proximity Ligation RT-PCR (PLiRT-PCR) for the Forensic Detection of Spermatozoa

Michelle A. Peck, BS, Forensic Science Department, Somers Hall, 2100 Foxhall Road Northwest, Washington, DC 20007; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road Northwest, Washington, DC 20007*

After attending this presentation, attendees will understand the protein detection method of proximity ligation real-time PCR (PLiRT-PCR) and how this assay could be used for the forensic detection of spermatozoa.

This presentation will impact the forensic science community by offering a potential alternative to microscopic identification of spermatozoa. PLiRT-PCR is an inexpensive, sensitive, fast, and amenable to automation technology that could contribute to the reduction of sexual assault backlog. The reproducible sensitivity of this assay could also promote the extension of the time since intercourse collection interval to support the advancements in DNA typing.

Identification of seminal fluid from sexual assault evidence is standard practice in forensic biology laboratories, though procedures for processing these samples may vary. Generally, for the presumptive indication of semen, practitioners use an alternate light source as an enhancement tool

followed by testing for Seminal Acid Phosphatase. If positive, the next step may be to test for Prostate Specific Antigen (PSA/p30) with commercially available immunochromatography kits. PSA has been identified at very low levels in other body fluids, thus a positive PSA result may not be considered by all practitioners to be confirmatory for seminal fluid. The only undisputable confirmatory test for the presence of semen is the microscopic observation of spermatozoa.

However, microscopic observation of spermatozoa can be extremely time-consuming. Automated sperm searcher systems decrease the time spent on a single sample; still, these systems can only process samples one at a time. Furthermore, the cost of fluorescent microscopes and automated sperm searching technology is a large financial commitment for a laboratory.

Sexual assault samples are a large contributor to the backlog that many laboratories face. The time, cost, and limited automation capabilities of microscopic observation limit the reduction in this backlog. Forensic laboratories would greatly benefit from the implementation of a faster, cost effective, and amenable to automation method for the identification of spermatozoa. PLiRT-PCR has the potential to be the technology that meets these needs.

PLiRT-PCR is a molecular assay that enables detection and quantitation of a target protein. Using antibody probes that are specific for the target, a representative DNA molecule that can be detected by real-time PCR (RT-PCR) is generated if the antigen is present. The amount of signal from this surrogate amplicon is indicative of the amount of protein in the sample. It is a powerful and highly sensitive assay that combines the specificity of an immunological reaction with the sensitivity of PCR. If a protein only present on spermatozoa could be successfully targeted with PLiRT-PCR, it could serve as a confirmatory assay for the presence of sperm.

Several additional aspects make the PLiRT-PCR assay compatible with forensic laboratories. First, thermocyclers and RT-PCR machines are commonly found in crime laboratories and thus would not be an added cost. Also, PLiRT-PCR minimizes sample consumption as it is sensitive down to femtomolar ranges. Finally, PLiRT-PCR minimizes the chances of sample switching and has the potential to be fully automated and incorporated into a robotic platform because there is only one tube transfer during the whole procedure, which occurs just prior to the final RT-PCR step.

As a proof of concept study, and to evaluate its potential for forensic use, a PLiRT-PCR assay for PSA was developed. Results showed that the PLiRT-PCR assay was able to detect PSA in a 1:5,000,000 dilution of a one year old semen sample. In contrast, 1:10,000 dilutions of this sample yielded negative results with a commonly used forensic immunochromatographic PSA test. Low levels of PSA were also detected in saliva and blood samples with the PLiRT-PCR assay, though this is expected due to the sensitivity of the assay. This presentation will discuss the proof of concept study and the preliminary results obtained with a PLiRT-PCR assay targeting a potential semen specific protein. Sensitivity, specificity, and time necessary for the assay will be addressed. A molecular method for the detection of semen could far surpass the capabilities of microscopic detection in terms of sensitivity, speed, cost, and automation.

Spermatozoa, Sexual Assault, PLiRT-PCR

A87 Investigations on the Use of Tissue-Specific MicroRNA Markers to Determine the Wound-of-Origin of Bloodstains

Donald J. Johnson, MS, California State University Los Angeles, School of Criminalistics, 5151 State University Drive, Los Angeles, CA 90032; Cheryl Andersen, MS, Los Angeles County Sheriff's Department, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032; Katherine A. Scriven, MS, 423 North Monterey Street, Apartment B, Alhambra, CA 91801; Amberly Klein, MS, California State University Los Angeles, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032; and Cindy Carroll, PhD, Los Angeles County Sheriff's Department, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032*

After attending this presentation, attendees will have an understanding of the limitations of bloodstain pattern interpretation in certain case circumstances and the potential use of tissue-specific microRNA assays to determine the relationship of discovered bloodstains to the homicide under investigation.

This presentation will impact the forensic science community by revealing a new approach to correlate bloodstains with injuries. The method offers a way to test suspects' alibis which cannot be accomplished with current methods. The presentation will additionally impact the forensic science community by demonstrating that molecular markers can provide information on the circumstances surrounding a crime.

The body of a homicide victim is oftentimes removed from the primary scene by the perpetrator and disposed of elsewhere. The location of the murder then becomes an important fact to establish in the investigation. Knowing where the murder took place can assist investigators in identifying suspects. Murders often result in significant bloodshed which can allow investigators to establish the location of the murder based on bloodstain pattern interpretation. However, the circumstances of other homicide cases are such that little blood is shed or even discovered due to the nature of the injuries or the act of cleaning by the perpetrator. Additionally, the suspected murder scene is often a place where the victim is known to have a history of physical activities—sometimes the suspected murder scene is the victim's residence. These circumstances can complicate investigations; because if small amounts victim's blood are found at the victim's residence or at a place where the victim visits, then the question becomes whether the bloodstains are related to the homicide or the result of some prior accidental injury. Unfortunately, current forensic methods used to correlate bloodstains with injuries are greatly limited when dealing with trace amounts of blood or bloodstains that have uninformative patterns.

However, in several cases the authors have been able to correlate bloodstains with particular wounds based on the cellular composition of the stains. In each of these cases, the victim's injury was a fatal gunshot wound to the head, and the body was found at a site away from where the homicide was thought to have occurred. However, several bloodstains from the victim were discovered at the defendant's house which was the suspected homicide scene. The defendant stated the blood was unrelated to the murder—the victim had previously cut his finger as a result of an accident. The size, shape, and distribution of the bloodstains were consistent with the defendant's alibi. However, each of the bloodstains contained visible pieces of tissues. These tissues were sectioned and stained for histological examination and were identified microscopically as brain. The presence of brain tissue in each of the bloodstains indicated the blood was shed as a result of head trauma. The finding refuted the defendant's alibi and was pivotal in the resolution of the case. Unfortunately, the finding of discernible pieces of tissue in bloodstains is rare. However, the authors hypothesized that trace quantities of wound-track cells are present in evidentiary bloodstains. However, the minute quantity of cells would render the histological approach impractical. The detection of these cells requires a method that is sensitive and specific. Sensitivity and specificity are properties of current forensic DNA typing methods; therefore, this

research investigated a molecular approach to correlate bloodstains with injuries.

The developed a PCR-based technique to detect trace amounts of wound cells in bloodstains is reported. In this proof-of-concept study, the laboratory rat was used as a model to investigate the use of tissue-specific micro-Ribonucleic Acid (miRNA) markers to distinguish bloodstains originating from different wounds. Specifically, the miRNA species, Rn_miR-124a_1, as a marker for rat brain tissue was studied. The basic procedure for the miRNA assay consisted of the following steps: (1) extraction of total miRNA from simulated head wound bloodstains using a rat blood brain mixtures using QIAGEN's miRNeasy mini kit; (2) synthesis of cDNA from miRNA with QIAGEN miScript Reverse Transciptase Mix; (3) amplification of the target miR124a-1 with Taq polymerase and oligonucleotide primers from QIAGEN miScript Universal Primer, and miScript Primer Assay; and, (4) identification of the miR124a-1 cDNA using the QuantiTect SYBR Green PCR Master mix fluorescence detection with the Rotor-Gene Q Real-Time PCR Detection System.

Preliminary studies included the optimization of the detection assay and the evaluation of the specificity of the marker. Additionally, a procedure for the collection of bloodstains for use by this assay, and the stability of the marker under different environmental conditions was examined. Proof-of-principle was achieved by the ability to distinguish bloodstains produced by a gunshot wound to the head versus bloodstains produced by a gunshot wound to the chest with use of the assay. This research illustrates that molecular markers can reveal information about the circumstances surrounding the deposition of biological evidence. This research stems from limitations encountered with current forensic methods, and the use of this approach may enhance the successful resolution of forensic investigations and the administration of justice.

Tissue-Specific MicroRNA, Bloodstains, Wounds

A88 A Multichannel Microdevice for Rapid Forensic DNA Analysis

Brian Root, PhD, MicroLab Diagnostics, 705D Dale Avenue, Charlottesville, VA 22903; Kristin Hagan, PhD, and Carmen R. Reedy, PhD, University of Virginia, 705D Dale Avenue, Charlottesville, VA 22903; Jessica V. Norris, PhD, ZyGEM-MicroLab Diagnostics, 705D Dale Avenue, Charlottesville, VA 22903; Michael Egan, BS, Lockheed Martin Corporation, 9211 Corporate Boulevard, Rockville, MD 20850; Robert Lovaglio, BS, and Orion Scott, PhD, ZyGEM-MicroLab Diagnostics, 705D Dale Avenue, Charlottesville, VA 22903; Douglas South, ME, Peter Trost, PhD, and Darren Albert, BS, Lockheed Martin Corporation, 9211 Corporate Boulevard, Rockville, MD 20850; Joan M. Bienvenue, PhD, 8801 General Griffins Court, Fredericksburg, VA 22407; and James P. Landers, PhD, University of Virginia, Department of Chemistry, McCormick Road, Charlottesville, VA 22904*

After attending this presentation, attendees will understand the development and functionality of a system developed for integrated microfluidic forensic DNA analysis.

This presentation will impact the forensic science community by demonstrating the advantages of using a microfluidic system for DNA analysis, including reductions in analysis time, sample and reagent volumes needed and concurrent time reduction that could impact processing of future forensic DNA samples.

STR typing is the accepted gold standard for human identification and is now successfully employed in forensic, civil, and military laboratories. Although highly successful and reliable, the process typically requires 8-10 hours to complete under routine conditions, employs large sample volumes, costly reagents, and is labor-intensive. Additionally, samples are susceptible to contamination as they are exposed to the environment at multiple points during sample processing. Transitioning sample processing and analytical methods to the microscale format will permit automation, miniaturization, and integration providing the end user a system capable of expedited, cost-effective analysis in a closed system that reduces sample handling and possible contamination.

Previously, a system capable of fully-automated processing and analysis of STR loci directly from buccal swab samples was presented. The system utilized a single, integrated glass microfluidic chip, and encompassed liquid DNA purification, PCR amplification, and electrophoretic separation and detection of STR loci. Although capable of detecting 16 loci in under 75 minutes, the techniques involved were not sufficiently robust for field analysis and only allowed for analysis of one sample at a time, warranting improvements to the system. Additionally, the microchip substrate was made from glass using standard microfabrication methods which are cost-ineffective from a mass production perspective.

The work presented here highlights improvements to the integrated system. The transition to plastic microchips for multiplexed integrated STR analysis is described, allowing for more cost-effective, single-use (disposable) chips. With the improved system, expedited purification of DNA from crude samples is performed and a mixture of DNA and PCR reagents (commercially-based) are guided into chambers on a device capable of multiplexed analysis for PCR. Rapid amplification of 16-18 STR loci is achieved through use of an IR laser for non-contact heating and a non-contact method for temperature sensing. A six-fold reduction from conventional amplification time is demonstrated while still achieving STR profile quality required for forensic interpretation. Simultaneous amplification of multiple samples in the multichannel microdevice will be presented, demonstrating the capability for increasing sample throughput. Following PCR, precise fluidic control allows for movement of the amplified product into the separation domain of the device. Electrophoretic separation of the amplified fragments is performed with five-color fluorescence detection using an improved detection system capable of multiplexed detection. Single-base resolution is achieved during a separation that consumes <12 minutes, a three-fold time reduction from conventional separation and detection processes. A software analysis system, interfacing between the raw data output and the interpretable profile, allows for automated and accurate allele calling of samples processed using the integrated system from multiple donors. An overview of the functionality of the integrated instrument capable of accepting the multichannel microfluidic device will be presented, with data supporting the capability of the microfluidic system for rapid, automated, end-to-end genetic analysis for human identification.

DNA, STR, Microfluidics

A89 Development of a Novel Human Mitochondrial DNA (mtDNA) Amplification Method for Use With Illumina® Next-Generation Sequencing Instrumentation

Brittania J. Bintz, MS, Western Carolina University, 111 Memorial Drive, NSB #231, Cullowhee, NC 28723; Mark R. Wilson, PhD, Western Carolina University, Forensic Science, Department of Chemistry/Physics, Cullowhee, NC 28723; Brandon C. Smith, BS, and Groves B. Dixon, BS, Western Carolina University, 111 Memorial Drive, NSB #231, Cullowhee, NC 28723*

After attending this presentation, attendees will gain understanding of the current methods used for library preparation using the Illumina® next-generation sequencing (NGS) platform. Additionally, attendees will learn of a novel method, developed in our laboratory, which enables researchers to bypass the recommended laborious and costly Illumina® library preparation method. This novel method allows researchers to utilize PCR to generate amplicons that can be sequenced directly. A high-fidelity TaKaRa™ enzyme with proofreading activity is used so that DNA is amplified accurately and efficiently. Data will be presented that illustrates

the advantages of using TaKaRa™ versus a traditional polymerase enzyme such as Applied Biosystems® AmpliTaq Gold®.

This presentation will impact the forensic science community in terms of mtDNA sequence analysis. It is apparent that the field is moving in the direction of employing next-generation sequencing technologies for forensic mtDNA analysis. However, these techniques are often expensive, and laborious. A method to increase the efficiency and cost effectiveness of the Illumina® next-generation sequencing workflow, enabling the technology to be used more readily in the forensic laboratory has been developed. Laboratories wishing to adopt this novel method will no longer need to prepare libraries for sequencing by fragmenting gDNA, repairing ends and adding A overhang, ligating adapters and selecting for high quality DNA of interest. This method incorporates Illumina® adapters into the amplicons during PCR. Laboratories that are not quite ready to adopt next-generation sequencing technologies can still benefit from this amplification strategy. The TaKaRa™ high-fidelity enzyme produces significantly higher concentrations of amplicons during PCR of both pristine and compromised sample types than Applied Biosystems® AmpliTaq Gold® DNA polymerase. Use of the TaKaRa™ enzyme may enable laboratories to obtain mtDNA sequence data from difficult samples when AmpliTaq® Gold does not produce results.

Challenging forensic DNA samples, including bones and hair, often contain DNA that is degraded and/or is present in very low amounts. In order to obtain a reliable DNA profile, mitochondrial DNA (mtDNA) analysis is often utilized on these sample types. Studies employing newly emerging DNA sequencing technologies have been designed to interrogate amplified targets down to the single molecule level. While these technologies are capable of producing large quantities of usable sequencing data, they are laborious and peripheral instrumentation can be costly. For example, typical library preparation for the Illumina® GA_{IIx} platform includes DNA fragmentation (often using an expensive Covaris® DNA shearing instrument), end repair and addition of a single A overhang, adapter ligation and DNA selection. Additionally, multiplexing experiments that maximize the use of flow cell space require an expensive Paired-End Module (PEM) fluidics system coupled to the Illumina® $GAII_X$. The novel method was developed using forensically relevant sample types for human mtDNA amplicon generation for single-read DNA sequencing on the Illumina® $GA_{IIx,}$ which enables laboratories to obtain next-generation sequencing data using familiar protocols without the additional instrumentation described above. This method includes traditional PCR amplification of target DNA with TaKaRa™ high-fidelity DNA polymerase with 3' à 5' exonuclease proofreading activity. A high-fidelity enzyme was chosen in order to reduce misincorporation of bases during amplification which may have an impact on NGS sequencing results downstream. Flow cell adapter sequences and multiplexing index tags are included on the 5' end of the mtDNA hypervariable (HV) region-specific primers and are incorporated into the amplicon during PCR. Specifically, the amplification primers were designed with multiplexing tags directly 5' of the target specific primer sequence so that resulting sequences can be parsed by tag using Sequencher® software that contains a specific parsing algorithm. This amplification strategy produces equal or higher concentrations of amplicons than the current protocol employed in forensic laboratories. Further, these amplicons can also be sequenced using Sanger methods without any apparent hindrance from the extended primer sequences. Thus, this method enables forensic laboratories to adopt one mtDNA amplification protocol for multiple downstream sequencing technologies. Additionally, this library preparation proves to be more efficient and more cost effective than methods recommended by Illumina®.

Sequencing, MtDNA, Amplification

A90 Method Development for Analyzing SNPs Associated With Stature

Rebecca M. Berlin, MS, 5620 Shadow Ridge Drive, Castro Valley, CA 94552; Jessica Barker, MS, 8400 Oldham Court, Williamsburg, VA 23188; Jacqueline T. Thomas, MS, 700 North 5th Street, Richmond, VA 23219; Bonnie L. Brown, PhD, Virginia Commonwealth University, Department of Biology, 1000 West Cary Street, Richmond, VA 23284-2012; Edward Boone, PhD, Virginia Commonwealth University, 1020 West Main Street, Richmond, VA 23284; and Tracey Dawson-Cruz, PhD, Virginia Commonwealth University, 1000 West Cary Street, PO Box 842012, Richmond, VA 23284*

The goal of this presentation is to demonstrate to attendees how SNPs (Single Nucleotide Polymorphism) can be analyzed to predict stature using biological evidence.

This presentation will impact the forensic science community by demonstrating that long bones are no longer needed to predict stature, instead more commonly seen biological evidence samples have the potential to be analyzed to predict stature.

The field of forensic molecular photofitting provides methods for the prediction of physical characteristics by the analysis of associated genetic markers. The prediction of physical characteristics presents scientists with the opportunity to provide investigators with reliable investigative leads and may prevent innocent people from being convicted. Several genetic markers for physical characteristics have already been thoroughly researched by the forensic community including ethnicity, red hair color, and eye color; however, researchers have been less successful with characteristics including stature, body weight, hair color (other than red), and age. Researchers have identified many potential genetic markers associated with stature; however, only limited populations studies have been performed to determine if a true correlation is noted between genotype and adult stature. To provide a predictive range from samples of unknown origin, the additive effect of multiple genetic markers related to stature needs to be evaluated. This study aimed to develop and evaluate a method that could be easily adapted by forensic DNA laboratories that is designed to specifically detect single nucleotide polymorphisms (SNPs) known to have a strong association with adult stature. The SNPs focused on in this study included two confirmed variants associated with stature, rs1042725 within HMGA2 and rs6060369 within GDF5, as well as two other variants found in regions or hotspots within the genome that have been associated with stature, PTCH1 (rs10512248) and BMP2 (rs967417). The SNaPshot Multiplex Kit, a primer based single-extension assay which analyzes up to ten SNPs in one reaction, was used to analyze HMGA2, GDF5, PTCH1 and BMP2. The method development using the SNaPshot Multiplex Kit involved designing and optimizing general primers and SNaPshot primers for HMGA2, GDF5, PTCH1, and BMP2. A sensitivity study was then performed to determine the optimal input of template DNA and to compare the full and reduced volume SNaPshot reaction. Following the method development, the PTCH1 and BMP2 height associated SNPs were successfully incorporated into a SNaPshot assay. The optimal input of template DNA for BMP2 was found to be 2.0ng for both the full and reduced volume SNaPshot reaction while PTCH1 had an optimal input of template DNA of 1.0-1.5ng for the full volume reaction and 2.0ng for the reduced volume reaction. All subsequent reactions were performed using the 2.0ng input of template DNA with the reduced volume SNaPshot reaction. Additionally, the data produced from a stature test pilot study of both males and females ranging from 196-149cm implicated the A allele as the height increasing allele for the PTCH1 SNP rs10512248, which was previously unknown. Lastly, the combined predictive power of only PTCH1 and BMP2 successfully predicted height from known samples with an error rate of 10.05cm. With the analysis of additional SNPs associated with stature, the combined predictive power of SNPs has the potential to produce an error rate similar to, if not better than, the current gold standard anthropological methods for height estimation. The availability of this type of assay for height prediction would eliminate the need for long bone and

extend the application for height prediction to more commonly analyzed biological evidence samples including saliva, semen, and blood.

Molecular Photofitting, Stature, Single Nucleotide Polymorphism

A91 Internal Validation of a Real-Time Quantitative Polymerase Chain Reaction Assay for Human Mitochondrial DNA

Marc L. Sprouse, BS, University North Texas, Health Science Center, 3500 Camp Bowie Boulevard, EAD 1-310, Fort Worth, TX 76107; Mark F. Kavlick, BS, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Nicole Phillips, MS, University of North Texas, 3500 Camp Bowie Boulevard, Room 310, Fort Worth, TX 76107; and Rhonda K. Roby, PhD, University of North Texas, Center for Human Identification, 3500 Camp Bowie Boulevard, Room 310, Fort Worth, TX 76107*

The goal of this presentation is to inform the attendees of an internal validation performed on a human mtDNA real-time quantitative PCR assay at the University of North Texas Center for Human Identification. Attendees will gain a practical working knowledge of the assay's design, chemistry and performance. In addition, attendees will learn of this assay's potential for improving the work-flow efficiency and success rate of mtDNA sequence analysis.

This presentation will impact the forensic science community by exploring ways in improving human mtDNA sequence analysis.

An internal validation was performed on a human mitochondrial DNA (mtDNA) real-time quantitative PCR (qPCR) assay following standard 8.3 of the "Quality Assurance Standards for Forensic DNA Testing Laboratories." The purpose of this internal validation was to demonstrate that the developed method performed as expected and is suitable to be used at the University of North Texas Center for Human Identification (UNTCHI). The internal validation studies conducted include: (1) precision and reproducibility; (2) sensitivity; (3) inhibition: and, (4) known and non-probative evidence samples. Data collected from 18 separate qPCR runs demonstrate this assay has a high degree of precision and reproducibility evidenced by consistent cycle threshold values of the quantification standards and controls. The mtDNA target in the lowest quantification standard was detected in each experiment indicating the assay's sensitivity of detection is extremely low at 0.0001 pg/µL or approximately six human mtDNA copies per microliter. The assay successfully produced results at various levels of template mtDNA when challenged with various concentrations of three different PCR inhibiting compounds. Finally, reportable mtDNA sequence data were obtained for forensic casework sample types, including whole blood and skeletal remains, which had been tested with the human mtDNA qPCR assay. The successful completion of this validation study demonstrates the suitability of the human mtDNA qPCR assay for use in forensic casework and identification of human remains. Using this assay can assist an analyst in determining: if a sample contains sufficient human mtDNA to proceed with downstream sequence analysis; the amount of sample to be used for mtDNA amplification; and, if a sample with inhibitors requires dilution or additional purification measures.

The University of North Texas Center for Human Identification is an accredited laboratory which performs nuclear and mitochondrial DNA analysis. MtDNA sequence analysis is especially useful for challenging samples, such as telogen hairs, teeth, and older skeletal remains where the amount of genetic material and its quality vary greatly and often fail to produce nuclear DNA typing results. Implementation of a sensitive quantitative assay for mtDNA will improve work-flow efficiency and increase success rate of these sample types. The amount of mtDNA used for amplification and the quantity of amplified product for sequencing is critical for obtaining high quality data. Too much product added to the cycle sequencing reaction results in noisy data and too little product generates low sequence signal. With an optimal amount of product added to the cycle sequencing assay, clean data are obtained. High quality sequence data which exhibits good signal intensity and very little baseline noise is critical for efficient interpretation of data and high throughput sequence analysis. Additionally, if an optimal amount of DNA is added to the amplification reaction, then downstream cycle sequencing procedures can be standardized. Using an optimized quantity of mtDNA in front-end amplification reactions for sequence analysis also preserves precious sample extract. This facilitates judicious use of the amount of sample extract consumed which is a principal concern when analyzing forensic samples. Although several methods have been developed to quantify DNA, real-time quantitative PCR (qPCR) assays offer great advantages such as a high degree of specificity, sensitivity and precision.

Quantitative PCR, Mitochondrial DNA, Internal Validation

A92 Advanced Forensic Sample Analysis Utilizing Genome Wide Identification: Complex Mixtures and Copy Number Variants

Kevin C. McElfresh, PhD, Casework Genetics, 13580 Groupe Drive, Suite 301, Woodbridge, VA 22192*

After attending this presentation, attendees will have a better understanding of SNP analysis of complex mixtures and the interpretation methods associated with forensic casework. Attendees will also have a basic understanding of the comparison of STR and SNP technology as it pertains to complex mixtures.

The presentation will impact the forensic science community by providing insight and understanding of the uses of Human Genome technology.

Ultra High Density Single Nucleotide Polymorphism arrays (UHDSNP) routinely used in Genome Wide Association Studies (GWAS) are now capable of analyzing from one million to over five million loci. The net effect of this analytical capability is the effective sequencing of the molecular differences in the human genome thus providing direct assay of the genetic differences between samples. GWAS analyze the SNPs on the autosomes, the SNPs on the X, Y and mitochondrial genomes, as well as the Copy Number Variant (cnv) loci, all in a single reaction and scan. The biggest advantage in adapting GWAS to Genome Wide Identification (GWID™) is the analysis of complex mixtures. In single-source match vs. non-match, GWID over analyzes the samples since the molecular differences are distinct. However, as the quality of the sample and/or the amount of sample decreases or the number of contributors increases, or both, the molecular complexity quickly outstrips the analytical capabilities of systems in which the results are based on secondary measures of actual molecular differences (capillary electrophoresis based sieving methods, i.e., STRs). The UHDSNP system in use at Casework Genetics (Illumina Omni1-Quad): assays 27 SNPs in the mtDNA genome, 139 cnv loci and 2,184 SNP loci on the Y chromosome, as well as 2,738 cnv loci and 24,756 loci unique to the X chromosome in addition to > 900,000 autosomal loci generating >1.1 million sequence points. The principle metric of GWID mixture analysis is the sum of the B allele frequency differences between the samples compared, providing a measurement of genetic similarity or dissimilarity between samples. The smaller the difference in the B allele frequencies, the more genetically similar the samples are. DNA from a series of test samples was initially analyzed as single source material using GWID. DNA from these samples was then used to create mixtures of two or more individuals, analyzed using autosomal GWID, and then re-analyzed using the autosomal and Y chromosome cnv loci. Scatter plots of these data correlate with the results of the autosomal data and provide additional insight into the analysis of complex mixtures. In this study, the samples for mixtures were also reanalyzed and compared to possible contributors from other studies by reassembling the manifest files and initiating a new analysis file. Table 1 provides representative data. Note

that a two person mixture can be included or excluded as being a subset of a three person mixture.

Comparison	Σ *f* B allele Differences
Buccal Swab : Semen (single source match)	16,804
Buccal Swab : Semen (single source exclusion)	255,148
Suspect : Victim + Semen Mixture (2 person mix exclusion)	177,806
Suspect : Victim + Semen Mixture (2 person mix inclusion)	39,149
2 Person Mixture : 3 Person Mixture (exclusion)	121,029
2 Person Mixture : 3 person Mixture (inclusion)	13,751

Table 1. B allele frequency differences between mixed and non-mixed samples.

The scatter plots of all cnv loci, with the Y chromosome cnv SNPs highlighted, mirror the results from Table 1, especially with regard to the analysis of mixtures within mixtures. Figures 1 and 2 are representative of this comparison. The red points are the cnv loci on the Y chromosome. These results will be discussed in light of their application to cases in which challenging samples were processed.

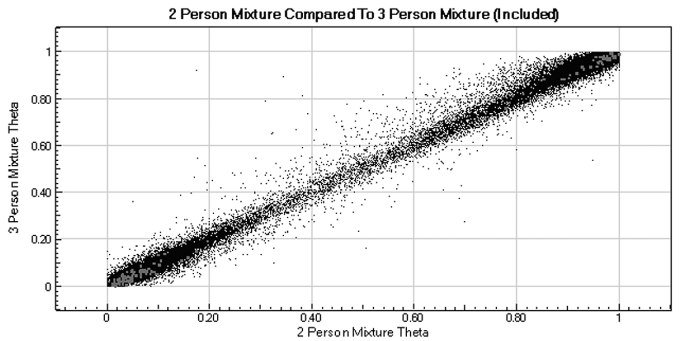

Figure 1. 2 Person Mixture Compared to 3 Person Mixture (Included).

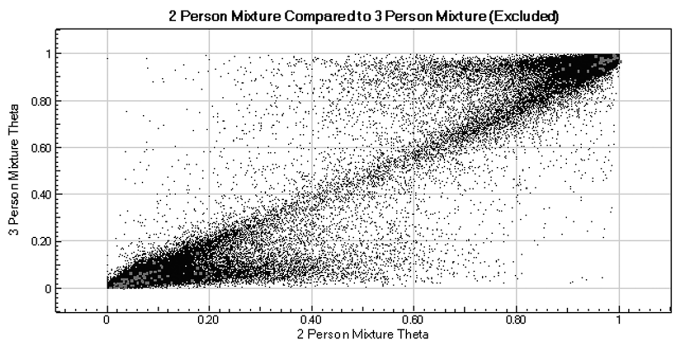

Figure 2. 2 Person Mixture Compared to 3 Person Mixture (Excluded).

SNPs, Complex Mixtures, Array Technology

A93 Development of a Single Mitochondrial DNA Amplification Strategy for Two Platforms: Next Generation and Sanger Sequencing From the Same Amplicon Library

Groves B. Dixon, BS, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will have learned the basics of how the Roche GS Junior works, the benefits of such an instrument, and how it may be incorporated into forensic casework.

This presentation will impact the forensic science community by demonstrating the applicability of this new and promising technology for forensic casework.

When forensic samples contain limited or degraded nuclear DNA, mitochondrial DNA (mtDNA) analysis is a valuable substitute for short tandem repeat (STR) genotyping.[1] Drawbacks to mtDNA analysis include inferior statistical strength compared with STR genotyping and interpretational challenges associated with rapid mutation rate and tendency toward heteroplasmy of the mitochondrial genome.[2] Heteroplasmy describes the presence of two or more unique mtDNA types within a single individual, tissue, cell, or mitochondrion.[3] Researchers now consider both length heteroplasmy (mixtures of mtDNA types that differ by indel mutations) and sequence heteroplasmy (mixtures that differ by substitutions) as expectations, rather than exceptions in mtDNA analyses.[4] The pattern of variation of heteroplasmy in the mitochondrial genome is still a matter of debate, making interpretation of similar but distinct mtDNA sequence data of particular difficulty to forensic technicians.[1,5,6]

Massively parallel sequencing (MPS) (also called Next Generation Sequencing, or NGS) technologies have the potential to generate orders of magnitude more sequence data than traditional Sanger sequencing at a competitive cost per base pair sequenced.[7] MPS platforms make use of spatially separated independent sequencing reactions of clonally amplified single molecules. This allows for the generation of thousands of independent sequence reads.[8] Thus, MPS allows greater breadth (the proportion of the genome that is sequenced) and depth (the number of independent sequencing reads taken of each nucleotide position in a region of interest) of sequence data.[2]

To improve the statistical strength and interpretational issues of mtDNA analysis, researchers recommend establishing a profile of the frequencies with which point heteroplasmy occurs at each nucleotide position and expanding the breadth of the mitochondrial molecule that is examined.[9-12] Because they enable significantly higher throughput and sensitivity than traditional Sanger sequencing methods, MPS technologies hold great promise for each of these recommendations.

In this study, the utility of the 454 Roche GS Junior Titanium MPS platform for forensic applications was assessed. The objectives included: (1) to optimize a single amplification protocol that enables forensic crime laboratories to analyze mtDNA using both Roche 454 MPS and Sanger methods: and (2) to assess the ability of the instrument to detect low level variants in mixtures of mtDNA.

The DNA from hair, blood, and buccal samples from twenty individuals was extracted. From these, modified amplicon libraries for use on the Roche GS Junior were generated. Reference sequences for mtDNA hypervariable (HV) regions were obtained for each donor with Sanger sequencing using these modified libraries. Mixtures of mtDNA HV amplicons were prepared in ratios of 95% / 5%, 98% / 2%, and 99% / 1%. These mixtures were sequenced using 454 pyrosequencing technologies to assess the ability of the Roche GS Junior instrument to accurately detect minor variants of mixed mtDNA.

Modified amplicon libraries for an MPS platform can be sequenced using traditional Sanger sequencing. This protocol allows for selective use of a sequencing method based on the quality of the sample. Straightforward exclusions can be interpreted directly from Sanger sequence data; however, in cases where Sanger sequence data provides insufficient resolution for confident interpretation, the analyst can return to the same original amplified library for MPS. Low level variants at mixture ratios of 99% / 1% were detected using the Roche GS Junior. Additionally, an optimized a protocol that allows seamless inclusion of the technology into forensic crime laboratories using current mtDNA testing methodology was developed.

A94 Molecular "Eyewitness": Predicting Phenotype and Geographic Ancestry via SNPs Analysis for Forensic Applications

Katherine L. Butler, MS, 716 Otis Place Northwest, Washington, DC 20010; Michelle A. Peck, BS, 4004 47th Street Northwest, Apartment 1, Washington, DC 20016; Jessica A. Hart, BS, 1204 South Washington Street, Apartment 403W, Alexandria, VA 22314; Moses S. Schanfiled, PhD, The George Washington University, 2100 Foxhall Road Northwest, Washington, DC 20007; and Daniele S. Podini, PhD, The George Washington University, Department of Forensic Science, 2100 Foxhall Road Northwest, Washington, DC 20007*

After attending this presentation, attendees will be able to illustrate the potential for the prediction of physical traits and geographic ancestry of an individual using SNPs analysis.

This presentation will impact the forensic science community by understanding DNA analysis targeted at inferring the possible ancestral origin and phenotypic characteristics (i.e., hair color, skin color, and eye color) of the possible perpetrator could yield information valuable to the investigators.

Often an STR DNA profile obtained from crime scene evidence does not match identified suspects or profiles from available databases. In such cases, further DNA analyses targeted at inferring the ancestral origin and phenotypic characteristics (i.e., hair color, skin color, and eye color) of the possible perpetrator could yield valuable investigative information. Such a tool would aid in prioritizing suspect processing, corroborating witness testimony, determining the relevance of a piece of evidence to a crime, and ultimately increase the ability to identify individuals related to the crime scene. The completion of the Human Genome Project and the International HapMap Project have provided the scientific community with a repository of reference information for the human nuclear genome, and efforts such as the 1000 Genome Project continue adding to this wealth of data. Numerous SNPs have been identified as having alleles associated with certain populations and/or correlated to specific physical characteristics.

The method chosen to develop a SNP based assay for ancestry and phenotype prediction is the Single Base primer Extension (SBE). This technique allows for the simultaneous typing of over 30 SNPs. Once an assay is optimized, it is possible to obtain robust results over a broad range of both quality and quantity of genomic DNA template. The sensitivity is in the range of STRs (down to 300 pg) and the method utilizes the same Capillary Electrophoresis equipment typically available in Forensic DNA laboratories.

The SBE technology has been used to develop panels which include 100 ancestry and phenotype markers selected from recent literature. Over 270 DNA samples along with corresponding ancestry/ phenotype survey information, and spectrophotometric skin color data have been collected from anonymous volunteers of varying ethnicity, gender, and age. These DNA samples, along with additional samples of known ancestry (without phenotype data), have been screened with the SBE panels. The genotypes and corresponding known characteristics are being evaluated to assess the predictive value of the candidate SNPs with the goal of identifying the optimal panel of SNPs to efficiently assess an unknown individual's characteristics. Different statistical approaches are being evaluated for effective ancestry and physical trait inference. *STRUCTURE 2.3* is a population genetics and anthropology software package, based on Bayesian statistics, which was developed to analyze the genetic composition of individuals and populations. It can be used for various purposes including, but not limited to, assigning individuals to populations. While this software is powerful, other tools are being evaluated which are potentially more appropriate for estimating the phenotype and ancestry of a particular individual. These include analysis of molecular variance (AMOVA), multinomial logistic regression, and principle component analysis (PCA). The ideal statistical tool would allow for a more complex model that could appropriately incorporate the ancestry information contained within different types of markers such as mtDNA and the Y chromosome.

The final goal is the selection of the most informative ~ 30 SNPs that will be incorporated into a robust and sensitive SBE assay for ancestry and somatic trait prediction. This analytical tool, utilizing technology currently available in forensic DNA laboratories, could be implemented in a kit form and used on casework as needed. Preliminary results show good correlation between a small set of SNPs and eye color, making blue or brown (light versus dark) eyes highly predictable. Furthermore, PCA analysis shows clear separation between black and red hair, while dark brown, light brown and blond hair are more difficult to separate. Similar results have been obtained with skin pigmentation and ancestry, indicating that developing models for the prediction of skin and hair pigmentation together with ancestry will be a challenging process.

SNPs, Phenotype Prediction, Ancestry Prediction

A95 A Sensitive Multiplex PCR Based Next-Generation Sequencing Assay for Resolution of Mixtures and Analysis of Forensic Samples

Cassandra Calloway, PhD, Saloni Pasta, PhD, and Christina Parodi, BS, Children's Hospital Oakland Research Institute, 5700 Martin Luther King Jr Way, Oakland, CA 94609; and Henry Erlich, PhD, Roche Molecular Systems, 4300 Hacienda Drive, Pleasanton, CA 94588*

After attending this presentation, attendees will have a broader understanding of the 454 next-generation sequencing technology and the applications for forensic analysis, specifically for mtDNA mixture analysis.

This presentation will impact the forensic science community by providing an overview of a new, sensitive multiplex PCR assay for analysis of forensically relevant samples including mtDNA mixtures and heteroplasmy using the 454 Next-generation sequencing technology.

Next-generation sequencing (NGS) technologies have proven to be a powerful tool for research and clinical applications and have the potential to revolutionize forensic DNA analysis. NGS technologies offer a high-throughput solution for parallel sequencing of thousands to millions of sequences and can be used for de novo sequencing of small whole genomes or direct sequencing of DNA products generated by PCR. While several NGS technologies are available, the 454 sequencing technology appears to be the most suitable for forensic applications because it can directly sequence 400-500 bp amplicons. The 454 Genome Sequencer is a scalable, highly parallel pyrosequencing system that uses emulsion- based PCR for "clonal" amplification of single DNA sequences. The "clonal sequencing" aspect of this technology allows unambiguous allele resolution and provides for quantitative detection of variants present in less than 1% in a mixture. The 454 sequencing technology has been successfully used to analyze mixtures in clinical samples. Recently, the feasibility of 454 sequencing technology for analysis of mixed DNA samples similar to those encountered in forensic evidence has been demonstrated by sequencing mtDNA and nuclear STR markers. However, each marker was amplified in single-plex and significantly more DNA was required than is typically available in forensic cases. Thus, before this technology can be routinely used for analysis of forensic samples which are often limited and/or degraded, assays which require much less DNA need to be developed for use with NGS technology.

To greatly reduce the amount of DNA consumed for NGS, a multiplex PCR assay for parallel sequencing of mitochondrial and nuclear DNA markers which can be used for analysis of pooled forensic DNA samples has been developed. The use of a multiplex PCR assay for targeted resequencing of multiple mtDNA and STR markers is essential for forensic applications whereby DNA is often limited. Fusion primers containing unique multiplex identifiers (MID) are incorporated in the PCR primers containing target and 454-sequences and used to amplify individual samples for pooling and sequencing in a single run, thereby increasing sample throughput and reducing per run cost. The results from a sensitivity and mixture study demonstrating the utility of this NGS technology for analysis of forensic samples and the 454 sequencing data from heteroplasmic samples will be presented. Preliminary results show that the starting amount of DNA can be significantly reduced by using the multiplex PCR assay, similar to conventional forensic methods.

This multiplex PCR based NGS assay will allow the practitioner a start to finish method for sequencing mtDNA and nuclear STRs in a single run. This system can be used for the resolution of mixed or heteroplasmic samples commonly encountered in forensic cases and would therefore provide forensic laboratories with a more sensitive alternative to standard forensic assays.

Next Generation Sequencing, mtDNA, Mixtures and Heteroplasmy

A96 Extraction and Identification of Lifestyle Markers During Mitochondrial DNA Testing of Human Hair

Christina Rainey, BS, Indiana University-Purdue University Indianapolis, 402 North Blackford Street, LD 326, Indianapolis, IN 46202; and John V. Goodpaster, PhD, Indiana University-Purdue University Indianapolis, FIS Program, 402 North Blackford Street, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will learn a procedure for the chemical analysis of human hair for lifestyle markers using the discarded fractions from a protocol for mitochondrial DNA sequencing.

This presentation will impact the forensic science community by showing how the fields of microscopic, chemical, and genetic analysis of hair can interact and be used to determine lifestyle markers of questioned hair samples. This presentation will demonstrate how the gaps between the fields of forensic hair analysis can be bridged by adopting the theme of "One Biologist's Trash is Another Chemist's Treasure."

Forensic hair analysis can be divided into three main areas: microscopic exams, chemical analysis, and genetic analysis. Each of these areas is focused on its own particular questions and analytes, and as such, these areas have developed independently of each other with their own literature, procedures, and practitioners.

The research presented here bridges the gaps between the areas of forensic hair analysis by adopting a theme of "One biologist's trash is another chemist's treasure." Several methods by which discarded fractions from a typical protocol for mitochondrial DNA (mtDNA) sequencing can be subjected to chemical analysis and the results provide information about the lifestyle of the subject, including cosmetic modifications to the hair, use of tobacco, and demographic information such as age and gender. It is hypothesized that any small organic compounds incorporated into the hair (e.g., hair dye components, nicotine/cotinine, integral lipids) will be released and partition into the organic layer during liquid-liquid extractions.

In practice, forensic science laboratories recommend that appropriate hairs should be selected for nuclear DNA (nDNA) analysis during the microscopic examination of the hair. In order to be suitable for nDNA, the hair root must be present. Hairs removed while actively growing (anagen phase) are more likely to yield partial or full DNA profiles. Hairs naturally shed when the hair follicle is dormant (telogen phase) are less likely to yield DNA profiles. Given that many cases when the root of the hair is absent or nDNA is otherwise unavailable (such as in telogen hairs), mitochondrial DNA (mtDNA) analysis can be utilized.

The first phase of a multi-phase project is presented here. Each phase involves three main developmental steps: validation, scale down, and extrapolation. Using literature methods for analytes of interest, the methods have been recreated and shown to be reliable using known standards. The published methods have been scaled down to the level of a typical mtDNA analysis (2cm length of hair) and the methods were extended to yield successful results when explicitly applied to the discarded rinses, washes, and organic layers of a mtDNA protocol.

The first phase of this project is concerned with the discarded fraction from the first step of an mtDNA hair analysis protocol. It is hypothesized that in addition to any residues of mounting media, neutral surface components will be extracted in the xylene wash. This includes surface lipids such a free fatty acids, fatty esters, squalene, and cholesterol. Residues of hair care products such as conditioners and hair gels are also extracted.

The validation step of this project was conducted by creating a standard mixture of surface lipids and relevant components of hair care products in xylene. Large volume injection gas chromatography/mass spectrometry (GC/MS) was used to achieve baseline resolution of all components. Linearity and limits of detection for each standard were determined.

The scale down step was accomplished by ultra-sonicating milligram quantities of hair in xylene and analyzing the extract. Microgram quantities were then analyzed which correspond to single hair fragments whose length is on the order of centimeters.

The first phase of this analysis was extrapolated by ultra-sonicating and analyzing xylene extracts of 2cm hair segments. The xylene extract was analyzed by GC/MS using large volume injection in a programmed temperature vaporizer (PTV).

This procedure will open up new possibilities for information that can be obtained from a hair sample, to include factors such as age (youth versus adult), tobacco use, and hair dyes. These methods could be applied during a typical extraction protocol for mitochondrial DNA and would result in an unknown sample being more fully characterized, while a comparison of a questioned and known sample would be more probative.

Forensic Hair Analysis, Lifestyle Biomarkers, Mitochondrial DNA Sequencing of Hair

A97 Demonstrating the Efficacy of Ethylene Oxide Sterilization for the Reduction of DNA in Plastics Used for DNA Extraction

Lisa M. Calandro, MPH, Ryo Hasegawa, BS, John Dektar, PhD, Liwei Qi, MS, Harmandeep Gill, PhD, and Jason Liu, PhD, Life Technologies, 850 Lincoln Centre Drive, Foster City, CA 94404*

The goal of this presentation is to describe the comparison of various sterilization methods for their ability to reduce the presence of amplifiable human DNA contamination. Additional studies also evaluated the effects of post-production sterilization on downstream DNA analysis.

This presentation will impact the forensic science community by providing information regarding options for decreasing the risk of DNA contamination, addressing a critical need as DNA typing methods become increasingly more sensitive.

Over the past several years, DNA analysis methods have become increasingly more sensitive with regard to the detection of very low quantities of DNA. Concurrently, laboratories have implemented automated processes to enable higher throughput and increased efficiencies within the laboratory. Many laboratories have moved away from manual extraction methods such as phenol: chloroform extraction in favor of automated bench top or high throughput systems. These systems are favored as they minimize the interaction between the analyst and the sample, reducing the risk of DNA contamination by the operator and the likelihood of sample switching errors. However, this trend has increased the burden on manufacturers of forensic products to ensure that collection devices and system consumables are free of extraneous DNA. This was highlighted in the recent "Phantom of Heilbronn" case in which a female profile, later attributed to contaminated swab collectors, was detected in evidence from numerous serious crimes throughout Germany. A joint publication issued by the ENFSI, SWGDAM and BSAG organizations (*Forensic Science International*: Genetics 4 (2010) 269–270) highlights the need for controls in the manufacture of consumables used for DNA analysis in order to minimize the introduction of human DNA. A number of measures can be introduced at the manufacturing site including manufacturing in a clean room environment, implementing extensive personal protective equipment (PPE) and automating the filling and assembly lines. Additional benefits may be achieved through post-packaging sterilization as a final measure of extraneous DNA removal. A series of studies to evaluate the efficacy of various sterilization methods including gamma irradiation, ultraviolet, electron beam and ethylene oxide (EtO) sterilization for the removal of DNA from plastics used for DNA extraction have been performed. Ethylene oxide is a widely accepted gas phase sterilization technique in the medical industry for the elimination of viable micro-organisms from medical devices and has recently been demonstrated to effectively minimize the presence of amplifiable DNA. In order to evaluate these sterilization methods applicable samples were spiked with extracted DNA and cellular material to mimic conditions of contamination. The spiked samples were provided to various sterilization vendors for treatment and then compared to untreated samples. The efficacy of DNA removal was evaluated using real-time PCR and STR-based detection methods. The studies demonstrated significant reductions in contaminating DNA from samples spiked with extracted DNA or cellular material using dual-cycle ethylene oxide treatment. Gamma irradiation, ultraviolet and electron beam treatment were less effective at reducing the presence of contaminating DNA. Further studies were performed to determine whether the ethylene oxide treatment would result in any deleterious effects on downstream sample processing for samples extracted with EtO-treated plastics. Treated and untreated plastics were used to extract a range of sample types. The extracts were subjected to downstream processing with real-time PCR and STR-based detection methods. Among the comparisons made for data generated from treated and untreated plastics were an evaluation of DNA recovery, profile quality, overall peak height, intra-color balance and artifacts. Ethylene oxide treatment was demonstrated to significantly reduce the risk of human DNA contamination without detrimentally affecting downstream results.

Contamination, Sterilization, DNA

A98 The Effects of Ionizing Irradiation on Liquid, Dried, and Absorbed DNA Extracts With and Without Preservatives

Margaret C. Kline, MS, National Institute of Standards and Technology, 100 Bureau Drive, Building 227 Room B226, Mailstop 8314, Gaithersburg, MD 20899-8314; and James M. Puhl, BS, and Marc F. Desrosiers, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mailstop 8460, Gaithersburg, MD 20899-8460*

After attending this presentation, attendees will become familiar with the possible effects of ionizing irradiation on samples of DNA extracts that are shipped or stored in various tube types and absorbed on storage papers.

This presentation will impact the forensic science community by presenting data intended to assist in the decision process of storing DNA extracts at ambient temperatures.

The stability of extracted DNA samples has been and continues to be the subject of much discussion and research. Storage conditions for DNA extracts range from frozen to ambient with ambient storage being the "green" method of choice. In addition to storage methodologies, issues associated with the shipment of extracted DNA samples should be considered. After the events of September 11, 2001, the ways packages are handled during shipping and upon receipt have changed.

This study was designed to examine the effects of various shipping scenarios on extracted DNA samples at two different DNA concentrations: 2ng/µL and 200pg/µL. DNA samples were shipped as: liquid in tubes, dried in tubes, dried with a preservative in tubes, dried stains on FTA paper, and dried stains on 903 paper with or without a preservative used during the drying process. Three different storage tubes were tested: perfluoroalkoxy fluoropolymer (PFA), polypropylene, and medical-grade polypropylene. Control samples of all test materials were held at laboratory ambient temperature (≈ 21°C), and refrigerated at 2°C to 8°C. Sets of shipping test materials were exposed to one of the following scenarios: (1) high dosage X-ray irradiation; (2) commercial carrier from Gaithersburg MD to Quantico VA where they received low dose X-ray irradiation and were then returned by way of a commercial carrier to Gaithersburg MD; and, (3) commercial carrier from Gaithersburg MD to Seattle WA and back. All materials are being evaluated at NIST using qPCR quantitation and Short Tandem Repeat (STR) testing. STRs are first evaluated using commercial 16 loci genotyping kits; if the larger STR loci in these kits fail to yield results, samples are evaluated using a commercial "miniSTR" kit.

In scenario one, DNA packs were added to containers of mail and processed at an industrial facility using an x-ray beam generated with energy of 5 MeV and a beam current of 23 mA. The mail containers were either trays of letters or tubs of magazines. The trays and tubs were filled into large metal totes and passed through the x-ray beam four times to achieve the target dose level. The radiation exposure resulted in the packages experiencing temperatures exceeding 57°C for 20 min to 30 min. In scenarios two and three, packages were shipped at ambient in late April to early May 2011.

The effect on liquid DNA extracts in tubes varied widely, regardless of how they were treated. Even in ambient storage, the samples in medical-grade polypropylene tubes completely evaporated or were greatly reduced in volume. The other tube types were better at maintaining volume but all were completely dried by the high irradiation and/or temperature in scenario one. Because of this volume loss, all "liquid" samples are reconstituted to their original volumes prior to qPCR and genotyping. Full STR profiles were obtained with all ambient stored materials and the scenario two samples.

The results of direct amplification of the samples absorbed on either FTA or 903 papers were variable. Even in ambient storage, no full STR profiles were obtained with either paper at the low DNA concentration. FTA paper yielded partial profiles for the high DNA concentration samples at ambient storage whereas the 903 paper and 903 with preservative generally yielded full profiles.

Quite variable qPCR quantitation STR typing results have been obtained for the highly irradiated samples of scenario one. MiniSTRs yielded degraded profiles for some but not all of these samples, with typing results improving with increasing qPCR-estimated DNA quantity.

Short Tandem Repeats (STRS), DNA, Ionizing Irradiation

A99 Evaluation of Concordance, Sensitivity, STR Amplification Input, and a True Zero Value for the Qiagen Investigator™ Quantiplex Kit

Jacqueline T. Thomas, MSFS, 19012 Mountainview Drive, Cornelius, NC 28031; Rebecca M. Berlin, MS, 5620 Shadow Ridge Drive, Castro Valley, CA 94552; and Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1000 West Cary Street, PO Box 842012, Richmond, VA 23284*

After attending this presentation, attendees will understand the novel aspects of a new DNA quantitation kit, Qiagen's Investigator Quantiplex kit, and learn about the outcome of an internal validation as well as how effectively the kit was used as a predictive screening tool for STR amplification success in a data set with low yield DNA samples.

This presentation will impact the forensic science community by informing it of the evaluation of a novel quantitation kit in a forensic DNA research setting and its ability to predict STR amplification success with a set of low yield DNA samples, thus aiding laboratories who may be interested in implementing a new quantitation kit.

Qiagen's Investigator™ Quantiplex kit, a total human DNA quantitation kit, has a 200 base pair Internal Control, a fast cycling time relative to current forensically relevant quantitation kits utilized, and a novel scorpion molecule containing a primer, probe, fluorophore, and quencher covalently linked for an optimized interaction. In this study, the Investigator™ Quantiplex kit was compared to the Quantifiler™ Human kit for concordance, sensitivity, optimal DNA input for STR amplification reactions, and determination of a true zero value, a value under which no useful STR data is consistently obtained, thus reliably predicting STR failure. Full and half volume reactions were also evaluated with the Investigator™ Quantiplex kit. For this study, buccal swabs were extracted using the Qiagen QIAamp® DNA Blood Mini Kit, quantified with Quantifiler™ Human or Investigator™ Quantiplex kits, and amplified with the ABI AmpF*l*STR® Identifiler kit using a previously validated reduced volume reaction. Amplified samples were separated on the 3100*Avant* Genetic Analyzer with a default ten second injection and standard STR analysis parameters. Data were analyzed with GeneMapper® ID v.3.2 using an analytical threshold of 50 RFU. On average, Investigator™ Quantiplex quantitated samples 0.558ng/µl lower than Quantifiler™ Human, but standard deviations were large. When compared to previous studies conducted in the laboratory, Investigator™ Quantiplex is slightly more sensitive than Quantifiler™ Human, and preliminary data in this study suggests Investigator™ Quantiplex may be more robust to inhibitors. Four samples known to contain an inhibitor were undetected using the Quantifiler™ Human kit but were detected by the Investigator™ Quantiplex kit and exhibited quantitation values ranging from 0.043ng/µl to 0.461ng/µl. With the Investigator™ Quantiplex kit, the half volume reaction was found to be analogous to the full volume reaction based on consistency of data and the range of quantitation values detected. Optimal DNA input into reduced volume AmpF*l*STR® Identifiler amplification reactions was determined to be 2.0ng, as this was the only input with which average heterozygote peak heights were obtained within the desired 1000 – 1500 RFU range. Samples with 0.25ng input DNA or greater resulted in average peak heights above 200 RFU, a typical stochastic threshold, but substantial standard deviations were observed. Samples with DNA inputs of 0.05ng and 0.10ng exhibited average peak heights above the analytical threshold but below 200 RFU. Allelic dropout was first observed with samples under 0.5ng total DNA input and was more extensive with samples under 0.25ng total input. For the samples with a 0.25ng total DNA input, all allelic dropout was attributed to the same sample. No true zero value was identified in this study, but samples undetected with the Investigator™ Quantiplex were consistently unlikely to result in enough useful data for statistical calculations or upload into CODIS (two alleles and 0.82 complete loci above the analytical threshold on average). Of the undetected samples in the true zero study, 66% yielded no allele calls and 78% yielded only a single allele or none. The Investigator™ Quantiplex kit displays a number of advantages, including time and cost savings, high sensitivity, and potential robustness to inhibitors. Future work should include completion of a reproducibility study with the half versus full volume reactions, and testing of more low level and inhibited samples.

Investigator Quantiplex, STR Success, DNA Quantitation

A100 Development and Validation of a Multiplex qPCR System for Male and Total DNA Quantification

Yuexun Liu, MD, Office of Chief Medical Examiner of New York City, 421 East 26th Street, New York, NY 10016; Dimitra W. Zegos, MS, University of Amsterdam, Spui 21, 1012 WX Amsterdam, NETHERLANDS; Grace L. Axler-DiPerte, PhD*; and Troy Holder, MS, Office of Chief Medical Examiner of New York City, 421 East 26th Street, New York, NY 10016; Adele A. Mitchell, PhD, Office of Chief Medical Examiner of New York City, 421 East 26th Street, Box 13-69, New York, NY 10016; and Mechthild K. Prinz, PhD, and Theresa A. Caragine, PhD, Office of the Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016*

After attending this presentation, attendees will acquire information about the development and validation of a novel multiplex qPCR system simultaneously quantifying total genomic DNA and male human genomic DNA.

The presentation will impact the forensic science community by providing a new total genomic DNA and human male genomic DNA quantification method other than the ABI Quantifiler Duo DNA Quantification kit and Promega Plexor HY kit, assisting other labs in their determination of which kit will most likely fit their current system.

STR analysis, the core technology in DNA identification, requires a defined range of template quantities to produce optimal results. Quantification of both total human DNA and male human DNA in mixed forensic samples provides critical information for the selection of either autosomal or Y STR profiling, and to determine the quantity of extract to amplify. Two commercially available kits commonly used in forensic laboratories to simultaneously measure total and male human DNA are Plexor HY and Quantifiler Duo®. A recently published study compared the two kits in terms of precision, sensitivity and accuracy.[1] The results showed both systems produced linear estimates for DNA quantity over a broad range of input DNA. However, the study also indicated that the Plexor HY kit performed well with low level amounts of DNA, whereas the values for the ratios of total DNA to male DNA were far more accurate for Quantifiler Duo®. One of the most important reasons for the differences in performance between the commercial kits is the Y chromosome target. TSPY is a multi-copy number Y chromosome target used in the Plexor HY kit, with varying copy numbers from 23 to 64 among different populations of males.[2] SRY, used in the Quantifiler Duo® kit, is a single copy target with no copy number variation reported among males. Although increasing the copy number of a target enhances sensitivity, it also results in more variation.

A novel multiplex qPCR method to simultaneously measure total and male only DNA in a more sensitive and accurate manner will be presented. The multiplex qPCR system includes three amplification targets, one of which is located on an autosomal chromosome, and the others are found on the Y chromosome. Three TaqMan probes corresponding to the three targets are labeled with different fluorescence. One of the Y chromosome targets is a single copy gene which is used to quantify male DNA accurately when the male DNA concentration is higher than 16pg/µl. The other Y chromosome target is a multi-copy number gene which was shown to measure as little as 0.32 pg/µL of male DNA. The novel multiplex qPCR system was compared with the Quantifiler Duo® kit and Plexor HY kit regarding accuracy, sensitivity, and precision. Purposeful male and female DNA mixtures and mock evidence samples were measured using the novel Multiplex qPCR system, and the profiles generated with the determined DNA concentrations were assessed. Studies demonstrate that this system overcame the drawbacks of both of the Quantifiler Duo kit and Plexor HY kit as it is more sensitive that the Quantifiler Duo® kit and more accurate than the Plexor HY kit.

Male DNA, Genomic DNA, Quantification

A101 Measurement of a Stochastic Threshold and Development of a Reduced Volume Reaction for PowerPlex® 16 HS and Identifiler™ Plus

Joseph Ring, BS, 9531 Crown Court, Richmond, VA 23294; and Kelly R. Johnson, MS, Brad Jenkins, MS, and Susan Greenspoon, PhD, Virginia Department of Forensic Science, 700 North 5th Street, Richmond, VA 23219*

After attending this presentation, attendees will learn how establishing a stochastic threshold can affect the interpretation of DNA profiles for lower template quantity samples and the resulting statistical analysis. In addition, attendees will learn how stochastic thresholds compare between PowerPlex® 16 HS, Identifiler™ Plus, and PowerPlex® 16.

This presentation will impact the forensic science community by allowing analysts to be more confident in their interpretations of DNA profiles, thus differing stochastic thresholds for commonly used STR multiplex kits can affect both the useful data obtained for forensic samples and the statistical analysis performed. The information gleaned from this study may allow other forensic laboratories in the midst of developing stochastic thresholds to improve their DNA typing result quality.

Validating a stochastic threshold has been deemed necessary by SWGDAM for interpreting STR typing results. The stochastic threshold is the threshold at which the analyst can be confident that if one peak for a heterozygote is above this threshold, then its sister allele will be present and should be at least above the analytical threshold. This increases confidence in homozygous calls made for single source samples and alleles attributed to each contributor in mixture analysis. Promega and Applied Biosystems have released two STR amplification kits (PowerPlex® 16 HS and Identifiler™ Plus, respectively), which claim to improve upon the DNA typing results obtained with their previous kits. Specifically, these kits allege better heterozygous locus balance, which could mean a lower stochastic threshold. To test the validity of these claims, the stochastic threshold was defined for both kits and compared to the PowerPlex® 16 threshold defined previously by the Virginia Department of Forensic Science. The amplification parameters of half-volume reactions (12.5mL) for PowerPlex® 16 HS and Identifiler™ Plus were first modified to closely mimic full-volume (25.0mL) reactions since typically, reducing the PCR reaction volume greatly enhances sensitivity. A half-volume (12.5ml) reaction with one cycle removed (31 cycles) provided sensitivity with PowerPlex® 16 HS that was comparable to its full-volume reaction. A half-volume reaction with the standard cycle number (28 cycles) provided sensitivity with Identifiler™ Plus multiplex that was similar to its full volume reaction, which was surprising. Stochastic thresholds were determined using half-volume reaction conditions under three injection times for each kit: two, five, and ten seconds for PowerPlex® 16 HS and five, ten, and twenty seconds for Identifiler™ Plus. The stochastic thresholds established using PowerPlex® 16 HS were 180, 320, and 370 rfu for a two, five, and ten second injection, respectively. The stochastic thresholds established using Identifiler™ Plus were 200, 300 and 380 rfu for a five, ten and twenty second injection, respectively. All of the thresholds established were equal to or lower than those for the corresponding injection time using PowerPlex® 16. The average peak height ratios for all three kits were statistically similar. The stochastic threshold was applied to single-source and mixture mock case samples typed using each of the kits and the useful data obtained, both for interpretation and statistical analysis, compared.

PowerPlex® 16 HS, Identifiler™ Plus, Stochastic Threshold

A102 What's New on the Water Front

Peter J. Diaczuk, BS, and Dominick Bongiovi, BS, John Jay College of Criminal Justice and the CUNY Graduate Center, 445 West 59th Street, New York, NY 11019*

After attending this presentation, attendees will learn about the minimum depth of water necessary to allow a 9mm bullet to ricochet without touching the submerged substrate, and at what angle the bullet has departed the water as a factor of incident angle

This presentation will impact the forensic science community by revealing the dangers inherent in bullet ricochet off of water, will offer the calculation used to make this determination, and will examine the parameters necessary to have a successful water ricochet.

A bullet can ricochet off of many different surfaces. These surfaces may be categorized based upon how the bullet interacts with them. Hard surfaces traditionally remain intact after low angle bullet ricochet because they will not yield to the bullet's impact. Materials such as concrete, steel or automobile glass fall into this category. Bullet ricochets off of hard unyielding surfaces tend to have ricochet angles that are less than the incident angle. Soft surfaces will not remain intact, but instead will deform or deflect, yielding to the bullet's impact. Materials such as sand, gypsum wallboard, or water are examples of surfaces that fall into this category. Bullet ricochets off of relatively soft yielding surfaces tend to have ricochet angles that are greater than the incident angle. When a bullet is fired at either of these materials, there is an angle at which a ricochet will no longer occur, but instead the bullet will either break apart into fragments after hitting the surface, or it may remain intact, to either penetrate (imbed but not exit) or perforate (enter and exit) the material.

This research was a continuation from earlier work involving the study of 22 caliber bullets that were ricocheted off of water. It was discovered that 22 caliber bullets could successfully ricochet off water that was just under half the diameter of the bullet and still not come into contact with the floor of the water tank. This was counter-intuitive, as it was expected that at such a shallow depth, the bullet would scrape the floor of the tank leaving traces of that interaction behind, and that the bullet would take with it some of the paint from the tank's floor. Careful inspection of the tank's floor revealed that no such interaction between the two had taken place, which was confirmed by recovery of the bullets and microscopically examining them for transfer as well. The next obvious question was whether larger bullets, such as 9mm, could also ricochet off shallow water and not contact the floor of the tank.

The witness panel set-up was down range and was used to determine if the bullets were in stable or de-stable flight and to generate a measuring point for angle calculations. The same water tank from the 22 caliber work was used for these experiments. High-speed photography was used to aid in determining the location of bullet impacts to the water. Trigonometry was applied for the calculation of ricochet angle. Incident angle was recorded using an angle finder directly affixed to the barrel of the firearm. Using this method, the angle at which 9 millimeter full metal jacket bullets did not ricochet at all (the critical angle) was determined to be approximately eight degrees. At angles greater than eight degrees, the bullets entered the water and remained submerged. Shots were then fired at an incident of two degrees into the water tank. The water depth was incrementally lowered until the bullet finally scraped along the floor of the tank. Recovered bullets, examined microscopically, confirmed the interaction had taken place. Not until the water level was lowered to less than the diameter of the bullet (0.36 inches) did the bullet hit the tank floor when the incident angle was only two degrees.

Ricochet, Bullet, Water

A103 Statistical Firearm Correlation Analysis

Matthew J. Bohn, PhD, Analytic Services, Incorporated, 1330 Inverness Drive, Colorado Springs, CO 80910; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will learn about the mathematical techniques of auto- and cross-correlation as applied to images from tool marks, more specifically with the markings left on shell casings as they are ejected from a weapon. The correlations will be followed by a statistical analysis that can aid a forensic examiner in comparative analysis. This analysis will enable a quantitative score with confidence intervals when comparing images of tool marks.

This presentation will impact the forensic science community by demonstrating mathematical techniques to make quantifiable statements regarding the confidence of comparative analysis.

Cross-correlation is a mathematical technique that compares the similarity of two sets of data and is often used in pattern recognition algorithms. The cross-correlation is calculated by shifting one data set with respect to another, multiplying the two data sets and summing the result. The technique is insensitive to amplitude and background and is invariant under translation. Because of these features, the cross-correlation is a powerful technique that can be used to quantify the similarity of two samples. Once the similarity of the evidence is quantified, the data can be presented at court using statistics. Quantifiable comparative analysis will strengthen the evidence presented at trial because the evidence is not solely dependent on the opinion of the forensic examiner, but based on quantifiable statistical techniques. Ultimately a national database of shell casings and bullet rifling could be developed and searches made to find and make linkage between forensic evidence found at a crime scene and previously collected data.

A firearms examiner examined and recorded all of the data used in this experiment. First, the examiner observes a shell casing under 40x magnification and notices unique markings that can be exploited using cross-correlation. Several images of this area are recorded of this shell casing and of shell casings from a different weapon of the same make and model. Using a Graphical User Interface (GUI) developed in MatLab, the examiner selects the region of interest in the image. The region of interest is then cut out of the image and the color information is converted to grayscale. The grayscale image is then normalized with a zero mean. Typically, the examiner can accurately align the horizontal striations to the pixels in the image when the photograph is made; however, if any rotations are needed, they can be accomplished by the software. Since the striations are aligned horizontally, average pixel intensity is calculated for each row in the selected area. This reduces the dimension of the problem to 1-D; the average pixel brightness across the striations. A normalized cross-correlation can be calculated in order to compare the similarity of the striations. Normalization is a crucial step in comparing cross-correlations because it provides a means of calibrating one "yardstick" versus another — otherwise the comparisons would be meaningless. A useful method for normalizing the cross-correlation is to divide the cross-correlation by the square-root of the auto-correlations. The auto/cross-correlation between photos of the same shell casing should be nearly one; whereas the shell casings from different firearms are expected to have cross-correlations significantly less than one. A statistical significance can be determined by comparing the means of the correlations of the same shell casings versus the correlations of the different shell casings use a z-score and a student's t distribution, since there are few images to compare. The null hypothesis is the difference in the means of the correlations. A p-value can be calculated based on the means, standard deviations, and number of samples. The null hypothesis that the two data sets have the same means can then be either accepted or rejected based on a predetermined significance level.

Cross-Correlation, Firearms, Comparative Analysis

A104 The Application of UPLC/MS/MS to the Analysis of Smokeless Powders and Gunshot Residue Samples

Jennifer L. Greaux, BS, and Bruce R. McCord, PhD, Florida International University, Department of Chemistry, 11200 Southwest 8th Street, University Park, Miami, FL 33199; and Danielle R. Lincoln, 1000 Holt Avenue, Box 1770, Winter Park, FL 32789*

After attending this presentation, attendees will understand the fundamentals of ultra-high performance liquid chromatography coupled with tandem mass spectrometry, the advantages of these separation and detection techniques, and their forensic application to gunshot residue analysis.

This presentation will impact the forensic science community by providing an alternative method that is quick, reliable, and sensitive enough for analyzing GSR samples collected in cases involving firearms. The method can also be used as an investigative tool by law enforcement personnel when trying to identify shooting suspects, particularly in situations where inorganic primer residues are unavailable or missing.

Ultra-high performance liquid chromatography with tandem mass spectrometry (UPLC/MS/MS) is being proposed as an alternative technique for the analysis of gunshot residue (GSR) and smokeless powder samples. When a gun is fired the primer and smokeless powder in the cartridge combust forcing the bullet out of the weapon. A release of vapors and particulates are deposited onto the shooter's hands and clothing. Generally referred to as gunshot residue, these particulates contain a mixture of organic and inorganic compounds that can be collected and analyzed to determine whether or not a person has fired a weapon. However, this research focused on the detection of organic GSR and examining compositional differences between brands and lots of smokeless powder. Identifying differences between powders can be useful when trying to link a suspected shooter to a specific weapon and/or ammunition. Live-fire residue samples were also collected and analyzed to test the usefulness of the method on field samples. It is desired to have a method that is quick, reliable, and sensitive enough for analyzing GSR samples collected in cases involving firearms.

In this project, a previously developed UPLC/MS/MS method was applied to the analysis of smokeless powders and gunshot residue samples. UPLC is a newer technique that offers increased efficiency and separation speeds when compared to traditional HPLC. This is possible because the system can accommodate smaller particle columns and higher backpressures which help to minimize band spreading and decrease analysis times. The method involved the reversed-phase separation of 20 different smokeless powder additives and reaction products on a C18

column. For detection, both parent and daughter ions were monitored by tandem mass spectrometry in order to accurately identify the individual components. Simultaneously, positive and negative ESI was used along with negative APCI in the same run to detect all of the relevant compounds. Optimized analysis times were under eight minutes with a gradient of 10%-73% organic at a flow rate of 0.500mL/min. To confirm the presence of each chemical, several parameters were monitored: retention time, MS time, and specific parent-to-daughter transitions.

For smokeless powder analysis, organic additives including nitroglycerine, diphenylamine, nitrodiphenylamine, and ethyl centralite, were extracted from various smokeless powder samples using methylene chloride. An aliquot was removed from the supernatant following extraction and evaporated to dryness under a stream of nitrogen gas. This extract was then reconstituted in the HPLC eluent. For the live-fire residue samples, the swab used for collection was cut and extracted with acetone in a centrifuge tube. The extract was evaporated to dryness and reconstituted in solvent. Other procedures were also tested in order to obtain higher recoveries of the organic compounds. These results demonstrate that organic GSR can be used as an investigative tool by law enforcement personnel when trying to identify shooting suspects, particularly *in situ*ations where inorganic primer residues are unavailable or missing.

GSR Analysis, Ultra-high Performance Liquid Chromatography, Tandem Mass Spectrometry

A105 Bullet and Cartridge Case Signature Identification Using Topography Measurements and Correlations: The Unification of Microscopic and Mathematical Comparisons

Robert M. Thompson, BS, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8102, Gaithersburg, MD 20899; Jun-Feng Song, MS, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8212, Gaithersburg, MD 20899; Alan X. Zheng, MS, Theodore V. Vorburger, PhD, and Thomas B. Renegar, BS, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8212, Gaithersburg, MD 20899; and James H. Yen, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8980, Gaithersburg, MD 20899*

After attending the presentation, attendees will understand the methods in both microscopic comparison and identification of bullets and cases, combined with 3D surface topography measurement and correlations. The results of blind testing of bullets fired from ten consecutively rifled barrels and ten consecutively manufactured slides will be presented.

This presentation will impact the forensic science community by building onto current firearm identifications based on image comparisons using optical comparison microscopes. Because ballistic signatures are geometrical micro-topographies by nature, the main objective is to demonstrate the usefulness of surface topography measurement techniques for firearm identification. These results provide an objective mathematical validation of identifications that is in harmony with the results of optical comparison microscopy employed by an experienced firearms examiner.

Methodology: A 2D and 3D Topography Measurement and Correlation System was developed at NIST for certification of NIST Standard Reference Material (SRM) 2460/2461 Bullets and Cartridge Cases. Based on this system, a prototype system for signature measurement and correlation of fired bullets has been recently developed at NIST for bullet identifications. The 3D topography data of the land engraved areas (LEAs) of fired bullets are captured by a commercial Nipkow disc confocal microscope. The LEAs were processed by the "edge detection" method to determine the "striation density" by which the surface area with low striation density on the LEA could be masked out from correlation. The modified 3D micro-topography data on the remaining "valid correlation areas" are compressed into a 2D profile which represents the 2D ballistics signature of the LEA. A correlation program using two methods has been developed for matching the paired profile signatures: the "CMS" (Consecutive Matching Striae) method used by many firearm examiners and the CCF_{max} (cross correlation function maximum) method developed by NIST based on analysis methods in surface metrology.

Cartridge cases that comprised test fires from ten consecutively manufactured pistol slides, fifteen unknown cases, and five "persistence study" cases examined and measured. The cases were microscopically examined, and the results were later confirmed as accurately associating all of the questioned cases back to the correct pistol slide sources. A Nipkow disc confocal microscope was used to gather the 3D topography data from the breech face area of each case. The software applied the cross correlation algorithm to quantify the similarity between two cases.

Results: A set of 20 known-matching bullets fired from ten consecutively manufactured barrels (two bullets from each barrel) were tested. Their 3D topography images were captured by the confocal microscope at NIST, and correlated by the prototype ballistics identification system using the cross-correlation function maximum (CCF_{max}) as a correlation indicator. The correlation result was excellent: correlation values of all ten pairs of known-matching bullets scored highest on all correlation lists, yielding a correct identification rate of 100%. For the 60 pairs of matched LEAs (each bullet includes six LEAs), correlation values of matching LEAs scored highest on 59 out of 60 correlation lists, yielding a correct identification rate for individual LEAs of 98.3 %.

An additional set of 15 unknown matching bullets fired from the same set of ten barrels was blind tested. These bullets were correlated with the 20 known-matching bullets mentioned above. Both the CCF and CMS method were used and showed excellent correlation results. When using the CMS method, one matching pair did not meet the selected CMS criterion (3X) for a "match," and 29 out of 30 pairs of matching bullets were correctly identified, yielding a correct identification rate of 96.7%. When using the CCF method, all 30 pairs of matching bullets scored at the topmost position on their respective correlation lists, yielding a correct identification rate of 100

Cartridge cases that comprised test fires from ten consecutively manufactured pistol slides, fifteen unknown cases, and five "persistence study" cases were microscopically examined and the results were later confirmed as accurately associating all of the questioned cases back to the correct pistol slide sources.

Using statistical analysis from the known match and known non-match correlations, a baseline cross correlation function *(CCF)* was established to identify matches. Based on the *CCF* results, and a statistical analysis of the match and non-match case scores, each of the 19 of the 20 unknown cases were correctly identified to the slides that it came from. One case was not identified back to its original slide and had an "inconclusive" scoring. However, this one case was identified to other unknown cases that were correctly identified to the same slide.

A106 Reflection Confocal Microscope Systems in the Forensic Laboratory — Problems Encountered in Bullet and Cartridge Case Examinations

Stephen A. Shaffer, BS, University of California, Davis, Department of Chemical Engineering and Materials S, One Shields Avenue, Davis, CA 95616; David G. Howitt, PhD, University of California, Davis, Department of Chemical Engineering, Davis, CA 95616; and Karen Cebra, MSFS, University of California, Davis, Department of Physics, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will better understand the factors which define the capabilities and limitations of confocal microscopy

in the forensic examination of bullets and cartridge cases. They will also understand how to select confocal instruments to fit their needs and the important factors in setting up those instruments for optimal use in the laboratory.

This presentation will impact the forensic science community by helping practitioners select and use incident light confocal microscopes for firearms examinations in the laboratory. Consequently, it should help in decision-making about the purchase of instruments and avoid the waste of limited resources as a result of improperly choosing equipment or using non-ideal settings of the instruments.

In December of 2009, funding was received to develop incident light confocal microscopy as a means determine surface topography of fired bullets and cartridge cases. Attempts have been made to determine to what extent impression markings as revealed by confocal microscopy can be used to individualize firearms and whether they can be interpreted in the same way as random striation markings on fired bullets and cartridge cases. Unexpected and challenging issues were encountered early in the work with confocal imaging on curved surfaces such as bullets and cartridge case firing pin impressions. Consequently, it became necessary to evaluate and, if possible, solve these problems before further work could continue. Theoretical issues, instruments, and optimal settings necessary to optimize confocal microscopy for the forensic examination of curved surfaces have been studied. The issues encountered, the scanning mechanisms and conditions determined to be optimal, and the instruments evaluated and ultimately selected for further research are reported here.

Based upon prior work, proposals were submitted to NIJ for funding to develop applications of confocal microscopy for firearms evidence examination. It was believed that the technique showed very significant promise in the forensic laboratory. Early in the research it was found that noise and the consequent lower quality of feature height measurement was directly related to the angle of the surface to the optic axis, and to other factors of instrument design. Evaluation of the instrument design element proved difficult due to limited information available from the manufacturers. However, both theoretical considerations and experimental results demonstrated the importance of numerical aperture and lens design on the quality of data obtained. It was determined that optimal magnification at the imaging plane is based on the consideration of both the maximum resolution available and the desired magnification (and resolution) necessary for the work at hand. In some instances optimal magnification is less than the maximum magnification available. While manufacturers' claims of vertical resolution initially appeared to greatly exceed theoretical limits, actual results obtained reveal that the digital image processing used in confocal microscopy does significantly improve on conventionally accepted limits of vertical resolution. After evaluating instruments from variety of manufacturers it was determined that two instruments from Zeiss MicroImaging, LLC, were well suited the continuing research needs of the research.

It has been determined that when carefully chosen and set up, confocal microscopes can yield the quality of data necessary for continued research, and can remain potentially valuable operational forensic laboratories.

Confocal Microscopy, Firearms Examination, Instrument Selection

A107 Detection of Ammonium Nitrate and Ammonium Nitrate Mixtures in Soil

Tammi Green, Albany State University, 504 College Drive, Albany, GA 31705; Candice Bridge, PhD, and Jesse D. Brown, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will learn a minimal preparation methodology to rapidly identify ammonium nitrate and ammonium nitrate mixture particles while in the presence of various soil matrices.

This presentation will impact the forensic science community by providing a methodological model for analytical processes to identify ammonium nitrate mixtures that is conducive to an in-theatre environment.

Homemade explosives (HME's) are commonly encountered in theatre, in both pre- and post-blast scenarios. In post-blast scenarios, the burned and unburned particles can settle onto the surrounding soil or sand. It can be difficult to physically separate residual explosive particles from soil for instrumental analysis. Several types of explosive mixtures can be used in improvised explosive devices (IEDs). One of the more commonly used HMEs is ammonium nitrate (AN) because it is readily accessible. While AN can be used alone as an explosive, it is generally mixed with a fuel, commonly referred to an ammonium nitrate mixtures (ANM).[1] It can be difficult to identify these fuels which can be a key identifier for the bomb builder, especially in post-blast scenarios. With the increase of soil samples being sent to forensic labs to be analyzed, this study will help analysts by giving them a methodological model for extraction and analytical processes that is conducive to an in-theatre environment.

The objective of this study was to determine if AN and ANM can be identified in different soil matrices using the following in-theatre hand-held instrumentation: Raman Spectroscopy, Infra-red (IR) spectroscopy, and an ion-trap gas chromatograph – mass spectrometer (GC-MS). The more commonly identified fuels used in this study were: powdered aluminum, powdered sugar, spics, and diesel fuel. Ammonium nitrate was powdered and mixed with the powdered fuel to simulate the close contact necessary to create a significant blast. This was not necessary to do for the ammonium nitrate mixed with diesel fuel because the fuel is absorbed into the AN pill providing the a similar close contact. Each ANM was analyzed and compared to the analysis of the individual components to determine if each fuel could be identified in the presence of the AN. Subsequently, these ANM were mixed with soil samples at predetermined concentrations and analyzed to determine if either the AN or the ANMs were readily identifiable. The soil samples matrices were silicon band sand, red clay, and humus (garden-top) soil.

The resulting spectrum or chromatogram of the individual components, ANMs, and soil mixtures were compared by a Pearson correlation with a Student's t-test to determine if samples were significantly different or similar (~1900 pair-wise comparisons made). Based on research thus far individual fuels can be identified in the presence of AN at a concentration of 10% w/w. For the ANMs, the hand-held IR instrument had the ability to identify residual components (the fuel), which when analyzed had a higher correlation value with the individual fuel than the mixture itself. When the ammonium nitrate mixtures were mixed in the sand, high correlation values (R_2 = ~0.8) were achieved between ANM in sand and the pure ANM. Similar correlation coefficients for the mixture and the individual components were achieved for the Raman spectroscopy analysis. The GC-MS analysis did not provide any identifiable peaks for AN nor the fuels except for the diesel fuel at 1mg/ml and a 5mg/ml concentrations. Current results suggest it will be possible to identify AN and the fuels in a soil matrix.

A108 Forensic Soil Analysis of New Jersey State Parks Using a Combination of Simple Techniques and Multivariate Statistics

Jennifer Bonetti, BS, Cedar Crest College, 18 York Place, Kingston, NY 12401; and Lawrence Quarino, PhD, Cedar Crest College, Department of Chemistry & Physical Science, 100 College Avenue, Allentown, PA 18104*

After attending this presentation, attendees will realize that soil evidence is not utilized to its fullest potential in forensic science laboratories and that probative analysis of samples may not involve expensive or complicated instrumentation.

This presentation will impact the forensic science community by serving to provide a method of analysis for soil evidence that provides meaningful results, yet is neither time nor labor intensive.

Soil evidence is found in a large number and variety of criminal cases, yet it is often overlooked in forensic laboratories. Although there are a number of published techniques for testing soil evidence at an analytical scientist's disposal, it seems as though labs without access to a trained forensic geologist are left floundering when it comes to gathering useful information from soil evidence. Recently, emerging techniques have become more and more complicated leading to time and labor intensive methods that are simply not practical for the average crime laboratory. For this study, two simple yet effective methods, particle size distribution and pH measurements, were combined to generate a quick and easy method that can still be used to discriminate between samples from different locations by applying multivariate statistics such as a Principle Component Analysis (PCA).

Five samples at 50 feet intervals from one another were obtained for this study from 12 state parks distributed evenly across the state of New Jersey. The method employed for the particle size distribution was a modification of the method outlined by the Health and Physics program at the University of Nevada, Las Vegas[1]. Small aliquots (1.0-1.8g) were taken from each sample for the particle size distribution. These samples were treated with sodium acetate, hydrogen peroxide, sodium citrate-bicarbonate buffer with sodium dithionite, and sodium hexametaphosphate to remove all cementing and organic materials from the samples before using a wet sieving technique with mesh sizes of #10, #35, #60, #120, and #230. The Kolmogorov-Smirnov test, a nonparametric statistical test, was utilized to identify statistically significant differences between state parks based solely on the particle size distribution data. This curve-comparison test showed less than 35% of park to park comparisons to be indistinguishable (determined by a p-value greater than 0.05).

The pH measurements were carried out in triplicate in both water and 1M $CaCl_2$ using 1.0 grams of soil in 10mL of liquid and analyzed with an Accumet AB15 pH meter. The pH measurements for soil in water and soil in 1M $CaCl_2$ were analyzed separately using a Student's two-tailed t-test without assuming equal variance. In water, four of 66 park to park comparisons were not statistically significant while in $CaCl_2$, five of 66 park to park comparisons were not statistically significant. Only one park to park comparison was indistinguishable using pH measurements in both water and $CaCl_2$.

Using a 2D and 3D Principle Component Analysis (PCA) as well as a 2D and 3D Linear Discriminate Analysis (without prior PCA preprocessing), the 12 state parks could be viewed as clusters and discriminated. These results suggest that for general forensic comparisons, there is no need for complicated, time-consuming, and expensive methods. With the correct statistical analysis, simple conventional methods can be utilized and yield extremely meaningful results.

A109 Storage and Handling Procedures for Using Soil Molecular Biology as Trace Evidence

Sabreena Larson, BS, and Niraj Patel, University of Nebraska-Lincoln, Department of Biochemistry, Lincoln, NE 68588-0664; Jason M. Hustedt, BS, University of Maryland, Department of Chemistry, Building 091, College Park, MD 20742; Victoria Freeman, University of Nebraska-Lincoln, 1901 Vine Street, Lincoln, NE 68588; Rhae A. Drijber, PhD, University of Nebraska-Lincoln, Department of Agronomy and Horticulture, 316 Keim Hall, Lincoln, NE 68583-0915; Cheryl P. Bailey, PhD, University of Nebraska-Lincoln, Department of Biochemistry, Lincoln, NE 68588-0664; and David O. Carter, PhD, University of Nebraska-Lincoln, Department of Entomology, 202 Entomology Hall, Lincoln, NE 68583-0816*

After this presentation, attendees will understand how soil sample handling and storage can alter soil microbial community fingerprints using capillary electrophoresis single-strand conformation polymorphism (CE-SSCP) and fatty acid methyl ester (FAME) analysis.

This presentation will impact the forensic science community because it presents some fundamental knowledge for using soil molecular biology as trace evidence.

The use of soil as trace evidence has been well documented for many of its chemical and physical properties. However, there is less understanding when it comes to soil biochemical properties. One method to explore soil biochemistry is to extract microbial DNA and fatty acids to make a fingerprint. This method is currently in the development stage. This study looks at the effects that storage and handling of soil has on the microbial fingerprint made by soil microbial DNA and fatty acids.

In this project four soil types from Nebraska that vary in soil texture were tested. Each sampling location contained three plots. From these plots, 20 soil cores were collected from a depth of 0cm to 5cm three different times over a one year period. After each collection the soils were sieved and placed in sealed plastic bags in their storage conditions (-80˚C, -20˚C, 4˚C, air dried, oven dried, and freeze dried). As a control, one soil sample from the collection had the microbial community DNA and fatty acids extracted within 36 hours; this became the "fresh" sample to which the storage samples would be compared. Soil was collected at the same location two weeks after the initial collection to identify if rapid changes in the soil microbial community itself exist; to determine if it is possible to go back to a crime scene and recover a similar microbial profile. Two methods have been chosen for the analysis of the soil microbial DNA and fatty acids. The microbial DNA is analyzed by capillary electrophoresis single-stranded conformation polymorphism (CE-SSCP) to form a nucleic acid fingerprint. In theory, CE-SSCP is well suited for forensic use, but is a newer method and still requires detailed testing. The microbial fatty acids are analyzed as fatty acid methyl esters (FAME) to form a lipid-based fingerprint. FAME is a robust and highly used protocol that will support CE-SSCP data.

Thus far, the results from FAME analysis show soil stored at -80˚C and -20˚C show no significant difference from the fresh sample. The other storage methods (4˚C, air dried, oven dried, and freeze dried) showed significant difference when compared to the fresh sample. Samples taken two weeks after initial sampling have shown significant differences in microbial fingerprint compared to fresh samples. These results determine the best way to store soil samples when using soil microbial biochemical molecules is at either -80˚C or -20˚C, as to not change the microbial fingerprint. It also demonstrates the soil microbial community can change rapidly, possibly making it difficult to develop a robust method when using the soil microbial community for a fingerprint when several weeks have passed between crime and investigation. Results from genetic analysis will be presented.

Single-Stranded Conformation Polymorphism, Fatty Acid Methyl Ester, 16S rDNA

A110 Elemental Analysis and Comparison of Bulk Soil Using LA-ICP-MS, µXRF, and LIBS Methods: An Inter-laboratory Study

Jose R. Almirall, PhD, Florida International University, Department of Chemistry and Biochemistry, OE116, University Park, Miami, FL 33199; and Sarah C. Jantzi, MS, Florida International University, International Forensic Research Institute, Department of Chemistry and Biochemistry, 11200 Southwest 8th Street, Room OE130, Miami, FL 33199*

After attending this presentation, attendees will better understand the use of elemental analysis methods for the analysis of bulk soil samples. Elemental analysis of soils has many applications in the environmental, forensic, and geological sciences. The provenance or origin of soil transferred to objects such as shoes or tires can be useful in a criminal investigation and elemental profiles can be used to discriminate soil samples originating from different geographic regions and also associate soil samples originating from the same source.

This presentation will impact the forensic science community by comparing standardized and validated elemental analysis methods for bulk soil analysis. Thirteen laboratories have participated in a round robin exercise, and the results will be presented here.

Laser ablation inductively-coupled plasma mass spectrometry (LA-ICP-MS), micro X-ray fluorescence (µXRF), and laser-induced breakdown spectroscopy (LIBS) were used in this study since all three techniques produce similar analytical figures of merit. LA-ICP-MS and µXRF methods are established elemental analysis instrumental techniques that are currently available in many forensic laboratories. A LA-ICP-MS method was recently optimized for analysis and comparison between different soil samples in an environmental forensic application[1,2] and LIBS produces sensitivity equal to or better than that of µXRF (especially in the low mass range). LIBS has recently attracted the interest of analytical chemists and forensic laboratories as a simpler, lower cost alternative to the more established analytical methods. In developing a LIBS method, there are many parameters to consider, including laser wavelength, spectral resolution, sensitivity, and matrix effects. The first LIBS method using a 266 nm laser for forensic soil analysis has been also been reported by our group and presented.[3]

A soil analysis round-robin test was organized by Florida International University and distributed amongst some of the members of the Elemental Analysis Working Group (EAWG). The aims of this first soil round robin (EAWG-RR5) were: a) to evaluate the inter-laboratory performance of the three methods in terms of accuracy (bias), precision (relative standard deviation, RSD) and sensitivity using standard reference materials (SRMs); b) to evaluate the newly released NIST SRM 2710a, which supersedes 2710; and c) to evaluate the utility of LIBS as an alternative technique to LA-ICP-MS and µXRF for bulk analysis of soils.

Samples were submitted to thirteen laboratories: six used LA-ICP-MS, five used XRF and two used LIBS. Four samples were sent to each laboratory for analysis, consisting of standard reference materials: NIST SRM 2704 Buffalo River Sediment, NIST SRM 2710 Montana I Soil, NIST SRM 2710a Montana I Soil, and NRC Canada PACS-2 Marine Sediment Reference Material. For LA-ICP-MS, one of the samples was used as the single-point calibrator. For µXRF and LIBS, participants were asked to construct a calibration curve from four additional samples with known concentrations of the elements of interest. Each sample and standard was homogenized in a high-speed ball mill and pressed into pellets. Participants were instructed to measure the following elements: ^{7}Li, ^{25}Mg, ^{27}Al, ^{42}Ca, ^{45}Sc, ^{47,49}Ti, ^{51}V, ^{55}Mn, ^{88}Sr, ^{137}Ba, ^{206,207,208}Pb (LA-ICP-MS); Ti, Cr, Mn, Fe, Cu, Sr, Zr, Pb (µXRF); Ba, Cr, Cu, Fe, Li, Mg, Mn, Pb, Sr, Ti, Zr (LIBS). For both LIBS and µXRF, the choice of appropriate spectral lines was determined by the user, optimizing for linearity, sensitivity, and precision.

Results for both LA-ICP-MS and µXRF were generally consistent for most elements, resulting in good intra-laboratory precision (< 8 % RSD for LA-ICP-MS; < 20 % RSD for µXRF) and low bias (< 10% for LA-ICP-MS; < 35 % for µXRF), which are important characteristics for forensic comparison of soils. Linear calibration curves were also obtained for both µXRF and LIBS. Results for LIBS showed good precision (< 15 %) and bias (< 15 %) for most elements. Some problem elements have been identified and are discussed. Limits of detection for trace and minor elements were in the 0.01 – 1 ppm range for LA-ICP-MS and 1 to 200 ppm for LIBS.

Unlike some other matrices such as glass, soil can be spiked with internal standard(s) and calibration standards can be easily created, allowing for quantitative analysis using an external calibration curve. The result of this first soil round robin study bodes well for future method development in the characterization and forensic analysis/comparison of bulk soil composition.

A111 The Potential Effects of Differential Transfer and Persistence on Forensic Soil Comparison

Andrew M. Bowen, MS, Stoney Forensic, Incorporated, 14101-G Willard Road, Chantilly, VA 20151*

After attending this presentation, attendees will understand how physical properties of mineral grains such as size, density, and shape could potentially affect their differential transfer to and persistence on evidence. The implications of this with respect to appropriate selection of soil comparison methodology will be discussed.

This presentation will impact the forensic science community by introducing a phenomenon that is well established in the geological literature and has the potential to significantly impact forensic soil comparisons, but has yet to be addressed in the forensic science literature or by many published forensic soil comparison methods.

A tremendous variety of methods have been advocated for forensic soil comparison in the forensic science literature. These include comparison of soil color, particle size distribution, bulk chemical composition, pH of water extracts, isotopic composition, pollen content, enzymatic activity, mineralogy determined by polarized light microscopy, SEM/EDS, or x-ray diffraction, FTIR spectroscopy, UV-Vis spectrophotometry, microbial DNA profiling, analysis of organic components by GC/MS, and many more. While a handful of these methods involve analysis of soil particles of one type or another by microscopic methods, the majority of the published methods involve analysis of bulk soil properties.

Despite the common use of bulk methods for forensic soil comparison, there are some reasons why these methods may not be appropriate in some forensic scenarios (particularly those involving very small sample sizes). Sedimentary geologists have put a significant amount of effort into understanding the behavior of different mineral grains in sediments that are transported and deposited by wind and water. They have developed mathematical models that describe the behavior of mineral grains having different size, density and shape being transported and deposited by a variety of fluids. A garnet sand grain with a density of 4.0 g/cm^3 would

settle in water at the same rate as a quartz sand grain (density of 2.65 g/cm^3) roughly one and a half times larger. This phenomenon produces many sediment samples containing coarse grains of light minerals along with fine grains of heavy minerals. Shape is important primarily for platy minerals like muscovite and biotite, which sort with coarser fractions of other minerals of similar size and density. Given that mineral grains with different size, density, and shape behave differently during transport and deposition in fluids, they may well behave differently during transfer from a source to an evidence item and may have different persistence on evidence after transfer. It is expected that coarser grains, denser grains, and more equant grains are less likely to be transferred to evidence, and less likely to persist on evidence, than their finer, less dense, and platy counterparts. If this is in fact the case, it has the potential to change the modal mineralogy and particle size distribution of soil evidence relative to its source, particularly in cases where the amount of soil transferred is quite small. While it is common practice for forensic soil comparison to be performed on a limited size fraction of soil, fractionation due to differences in density and shape are unaccounted for in most published methods and have the potential to produce false negatives during comparison of bulk properties.

Methods based on microscopic analysis of the soil particles themselves (e.g., minerals, pollen) enable analysts to directly observe the particles and determine whether the questioned and known samples have particle assemblages consistent with each other. Both the identities of the particles (mineral types, pollen taxa) and their character (mineral varieties, state of preservation of pollen) can be observed and compared along with their relative abundance. These methods have the potential to be more robust to the differential transfer and persistence of minerals, especially if research is conducted that provides insights into expected trends, such as an increase in platy minerals and decrease in dense minerals in a given size fraction on evidence relative to source soil. Methods based on microscopic analysis of soil particles described in the literature include optical mineralogy, automated SEM/EDS analysis (QEMSCAN®), SEM analysis of quartz surface texture, palynology, mycology and cathodoluminescence of minerals.

With the exception of an article discussing changes of particle size distribution before and after transfer to the sole of a shoe, virtually no research has been conducted in the area of how transfer and persistence issues might affect forensic soil comparison. Additional research should be conducted to determine the effects of differential transfer and persistence of different mineral types in forensic scenarios. The results of such research would likely provide insights into the appropriate selection of methodology for conducting forensic soil comparisons.

Soil, Minerals, Transfer and Persistence

A112 Development of a Pigment Classification Scheme by Raman Spectroscopy

Christopher S. Palenik, PhD, and Skip Palenik, BS, Microtrace, Limited Liability Company, 790 Fletcher Drive, Suite 106, Elgin, IL 60123-4755*

After attending this presentation, attendees will understand a broad overview of the development of a procedure for systematically identifying pigments in samples of forensic interest by Raman spectroscopy.

This presentation will impact the forensic science community by understanding how pigments in paint are overlooked in paint evaluation samples. The presentation will discuss results of several years of research on pigment identification. The presentation will also present a scheme for approaching and conducting pigment identification.

Colorants (pigments and dyes) are everywhere. In theory, they seem like an obvious material to exploit as forensic evidence; yet beyond the macroscopic color that colorants impart to a material, the identity of individual pigments or dyes are largely ignored in forensic casework. The reason for this is the small size and low relative concentration of pigments in a given application. Successful efforts have been made to characterize select pigments in specific forensic applications (by XRF, FTIR, PLM and microchemistry, for example); however, each of these approaches has been subject to a particular limitation that has prevented the widespread application of pigment evidence to forensic investigations.

The development of Raman microspectroscopy has opened a new avenue for the possibility of identifying pigments in a consistent and reliable manner. The art community has embraced this technology and has made great strides in developing Raman spectroscopy as a practical analytical tool for pigment identification; however, the requirements of the art and conservation disciplines differ somewhat from those of the forensic laboratory. To this end, a program of research in the analysis of pigments by Raman spectroscopy with the aim of developing a practical approach for forensic scientists to exploit pigment evidence in casework has been conducted. These results have applications for both comparative forensic examinations as well as developing investigative leads, the latter of which could assist with sourcing paint samples.

In this research, samples were selected from a physical pigment reference collection of over 1,100 pigments. Samples were selected to represent as many organic and inorganic pigments as possible. When multiple samples of a given pigment existed, samples with stronger provenance were selected. Each pigment sample was analyzed by Raman spectroscopy, under varying conditions to obtain the best possible spectrum. In total, over 250 different pigments were examined and a database of Raman spectra was established.

Due to the fact that pigment samples are not always uniformly named by manufacturers (despite Colour Index naming conventions) and that samples have varying provenance, pigment identity was verified by several orthogonal methods. For example, Raman spectra were checked for consistency by comparing to other samples of the same pigment. Spectra were also compared to other chemically related pigments to ensure that chemically related pigments were spectroscopically related. All pigments were also elementally analyzed to ensure that the elemental data was qualitatively consistent with published compositions. Pigments with varying polymorphs were verified or identified by powder x-ray diffraction. Ultimately, any impure pigments or those with conflicting data that could not be resolved were withdrawn from the collection.

The Colour Index, maintained by the Society of Dyers and Colourists and the American Association of Textile Chemists and Colorists, provides a basic level of chemical grouping in there classification approach; however, it was established that the chemical groups specified by the Colour Index were not sufficient in scope to provide the level of classification necessary to take advantage of the level of data in a Raman spectrum. As such, a new program of chemical groups was devised (drawing from many literature sources, as well as our own knowledge) that was consistent with the spectroscopic data. Major peaks from the pigment reference spectra were then used to spectrally sort pigments into the defined chemical groups. The result was the development of a forensic pigment identification scheme that permits identification of the majority of pigments in modern commercial use through a flow-chart type approach. The scheme is expandable to accommodate other pigments that are not currently in the collection. Pigments with strong fluorescence obviously cannot be grouped by this method; however, they are included in the appropriate chemical group.

Ultimately, this identification scheme permits specific identification of pigments (when possible), but also allows an examiner to determine the extent to which a pigment can be identified or grouped. For example, pigments within certain chemical groups have indistinguishable Raman spectra, which mean that a pigment can only be identified to a certain level (e.g., certain diarylide pigments). In other cases, pigments can be identified as a single specific pigment. The benefits of such an identification scheme will be illustrated through the analysis of a small group of paint samples.

Pigment, Raman Spectroscopy, Paint

A113 Development of a Field Method for the Identification of the Hallucinogenic Herb *Salvia Divinorum* Using ATR-FTIR

Rebecca L. Mead, BS, Elise R. Chom, MS, and J. Graham Rankin, PhD, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will have an increased understanding of the need for an in-field test for the identification of *Salvia divinorum*. They will also become familiar with the use of ATR-FTIR to identify *Salvia divinorum* in the field.

This presentation will impact the forensic science community by presenting a new method of identification of *Salvia divinorum* that can be used as a simple in-field presumptive test that does not require the extraction of salvinorin A prior to analysis.

Salvia divinorum is a hallucinogenic plant that is smoked or chewed as a substitute for marijuana. The short-lived "high" is a result of the chemical salvinorin A, which is a component of *Salvia divinorum* that has not been found in any other species. Currently, *Salvia divinorum* and/or salvinorin A is illegal in twenty-two states and is regulated in eight additional states. Several countries have also outlawed or regulated *Salvia divinorum* and/or salvinorin A. With the recent increase in regulation of Salvia divinorum across the country, there is a need for a quick and simple preliminary test for *Salvia divinorum* that can be used in the field.

Currently, *Salvia divinorum* is not identified in crime laboratories. Instead, salvinorin A, the active component, is extracted from the plant material and analyzed using gas chromatography/mass spectrometry and thin layer chromatography. However, no in-field tests have been identified to aid in the quick presumptive identification of *Salvia divinorum* or salvinorin A. Previous studies have shown that no color test can definitively identify *Salvia divinorum* or salvinorin A, and *Salvia divinorum* does not possess unique physical characteristics that can be used for identification like marijuana. While confirmatory tests are sufficient for identification once the seizure reaches the laboratory, the lack of a field test will result in either too many or too few samples being sent to the lab for analysis. Also, all techniques currently used for identification require an extraction step, thus identifying salvinorin A rather than *Salvia divinorum* itself. Developing an in-field presumptive test to aid in the identification of *Salvia divinorum* will allow law enforcement to determine if vegetation found in the field is possibly *Salvia divinorum*. ATR-FTIR is a simple technology that does not require any sample preparation. Within minutes, a trained law enforcement officer with a portable FTIR instrument can determine if vegetation could be *Salvia divinorum*. In the laboratory, FTIR spectroscopy would provide a category A confirmatory test for identification that would not require an extraction as currently used methods do.

This study addresses differences and similarities in the infrared spectra of *Salvia divinorum* and more than thirty other species of Salvia as well as common herbs that may be confused with *Salvia divinorum* and extract enhanced products of *Salvia divinorum*. Additionally, as part of the validation of this method, the top and bottom of the leaves were compared to determine if a difference is present that would affect the leaf's identification. Salvinorin A is also being analyzed to determine if FTIR spectroscopy can be used to identify the pure substance. Finally, a portable FTIR instrument is being used to ensure the results found are comparable with those obtained with a research grade bench ATR-FTIR spectrometer.

***Salvia Divinorum*, Plant Identification, ATR-FTIR**

A114 Using Analytical Techniques to Distinguish Illicit and Over-the-Counter Drugs in Trace Evidence

Sulekha R. Coticone, PhD, Florida Gulf Coast University, Academic Building 7 #431, 10501 FGCU Boulevard, Fort Myers, FL 33965; Nancy L. Ludwigsen, MS, Sarasota Sheriff's Office, PO Box 4115, 2071 Ringling Boulevard, Sarasota, FL 34230; and Brittany Morgan, BS*, Florida Gulf Coast University, 10501 FGCU Boulevard, Fort Myers, FL 33965*

After attending this presentation, attendees will understand the difference between the data obtained from analytical techniques utilized to identify over-the-counter and illicit drugs.

The presentation will impact the forensic science community by providing an in depth comparison of techniques which can enhance the analysis of data obtained from crime scenes.

The illegal drug trade consists of the manufacturing, distribution, and sale of controlled substances. The most recent annual data from the Federal Bureau of Investigation (FBI) show that 12.2 percent of more than 14 million arrests in 2008 were for drug violations, the most common arrest crime category. Additionally, the abuse of common over-the-counter pain medication drugs has also escalated in the past decade. The drugs with the highest dependence or abuse levels were marijuana, prescription pain relievers, and cocaine. Many of these drugs are considered "controlled substances" that have a legally recognized potential for abuse. Officials responding to crime scenes (e.g., firefighters, police, and hazmat teams) are often ill equipped to handle the ever growing magnitude of drugs that are encountered at crime scenes. These samples generally are collected and sent to crime labs for extensive analysis which can be time consuming and impede the criminal justice system. However, recently several analytical techniques have been developed which can be used in a portable mode. These techniques can be used to identify white powders which are otherwise indistinguishable based on color, texture, and odor. The present study examines the different analytical techniques that can be used to identify the unknown compounds frequently encountered by first responders in the field. The two analytical techniques for chemical identification which can be used in the portable mode include Fourier transform infrared spectroscopy (FTIR) and Raman Spectroscopy. While infrared spectroscopy utilizes infrared radiation to probe the chemical structure of the drug/compound, Raman spectroscopy utilizes a monochromatic light source (e.g., a laser) focusing onto a sample and analyzing the resulting scattered light. In both cases, the radiation interacts with the bonds of the compound producing a unique spectral fingerprint of the drug. The identity of the compound is determined by comparing spectra against a database of FTIR or Raman spectra of known spectra present in a library. In this study, different drugs (Aspirin, Acetaminophen, Caffeine, and Excedrin) were tested and compared with common household materials, such as talcum powder, using the two different analytical methods. Specifically, data was compared data from the above mentioned techniques for Excedrin and its individual components: caffeine, acetaminophen, and aspirin. Raman spectroscopy had the advantage of providing sharper peaks for symmetric bonds in aromatic compounds and those that contain double bonds, while FT-IR showed stronger peaks for asymmetric hydroxyl and carbonyl groups. In addition, fewer peaks of interest in Raman spectra may facilitate mixture analysis. Even though both techniques probe the structures using molecular vibrations, they did differ in the information that they provide. In conclusion, it was found that these two methods are also easy to use, give quick results, and are now available in a portable form which can be used for detection at crime scenes.

OTC Drugs, Illicit Drugs, Analytical Techniques

A115 Development and Validation of a Quantitative Method for Identification of Synthetic Cannabinoids Using GC/MS

Jennifer L. Rehme, BS, Amanda Heeren, MS, and J. Graham Rankin, PhD, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will have a solid grasp on the properties and characteristics of synthetic cannabinoids and the current trends in use and regulation of the drugs, as well as how to effectively analyze samples to determine the type and quantity of synthetic cannabinoid used in the herbal matter tested.

Due to the increasing abuse of these herbal incense products, this presentation will impact the forensic science community by informing attendees about new developments in the battle against the use and abuse of synthetic cannabinoids as well as a method that has been developed to quantitate the synthetic cannabinoids in each product tested in a quick and accurate way.

These products often have names that are ambiguous or suggestive drug references. While labeled as "Not for Human Consumption" and purportedly for use as incense only, these are a part of a growing trend to use as a way to get around the legality of using marijuana but still obtain a high. These products are laced with chemicals known as synthetic cannabinoids, named for their structural similarity to the psychoactive ingredient in marijuana. The structural similarity allows them to bind to the same receptors in the brain and other organs, giving the user the same effects of marijuana. These products have been seen in the market since at least 2004 when they were quickly banned by the military. Since then, a number of states have followed suit and begun banning these products.

With the recent temporary scheduling of five of these compounds in March 2011 by the DEA, there has been a need to find a method that accurately and quickly determines the type and quantity of synthetic cannabinoid in each seized product. The method needs to have the ability to separate out the components as to allow the analyst to distinguish synthetic cannabinoids from other components such as Vitamin E, which is often added to try to disguise the synthetic cannabinoid's presence. The fact that Vitamin E is easily separated from the synthetic cannabinoids by gas chromatography negates any attempt at disguising the active ingredients. Gas chromatography/mass spectrometry (GC/MS) has been previously shown to be a good method for the qualitative analysis of the synthetic cannabinoids. However, quantitative analysis has been limited until now due to the limited availability of reference standards and that most states do not require quantitative analysis for seized drugs. This presentation will describe a method used to obtain accurate results using a GC/MS and will show how the synthetic cannabinoids in such products can be quantitated using this method.

In order to develop a quantitation method, various synthetic cannabinoid standards were obtained from commercial sources and subsequently analyzed by gas chromatography/mass spectroscopy. The reference standards analyzed include the following: JWH-018; JWH-073; JWH-200; JWH-250; and (±)-CP 47,497 (C8) homolog. Using tetracosane as an internal standard and a standard curve, the data obtained was applied to the analysis of various brands of herbal incenses obtained from Huntington area head shops in 2010 and a service station in Kentucky in 2011. GC/MS data is presented for all reference standards as well as for all samples analyzed.

Synthetic Cannabinoids, Herbal Incense, JWH Compounds

A116 Target Compound Ratio Analysis of Medium Petroleum Distillates

Kendra A. Wilbur, BS, Amanda Heeren, MS, and J. Graham Rankin, PhD, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

The goal of this presentation is to present initial results of a quantitative method developed to differentiate between medium petroleum distillates (MPD) and residues of MPDs. The method is an extension of a method developed for the differentiation of kerosene samples as neat liquids and residues using Gas Chromatography/Mass Spectroscopy with a target compound ratio analysis method. Comparison to determine if a sample is from a specific source is a problem in the application of fire debris analysis. The long-term goal of the project is to develop a uniform statistical method to determine degrees of similarity between any two ignitable liquid residues in fire debris analysis.

This presentation will impact the forensic science community by providing a methodology and a statistical basis for declaring similarities between any two medium petroleum distillate samples as required by the courts and the National Academy of Sciences Report.

Petroleum-based products are the most commonly used accelerants in the United States. Most of these products are readily available to the public and are flammable. Gasoline is the most often encountered ignitable liquid, followed by kerosene and medium petroleum distillates. Medium petroleum distillates as classified by the American Society for Testing and Materials (ASTM) E1618 include paint thinners, dry cleaning solvents, and charcoal lighters. Medium petroleum distillates have a boiling point range of 120 to 240°C and contain C_8 to C_{13} compounds, which include normal and branched alkanes, some cycloalkanes, and some aromatics. Differences between manufacturing processes should provide variation between medium petroleum distillates, which is often seen in reference collections because of the lack of homogeneity within the class of MPDs. This research was performed to determine the key components and peak ratios of medium petroleum distillates to provide an analytical and statistical basis for the differentiation between these products.

High resolution GC/MS data was analyzed using target compound ratios from key compounds found in medium petroleum distillates. Compounds eluting off of the non-polar polydimethylsiloxane column generally elute in order of increasing boiling points. Therefore, peak ratios comparing closely eluting compounds are less affected by preferential evaporation in the course of a fire.

Previous research performed on kerosene and gasoline has established a number of compounds that can be used to distinguish kerosene and gasoline samples from different sources. In this work, seventeen compounds have been identified from mass spectra and retention times in medium petroleum distillates as possible candidates. From those compounds, sixteen ratios were calculated and compared for reproducibility within ignitable liquid and significant differences between liquids. Evaporation and burn tests were also performed to test the robustness of the ratios under conditions that may occur during an actual fire.

Several "green" paint thinners and solvents have been analyzed which are listed as non-flammable. The composition of these newer products, although not likely to be used by an arsonist, may occur as incidental liquid residues in fire debris.

A database of gasoline, kerosene, and MPD analyses is being developed from a large number of samples in each class and a variety of different sources, which will be used to establish statistical criteria for comparison between two different samples with a probability of error.

Medium Petroleum Distillates, Fire Debris Analysis, GCMS

A117 Ignitable Liquid Residue Distribution in Pour Patterns as Affected by Substrate Type and Ignitable Liquid Class

Bob Sullivan, Cabell County Prosecutor's Office, 6007 US Route 60 East, Suite 109, Barboursville, WV 255504; and J. Graham Rankin, PhD, and Dana L. Greely, BS, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

The goal of this presentation is to present the effects of substrate type on the migration of ignitable liquids in a pour pattern during a fire and to present the best place to collect an evidence sample from in each case.

This presentation will impact the forensic science community by providing fire investigators with an expanded knowledge of the primary areas to sample from a suspected ignitable liquid pour pattern on various substrates in order for the fire debris analyst to obtain the best results in the lab.

Collection of fire debris evidence from a fire scene most commonly falls on the shoulders of the fire investigator in charge of the scene. The sample is then sent to the lab to be analyzed by a fire debris analyst for the presence of ignitable liquid residues. For the best chromatographic results, the evidence samples must be collected from an area of the pour pattern suspected to contain the highest concentration of ignitable liquid residue. The question is whether it is best to collect from the center of the pour pattern, the edges of the pour pattern, or somewhere in between.

One factor to consider is whether the substrate the ignitable liquid was poured onto has any effect on the prime area to collect the sample from. Carpeting, for example, can wick the ignitable liquid away from the original pour pattern diluting the ignitable liquid over a larger area. Some newer synthetic carpets can also self-sustain combustion beyond the edge of the original pour pattern leaving a completely unrelated pattern. Sampling from the edge of this pattern could potentially give negative results. Also, different types of wood may absorb the ignitable liquid allowing for a deeper burn pattern while others may resist it allowing the ignitable liquid to spread farther and burn faster with little effect on the substrate.

An experiment was designed to test the concentrations of ignitable liquid residues in different specified areas of pour patterns post-burn. A circular pour pattern representing a central dump of the ignitable liquid was tested, as well as a line pattern representing a trail pattern. Substrates were allowed to burn to 70% completion and were extinguished with water. Multiple samples were collected at designated areas across the pattern. Any volatile ignitable liquid residues present were collected by passive headspace analysis on activated charcoal strips and submitted to analysis by GC/MS. Total ion chromatograms for each sample were analyzed qualitatively and quantitatively. The ratio of the total peak area to that of the internal standard, 3-phenyltoluene, was calculated and compared.

Initially, the results have shown that higher concentrations of ignitable liquid residues can be found toward the center of the pour patterns than toward the outer edges under these conditions. This would suggest that the center of a pattern would be the best place for fire investigators to sample from for the best results. Differences in relative concentration of ignitable liquid residue due to substrate, actual pour pattern, and class of ignitable liquid will be presented.

Fire Debris Analysis, Pour Pattern, Ignitable Liquid

A118 Effects of Various Substrate Types on E1618 Pattern Classification of Ignitable Liquids Present in Fire Debris

Amanda Heeren, MS, J. Graham Rankin, PhD, and Jared Vititoe, BS, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will gain an understanding of how substrate type affects the ASTM E1618 classification of ignitable liquids present in fire debris samples. Attendees will also gain an understanding of the methods and techniques currently used in the analysis of debris collected from fire scenes.

This presentation will impact the forensic science community through a discussion of the potential troubles associated with the analysis of specific burned problem substrates, such as misinterpretation and misclassification of ignitable liquids present.

Charred and uncharred substrates of various types will be compared and ignitable liquids, if present, classified according to ASTM method E1618. This presentation will benefit the fire debris analysis community by informing analysts and researchers of the potential of common fire debris substrates to produce products that may interfere with the GC/MS analysis and E1618 classification of ignitable liquid residues in fire debris.

Due to the extraction procedure for ignitable liquid residues, compounds present in the substrate, such as various polymers and glues, may co-adsorb to activated charcoal strips with the ignitable liquid residues present in fire debris. These interfering products will also be present on the chromatograms generated during analysis. Additionally, pyrolysis and combustion products generated from the burning of the substrate may potentially affect the chromatographic analysis of ignitable liquids. As non-wooden substrates (carpet/padding 52%, fabric/paper 11%, and vinyl flooring/plastics 10%) constitute a large percentage of the substrates submitted as fire debris samples to a crime laboratory, it is important for fire debris analysts to be aware of the difficulties such substrates may cause in ignitable liquid analysis.

In this study various fire debris substrates were selected for E1618 analysis of the ignitable liquids gasoline, kerosene, and charcoal lighter fluid. These ignitable liquids are classified as gasoline, heavy petroleum distillates, and medium petroleum distillates, respectively. The substrates chosen were yellow pine, carpet, and carpet pad, which after charring to approximately 50% by weight with a propane torch to simulate burned fire debris, were analyzed with 10µL spikes of 50%, 75%, and 90% ignitable liquid evaporates. Additionally, uncharred substrates were also spiked with 10µL of each of the ignitable liquid evaporates. Un-spiked samples of each substrate, charred and uncharred, were also analyzed as substrate blanks. Ignitable liquid vapors were then concentrated according to the ASTM E1412 method on activated charcoal strips with carbon disulfide as the eluting solvent. 3-phenyl toluene was added to carbon disulfide as an internal standard.

It was experimentally concluded that a substrate may affect E1618 classification. For yellow pine, several notable terpenes were present in the uncharred blanks (1S-α-pinene, 5.6 min; β-pinene, 6.2 min; 1,5-dimethyl-1,5-cyclooctadiene, 7.0 min); however, these peaks were present but effectively buried in the samples that were un-charred and spiked with ignitable liquids. In the charred samples, the terpene chromatographic peaks were severely diminished, nearly undetectable, a phenomenon reasonably explained by the volatility of terpenes. For carpet, several minor precursory products were present in the substrate blanks, mostly olefins from the carpet fibers (such as dodecene, 8.6 min). However these peaks were insignificant in the ignitable liquid spiked samples. Carpet pad had very few detectable compounds in the substrate blanks. These few peaks were present in minor concentrations and easily masked in the baseline of the spiked samples. With kerosene the ignitable liquid pattern was found to shift to the lighter end of the chromatogram for both yellow pine and carpet pad, a phenomenon not observed with the other ignitable liquids or in the

other substrates. With yellow pine the entire chromatographic pattern was observed shifting approximately one carbon lower (heavier components not recovered) in comparison to the neat ignitable liquid. This phenomenon did not change the classification of kerosene as a heavy petroleum distillate (C_8-C_{20+}) in this substrate. The relative abundance of the normal paraffins was reduced relative to the branched and cyclic hydrocarbons, as has been reported previously for yellow pine. Thus, during analysis, analysts should be informed and remain cognizant of the substrate being analyzed as it may affect their interpretation and E1618 classification of the results.

Fire Debris Analysis, ASTM E1618, Substrate Effects

A119 New Gas Chromatography-Positive Chemical Ionization Tandem Mass Spectrometric Method for the Detection of Methylenedioxypyrovalerone (MDPV), 4-Methylmethcathinone (Mephedrone), and 4-Methoxymethcathinone (Methedrone)

Lindsey E. Hume, BS, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701; Randall D. Fornshell, BS, and Timothy P. Rohrig, PhD, Sedgewick County, Regional Forensic Science Center, 1109 North Minneapolis Street, Wichita, KS 67214; and J. Graham Rankin, PhD, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will be familiar with a new approach for the analysis and identification of common "bath salts" ingredients utilizing GC-MS/MS with chemical ionization.

This presentation will impact the forensic science community by providing a definitive method for the identification of synthetic cathinones which are becoming increasingly popular among recreational drug users and are rapidly being regulated by state and national governments.

MDPV, mephedrone, and methedrone are some of the most common compounds currently seen in products being marketed as "bath salts." They are structurally similar to the scheduled stimulants cathinone, and methcathinone. Therefore, the synthetic cathinones, including mephedrone, methedrone, and MDPV, are also structurally similar to each other. As a result, they have similar fragmentation patterns, often with poor molecular ions, when characterized by traditional GC-MS methods utilizing electron ionization. In this study, different GC-MS techniques, including electron and chemical ionization and single and triple quadrupole (QQQ) mass spectrometry, were evaluated in order to determine the most definitive method for identification of synthetic cathinones. Here, it is proposed that GC-MS/MS with chemical ionization in multiple reaction monitoring (MRM) mode can unequivocally detect the presence of and identify the studied compounds.

The method was also developed with the designer drug market in mind. As has been demonstrated recently with the synthetic cannabinoids, "bath salts" have also shown the tendency to have variable contents as bans on certain compounds are enacted. Most often, "bath salts" are marketed as a "legal high," so changing the active compounds in accordance to the new laws is common. As these new compounds arrive on the market, and are also likely regulated, forensic analysis will need to be able to detect them in addition to those currently controlled. This method was developed so that any synthetic cathinones can be run, responses can be optimized, and the appropriate MRM ions can be added to the method with minimal adjustments to facilitate rapid analysis.

Electron ionization, with both single and triple quadrupole analysis, gave very similar spectra for mephedrone and methedrone. Chromatographic peaks also had poor shapes. MDPV exhibited a low-detail fragmentation pattern, but a characteristic peak at *m/*z 126 was detected, due to the presence of the pyrrolidinyl group on the alkyl chain of the compound, that helped distinguish it from the other investigated compounds. Because of similar fragments in single quadrupole analysis for the other two drugs, fragments chosen for tandem mass spectrometry also produced similar patterns. Chemical ionization significantly increased the intensity of the protonated molecular ion relative to the nearly nonexistent molecular ion produced with electron ionization. When triple quadrupole analysis was paired with chemical ionization, unique mass spectra were also observed through the selection of the protonated molecular ion as the precursor ion at Q1. Additionally, chromatographic peaks were clean and lacking the shoulder present in electron ionization analyses.

Compounds that could potentially interfere with the compounds of interest were also subjected to the method. Compounds studied for possible interference included amphetamine, caffeine, cathine, ephedrine, ketamine, phentermine, alprazolam, benzylpiperazine (BZP), clonazepam, cocaine, codeine, diazepam, heroin, hydrocodone, methamphetamine, 3,4-methylenedioxyamphetamine (MDA), 3,4-methylenedioxymethamphetamine (MDMA), oxycodone, pseudoephedrine, trifluoromethylphenylpiperazine (TFMPP), cathinone, inositol, and phenethylamine. No interference was observed, though peaks were occasionally present in the chromatogram. Future studies should be performed to optimize compound-specific conditions for the analysis of other synthetic cathinones in order to confirm the broad application to this class of drugs.

Bath Salts, Designer Drug Analysis, Cathinones

A120 Ignitable Liquid Residue Source Elimination by Molecular Weight Estimation

John J. Lentini, BA, Scientific Fire Analysis, Limited Liability Company, 32836 Bimini Lane, Big Pine Key, FL 33043*

After viewing this presentation, attendees will understand a simple method for excluding a suspected source of ignitable liquid residue using basic chemical fundamentals.

This presentation will impact the forensic science community by utilizing this straightforward method of analysis for fire debris analysts in order to provide additional useful information to fire scene investigators.

The literature of fire debris analysis is replete with descriptions of attempts to match an ignitable liquid residue to a suspected source. Many different methodologies have been suggested for making comparisons, and more recent attempts have focused on chemometrics such as principal components analysis. Because gasoline is the single most commonly used accelerant, most of the efforts at identifying the source of ignitable liquid residues have focused on gasoline. In environmental forensics, other methods have been used to identify the source of hydrocarbons spills. Two-dimensional gas chromatography-mass spectrometry and the analysis of biomarkers have been successfully applied. Unfortunately for fire debris analysts, the quantity of extract is often far too small to be analyzed using the same methods available to environmental chemists.

Most forensic science laboratories today follow ASTM E1618, *Standard Test Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography-Mass Spectrometry*. This methodology is, and historically has been, designed to allow for classification of ignitable liquid residues into any number of recognized classes. The 2010 edition of the standard recognizes eight classes of ignitable liquid: gasoline; petroleum distillates including de-aromatized distillates, isoparaffinic products; aromatic products; naphthenic-paraffinic products; normal alkane products; oxygenated solvents; and others-miscellaneous. Most of these classes of ignitable liquid residues can be further subclassified as light, medium, or heavy. Gasoline has no subclasses, and oxygenated solvents are only characterized as light or medium.

Making distinctions within a class, or finding the source of an ignitable liquid residue are outside of the scope of ASTM E1618. The standard states, "This test method is intended to allow identified ignitable liquids to be characterized as belonging to one of the classifications. Distinguishing between examples within any class may be possible, but such further characterization is not within the scope of this test method."

Two case reports will be presented. In each case, an attempt was made to connect a suspect to a fire scene by comparing ignitable liquid residues. In one case, a plastic milk jug was found a few blocks from the scene, and was suspected as being the container used to carry a heavy petroleum distillate (HPD). In the second case, medium petroleum distillate (MPD) found in two samples of fire debris from the scene was believed to have come from the same source as medium petroleum distillate found on the suspect's shoes. In both cases, analysis of the average molecular weight (expressed as carbon number range) revealed that the suspected source was heavier than the extract from the scene.

When exposed to a fire, ignitable liquid evaporates, and its average molecular weight necessarily increases. No predictable experience will cause the average molecular weight of the fire-exposed liquid to decrease. If the suspected source of an ignitable liquid, which was not exposed to the fire, exhibits a higher average molecular weight than the residue extracted from samples collected at the scene, the suspected source can be conclusively eliminated.

Using this straightforward method of analysis, fire debris analysts will be able to provide additional useful information to fire scene investigators.

Accelerant, Ignitable Liquid, Identity of Source

A121 Analysis of a 100-Year-Old Alleged Opium Sample: Quality Assurance and Legal Issues

Thomas M. Blackwell, BS, Drug Enforcement Administration, 99 Tenth Avenue, Suite 721, New York, NY 10011*

After attending this presentation, attendees will better understand the importance of best laboratory practices and quality assurance in everyday work and how this can drastically affect legal implications in drug analysis from a criminal standpoint as well as a business perspective. A comparison of best laboratory practices and quality assurance measures from 1887 and today will also be addressed.

This presentation will impact the forensic science community by emphasizing and addressing proper documentation, quality assurance practices of accepted methodologies, bias, and the importance of reviewable data as they pertain to our current legal system. In today's world of accreditation and transparency, quality assurance is more important than ever. Analysts and managers struggle with a continued question, "What's more important, quality or quantity?" The answer to this question is simply both. Quantity and quality must be weighed together to ensure efficiency and functionality; however, picking one over the other may result in the lack of reviewable data or accepted practices that have no validation. It is critical for a reviewer to be able to reconstruct an analysis or be able to know how an analyst arrived from "point A" to "point B."

This presentation will demonstrate the incongruities associated with the analysis and legal status of imported opium in 1887 as three different "morphia" (or morphine) content results were reported for one sample. Handwritten reports detailing little to no information were supplied with no analytical data or description of tests performed to support the quantitative results. This practice indicates that the analyst/law officers were often taken "at their word" over 100 years ago.

In 1887, opium was legally imported into the U. S. from China as long as the morphine content was *above* 9% in an "unprocessed" or "crude" opium sample. This type of "smoking" opium had a peculiar flavor and was largely used in Hong Kong. However, Chinese immigrants living in the United States favored a different class of crude opium known as "Patua" which had a morphine content of less than 7% and, thus, was illegal in the United States.

Opium was often imported as crude or processed opium and subsequently appraised by the U.S. Customs House. Part of the appraisal processes involved the analysis of morphine content. Initial assays conducted in 1887 indicated that morphine was present at a level of 11.30%, rendering the shipment legal in the United States. Subsequent purchase of this opium at auction by sellers of Persian opium objected to the classification as crude "Patua" opium, since they argued that this class of opium rarely, if ever, contained more than 7% morphine. The importation of this "illegal" opium would be a detriment to their legitimate sales. They, therefore, submitted a formal complaint to the Customs House who, in turn, ordered a reanalysis. The sample was reanalyzed (2x) by Customs House analytical chemists later that year who reported the morphine content to be on average 4.1% (separate analyses of 4.05% and 4.25%). This new result caused the U.S. Customs House Department to launch an investigation. The larger value of 11.30% was subsequently dismissed upon conclusion of the investigation.

A U.S. Marshall conducting research in the 19th century records of the Bureau of Customs found a case file that included an envelope of alleged opium. This led to a request by the National Archives in 1993 requesting that DEA analyze the sample. Analysis of the sample utilizing gas chromatography/flame ionization detector (GC-FID), gas chromatography/mass spectroscopy (GC/MS), and infrared spectroscopy (IR) of the sample indicated that the alleged opium contained morphine (75%) and codeine (4.5%). Typically, the naturally occurring alkaloids of an opium poppy (morphine, codeine, thebaine, noscapine, and papaverine) are required to be present in a substance deemed to be opium. Yet, it is unclear if this was a requirement in 1887 due to the lack of reviewable data. Interestingly, the reported morphine content in 1887 was 4.1% (re-analysis), yet modern GC-FID analysis of the sample indicated that codeine was present at 4.5%. So the question arises, was codeine being erroneously identified and quantitated in the 1880s instead of morphine?

Assuming that morphine was the correct analyte being tested, why was there such a large disparity in quantitative values (11.30% vs. 4.1% vs. 75%)? Best laboratory practices and proper quality assurance practices such as: clear and concise documentation; reviewable data; analytical schemes; chain of custody; and, sampling protocols, which are critical in today's forensic science arena, could have alleviated much of this disparity. All of these issues are routinely depicted on popular television shows and by current real world events surrounding forensic laboratory closures in various states. Although a number of handwritten notes surfaced from the 1887 opium sample, no data relating to the chemical testing of the morphine could be located.

Morphine, Opium, Quality Assurance

A122 The Characterization and Discrimination of Pink and Red Nail Polish Lacquers – A Preliminary Study

Edward Sisco, BS, 4808 Cherokee Street, College Park, MD 20740; Michelle R. Robinson, BS, University of Texas at Austin, 1 University Station A5300, Austin, TX 78712; Madison Lands Palmer, BS, Kansas City Police Department, 6633 Troost Avenue, Kansas City, MO 64131; and Patrick Buzzini, PhD, West Virginia University, 304 Oglebay Hall, 1600 University Avenue, PO Box 6121, Morgantown, WV 26506-6121*

After attending this presentation, attendees will learn about the most discriminating analytical sequence for pink and red nail polish lacquers when they are recovered as physical evidence.

This presentation will impact the forensic science community by providing information about the chemical compositons of the studied nail polish lacquers as well as about their between-sample discriminations.

Suppose that a nail fragment is recovered from an upper garment seized from an individual suspected of having raped a woman. On the fragment a colored layer is observed and it is assumed to be nail polish lacquer. What is the best approach to examine this colored substance?

The goal of this study was to detect the different components for the characterization of nail polish samples, to evaluate the discriminating power of the available methods, and to identify an appropriate analytical sequence.

One hundred ten pink and red-colored nail polish lacquers of different common brands were collected. The samples were examined using visual and microscopical (unassisted eye observation followed by stereomicroscopy) observation, reflectance visible microspectrophotometry (MSP), Fourier transform infrared (FTIR) spectroscopy, Raman spectroscopy, and elemental analysis with scanning electron microscopy/energy dispersion spectroscopy (SEM-EDS).

The results indicate that color was the most discriminating feature. However, although most of the red and pink samples studied could be easily distinguished based on their shades, there were several instances when there was difficulty in determining whether a sample was red or pink. Microspectrophotometry proved to be the most discriminating technique. Out of 5,995 possible pairwise comparisons, 52 pairs could not be differentiated according to their MSP spectra. It was observed that some samples were difficult to distinguish by MSP but could be differentiated by visual examination and vice versa. Therefore, it was confirmed that visual examination and microspectrophotometry are complementary methods. The presence, distribution, and colors of sparkling (or glitter) particles played an important role as discriminating features.

On the other hand, infrared spectroscopy provided confirmation that all the samples of our dataset were nitrocellulose-based substances. Though the presence of additional absorption bands allowed for observing further discriminations, infrared analyses discriminated 43 pairs of the 52 indistinguishable with MSP. Raman spectroscopy (using a near-infrared laser source at 785nm) allowed for the detection of the main pigments contained in the analyzed samples. For red colored samples, C.I. Pigment Red 57:1 (C.I. 15850:1) was the most commonly encountered, while for pink samples the most frequently detected pigment was C.I. Pigment White 6:1 (C.I. 77891). The latter was the anatase form of titanium dioxide. The 785nm laser line, which was the only wavelength used, was not successful in detecting the mixtures of pigments as they were described on the sample bottles. Therefore, low discriminations were observed with the Raman technique. In some cases, it was possible to discriminate pairs that could not be distinguished using MSP and FTIR. Such discriminations were possible by means of the consideration of the presence (or absence) of additional Raman bands along with those of the main pigment. Elemental analysis with SEM-EDS allowed for obtaining a commonly observed profile based on silicon, sulfur, titanium, magnesium, aluminum, and phosphorous. Some differentiations of X-ray spectra were possible on the basis of a higher intensity of the sulfur signal as well as the occasional presence of other elements (such as bromine or tantalum).

To conclude, this preliminary study indicated that the following analytical sequence was the most appropriate one for the characterization and discrimination of pink and red nail polish lacquers: stereomicroscopy, MSP, FTIR spectroscopy, and Raman spectroscopy. This sequence allowed for the observation or detection of the following properties: color observation and sparkling particles, color measurement, binder, plasticizers and additives, and organic pigments.

Nail Polish Lacquers, Trace Evidence, Microscopy

A123 GSR Analysis: Correlating Quantities of Trace Metals (Pb, Sb, Ba) by ICP-MS to the Presence of GSR by SEM

Megan M. Fletcher, MSFS, South Carolina Law Enforcement Division, 4416 Broad River Road, Columbia, SC 29210; and J. Graham Rankin, PhD, and J. Alexander Messina, BS, Marshall University, Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will have a better understanding of the trace metal (Pb, Ba, and Sb) quantities identified by the Inductively Coupled Plasma – Mass Spectrometer (ICP-MS) that correlate to the presence of gunshot residue (GSR) and associated particles reported using the Scanning Electron Microscope – Electron Dispersive Spectrometer (SEM-EDS). Attendees will also understand the effect that time and physical activity have on the quantities of trace metals associated with gunshot residue found on a person's hands after shooting a firearm.

This presentation will impact the forensic science community by highlighting the importance and validity of using the ICP-MS as a means to quantify trace metals associated with GSR by demonstrating a correlation between quantities of metals to the presence of GSR by SEM-EDS, thereby allowing the crime lab a greater throughput for GSR cases. The data gathered in this study from the SEM also has the potential to substantiate a timeline that shows the degradation of GSR evidence over time.

Traditionally, the Scanning Electron Microscope (SEM) has been used for the analysis of gunshot residue evidence because of its ability to identify gunshot residue particles elementally and morphologically. Some disadvantages of using only the SEM in gunshot residue analysis include low throughput ability and a lack of quantitative ability. For agencies with a high volume of cases which involve GSR kits, the Inductively Coupled Plasma – Mass Spectrometer (ICP-MS) is a viable response to these disadvantages. The sensitivity, precision, and accuracy make it an ideal candidate for analyzing GSR evidence from the hands of people suspected of having been around a gun when it has been fired. Literature reports the ICP-MS limits of detection for Pb, Ba, and Sb to be 0.1µg/L, 0.02µg/L and 0.05µg/L respectively. The use of both the ICP-MS and the SEM will allow the agency higher throughput and an ability to quantify trace metals on a person's hands while maintaining the ability to conclusively identify GSR particles.

GSR kits, consisting of both SEM particle lifts and swabs, were taken at zero, one, two, four, and six hour intervals post-firearm discharge. All subjects continued their general laboratory and office duties and kept a record of those daily activities. Two sets of data were generated using two different calibers of weapons (a .22 caliber semi-automatic and a .44 caliber revolver) in order to achieve minimum and maximum quantities of gunshot residue. Particle lifts were taken from the right palm, right back of the hand, left palm, and left back of the hand of the participating shooters. These lifts were then followed by sample swabs of 5% nitric acid (two swabs per region of the hand) as well as one set of control swabs taken from a region of skin that should not have come into contact with GSR during a shooting, such as the covered back of the shooter's calf or shoulder.

Quantities of metals from the ICP-MS were calculated from each sample from the GSR kits and these quantities were compared to results obtained from the sample area using the SEM. Quantitation values of the previously mentioned GSR kits were separated by region of hand, as well as element, and then averaged for practical application. In order to provide minimum quantities that correlate to the presence of GSR and related particles, only .22 caliber results were used in the calculations.

SEM confirmed samples were categorized based on the particles found. Four classes were used to distinguish the samples: round Pb-Ba-Sb particles (gunshot residue), non-round Pb-Ba-Sb particles, round lead particles, or negative. Trend lines were then created to display particle behavior as a function of time. A negative correlation was observed between the amounts of GSR or GSR related particles and the length of the time intervals, while negatives had a positive correlation.

ICP-MS, Gunshot Residue, Metals Analysis

A124 Wikis in Criminalistics: An Example of Constructive Alignment and Collaborative Knowledge Building

Shirly Berends-Montero, PhD, Netherlands Forensic Institute Academy, Laan van Ypenburg 6, The Hague, 2497GB, NETHERLANDS*

After attending this presentation, attendees will understand the concept of constructive alignment and will recognize at least one tool for collaborative knowledge building.

This presentation will impact the forensic science community by creating awareness about the optimization of the process of teaching/training-learning forensic science at all levels and all fields, through the use of pedagogical and didactical models.

For some time, forensic sciences have been experiencing a paradigm shift in which ideas and protocols used for many years are thought to be obsolete and logically incorrect. Worldwide, individuals and organizations active with forensic sciences are discussing the optimal approach to the different phases of the forensic process with "a sound scientific foundation and justifiable protocols..[1] As a consequence, knowledge is being created, modified, and applied at a rapid rate. As proposed in the model of personal and social knowledge-building by Stahl (2000), the initial ideas of an individual about a problem ought to be crystallized in words and made public in order to engage in the cycle of "social" knowledge-building.[2] Through feedback, argumentation and negotiation, the formalization of the created collaborative knowledge is possible and can be followed by its integration into an individual's comprehension.

These processes or phases in the above mentioned model are recognizable in actual situations within the forensic sciences. Collaborative Knowledge Building (CKB) becomes ideal in many learning situations within a forensic science educational program. Integrating CKB into the curriculum provides the student/trainee with a realistic environment of multidisciplinary teamwork far from the individualism taught in the lower levels of formal education. Active learning takes place when using CKB while engaging in the dynamism of social networking. The involvement of the student/trainee in such an activity can begin while learning the same principles that are under fire. Stimulating the forensic science student/trainee to learn and defend these principles with sound argumentation against the scrutiny of peers seems not only a good idea but a necessity.

Just like with other approaches to active learning, the essence of the constructive alignment theory, the instructor/trainer doesn't have the central role in knowledge transfer, but takes diverse roles as organizer, planner, coach, and facilitator of the learning process.[3] In addition, the instructor/trainer can turn to different CKB technologies such as the use of wikis, discussion boards, and webblogs to integrate in the course design. These tools offer other advantages for both teaching/training-learning situations and developing new knowledge, among others the ubiquity, asynchronicity, and the possibility for anonymity while using the tool. In addition, under quality control, they can become reference material for professionals in the field.

Criminalistics is a course given within the first year of a two-year master's program in forensic science at the University of Amsterdam. The students come from different bachelor's programs in the area of biology, chemistry, physics, mathematics, and computer science. To unify the group is almost an impossible mission. Fortunately, for the basic principles in forensic science, only the general scientific critical thinking level is needed; the content knowledge can be built with time. However, doing this with such a variety of students becomes a difficult task when it is desired that the student's motivation remains high during the activities. Wikis are said to be useful in expanding community involvement and interest, because wikis grow and evolve as a direct result of people adding material to the site.[4] For that reason, a wiki was chosen to be part of the criminalistics course. The content of the wiki was infrared spectroscopy and its applications to forensic science for identification and comparison of different samples (adhesive tapes, explosives, fibers, documents, drugs, and car paint). Each team had to work on one sample type and review a second type. This activity was designed to align the course to the learning outcome, "Indicate the steps necessary to select a type of analysis method to address a specific research question." The assessment of the activity was divided into two parts, the wiki itself (CKB) and a quiz (content). The students found the activity useful in learning about the subject and considered the team work beneficial. On the other hand, there was correlation between the results from the quiz and the results from the part of the final exam that assessed the above mentioned learning objective.

Constructivism, Education, Training

A125 Detection of Designer Cathinones in "Bath Salts" Using Ion Mobility Spectrometry

Bryan E. Cetroni, West Chester University of Pennsylvania, 341 Corner Ketch Road, Downingtown, PA 19335; and Monica Joshi, PhD, West Chester University of Pennsylvania, Department of Chemistry, 750 South Church Street, Schmucker Science South, West Chester, PA 19383*

After attending this presentation, attendees will gain insight into the utility of ion mobility spectrometry for the detection of novel designer stimulants that have gained popularity as legal highs.

This presentation will impact the forensic science community by expanding the current detection menu of ion mobility spectrometers to include synthetic cathinones thereby improving the field detection of these stimulants.

Recent news and law enforcement reports indicate that there is increasing concern regarding the abuse of designer stimulants being marketed as components of several legal products.[1,2] Of these products, the so called "bath salts" have taken prominence and have been readily available over the internet through European websites and in various local gas stations, smoke shops, and tattoo parlors. The active stimulants found in these products are several derivatives of cathinone which is a central nervous system stimulant. These chemicals have been reported to provide euphoric effects that are similar to drugs such as cocaine and the phenethylamine class of drugs which include methamphetamine and methylenedioxymethamphetamine (MDMA). The increased prevalence of these "legal highs" has led some states to ban the sale of these substances though the chemicals are currently not regulated by the controlled substances act.[1] There is very little research on the detection and analysis of these chemicals mostly due to their recent rise in popularity. The Drug Enforcement Administration (DEA) reported the characterization of Methylenedioxypyrovalerone (MDPV) using various spectrometric and mass spectrometric methods.[3] There is a need for a rapid and robust analytical method that can serve as a screening method for these chemicals. Ion mobility spectrometers (IMS) are widely used in airports and other high security areas to detect trace levels of illicit substances such as explosives and drugs of abuse. It will be demonstrated that several synthetic cathinones such as mephedrone, MDPV, and naphyrone can be detected with an ion mobility spectrometer. All five target compounds included in this study produced characteristic peaks in the positive ion mode and the reduced mobility for each peak is used as the qualitative measure of the ion peak produced. A majority of the compounds produced single reproducible ion peaks while the fragment and dimer peaks found were concentration dependent. Assigning accurate masses to the peaks can be achieved by coupling a mass spectrometer to an ion mobility spectrometer and this is being investigated further. The discussion includes data on the limits of detection and limits of quantitation of these compounds. The overall limit of detection for all five target compounds was below five nanograms. Current detection menus of IMS instruments include detection parameters for amphetamine and its derivatives. The data presented will demonstrate the differentiation of the cathinones from these compounds. A discussion

on the resolution of these compounds in a bench-top IMS instrument and future studies to improve and expand the current stimulant detection menu will also be presented. Currently studies are being conducted to test several bath salts and possible interfering substances to validate the IMS method for the different compounds of interest.

Designer Stimulants, Ion Mobility Spectrometry, Bath Salts

A126 The Effects of Containment System Selection for the Storage of Surrogate Continuation Aids

Katylynn Beltz, BS, Florida International University, 11200 SW 8th Street, Room CP344, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the steps taken to determine the optimal containment system for storing various detection canine surrogate continuation aids. The determination of the proper containment system is a critical step in determining both the effects of containment on the odor availability of the surrogate continuation aid and the ease at which the aids become contaminated. Headspace analyses using solid-phase microextraction (SPME) coupled with gas chromatography with either electron capture or mass spectrometry detection was used to identify and quantify the odorant emanating from the secondary containment system over a series of weeks. Headspace analyses of the surrogate continuation aids were also performed to determine if cross-contamination of the surrogate continuation aids held within the containment vessel was also occurring.

This presentation will impact the forensic science community by reducing the current gap in knowledge in the field, allowing for reliable system of training aid containment to be implemented in the field. Maintenance of the integrity of the surrogate continuation aid odors is imperative to ensure standardization of training, increasing the reliability of the canine to detect the various illicit odors.

The goal of this study is to determine the optimal containment system for storing various detection canine surrogate continuation aids. Selection of the proper storage system is necessary for the maintenance of potency, efficacy, and functional integrity of canine surrogate continuation aids as cross-contamination of the surrogate continuation aids are always of great concern. Currently canine handlers and trainers use a variety of containment systems (glass, plastic, cloth, etc.) for surrogate continuation aid storage; however, an in-depth and systematic study is required to determine the optimal containment system, taking into consideration different factors that potentially play important roles in the potency and efficacy of the surrogate continuation aids.

In order to establish a consistent and optimal practice among canine handlers, law enforcement agencies and other allied parties formed the Scientific Working Group on Dog and Orthogonal Detector Guidelines (SWGDOG) which has produced a series of best practice guidelines covering different aspects of canine and orthogonal detectors. While SWGDOG has identified several areas of continued research, the effects of containment system on odor availability and the development of methods to monitor the levels of contamination of surrogate continuation aids have been identified as critical research topics. Both of these critical research topics have been addressed in this research study.

The determination of the proper containment system is a critical step in determining both the effects of containment on the odor availability of surrogate continuation aids and the ease at which the aids become contaminated. Three levels of containment have been identified for the proper and adequate storage of a canine surrogate continuation aids. The primary level of containment should deliver a known and controllable amount of odor to the atmosphere, for example through selective permeation. The secondary level of containment encloses the surrogate continuation aid in primary containment. Requirements for secondary containment include: airtightness, sufficient size to hold the surrogate continuation aids, portability, and have no adverse effect on the surrogate continuation aid. The final, tertiary level of containment must be airtight, sufficiently large to hold the surrogate continuation aids in secondary containment, and portable.

Airtightness tests were performed on the secondary containment systems to initially screen viable options since permeation out of the secondary containment system will be reduced if the system is found to be airtight. Once potential secondary containment systems were selected, a cross-contamination study was performed to determine which secondary containment system demonstrates the least permeation of the volatile odorants out of the containment system. Volatile odorants selected for testing included the surrogate continuation aids found in the International Forensic Research Institute (IFRI) Prototype Surrogate Explosives Kit as these results are needed to advance the technology of Controlled Odor Permeation Systems (COMPS) and a standardized training kit. Headspace analyses using solid-phase microextraction (SPME) coupled with gas chromatography with either electron capture or mass spectrometry detection was used to identify and quantify the odorant emanating from the secondary containment system over a series of weeks. Headspace analyses of the surrogate continuation aids were also performed to determine if cross-contamination of the surrogate continuation aids held within the containment vessel was also occurring. Permeation rate comparisons, through gravimetric analyses, were made between various containment media to determine if the containment vessel affects the effective life-span of the aid.

From the small scale studies completed, the canning jars demonstrate the best performance for being the optimal secondary containment system; however, these jars have metal lids that potentially form rust over time and may add unwanted odor to the surrogate continuation aids. To abate this concern, we have expanded the selection of containment systems beyond ones currently used in the field for testing.

Maintenance of the integrity of the surrogate continuation aid odors is imperative to ensure standardization of training, increasing the reliability of the canine to detect the various illicit odors. This study reduces the current gap in knowledge in the field, allowing for reliable system of surrogate continuation aid containment to be implemented in the field.

The Science and Technology Directorate of the U.S. Department of Homeland Security partially sponsored the production of this material under Interagency Agreement IAA # HSHQDC-10-X-00297 with the National Institute of Standards and Technology (NIST).

Detection Canines, Storage, Explosive Surrogate Continuation Aids

A127 Comparison of Aggregating Agents for Surface-Enhanced Raman Analysis of Benzodiazepines

Erika L. Doctor, MS, Florida International University, CP 175, 11200 SW 8th Street, Miami, FL 33199; and Bruce R. McCord, PhD, Florida International University, Department of Chemistry, University Park, Miami, FL 33199*

The goal of this presentation is to show attendees the applicability of surface enhanced Raman spectroscopy to the analysis and detection of trace

quantities of benzodiazepines. The optimization of various parameters of this technique as well as the limits of this method will also be discussed.

This presentation will impact the forensic science community by showing a technique that has better selectivity and sensitivity than current immunoassay screening techniques for benzodiazepines.

Benzodiazepines are commonly prescribed medications for anti-anxiety and anti-depression. The effects these compounds have on the central nervous system such as drowsiness, amnesia, confusion, and impaired coordination have made these drugs prominent in the commission of drug-facilitated sexual assaults. There has been a significant increase in the prevalence of these types of drugs in case submissions. The target detection limit for these compounds in biological samples is 50ng/mL, which is well below therapeutic concentrations.

Surface-Enhanced Raman spectroscopy (SERS) has previously been shown to detect trace quantities of compounds, such as nicotine, in aqueous solutions. This technique has the advantage of overcoming the low sensitivity and quenching the unwanted fluorescence effects seen with conventional Raman spectroscopy. SERS spectra are obtained by applying a compound of interest onto a SERS-active metal substrate such as colloidal metal particles or metal films. In this case, the colloidal particles are spherical gold nanoparticles in aqueous solution.

To further increase the enhancement of the SERS signal, aggregate solutions are used. These agents are salt solutions which cause the nanoparticles to amass and form hot-spots which increase the signal intensity. Chlorine salts generally provide the greatest enhancement for two reasons. The chlorine ions displace the stabilizing agent to cause aggregation and they affect the ionic strength of the surrounding solution changing the surface charge of the substrate, therefore increasing the signal intensity. While a single aggregating salt will affect a substrate the same, it has different effect on the signal of various analytes. Aggregating agents must be assessed for each individual drug to determine the optimum aggregating agent for a range of benzodiazepines.

Aqueous colloidal dispersions of gold spherical nanoparticles were prepared using a modified Lee Meisel 1% sodium citrate reduction method. Particle size and shape were confirmed with an average size of approximately 30 nm. Diluted benzodiazepine and metabolite samples were prepared in 10% methanol. Four aggregating agents were compared for enhancement of spectral characteristics. $MgCl_2$, $CaCl_2$, NaCl, and KCl were chosen and prepared at a concentration of 1.67 M. Aggregate solutions were added to colloidal dispersions followed by the addition of a range of benzodiazepine concentrations (1ng/mL – 1000ng/mL) and SERS spectra were obtained.

It was found that each aggregate had different enhancement effects on each individual drug. Overall $MgCl_2$ provided the lowest limit of detection, 2.5ng/mL, and linearity over a range of concentrations for a variety of drugs chosen. It was also observed that generally the higher the chlorine ion concentration, the higher the SERS intensity observed. Lastly, the cations of the aggregating solutions had an effect on the SERS signal. The smaller the cation the higher the intensity produced.

This method has shown the applicability of SERS for the detection of trace quantities of benzodiazepines in aqueous solutions as well as the optimization of the technique over a wide range of compounds. This technique can be adapted for use in the detection of trace benzodiazepines in toxicological samples such as urine. SERS is more specific than currently used immunoassays giving spectral information about the compound present. Also, this technique has more sensitivity than immunoassays and in the case of benzodiazepines such as lorazepam that have poor cross-reactivity, the drug can be detected.

Benzodiazepine, Surface-Enhanced Raman Spectroscopy, Drug Chemistry

A128 Preparation of Molecularly Imprinted Monolithic Polymers as the Stationary Phase for Liquid Chromatography

Yuanwei Gao, BS, and Seongshin Gwak, BS, Sam Houston State University, 555 Bowers Boulevard, #1528B, Huntsville, TX 77340; and Jorn C.C. Yu, PhD, Sam Houston State University, Box 2525, College of Criminal Justice, Sam Houston State University, Huntsville, TX 77341*

After attending this presentation, attendees will learn the theory of MIP, preparation of MIP, and the practical use of MIP in analytical instrumentation such as high performance liquid chromatography (HPLC).

This presentation will impact the forensic science community by showing how molecularly imprinted monolithic polymers (MIMPs) were prepared in three different types of materials including polyetherether ketone tubing, polymer sheathed fused silca tubing, and empty stainless steel columns by *in situ* polymerization with thermal initiation. Attendees will be able to learn how different materials impact the practical use of MIMPs in an analytical column.

The preparation of MIPs usually consists of three steps. First, the functional monomers and template (target) molecules are mixed and interacted by either non-covalent or covalent bonding. Then, the functional monomer aggregation follows in order to allow the formation of the alignment in the presence of cross-linkers. In other words, imprinting of template molecules in a polymer is achieved by the polymerization of the functional monomers and cross-linkers in the presence of template molecules. Finally, the imprinted templates are removed from the polymer to produce binding sites, which are specific to the template molecules. These binding sites on MIPs have a permanent memory of the template molecules in terms of complementary size, geometry, and orientation of functional groups. These specific binding sites can selectively recognize the target molecules, even in a complex sample solution. It has been demonstrated that MIPs have molecular recognition property as a bio-mimetic recognition layer in enzyme-linked immunosorbent assay (ELISA), chemical sensor systems, selective molecularly imprinted solid phase extraction (MISPE), and in HPLC with a chiral stationary phase.

Molecularly imprinted monolithic polymers (MIMPs) were first studied in the early 1990s. This type of MIPs can be prepared directly in a column or a capillary. Therefore, the process is relatively simple and it can reduce the amount of template molecules consumed during the preparation of MIPs. In this work, MIMPs using (-)-pseudoephedrine as a template were prepared inside of capillaries or columns by *in situ* polymerization. The idea was to prepare a MIP stationary phase for chiral separation of methamphetamines. In order to identify an optimal polymerization condition for the preparation of MIMPs, the back pressure of each polymer was monitored by a liquid chromatography (LC) pump under an isocratic flow condition. The separation of (-)-pseudoephedrine from its stereoisomers including (+)-ephedrine, (-)-ephedrine, and (+)-pseudoephedrine were tested in different mobile phases and flow rate conditions using LC equipped with a tandem mass spectrometer (MS/MS). The final polymerization condition for the preparation of MIMPs was determined using a polymerization mixture with (-)-pseudoephedrine as the template, methacrylic acid as the functional monomer, and ethylene glycol dimethacrylate as the cross-linker. Concentration ratio of template, functional monomer, and cross-linker was 1:3:27. The porogenic solvent mixtures which include toluene and 1-dodecanol, and cyclcohexanol and 1-dodecanol were used with the ratio of 1:9.5 and 1:9.3, respectively. The back pressures of MIMP columns were monitored with flow rates from 0.01 to 0.15 mL/min isocratically. The MIMP column prepared with toluene as porogen showed relatively lower backpressure than the one with cyclohexanol. Although the separation of (-)-pseudoephedrine from its stereoisomers has not yet been achieved, the next step is to maximize the selectivity of MIMP by optimizing the polarities of the mobile phases. Once the optimal condition is determined, MIMPs may be prepared in narrower inner diameter tubings (such as nano-LC columns) to maximize

the advantages of using MIMPs for chiral separation in advanced LC systems.

Forensic Science, Molecularly Imprinted Polymer, Chiral Separation

A129 ASTM Classification of Ignitable Liquids and Residues by Chemometric Techniques

Caitlin Rinke, BS, University of Central Florida, PO Box 162367, Orlando, FL, 32816; Erin Waddell, BS, Mary R. Williams, MS, Michael Sigman, PhD, and Emma Song, BS, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

The goal of this presentation is to establish a methodology with known error rates for the identification and classification of ignitable liquids in fire debris samples.

This presentation will impact the forensic science community by introducing an objective method to be applied to ignitable liquid and pyrolysis product classification in fire debris analysis. The methods investigated are intended to provide statistical support for current laboratory practices.

Models were developed to assign ignitable liquids to the ASTM classes based on the total ion spectrum (TIS) for each sample from a library of ignitable liquid gas chromatography-mass spectrometry (GC-MS) data and a library of pyrolysis product GC-MS data. The first step of model development was to reduce the dimensionality of the data through the use of principal components analysis (PCA) to construct a set of latent variables. This was followed by linear discriminant analysis (LDA) and quadratic discriminant analysis (QDA) based on the PCA scores. Cross-validation was performed by randomly selecting 20% of the samples from each class for a test set. The remaining 80% of the samples were used to develop a model for classification by LDA and QDA. Classifications for the test set were generated from the model and evaluated by comparison to the Technical Working Group for Fire and Explosions (TWGFEX) Ignitable Liquid Reference Collection (ILRC). The cross-validation steps were repeated 100 times with a new test set being selected and classified each time. Total correct classification percentages were calculated as the sum of the cross-validation tests. All models developed on ignitable liquid and substrate library data were applied to fire debris samples.

The LDA and QDA models were developed to classify samples as: (1) ignitable liquid or substrate; and, (2) by ignitable liquid ASTM class or substrate. Models in both categories included: (a) all ASTM E1618 classes; (b) all ASTM classes other than miscellaneous and oxygenates; and, (c) all ASTM classes but combined the classes of isoparaffinics and normal alkanes as well as petroleum distillates and naphthenic paraffinics. Although the samples within the training and testing sets performed well, fire debris samples were found to have a significantly lower correct classification rate. This was attributed to the presence of pyrolysis products that led to incorrect classifications.

The influence of pyrolysis products on correct classification rates presented a major challenge in this research and has led to consideration of additional methodologies. Other methods under investigation to increase the correct classification rate of these samples include partial least squares discriminant analysis (PLS-DA), soft independent modeling of class analogy (SIMCA), and method of normalized coordinates.

A130 The Use of Canine Field Testing to Optimize the Operating Parameters of a Non-Contact Collection Device for Human Scent

Jessica S. Brown, BS, Florida International University, 11200 SW 8th Street, CP 344, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the significance of utilizing the optimal operating settings of dynamic airflow devices used for the non-contact collection of human scent, and the impact they have on canine response when discriminating individuals.

This presentation will impact the forensic science community by highlighting the importance of collecting human scent from crime scenes or articles of evidence utilizing the optimal collection time and airflow speed of the human scent collection system to provide sufficient scent for canine discriminating purposes. In addition, this will encourage the standardization of human scent collection protocols for law enforcement officials.

The collection of human scent from crime scenes can aid investigators in determining whether a suspect/victim was present at a particular location. The tool often used to correlate a person scent to a specific location is a human scent discriminating canine which is trained to detect the scent of an individual excluding all other scents. The collection of human scent can be performed by several different methods: swiping, passive collection, and non-contact collection. Swiping of an object allows for the rapid collection of human scent onto a sorbent material; however, this method of collection introduces the potential of destroying important evidence, such as fingerprints. Passive collection of human scent is a lengthier process which involves placing a sorbent material near an object for a prescribed period of time resulting in the transfer of human scent from the object to the material. Lastly, non-contact collection utilizes a dynamic airflow to draw human scent away from an object and onto a sorbent material. The non-contact collection of human scent is a quick process leaving any potential evidence intact for further forensic analysis.

The Human Scent Collection System (HSCS) is a device which was created for the non-contact collection of human scent from objects and/or locations. Once collected onto a sorbent material, human scent can be presented to a human scent discriminating canine for matching purposes (e.g., scent identification line-up or tracking/trailing individuals). The HSCS is a lightweight, cylindrical device that provides a dynamic airflow, drawing human scent onto a 4”x4” cotton gauze pad. Features such as a digital screen, battery operation, pre-set collection times, and airflow speeds make the HSCS easy to use. The HSCS offers two collection time settings of 30 seconds (default) and 60 seconds, as well as three airflow settings of low, medium (default), and high. These programmed settings aid with standardizing scent collection between individuals or agencies and can be easily reproduced.

Field trials were conducted to determine the optimal operating parameters of the Human Scent Collection System. The responses from human scent discriminating canines were used to gauge which combination of time settings and airflow speeds would allow for sufficient human scent collection for tracking/trailing purposes. A total of 11 canine teams were used for testing. To summarize the design of the field trials, a target walked a path leaving a scent trail at a test site. Subsequently, scent from the hands and saliva of the target was collected (onto a cotton gauze pad) utilizing the HSCS. Once all targets produced scent trails and their scent samples were collected, canine teams were taken to the start of the scent trail and a corresponding scent sample would be presented to the canine for matching purposes. Canine response to the scent sample was evaluated based on three responses: (1) did the canine begin to trail; (2) the canine’s first decision; and, (3) the canine’s second decision. Canine response to human scent, collected using the HSCS, indicated that the optimal operating parameters were 60 seconds collection time and a high airflow speed.

Human scent, Canines, Scent Collection Device

A131 Avian Olfaction in Forensic Context: A Preliminary Analysis of Naturally Occurring Volatile Organic Compounds Associated With Feathers From Procellariiforms

Claudia L. Sanchez, BA, Florida International University, 14540 Balgowan Road, Miami Lakes, FL 33016; Paola A. Prada, PhD, Florida International University, 11264 SW 128th Court, Miami, FL 33186; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will have a better understanding of avian olfaction as another form of biological detection within a forensic context.

This presentation will impact the forensic science community by providing a foundation of work to understand avian olfaction.

Biological detection, particularly using canines, is in high demand because of its proven detection capabilities for a variety of forensic specimens including drugs and explosives. This work lays the foundation for a potential alternative means of biological detection through avian olfaction. Little is known about the behavioral and physiological sensitivity of birds to a wide range of odorants, and specifically, whether olfactory behaviors can be tuned and directed for applied uses as is the case with canines. A preliminary foundation for this work entails an instrumental evaluation of naturally occurring volatile organic compounds (VOCs) of feather samples to identify naturally occurring chemicals to further the understanding of the types of compounds that are present in their environment prior to explore their potential use in the detection of forensic odorants.

The instrumental evaluation of these biological samples collected from the field is conducted using solid-phase microextraction in conjunction with gas chromatography/mass spectrometry (SPME-GC/MS) utilizing Gould's petrel feather samples. These birds belong to the species of seabird in the Procellariidae family. They have the largest olfactory bulbs among all birds and thus represent an extreme class with a potentially high olfactory capability. They rely on olfactory cues both for foraging and navigation, and are thought to use individual-specific olfactory cues for rapidly and accurately relocating their home burrow when returning to the colony at night during the breeding season. The importance of olfaction in birds remains a matter of controversy. However, experimental behavioural studies regarding the use of olfaction in birds have found evidence of olfactory capability in birds of a variety of species of procellariformes that use the olfactory sense in several different functional contexts including orientation, reproduction, and even for some social aspects such as individual recognition and mate choice. Virtually nothing is known about the behavioral and physiological sensitivity of petrels to either synthetic or naturally occurring odorants, or what types or combinations of volatile organic compounds they naturally encounter. As a first step, the authors are conducting a preliminary analysis of volatile organic compounds found in 84 feather samples collected from Australia. The identification of over 100 compounds has been achieved using heated headspace extraction methodologies with sensitive instrumental detection. A comparison of the levels of the most common occurring volatile compounds (such as pristane) is being studied to understand olfaction in natural processes such as kin recognition. Thus far, significant levels of common forensic odorants such as those previously identified for drugs and explosives have not been observed. The importance of understanding avian olfaction in a natural habitat is a crucial first step in the exploration which may lead to potential future use of these animals as another form of biological detection for forensic purposes like national security that has been affected due to the increased threats of violence. Often times these threats are carefully hidden from human detection. To address this need, this investigation is a laboratory effort to develop science-based solutions that can be effectively deployed and used in a variety of real-world settings such as the detection of explosives.

Olfaction, Forensic Context, Feathers

A132 Micro-Absorption Spectroscopy as a Non-Destructive Tool for Forensic Analysis

Silki Arora, PhD, University of Central Florida, 1851 Bonneville Drive, Orlando, FL 32826; and Alfons Schulte, PhD, University of Central Florida, 4000 Central Florida Boulevard, PS 411, Orlando, FL 32816*

The goal of this presentation is to illustrate a new method for forensic analysis on the micron scale that combines absorption spectroscopy and confocal microscopy. Results on the characterization of representative samples, including sensitivity and linear dynamic range of micro-absorption measurements will be presented.

This presentation will impact the forensic science community by illustrating a method that uses spatially resolved absorption spectroscopy on a micron scale. It may improve trace analysis of samples that are obtained in micron size with minimal sample preparation.

The ability to investigate samples at a micron level with non destructive probes is a key factor in forensic studies. Fluorescence probes employing confocal or other geometries are available; however they generally require labeling and are limited by photo-bleaching and quenching. On the other hand, micro-spectroscopy based on absorption measurements provides a convenient label free way for characterizing an unknown material. A new experimental approach for micro-absorption spectroscopy is developed and applied to the investigation of fluid and solid samples relevant to forensics. By exploiting the spatial variation of the intensity due to Beer-Lambert's law ground state absorption spectra with a spatial resolution better than 1.4 micron in the lateral and 3.6 micron in the axial direction is measured. A confocal detection system is employed to probe and spectrally resolve the attenuation of a white light beam in the axial direction. It enables the measurement of absorption spectra of biological assemblies at the single cell level and small samples with a thickness of few microns. Confocal absorption microscopy is nondestructive and is capable of collecting both spatial and physical information based on light absorption by microscopic structures.

The quantities of samples often obtained in crime investigations are minute. Micro-absorption spectroscopy enables measurements on smaller sample volumes and with rapid acquisition time on the timescale of seconds. To examine the sensitivity of the technique, absorption spectra of nanoliter solutions in micro-capillaries with a pathlength of 50 microns are investigated. Through measurements of the transmitted intensity in calcein dye solutions at fixed pathlengths, it is established that the absorbance varies linearly with concentration over the range from 0.1 to 2 mM. Preliminary results indicate detection limits of better than 0.1mM in a sample volume of less than a picoliter.

The technology has been used to analyze micro-fibers and can be employed to distinguish the fibers from the known and suspected material at the molecular level. Another important aspect that is addressed is to acquire a spectrum of an individual hair, which is difficult using a Raman spectroscopic probe as it may lead to damage of the sample. As an application to the analysis of biological samples at the single cell level, the visible absorption spectrum of hemoglobin in a single live red blood cell (diameter ~ 7 microns) is measured under physiological conditions. Spectroscopic changes due to heme degradation under pathological conditions are investigated. Variations in the composition of inhomogeneous samples (e.g., thin films) can be determined from spatially resolved absorption spectra. Extensions of the micro-spectroscopic method to the ultraviolet and infrared regions of the spectrum will be discussed.

Micro-Absorption Spectroscopy, Nano-Liter Samples, Non-Destructive

A133 Vacuum-Based GSR Recovery

Jessica A. Motl, BS, 4312 Homestead Circle, San Angelo, TX 76905; Stephen S. Houck, BS, William M. Davis, PhD, and Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will learn about newly available apparta that enhance the collection of GSR from fabric using standard vacuums. Specific attention will be made to the quality control aspects of this evidence collection technique.

This presentation will impact the forensic science community by showing how Vacuum-Based GSR Recovery technique is known to be well-suited in the recovery of GSR from fabric.

Gunshot residue (GSR) is formed from primer detonation. The aerosol produced in the conflagration produces particles, upon condensation, composed of lead, barium, and antimony and the various combinations of those elemental oxides. These particles can deposit on the hands, face, and clothing of the shooter and/or any bystander in close proximity to the event. Current methods of testing surfaces for the presence of GSR include using a stub with double sided carbon tape that is then analyzed using scanning electron microscopy coupled with energy dispersive X-Ray analysis (SEM/EDX).

Testing clothing for GSR presents several unique challenges. These include the GSR particles becoming lodged within the weave of the fabric and the inability of current GSR testing methods to analyze the entire article of clothing for GSR in a non-random fashion. Current methods are inadequate due to the clothing providing such a large testing area and stubs losing stickiness. Vacuuming fabric presents an intuitively obvious solution to collecting residues of any kind. Custom-built devices have been reported in the literature but owing to limited capabilities in most forensic laboratories these may not be an adequate solution. A unit comprised of a nozzle, filter canister and vacuum adapter was recently purchased. The configuration of the device allows for easy cleaning and filter pore-size variablility.

Preliminary particle recovery was performed using barium silicon oxide ($BaO•SiO_2$). $BaO•SiO_2$ is a suitable model for GSR in that it can be applied to a substrate via an atomized spray. Particles are typically less than 10 microns. Additionally, large quantities of particles are deposited using a suspension $BaO•SiO_2$ in water. To ensure that no carryover was present, before testing any clothing with the attachment, the entire set up, complete with a new filter, was tested by pulling room air through the assembly for five minutes. The filter was then analyzed on the SEM. The filter had to produce negative results before being the assembly could used for testing and analysis. Rinsing the assemblies with water proved to be insufficient in removing whereas sonication followed by rinsing eliminated carry-over as measured in these experiments

Testing clothing exposed to GSR was then done. A lab coat and a long sleeve shirt were worn independently by an individual as shots were fires from a handgun. The first test, on the right sleeve of the lab coat from the elbow down to the cuff, illustrated that the vacuum filter did pick up GSR, the stub was able to pick up GSR from the filter, and the SEM was able to analyze the GSR from the stub. This initial test timed-out when the SEM reached 50 particles (a particle density of 0.83 particles/mm).

The left sleeve of the lab coat, from the elbow down to the cuff, was vacuumed using the attachment, and the same area was subsequently stubbed. These two stubs were analyzed on the SEM and the results illustrated that the filter did condense the GSR found on the sleeve. The vacuum filter and subsequent stub for the left sleeve of the lab coat displayed 50 particles (0.80 particles/mm and 22 particles (0.23 particles/mm) respectively.

The right sleeve was tested in the same manner described for the lab coat (from the elbow to the cuff), with the results showing eight particles for the vacuum filter and one particle for the stub. The inside of the front panels of the lab coat were vacuumed and the outside of the panels were subsequently stubbed. The vacuum filter timed out at 50 particles (2.59 particles/mm') and the stub displayed 45 particles (0.48 particles/mm').

It should be noted that the same assembly was used for all of the above measurements. Each cleansing was successful at removing any GSR that may have adhered to the plastic portions of the unit. A new filter was placed in-line for each recovery.

In summary, testing of the vacuum filter attachment produced positive results, illustrating that the filter picked up and condensed GSR particles for a less random, more uniform testing method. Although the filters were disposable, the apparatus and cartridges were re-used, increasing the risk of carryover contamination. Cleansing by sonication followed by rinsing and a quality control system effectively illustrated the vacuum attachment can be used and re-used without contamination.

GSR, Vacuum, Fabric

A134 Electrophoretic Separation of Drugs of Abuse Using Laser-Induced Fluorescence Detection

Bruce R. McCord, PhD, Department of Chemistry, Florida International University, University Park, Miami, FL 33199; and Britt E. Turnquest, BSc, Florida International University, 11200 SW 8th Street, Miami FL 33199*

After attending this presentation, attendees will have a better understanding of how amphetamine-related drugs of abuse can be derivatized, separated and detected using the fluorescent tag 5-(4,6-dichloro-s-triazin-2-ylamino) fluorescein (5-DTAF) and capillary electrophoresis system with laser-induced fluorescence detection. Also, the effects of various organic modifiers and surfactants on elution and resolution will be discussed.

This presentation will impact the forensic science community by providing an excellent screening method for trace amounts of phenethylamines and other related compounds which are efficacious at low doses due to their readily being absorbed, distributed and metabolized within the human body.

In capillary electrophoresis, a voltage is applied at the distal ends of capillaries filled with an electrolytic solution. These results in compounds being separated based on their mass-to-charge ratios. This method uses sample volumes in the nanoliter range and is capable of detection in the ng/mL range. For this study five commonly encountered drugs and precursors (used in illicit preparations) were investigated: amphetamine; methamphetamine; norephedrine; ephedrine; and, methylenedioxyamphetamine (MDMA). These compounds represent both primary and secondary amine moieties as well as three variations to the phenethylamine parent structure. Laser-induced fluorescence is a commonly utilized detection method in electrophoretic separations. This is due to its high sensitivity and specificity despite the short optical path length necessary when using capillary columns. Because compounds which natively fluoresce are rare, in order to utilize this detection method, the analytes of interest must first undergo derivatization. Fluorescence derivatization is the process whereby non-fluorescent analytes are coupled to an additional compound in order to produce an overall fluorescent molecule.

Due to their structure phenethylamine related compounds all have a pKa approximately within the range of 9.0 to 10.0 and migrate at a fairly similar rate. To compensate for this, modifiers in the form of surfactants and/or cyclodextrins were added to the run buffer to provide a pseudo-stationary phase. Organic solvents are also added to affect the equilibrium between the sample and this pseudo-phase. As a result, the individual drugs separate into distinct zones which are then excited by the laser as they pass the detection window on the way to the cathode. The signal from this excitation and subsequent emission is then collected by the detector and converted into an electropherogram for interpretation.

Drug standards were obtained from the International Forensic Research Institute at Florida International University and dissolved in analytical-reagent grade methanol for storage at 4°C. Prior to analysis,

samples were diluted to appropriate concentrations using deionized water. For this method a micellar running buffer comprised of 50mM borate, pH 9.5/30mM Brij-35 was used for the separation of the analytes. A background electrolyte of 50mM borate, pH 9.5, and a derivatization buffer of 0.5M $NaHCO_3/Na_2CO_3$, pH 9.5 were also utilized. Experiments were conducted using a Beckman P/ACE MDQ unit interfaced with a computer utilizing Karat 32 software (version 7.0). The fused-silica capillary was 60.5cm (effective length 50cm) with an internal diameter of 50µm. An argon ion laser was used as an excitation source (488nm) and electropherograms were recorded by monitoring the emission intensity at 520nm. New capillaries were conditioned by thorough rinsing with 0.1M sodium hydroxide, deionized water, and micellar running buffer in series.

Amphetamines, Capillary Electrophoresis, 5-DTAF

A135 Fast Gas Chromatography Applications in Ignitable Liquids and Drug Identification

Charles R. Cornett, PhD, Rebecca L. Hansen, BS, and Ashley Halligan, BS, University of Wisconsin-Platteville, Department of Chemistry, Platteville, WI 53818; Leah J. Macans, BS, Wisconsin State Crime Laboratory - Milwaukee, 1578 South 11th Street, Milwaukee, WI 53204-2860; and Joseph Wermeling, PhD, Wisconsin State Crime Laboratory - Madison, 4626 University Avenue, Madison, WI 53705-2174*

The goal of this presentation is to highlight applications of fast gas chromatography (Fast GC) in ignitable liquids as well as drug identification while also assessing the use of hydrogen mobile phase.

This presentation will impact the forensic science community by demonstrating the value of Fast GC and hydrogen mobile phases to forensic analysts in units using conventional gas chromatography by demonstrating statistically significant improvements in retention time, resolution, and laboratory supply costs with implementation.

The objective of this project is designed to assist crime laboratories' assessment of new separation techniques and gauge the feasibility of implementation. The first objective of this project is an assessment of the expected gain in resolution and sample throughput in ignitable liquid and drug identification analysis using a combination of Fast GC and hydrogen carrier gases. This area of application is prime ground for realizing the full potential of Fast GC – H_2. In 2008, a joint project funded by the Midwest Forensics Resource Center between the University of Wisconsin – Platteville (UWP) and the Wisconsin State Crime Laboratory – Madison demonstrated incredible reductions of over 50% in retention times of ignitable liquids from arson debris using the Fast GC. This study also found that the use of hydrogen as a carrier gas more than compensated for resolution losses related to Fast GC. In fact, the more compressible hydrogen carrier produced improvements in resolution for the Fast GC analysis compared to a conventional GC technique using helium carrier gas ($p < 0.01$). Fast GC-H_2 separation of drug identification samples could potentially decrease retention times of straightforward matrices to several tens to a few hundred seconds. In addition to presenting the 2008 results to the AAFS, this presentation addresses the limiting factors of this technique including the scanning rate of the quadrupole mass spectrometer and effects on detection limits of illicit drugs.

Experimental design involves the Fast GC and conventional analysis of one dozen Scheduled compounds including cocaine, tetrahydrocannabinol (THC), heroin, 3,4-Methylenedioxymethamphetamine (MDMA), trifluoromethylphenylpiperazine (TFMPP), lysergic acid diethylamide (LSD), buprenorphine, synthetic cannabinoids, alprazolam, clonazepam, boldenone, and nandrolone. The figures of merit selected for ANOVA ($p < 0.05$) comparisons center on retention times and chromatographic resolution of a master standard containing these twelve compounds. Given that many laboratories may hesitate to modify existing units for Fast GC, the first assessment examines the benefit in simply switching to the less expensive hydrogen mobile phases from the helium mobile phase. The control in this experiment is the conventional GC operating with a standard DB-5, 30 m column and helium mobile phase. The hydrogen is employed instead, and a data set is generated with resolutions compared to the helium gas. Subsequently, the heating ramp of the conventional GC is increased without altering other variables to assess just how aggressive of a heating ramp can be used to reproducibly equal the conventional use of helium. The second set of experiments uses solely helium while comparing Fast GC and conventional GC in the event that a laboratory is not ready or able to convert to hydrogen carrier but is interested in the Fast GC gains. In this particular case, the data demonstrate the resolution decrease for cost: benefit analysis. Finally, the two variables (Fast GC and hydrogen mobile phase) are combined to assess the maximum benefit.

Fast GC, Ignitables, Drugs

A136 SWGDOG and ICODD: Latest Dog and Orthogonal Detector Best Practices and Development of an Accreditation Program

Jessie Greb, MBA, Florida International University, 11200 SW 8th Street, CP 330, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand how the establishment of best practices for detection teams is improving interdiction efforts and courtroom acceptance of dog alert evidence as well as the importance of creating an accreditation commission, the International Commission on Detector Dogs (ICODD).

This presentation will impact the forensic science community by providing a better understanding of how SWGDOG best practices and accreditation through ICODD are improving the consistency and performance of deployed detector dog teams and their optimized combination with emerging electronic detectors.

The Scientific Working Group on Dog and Orthogonal Detector Guidelines (SWGDOG) has been developed by a membership of respected scientists, practitioners, and policy makers representing diverse backgrounds. SWGDOG has been cooperatively funded by the NIJ, FBI, DHS, and TWSG with general meetings held biannually since 2005. This project was undertaken as a response to concerns coming from a variety of sectors including law enforcement and homeland security regarding the need to improve the performance, reliability, and courtroom defensibility of detector dog teams and their optimized combination with electronic detection devices.

The approval of each subcommittee best practice document takes six months to complete, including a two month period of public comments. The nine SWGDOG subcommittees and target timetable for posting of the best practice guidelines are as follows: (1) Unification of terminology (Part A - April '06; Part B - October '06; Part C - March '07; Part D - August '07; Part E - March '08; Part F – September '08; Part G – March '09; Part H – Sept. '09; Part I – March '10; Part J – September '10; Part K – March '11); (2) General guidelines for training, certification, maintenance and documentation (April '06) - Publication in FSC October '06; First Revision (September '08); Second Revision (September '09); (3) Selection of serviceable dogs and replacement systems (October '06) Publication in FSC October '08; (4) Kenneling, keeping, and health care (October '06); (5) Selection and training of handlers and instructors (Part A - October '06; Part B – March '10); (6) Procedures on presenting evidence in court (October '06; First Revision Sept. '10); (7) Research and technology (March '07; First Revision September '10); (8) Substance dogs: Agriculture; Arson; Drugs; Explosives; (August '07); Human remains (September '09); Contraband (March '11); Pest (March '11); Currency; Firearms (September '11); (9) Scent dogs: Non-specific Human Scent Wilderness Area Search; Location Checks; Article Search; Scent identification line-ups ; Live People in Disaster Environments; Track Trail people based on Last Known Position; Pre-scented Canines Aged Trail;

Live People in Avalanche (Part A - March '07; Part B – August '07; Part C – March '08; Part D – September '08; Part E – September '09; Part F – March '10; Part G – September '10; Part F – March '11); and, (10) Outreach & Education: PowerPoint, branding materials approvals (September '10)

The current success of SWGDOG is being manifested by a shift of some national canine organizations to adopt the approved SWGDOG best practice guidelines. The mission of the International Commission on Detector Dogs *(www.ICODD.org)* is to globally improve the performance of detector dog teams through information sharing and implementation of SWGDOG best practice guidelines through voluntary accreditation of certification bodies. Annual ICODD meetings include open discussions of current, pending, and needed best practice guidelines and provide the mechanism for certifying bodies to apply for accreditation through the Accreditation Council made up of representative commission members.

Detector Dog, Best Practices, SWGDOG

A137 Characterization of Legal Highs

Melody P.L. Cai, BSc, Tracy P.S. Toh, BSc*, Ying Ying Tan, BSc, and Angeline T.W. Yap, PhD, Health Sciences Authority, 11 Outram Road, Singapore 169078, SINGAPORE*

The goal of this presentation is to demonstrate the characterization of five legal highs that have either been encountered in Singapore or have already surfaced in other countries.

This presentation will impact the forensic science community by establishing the usage of structure elucidation techniques which will enhance the forensic laboratory's ability and confidence in the identification of legal highs.

New synthetic drugs such as the cathinones (e.g., methylone, butylone MDPV) and cannabinoids (e.g., JWH-018, HU-210, CP 47,497) are making their headways into many countries. These synthetic drugs are often termed as legal highs as they are analogues of existing banned drugs of abuse, bearing similar chemical structures and psychoactive properties as their illegal counterparts. These products are often marketed using labels such as "bath salts," "incense," and "botanical specimens." These seemingly licit product names are used as a ploy to deceive the legal forces from their true recreational use. Consequentially, legal highs have become increasingly popular as legal alternatives to illicit psychoactive substances for the drug abusers. This in turn, brings about a high demand for legal high which is further facilitated by their widespread and easy availability on the internet. Labels on the packaging of legal highs sold over the internet are often unreliable indicators of its actual contents. Consumers may be led to believe that the products are legal which makes internet sales of legal highs highly lucrative.

The accessibility of legal highs for recreational usage and the constant emergence of new legal highs have posed challenges to forensic laboratories around the world in their testing and identification. Due to the novelty of these drugs, reference materials of such legal highs are often not available. Literature reports containing detailed analytical data of such drugs are often limited and, in most cases, unavailable as well. These have made their identification extremely challenging. Hence, there is a need for forensic laboratories to constantly identify alternative techniques and develop capabilities to fully characterise these new legal highs.

The objective of this paper is thus to demonstrate the characterization of five legal highs that have either been encountered in Singapore or have already surfaced in other countries. These five include methiopropamine, methoxetamine, and three synthetic cannabinoids. Methiopropamine is a thiophene-based structural analogue to methamphetamine. It possesses similar chemical structure except for the replacement of the heterocyclic moiety for a phenyl group. Another legal high encountered, methoxetamine, is an analogue of ketamine. Being structurally similar, these legal highs are believed to be able to exhibit similar psychoactive properties as their illicit counterparts. As methiopropamine and methoxetamine are both very new to the drug market, very little information on these two drugs is available.

Synthetic cannabinoids, or "Spice," are examples of legal highs marketed as herbal products. They are easily available over the internet and their popularity as "legal drugs" have rapidly increased due to their reputation of being potent herbal intoxicants and also as "legal" alternatives to the strictly regulated cannabis.

In this paper, several techniques were used in the characterization of these five drugs. Accurate mass analysis was performed using the orbitrap and time-of-flight mass spectrometry while gas chromatography/mass spectrometry (GC/MS), Fourier transform infrared spectrometry (FTIR), and nuclear magnetic resonance spectroscopy (NMR) were employed in structural eludication. The analytical data and the interpretation of the results obtained will be presented in this paper. The establishment of the usage of such techniques will enhance the forensic laboratory's ability and confidence in the identification of these legal highs.

Legal High, Characterization, Forensic

A138 Development of a Rapid Screening Method for Differentiation of the Traditional and Emerging Amphetamine Type Stimulants (ATS)

Omya Fekry, MSc, Michael D. Cole, PhD, and Beverley R. Vaughan, PhD, Anglia Ruskin University, East Road, Cambridge, Cambridgeshire CB1 1PT, UNITED KINGDOM*

The goal of this presentation is to make attendees aware of how presumptive test methods can be when applied to Ampethamine Type Stimulants. It provides a programmed approached to drug screening not previously described.

This presentation will impact the forensic science community by giving them the opportunity, for the first time, for law enforcement officers and forensic scientists to screen for new ATS drugs in both the field and the laboratory. This allows for instant informed decision-making concerning which samples to subject to further analytical testing. Prior to this method, such decisions were not possible.

Over the last decade there has been an enormous increase in the number of 'designer drugs' entering the illicit drug market. Many of these compounds are amphetamine type stimulants (ATS's). According to the recently published annual reports by the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA), in 2008 some 13 new substances were reported; in 2009, 24 were reported, and, in 2010, 41 new substances were described.[1] Alongside this, there have been well-documented decreases in the purity of these drugs in addition to an increase in the complexity of the drug mixtures. This emphasizes the need for a rapid, selective, and sensitive screening technique to be implemented.

In the United Kingdom there has been a move toward rapid action in law enforcement under the Misuse of Drugs Act, 1971 and its amendments involving these new designer compounds. Similar actions occur in the United States. In response to this, the clandestine chemists rapidly shift synthesis to analogues and derivatives of controlled drugs and continue to search for new alternatives to avoid prosecution.

Uncontrolled analogues and derivatives of well-known drugs of abuse are popular due to their diverse range of biological activities.[2] The use of and demand for these designer compounds is becoming increasingly popular due to their internet sales and and regular advertisement as "legal highs." In controlling possession of these compounds, the ability to detect new designer drugs, alongside commonly occurring amphetamines in locations other than analytical laboratories, has still not been thoroughly evaluated. Presumptive tests for controlled substances, for example the Marquis reagent for identification of opiates, amphetamines and ring substituted amphetamines, are occasionally used by forensic scientists and law enforcement officers on site. They are heavily used as screening methods in the laboratory setting.[3] The need for a rapid screening method

for commonly occurring drugs, as well as those newly used, is increasingly urgent as the number of drugs on the market increases exponentially.

The method described here uses a two stage approach in order to discriminate between a variety of ATS and precursor chemicals used in the synthesis of drugs of abuse. The initial stage involves the use of a series of seven presumptive test reagents that provide differentiation between compounds dependent on the functional groups present in the target molecules which include 14 examples of phenylethylamines, cathinone derivatives, ring substituted- and beta keto- amphetamines.

The second stage involves the use of thin-layer chromatography to provide further discrimination between the drugs. Samples were chromatographed on silica gel plates, developing the chromatogram in a chloroform-methanol solvent system (9:1 v:v). After development, separated compounds were visualised under UV light (254nm) and subsequently sprayed with 0.5M NaOH following by 1% Fast Black K Salt in distilled water which was applied directly to the plate. A range of colors were obtained with molecules from different classes.

The limit of detection using the presumptive tests lies in the low microgram range. TLC is more sensitive with visualisation of compounds possible between 0.625 and 10µg on plate. Successful validation of the method was performed in the form of blind trial testing after which the contents of the drug mixtures were confirmed by Gas Chromatography - Mass Spectrometry (GC/MS). This method allows non-specialists to make informed decisions concerning whether further laboratory analysis is required on suspected drug seizures.

ATS, Presumptive Testing, Drug Screening

A139 Testing AFIS Search Accuracy at the Limits of Minimal Minutiae

Gary H. Naisbitt, PhD, Aaron Hall*, and Dale Zinn, Utah Valley Forensic Science Program, Criminal Justice Department, Mailstop 286, 800 West University Parkway, Orem, UT 84058*

After attending this presentation, attendees will appreciate how low numbers of minutiae affect the search accuracy of AFIS software.

This presentation will impact the forensic science community by presenting an example of validating AFIS performance prior to conducting searches to establish that the system is performing within its designed specifications and quality control boundaries and the limits of minimal numbers of minutiae will be investigated by taking latent prints images from the AFIS database, manually reducing the number of minutiae to between fifteen and eight minutiae points, then searching a known set of print images of the same finger. A probability of success can be determined by comparing realized search results against the number of known true candidates.

The goal of this project is to test the probability that a fingerprint can be unambiguously identified from as few as eight minutiae points. An AFIS validation protocol was used at the beginning and end of each experimental session to verify the software was working as designed.

Previously, latent print screening results of commercially available AFIS software was found to be only seventy percent accurate when compared to known theoretical outcomes (Robert E Ryberg, AAFS Proceedings 2010). The problem was traced not to rotational orientation, rather to how the print's image was cropped. Cropping near the edge of the image, even without eliminating minutia, caused a different set of minutiae to be extracted than when the same image was centered in the field (Aaron Hall, AAFS Proceedings 2011). To overcome this source of error, a standardized AFIS image presentation protocol based on centralizing the print image was developed to maximize latent print database enrollment accuracy. This image presentation protocol tests AFIS performance with a set of standard latent print images with known outcomes to assure the AFIS system was performing to its designed specification and within quality control boundaries. Performing this validation protocol before and after a session searching unknown latent prints enables individual fingerprint examiners to validate the performance of their own AFIS system each time they use it.

This validation protocol was used to assure best possible performance in the following study that measured search accuracy when the unknown latent had low numbers of minutiae.

The AFIS database contained thirty rolled and thirty slapped latent print images of the same finger and the AFIS system was validated according to the protocols referenced above. A duplicate latent print image was taken from AFIS database to be the unknown latent print and the search accuracy of each latent print image was determined to be 100% when compared to its known duplicate in the AFIS database. The AFIS minutiae editing tool was used to reduce the number of minutiae to sixteen and the resulting image was searched to produce a list of matching candidate prints that were judged against the known print as either a True of False result. In subsequent trials, the number of the minutiae were reduced incrementally to a minimum of eight and searched as before.

An example candidate list for a single print in which the database contained thirty different prints of the same finger is (minutiae: true candidates): 15:22, 14:18, 13:16, 12:10, 11:4, 10:2, 9:1, 8:0. Several prints of different patterns will be presented.

AFIS Search Accuracy, Minimal Minutiae, Validation

A140 The GC/MS of Salvinorin A in Blood Plasma as Well as an Evaluation of Standard Color Tests for the Presence of Salvinorin A

Julia A. Garofalo, BS, and Thomas H. Pritchett, MS, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will have the foundation for developing a GC/MS method in their laboratory for the analysis of Salvinorin A and its metabolite Salvinorin B in blood plasma samples. The attendees will also learn which of the standard color tests are not capable of identifying Salvinorin A.

The presentation will impact the forensic science community by adding a new method for detecting a drug, Salvinorin A, which is now becoming regulated in many states. It will also impact the community by alerting practitioners of the color tests which are incapable of correctly identifying Salvinorin A.

In recent years, *Salvia divinorum* has become a major focus by state legislatures throughout the United States looking to prohibit the sale of the psychoactive plant. In some states (Alabama, Delaware, Louisiana, Michigan, Missouri, and Ohio) laws have been passed and many other states (Alaska, California, Florida, Iowa, Maryland, New Jersey, New York, Oregon, Pennsylvania, and Texas) are in the process of creating legislation to prohibit *S. divinorum* sales.[1] With the increasing number of states creating legislation making the sale *S. divinorum* illegal, the need for reliable presumptive and confirmatory testing methods is essential. Potential presumptive color tests were evaluated and an extraction method of Salvinorin A from plasma using selected ion monitoring gas chromatography/mass spectrometry for analysis was developed for this research.

Presumptive color tests were conducted to determine if *S. divinorum* vegetation and Salvinorin A standards would produce a positive colored

result. Dried *Salvia divinorum* leaves, enhanced "extracted" leaves in 20x, 10x, and 5x potencies, liquid tincture Shepardress Essence, and standard solutions on Salvinorin A were all tested with multiple color tests that are used to preliminary determine common illicit drugs. The *S. divinorum* and Salvinorin A solutions did not react with any of the standard color tests: cobalt thiocyanate (cocaine HCl), Marquis reagent (amphetamines), Mecke reagent (MDMA), *p*-dimethylaminobenzaldehyde (LSD), and most notably the Duquenios- Levine test for marijuana. The *S. divinorum* vegetation and the Salvinorin A solutions were also tested with color tests for Vitamin A, another common diterpene, but again no reactions were produced. Additional reagents, like antimony trichloride, designed to detect the lactone were also evaluated and found to be non-effective. Further color tests are currently being conducted along with presumptive oral tests on saliva and these results will also be presented.

The psychoactive compound found in the plant, Salvinorin A, was extracted from spiked 1mL defibrinated sheep plasma samples using a cyclohexane/ethyl acetate (85/15(v:v) solution. Salvinorin A was detected from 1000 ng/mL down to 10 ng/mL using gas chromatography/mass spectrometry (GC/MS). 17-α-methyltestosterone was used as an internal standard for the study. Both the Salvinorin A and the 17-α-methyltestosterone were determined in the selected ion monitoring mode. The ions selected were 94, 273, 432 m/z for Salvinorin A and 124, 229, 302 m/z for 17-α-methyltestosterone. The underlined ions were selected for the quantification measurements. The major metabolite of Salvinorin A, Salvinorin B can also be detected in the plasma samples. The total run time was 20.67 minutes and the retention times for Salvinorin A and 17-α-methyltestosterone were 14.995 and 11.958 minutes, respectively. The optimized GC/MS assay was evaluated in terms of limit of detection (LOD), limit of quantification (LOQ), precision, accuracy, analytical recovery, and linearity. The preliminary LOD and LOQ for the assay were determined to be 10 ng/mL, and the other optimization parameters are still being evaluated.

A141 Characterization of Methylenedioxypyrovalerone (MDPV) and Mephedrone in "Legal High" Products by Chemical Color Tests and Microcrystalline Tests With Confirmation by LC/MS

Emmi Slivka, BS, 675 East Street Road, Apartment 605, Warminster, PA 18974; Jillian Yeakel, MSFS, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; and Barry K. Logan, PhD, and G. John DiGregorio, MD, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation attendees will be able to identify methylenedioxypyrovalerone (MDPV) and 4-methylmethcathinone (mephedrone) in legal high products using common forensic chemical techniques including color tests, microcrystalline tests, and liquid chromatography/mass spectrometry (LC/MS). Attendees will also be able to recognize various commercial "legal high" products purchased over the internet, to name the substances they may contain, and to describe their legal status.

The presentation will impact the forensic science community by increasing awareness of the abuse of these products and the drugs they contain.

Over the last two years, new synthetic drugs with properties similar to cocaine, the amphetamines, or ecstasy have become popular due to the fact that they are legally obtainable and not controlled, in spite of the fact that they may be dangerous or addictive. These include the phenylethylamine derivatives MDPV and mephedrone. A number of states have controlled these substances and the U.S. Drug Enforcement Agency (DEA) has labeled them as a drug of concern. The drugs are sold over the internet as "legal highs" and have been marketed as "bath salts" or "plant food" to attempt to disguise their true use. Additionally, they have been implicated in several deaths.

Five bath salt samples were purchased from various online sources and were sold under various names. In addition, a package labeled "plant food" was submitted for analysis by a law enforcement agency. All samples were packaged and labeled "not for human consumption." Standards of MDPV and mephedrone were obtained and analyzed along with the commercial products.

Standard forensic color tests produced consistent positive results for MDPV and had inconsistent results with mephedrone. MDPV turned a bright yellow with the Marquis, Mecke, and Froehde color reagents. Cobalt produced a blue color change and Mandelin produced an olive green change when tested with MDPV. Products purchased over the internet labeled as "bath salts" all had similar positive results to the MDPV standard. Mephedrone did not have a color change with any reagents except for Mandelin and these results were inconsistent. The "plant food" did not have positive results with most of the color test reagents.

Gold chloride in phosphoric acid provided specificity for MDPV and mephedrone standards when performing microcrystalline tests. MDPV crystals appeared needle like in shape with a green/yellow tint under polarized light. Mephedrone produced thin needles with magenta, yellow/green color under polarized light. The mephedrone crystals did not form immediately and developed after an hour.

Following screening by color tests confirmatory analysis was performed using liquid chromatography/mass spectrometry with isocratic elution. The elution had a ratio of 10% ammonium acetate and 90% acetonitrile/isopropanol (50:50). The analysis was performed on an aqueous C18 analytical column with a total run time of 10 minutes. Mephedrone and MDPV were chromatographically separated and distinguishable from other drugs based on retention time and mass to charge ratio. The developed method was found to be very sensitive with limits of detection below 10ng/mL for mephedrone and MDPV.

The purchased legal high products were able to be analyzed using the above methods following dilution in the mobile phases. Most legal high products marketed as "bath salts" were found to contain MDPV while the product marketed as "plant food" was found to contain mephedrone. The LC/MS results regarding the bath salts confirm the effectiveness of the MDPV presumptive color tests.

Forensic Science, Mephedrone, MDPV

A142 Detection and Simultaneous Quantitation of ß-Naphyrone and 3,4-Methylenedioxypyrovalerone by Gas Chromatography-Mass Spectrometry

Gina M. Parada, BS, and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 10104; Michelle Dawes, MSFS, 2217 Polo Run Drive, Yardley, PA 19067*

After attending this presentation, attendees will have a better understanding of the use of Gas Chromatography-Mass Spectrometry (GC-MS) to identify and simultaneously quantify ß-naphyrone and 3,4-methylenedioxypyrovalerone (MDPV) in solid-dosage samples.

This presentation will impact the forensic science community by providing a simple method for screening, identification, and quantitation of the target cathinone analogues in illicit powders.

Naphyrone and MDPV are synthetic cathinone analogues which are part of a group of newly emerging "designer drugs" originating in the United Kingdom and have been recently advertised for purchase on a

number of websites. Naphyrone and MDPV, derivatives of pyrovalerone, are psychoactive drugs that act as norepinephrine-dopamine reuptake inhibitors producing stimulant and psychoactive effects related to those of amphetamine and cathinone. Both compounds have been misrepresented as a so-called "legal high." Naphyrone, the naphthyl analogue of cathinone, bears a close structural resemblance to mephedrone and MDPV. This substituted cathinone contains a phenethylamine core whose alpha carbon contains an alkyl group and beta carbon contains a ketone group. Naphyrone has been known to users under the various street names and sold as "bath salts" and pond cleaner, and have been referred to as a "legal high" that is stronger than cocaine, amphetamine, and MDMA. Published analytical studies on the bath salts reported the presence of naphyrone, cathinones, caffeine, MDPV, flephedrone, mephedrone, butylone, and other constituents.

MDPV, first seized in Germany in 2007, has reportedly been sold as a legal drug alternative and marketed as "bath salts" under various names. Other reports also indicate it is being sold with labels indicating "for novelty use only" and typically sold in 500mg packets on internet sites based in Europe. MDPV has been controlled (Schedule I) in some states.

This study identifies MDPV in a product sold as a "bath salt" not for human consumption. The unlabeled clear plastic baggie contained 0.32 grams of a light tan powdery substance. A small portion of the powder tested inconclusive with two color spot tests, Chen's and Simon's reagent. A UV/Vis spectrum recorded at a scan rate of 1200nm/min in methanol with a 1cm cell path length in the range of 200-800nm resulted in a λ_{max} = 232nm and peaks at 282nm and 315nm. Infrared analysis using attenuated total reflectance (ATR) accessory compared to a MDPV HCl certified standard. The spectrum was collected using 32 scans between 4000 cm^{-1} and 400 cm^{-1}. GC-MS data was acquired using a quadrupole mass-selective detector (MSD). A GC-MS method has been developed and validated where Naphyrone and MDPV can be simultaneously analyzed and quantified using phenyltoloxamine as an internal standard. Calibration curves obtained from a working standard of naphyrone and MDPV exhibited a favorable R^2 value (> 0.99) with a linear dynamic range between 900 – 3.00 ug/mL. The most abundant ion, *m/z* =126, present in the mass spectrum of both compounds was used in the SIM mode for quantification. Naphyrone and MDPV were well separated from other related drugs using a 30 m x 0.25 mm x 0.25 µm phenylmethylsilicone capillary column using Helium as a carrier gas with a linear gas velocity of 38 cm/sec. Methanol was used as the solvent and a sample volume of 1µL was injected in the split mode with a split ratio of 56.4:1. The gas chromatographic oven program was the following: 130°C for 2.00 min, 15°C/minute ramp up to 250°C, and hold for 10 minutes for a total run time of 20 minutes. A retention time optimization study provided the optimum separation conditions. Quantitative analysis indicated the bath salt sample was nearly pure MDPV hydrochloride.

Forensic Science, Naphyrone, MDPV

A143 Chiral Separation of Amphetamine Type Substances Using Ion Mobility Spectroscopy-Mass Spectrometry

Howard K. Holness, MBA, Florida International University, 11200 Southwest 8th Street, CP330, Miami, FL 33199; and Jose R. Almirall, PhD, Florida International University, Department of Chemistry, 11200 Southwest 8th Street, University Park, Miami, FL 33199*

After attending this presentation, attendees will be introduced to a novel technique, Chiral Ion Mobility Spectrometry (CIMS), which may be used for the separation of controlled and non-controlled enantiomers found in amphetamine type substances (ATS). The presentation will highlight both the degree of separation of enantiomers found in amphetamine type substances utilizing inexpensive achiral modifiers and the mechanism by which these separations take place and coupled to a mass spectrometer for unambiguous identification of the ATS compounds of interest.

This presentation will impact the forensic science community by describing a novel method for chiral separations offering advantages over the more time consuming and expensive methods currently in use. The high cost of chiral separation chromatography columns, the time needed, and the complexity is somewhat problematic for routine use. CIMS is a possible solution to these challenges by providing a high speed and low cost analytical technique not only for chiral separations but also as potential high throughput general drug analysis technique.

Chiral Separations have been a challenging aspect of analytical chemistry. There currently exists thousands of chiral separation phases predominantly used in liquid chromatography, gas chromatography and some capillary electrophoretic assays. The chiral phases themselves are expensive, while the time and resources required in selecting an appropriate phase for a particular enantiomer adds complexity. This presentation highlights a proposed separation mechanism when using achiral modifiers in the gas phase to separate enantiomers found in Amphetamine Type Substances (ATS). The presentation will show, for the first time, the use of straight chain achiral alcohols as drift gas modifiers and propose a mechanism for the gas phase chiral interactions responsible for the separations. Experimental results suggest that the interaction between the modifier and the analyte is ion-neutral based, with numerous modifiers adducting to a single analyte molecule. This interaction has been exploited to produce the desired separation of enantiomers of forensic interest using inexpensive achiral modifiers as opposed to the more expensive enantiomerically pure chiral modifiers such as S-2-Butanol. Common precursors used to make methamphetamine are ephedrine and pseudoephedrine, both chiral in nature. The ability to detect and separate these enantiomers as impurities in seized drugs has proven valuable as a forensic tool in many criminal investigations and has also been used for drug provenance studies. Achiral modifiers are used to separate RS and SR Ephedrine from SS and RR Pseudoephedrine. The resulting ion clusters formed have been characterized utilizing electrospray ionization to feed an ion mobility spectrometer coupled to a quadrupole mass spectrometer. The experimental data suggests that gas-phase chiral separations are possible and outlines a new, fast, and effective tool that may ultimately identify synthetic pathways and provide fast analysis and identification of seized amphetamine type substances.

This presentation will describe the capabilities of gas-phase chiral separations using commercially available electrospray ionization (ESI) ion mobility mass spectrometry (IMS-MS), to quickly separate and identify enantiomers introducing achiral modifiers into the drift gas. This approach provides an alternative technique to the more commonly used gas, liquid and capillary electrophoretic assays that are currently slower and more costly to perform. The proposed mechanisms of the separation will also be discussed.

Ion-Mobility, Chiral, Mechanism

A144 Detection of Illicit Drugs by Linear Ion Trap LC/MS/MS

Yuriy Uvaydov, MS, 99 Tenth Avenue, Suite 721, New York, NY 10011*

After attending this presentation, attendees will learn how linear-ion-trap liquid chromatography mass spectrometry (LCMS/MS) can be applied for the analysis of commonly encountered drugs of abuse. This presentation will highlight advantages and limitations of ion-trap detection of illicit drugs over traditional single quadrupole LC/MS and GC/MS techniques.

This presentation will impact the forensic science community by demonstrating how ion-trap LCMS/MS can be effectively applied for screening multi-unit submissions of evidence for the presence of controlled substances utilizing full-scan and tandem mass spectrometry (MS/MS).

Analysis of seized drug evidence consists of a series of presumptive and confirmatory tests. Traditional presumptive tests include color, microcrystal, thin-layer-chromatography (TLC), GC, and/or high

performance liquid chromatography (HPLC). Typically, mass spectral identification is required for confirmation of controlled substances in many forensic laboratories. The majority of cases encountered by forensic chemists are easily analyzed utilizing these traditional methodologies. However, with a continuing demand for faster, more efficient methodologies, the introduction of newer analytical instrumentation into the classical workflow is essential.

Advances in electrospray ionization (ESI) mass spectrometry have led to the increased popularity of direct analysis of drugs with minimal or no sample preparation allowing for faster analysis time. Additional advances in separation science have recently been attributed by the ion trap technology. For simple matrices, time-consuming chromatographic separations may not be required as multiple reaction monitoring (MRM) transitions can provide molecular confirmation. The purpose of this work has been to develop a method for rapid detection of drugs (target or unknown) utilizing a linear-ion-trap that will provide valid and reproducible data while maintaining cost-effectiveness.

In an effort to reduce case backlog and maintain quick analysis time, a non-chromatographic qualitative screening method was developed using ThermoFinnigian LXQ linear-ion-trap LCMS/MS. Analytes of interest were infused directly into the mass spectrometer using autosampler injections via a zero-dead-volume union. The mobile phase consisted of 50%/50% of (A) 0.1% formic acid in water, and (B) 0.1% formic acid in acetonitrile, delivered at 0.400mL/min. Mass spectral acquisition of data was performed with multiple scanning events using collision-induced-dissociation (CID) for full-scan and data-dependent auto MS/MS. Positive ionization mode was employed.

Applications presented will include the analysis of illicitly made tablets containing 3,4-methylenedioxymethamphetamine (3,4 MDMA), benzylpiperazine (BZP), caffeine, and trifluoromethylphenylpiperazine (TFMPP) as well as pharmaceutical tablets containing oxycodone, hydrocodone, and codeine. In addition, the analysis of commonly encountered benzodiazepines such diazepam, alprazolam, and clonazepam will be discussed. Preliminary results revealed sufficient MS resolving power for qualitative screening of analytes in multi-component mixtures without the need for chromatographic separation. The sensitivity of the linear-ion-trap LCMS/MS has been demonstrated in the nanogram range allowing for the detection of active ingredients in tablets containing less than one percent of the analyte of interest. For monoisotopic compounds such as methamphetamine and phentermine, detection utilizing chromatographic separation is required. The data showed that the linear-ion trap LCMS/MS can be used in compliment with GC/MS or LC/MS to provide principal means of identification. This approach, along with other limitations and challenges of different types of analyses, will also be discussed.

Linear-Ion-Trap, Seized Drugs, Mass Spectrometry

A145 Evaluation of Fast Gas Chromatography Coupled With Hydrogen Mobile Phases in Drug Identification

Charles R. Cornett, PhD, and Rebecca L. Hansen, BS, University of Wisconsin - Platteville, Department of Chemistry, Platteville, WI 53818; and Leah J. Macans, BS, Wisconsin State Crime Laboratory - Milwaukee, 1578 South 11th Street, Milwaukee, WI 53204-2860*

The goal of this presentation is to disseminate an assessment of both fast gas chromatography technology and the use of hydrogen as a replacement for helium mobile phase in drug identification.

This presentation will impact the forensic science community by presenting research which demonstrates a significant impact on the analysis time in drug identification. Fast gas chromatography significantly shortens the retention time of individual species and the replacement of helium mobile phase with hydrogen gas more than recoups lost resolution from the shorter columns while saving laboratories supply money.

The objective of this project is designed to assist crime laboratories' assessment of new separation techniques and gauge the feasibility of implementation. The first objective of this project is an assessment of the expected gain in resolution and sample throughput for a drug identification unit using a combination of Fast GC and hydrogen carrier gases. This area of application is prime ground for realizing the full potential of Fast GC – H_2. In 2008, a joint project funded by the Midwest Forensics Resource Center between the University of Wisconsin – Platteville (UWP) and the Wisconsin State Crime Laboratory – Madison demonstrated incredible reductions of over 50% in retention times of ignitable liquids from arson debris using the Fast GC. This study also found that the use of hydrogen as a carrier gas more than compensated for resolution losses related to Fast GC. In fact, the more compressible hydrogen carrier produced improvements in resolution for the Fast GC analysis compared to a conventional GC technique using helium carrier gas ($p < 0.01$). Fast GC-H_2 separation of drug identification samples could potentially decrease retention times of straightforward matrices to several tens to a few hundred seconds. This presentation addresses the limiting factors of this technique including the scanning rate of the quadrupole mass spectrometer and effects on detection limits of illicit drugs.

Experimental design involves the Fast GC and conventional analysis of one dozen Scheduled compounds including cocaine, tetrahydrocannabinol (THC), heroin, 3,4-Methylenedioxymethamphetamine (MDMA), trifluoromethylphenylpiperazine (TFMPP), lysergic acid diethylamide (LSD), buprenorphine, synthetic cannabinoids, alprazolam, clonazepam, boldenone, and nandrolone. The figures of merit selected for ANOVA ($p < 0.05$) comparisons center on retention times and chromatographic resolution of a master standard containing these twelve compounds. Given that many laboratories may hesitate to modify existing units for Fast GC, the first assessment examines the benefit in simply switching to the less expensive hydrogen mobile phases from the helium mobile phase. The control in this experiment is the conventional GC operating with a standard DB-5, 30 m column and helium mobile phase. The hydrogen is employed instead, and a data set is generated with resolutions compared to the helium gas. Subsequently, the heating ramp of the conventional GC is increased without altering other variables to assess just how aggressive of a heating ramp can be used to reproducibly equal the conventional use of helium. The second set of experiments uses solely helium while comparing Fast GC and conventional GC in the event that a laboratory is not ready or able to convert to hydrogen carrier but is interested in the Fast GC gains. In this particular case, the data demonstrate the resolution decrease for cost: benefit analysis. Finally, the two variables (Fast GC and hydrogen mobile phase) are combined to assess the maximum benefit.

Fast GC, Drug, Identification

A146 2012 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

After attending this presentation attendees will learn about the history and current development of the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG). SWGDRUG was formed in 1997 in a joint effort between the U.S. Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). The mission of SWGDRUG is to recommend minimum standards for the forensic examination of seized drugs and to seek their international acceptance. This presentation will provide attendees with an update on SWGDRUG activities during the year 2011, including revisions to SWGDRUG recommendations and other work products in development.

This presentation will impact the forensic science community by providing current recommendations, new developments, and future projects and direction of SWGDRUG as it relates to the analysis of seized drugs.

During January 2011, version 5.1 of the SWGDRUG Recommendations was approved and made available to the general public via the group's website (www.swgdrug.org). This version of the recommendations included revisions to Part III A and Section 6 pertaining to "Reporting." Version 6.0 of the SWGDRUG Recommendations was approved in July 2011. This latest version includes a new section (Part III C) providing recommendations for the analysis of clandestine laboratory samples. Version 6.0 is also available through the SWGDRUG website.

In the first part of 2011, SWGDRUG also made available the first version of its mass spectral library. Laboratory analysts throughout the world can download this library from the SWGDRUG website and onto their laboratory instruments. The library contains more than 1400 spectra, including many of the recently encountered synthetic cannabinoids and their isomers. Initial feedback from analysts and library users has been highly positive. The library will be updated on a regular basis and contributions from the forensic community are strongly encouraged.

During 2010, the SWGDRUG core committee finalized and approved Supplemental Document SD-3. This document provides four examples of measurement uncertainty calculations for weight determinations. Since the document's release, comments were received from the forensic community and the document was revised to provide clarifications and useful information to future users. This presentation will include a general summary and discussion of the latest version of SD-3 dated July 2011.

During the first half of 2011, users of the SWGDRUG website were also encouraged to submit comments regarding the use and impact of SWGDRUG Recommendations within the forensic science community. The SWGDRUG core committee is constantly interested in obtaining direct feedback from laboratory analysts and managers as to the use of SWGDRUG Recommendations and other documents. A general overview of the community feedback received throughout 2011 will be presented.

Currently, members of the SWGDRUG core committee are working on the following projects:

- Examples of laboratory reporting
- Supplemental document containing examples of measuremen uncertainty calculations for purity determinations
- Online resource center for drug analysis training

The SWGDRUG core committee is comprised of representatives from federal, state and local law enforcement agencies in the United States, Canada, Brazil, Great Britain, Germany, Austria, Switzerland, Australia, and Singapore. The following forensic organizations are represented: the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalistica y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC). Core committee members also include forensic science educators and representatives from forensic science organizations across the United States, the American Society of Crime Laboratory Directors (ASCLD), the American Society for Testing and Materials (ASTM), and the National Institute of Standards and Technology (NIST).

Criminalistics, SWGDRUG, Drug Analysis

A147 Density Determination Via Magnetic Levitation

Robert D. Blackledge, MS, 8365 Sunview Drive, El Cajon, CA 92021; and Matthew R. Lockett, PhD, Katherine A. Mirica, PhD, Charles R. Mace, PhD, and George M. Whitesides, PhD, Harvard University, Department of Chemistry and Chemical Biology, 12 Oxford Street, Cambridge, MA 02138*

After attending this presentation, attendees will have learned of a new method of helping to characterize trace evidence items by determining their density.

This presentation will impact the forensic science community by introducing a method of determining the density of small, irregularly shaped objects and of liquids, that is non-destructive, quick, easy, and inexpensive, is independent of instrument/operator/location, and provides values that may be entered into a searchable database.

Density is one parameter that may be used to characterize a trace object. Although the formula for density (or specific gravity) is simply mass divided by volume, this is not so easily done for tiny, irregularly-shaped objects. In the past the density of small objects has been compared/determined using the sink/float method. When the tested objects suspended in a liquid medium neither rose to the surface nor sank to the bottom, their density was the same as the liquid. This could be a slow process as the liquid medium was gradually made less or denser by the addition of drops of either a miscible heavier or lighter liquid followed by mixing. Once this equilibrium point had been reached, one could determine the density of the liquid and hence the density of the object by removing sufficient liquid to fill a previously weighed pychnometer and then weigh the now full pychnometer. One could then obtain an actual value of density that could be entered into a database.

This presentation will introduce an entirely different method of obtaining density that is quick (just a few minutes), requires no expensive instrumentation (not even a source of electrical power), does not require highly-trained operators, does not destroy the sample, is readily calibrated with a series of density standards, provides values that can be entered into a searchable database, and that can distinguish between samples whose density differs by as little as 0.0002 g/cm^3. The method is based on magnetic levitation (MagLev) and involves placing diamagnetic samples into a container filled with a paramagnetic fluid, which is then placed between two permanent magnets. The vertical position of the sample, in the presence of the magnetic field, correlates with density. The vertical position depends on mass/volume rather than mass or volume separately and thus eliminates the need for standardized sample sizes.

Additionally, the MagLev concept may be used to separate similar items that vary in density. This will be illustrated by a photomicrograph showing how a mixture of two visually-similar types of glitter (both silver in appearance, both hexagonal and the same size) is clearly separated by vertical position in the cuvette containing a paramagnetic liquid. A disposable pipette may then be inserted to draw out those particles at a given level.

For heterogeneous samples, the distribution of densities may be a distinguishing characteristic. The MagLev method could replace the density gradient columns that in the past have been used to compare various size fractions of soil samples. In the past, the preparation of the density gradients was a slow, tedious process and involved liquids that are health hazards. Then once the soil fraction was added to the prepared density gradient column it might take a day or more for the sample to reach a stable distribution. With MagLev the entire process from start to finish would take only a few minutes.

For the determination of density, is there a limitation on particle size? Particles as small as 7µm in diameter are no problem, but for those 2µm or smaller Brownian motion prevent an accurate measurement. What if your sample is water soluble? Not a problem. There are paramagnetic ions that are chelated and are not water soluble, but are soluble in various non-aqueous solvents. Have a liquid sample? Not a problem; just add a drop to an immiscible paramagnetic liquid.

Does the MagLev process alter your sample? Results will show that smokeless gunpowder samples undergo no change. Also, the density of a glitter sample was measured and then some was added to a commercial nail polish. A portion of the liquid polish was diluted in hexane and then passed through filter paper, the glitter particles removed from the filter paper and their density again was measured and was unchanged.

Results will be shown from eleven different glitter samples, six different commercial smokeless gunpowder samples, and glitter particles extracted from a brand of commercial nail polish.

Density, Magnetic Levitation, Trace Evidence

A148 Forensic Characterization of Surface-Modified Fibers Via X-Ray Photoelectron Spectroscopy

Robert D. Blackledge, MS, 8365 Sunview Drive, El Cajon, CA 92021; Marie Ernstsson, MS, and Kenth Johansson, MS, Ytkemiska Institute for Surface Chemistry, Box 5607, Stockholm, SE-114 86, SWEDEN; Dolores C. Miller, MS, IBM Almaden Research Center, Materials Analysis and Characterization, San Jose, CA 95120-6099*

After attending this presentation, attendees will understand how x-ray photoelectron spectroscopy may be used to characterize fibers that have received one or more surface modification treatments.

This presentation will impact the forensic science community by showing how single fibers (one of the most common and most important types of trace evidence) may be subcategorized by using x-ray photoelectron spectroscopy to detect and characterize any thin surface modification layers.

X-ray photoelectron spectroscopy (XPS) is virtually unknown to forensic science. X-ray photoelectron spectroscopy (XPS) is a quantitative spectroscopic technique that measures the elemental composition, empirical formula, chemical state and electronic state of the elements that exist within a material. XPS requires ultra-high vacuum (UHV) conditions. XPS spectra are obtained by irradiating a material with a monochromatic beam of X-rays while simultaneously measuring the kinetic energy and number of electrons that escape from the top 1 to 10nm of the material being analyzed.

A proof of concept study shows that via XPS single fibers, that in all other respects are identical, may be characterized and distinguished if one fiber has no surface modification while the other does, or if one fiber has one manufacturer's proprietary surface modification while the other has some other manufacturer's (different) proprietary surface modification.

Today most fabrics have received one or more type of surface-modification treatment such as stain resistance, permanent press, or water proofing. For example, white cotton fibers are so common and have so few distinguishing features that today they are largely ignored by forensic scientists. XPS can distinguish, on a single fiber basis, between the following otherwise identical cotton fibers:

1. white cotton fiber with no surface modification,
2. white cotton fiber with some type of silicone surface modification,
3. white cotton fibers that have a surface modification (some type of fluorocarbon) applied by a plasma process,
4. white cotton fiber with some type of silicone surface modification plus the 3M Company's surface modification treatment (some type of fluorocarbon applied by a wet process),
5. white cotton fiber with some type of silicone surface modification plus some other company's (not specified) proprietary surface modification treatment (some type of fluorocarbon applied by a wet process but different than 3M's).

All elements except hydrogen and helium may be detected and measured by XPS. Low resolution survey spectra identify all the elements in the surface layer and their relative abundances, while separately for each element high resolution spectra show the different bonding states and the relative amounts for each state for a particular element. Because carbon can exist in so many different bonding states, XPS is particularly effective in characterizing different types of polymers that exist as thin surface layers.

Additionally, the thickness of a very thin surface layer, as well as the change in composition below it, may be determined by angle-resolved XPS. As with hammering in a nail at an acute angle compared to the normal, the penetration of the x-ray beam into (perpendicular) the sample is decreased as the angle become more acute.

Also, through XPS Imaging the coverage in the x,y plane of a given element may be mapped. It will be shown that by mapping for F the extent of coverage of a thin fluorocarbon surface layer may be determined on a single fiber.

This presentation will show how, from just a single fiber x-ray, photoelectron spectroscopy (XPS) can nondestructively distinguish these surface modifications.

Fibers, Surface Modifications, X-Ray Photoelectron Spectroscopy

A149 Raman Laser Polarization and Its Effect on Fiber Analysis

Ming Z. Zhou, MS, and Richard S. Brown, MS, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Suite 400, Duluth, GA 30096; and Thomas J. Hopen, MS, Alcohol, Tobacco, Firearms Forensic Science Lab, 2600 Century Parkway, NE, Suite 410, Atlanta, GA 30345*

After attending this presentation, attendees will have an understanding of the application of Polarized Raman spectroscopy for fiber identification and characterization. In addition, this presentation will introduce the phenomenon of how the polarization of a Raman laser affects the Raman spectrum of synthetic fibers.

This presentation will impact the forensic science community by providing an alternative approach to distinguish and discriminate between synthetic fibers since the Raman laser polarization effect on synthetic fibers has never been explored in the forensic community.

Fibers are a frequently encountered form of trace evidence. Many techniques and types of instrumentation have been developed and used to analyze fibers in the forensic community, for example, the comparison microscope, the fluorescent microscope, the polarized light microscope, the UV-Vis micro-spectrometer and the FTIR micro-spectrometer. Each of these techniques is capable of providing unique and useful information about a fiber.

Recently, Raman spectroscopy has started to establish its place in the forensic science community. Raman spectroscopy has been used to analyze paint chips, inks, drugs, condom lubricants, and dyes. The growth of Raman spectroscopy in the forensic science community is due to its short analysis time, minimum sample preparation, and non-destructiveness. Many articles published on fiber analysis have indicated that Raman spectroscopy is useful for identifying the dye(s) in the fiber. However, Raman spectroscopy should also be explored for fiber type identification and characterization.

Like Infrared spectroscopy, Raman spectroscopy yields vibrational spectra that indicate the chemical structure of a material. Raman spectrometers are often equipped with a polarized laser source. As in polarized light microscopy, the polarized laser interacts with different orientations of an anisotropic material. A drawn out fiber exhibits pseudo crystallinity that can be exploited by the polarized Raman laser source to yield additional information on the chemical structure of the fibers. This information may be useful in forensic fiber analysis. Depending on the orientation of the fiber, the polarized laser can interact differently with the functional groups of the fiber, producing a slightly different Raman spectrum for a given fiber orientation. Depending on the type of fiber, the difference can be seen in relative peak intensities, and additional peak(s).

Polyester, nylon, and acrylic fibers were analyzed with a WITec Confocal Raman Microscope with a 532 nm polarized laser source in this study. Five fibers for each fiber type were analyzed to ensure representativeness. Each fiber was measured in its perpendicular and parallel orientation with respect to the polarization of the laser source. For polyester fiber, dramatic differences were observed when comparing the perpendicular and parallel orientation at the 2800 cm^{-1} to 3000 cm^{-1} range. The peaks in the perpendicular orientation have relatively higher peak intensity. In addition, it has four distinguished peaks instead of three in the parallel orientation. The overall pattern of the peaks in that region is completely different. Minor changes were also observed in the 1300 cm^{-1} to 1400 cm^{-1} region, there are four peaks for the perpendicular orientation and two for the parallel orientation. For acrylic fiber, the only noticeable

change observed was at peak position 1220 cm^{-1}, that peak was there in the parallel orientation and disappeared in the perpendicular orientation. For nylon fiber, the N-H stretching at 3305 cm^{-1} is relatively more intense in perpendicular orientation. In addition, there is an extra peak at about 1550 cm^{-1} in the parallel orientation. Also, the relative intensity of peaks at 1435 cm^{-1} and 1630 cm^{-1} were switched in the two different orientations. All the differences are due to the interaction between the polarized Raman laser and the different pseudo crystalline orientation of the fibers.

This preliminary study focuses on the most common synthetic fibers. Future studies can be conducted with different laser wavelengths and natural fibers.

Raman, Polarization, Fiber

A150 Microwave-Assisted Extraction for Qualitative Analysis of Carpet Fibers

Antonette D. Cabauatan, BA, 2507 Carey Way, Apartment 3, Pittsburgh, PA 15203; and Stephanie J. Wetzel, PhD, Duquesne University, Department of Chemistry and Biochemistry, 600 Forbes Avenue, Pittsburgh, PA 15282*

After attending this presentation, attendees will learn about how polymer additives can be employed to objectively compare carpet fibers.

This presentation will impact the forensic science community by providing a potential method for comparing carpet fibers that could one day be applied in crime labs.

Synthetic polymers are used in the manufacturing of many manmade products, including carpets. Synthetic polymers are long-chained molecules that are compounded with many, varied, and proprietary additives that chemically modify the polymer to improve its performance. In forensic science, carpet fibers can be used as evidence. Microscopy and spectroscopy are current methods used in the identification and comparison of carpet fibers. However, these techniques cannot determine the origin of a carpet fiber, thereby making these methods very subjective.

In this study, polymer additives were extracted from nine different carpets (made of nylon, polypropylene, or olefin) in 1:1 acetone:hexane through microwave-assisted extraction (MAE). Each carpet was tested four different times. The extracts were then analyzed through gas chromatography – mass spectrometry (GC/MS). Because each carpet yielded four chromatograms, the peak lists for these chromatograms were combined to make an averaged chromatogram for each of the carpets. These averaged chromatograms were then used to compare the carpets for base polymer and manufacturer differences. For comparison purposes, peaks were accepted at a 3:1 signal-to-noise (S/N) ratio. Moreover, it is hypothesized that similarities and differences can be seen between the various carpets.

The carpets were first compared in regards to their base polymer: nylon, polypropylene, or olefin. It was found that carpets made of nylon had a significant amount of differences when compared to polypropylene and olefin. Specific peaks and certain peak patterns were identified. Differentiating polypropylene and olefin carpets was more difficult considering olefin carpets are a mixture of polypropylene and polyethylene polymers. This in turn made it very hard to identify specific peaks and peak patterns between carpets made of polypropylene and olefin.

Because manufacturers chemically modify their carpets, it was determined if manufacturer type contributed to a carpet's profile. For example, the nylon carpets were compared among each other to establish whether any similarities or differences exist. With the nylon carpets, it was found that manufacturer type contributed to the observed differences. Moreover, a carpet made with a polymer (e.g., nylon) from the same company exhibited differences when different carpet manufacturers modified that polymer. Carpets made of polypropylene and olefin still exhibited some difficulties when comparing them in regards to manufacturer type. While significantly fewer peaks could be identified for polypropylene (and olefin) with at least a 3:1 S/N, carpets made of polypropylene (or olefin) could still be distinguished from one another.

In conclusion, this research successfully showed that carpet fibers can be analyzed and compared through a more objective method. Differences could be seen between carpets made of different base polymers. It could also be seen that carpets made of the same polymer can still be distinguished from each other due to the various chemical modifications that manufacturers apply to the polymers.

Carpet Fibers, GC/MS, MAE

A151 Forensic Characterization and Identification of Dyes Extracted From Millimeter-Length Fibers Using Ultra-Performance Liquid Chromatography/Mass Spectrometry

Oscar Cabrices, PhD, Stephen L. Morgan, PhD, Scott J. Hoy, BS, Andrei Kovaltshuk, BS, Molly R. Burnip, BS, and Nicholas M. Riley, BS, University of South Carolina, Department of Chemistry and Biochemistry, 631 Sumter Street, Columbia, SC 29208*

The goal of this presentation is to communicate to the forensic community results from ongoing research on development and validation of methods for chemical characterization of dyes extracted from millimeter to sub-millimeter length trace evidence fibers.

This presentation will impact the forensic science community by using the working hypothesis that liquid chromatographic separation and detection of individual dye components by mass spectrometry (LC/MS) provides a qualitative and semi-quantitative fiber dye "fingerprint," with the prospect of enhancing discrimination for comparison of known and questioned casework fibers. Determining the number and relative amounts of dyes present, and characterizing those dyes at the molecular level by MS, offers an entirely new level of information that is not otherwise available from microscopic or spectroscopic methods. Such information may also open the possibility of tracing specific dye formulations to the textile manufacturer.

Determining the number and relative amounts of dyes present, and characterizing those dyes at the molecular level by MS, offers an entirely new level of information that is not otherwise available from microscopic or spectroscopic methods. Such information may also open the possibility of tracing specific dye formulations to the textile manufacturer. The target size for forensically relevant fibers derives in part from fiber examinations and population studies reporting that recovered fibers are often as small as 2mm in length, depending on the degree of dyeing. Because extraction of dyes from a fiber is destructive to the evidence, the ability to extract and identify dyes from trace fibers that are a millimeter or less in length is critical. The laboratory involved in this study has previously developed extraction/capillary electrophoresis (CE) methods for acid dyes on nylon, vat and reactive dyes on cotton, and basic dyes on acrylic, and demonstrated CE/MS analysis of basic dye extracts from two mm single acrylic fibers.

The current work explores the application of ultra-performance liquid chromatography (UPLC) for analysis of dyes extracted from fibers. UPLC uses high pressures (>10,000psi), smaller column particles (<2µm), and short columns (~5cm) for high speed, resolution, and sensitivity. If sufficient fiber is available, UV/visible diode array detection may be suitable for rapid low cost screening of trace evidence samples by UPLC. With extractions from 10mm single fibers of nylon, acrylic, and polyester, the amounts of eight different corresponding acid, basic, and disperse dyes ranged from 5 to 20ng with standard deviations from 1 to 3ng. UV/visible detection limits are in the low ng range for dye extracts from 10mm fibers, although quality of absorbance spectra is compromised at lower lengths.

Liquid chromatography tandem mass spectrometry (LC/MS/MS) has been widely used in forensic toxicology due to its high sensitivity and selectivity. With tandem MS/MS with multiple reaction monitoring (MRM) of specific molecular ion-fragment ion transitions we have reliably detected extracted dye amounts as low as a few tenths of ng from commercial textile fibers as small as 0.5mm in length. For example, five

0.5mm length nylon fibers commercially dyed with three acid dyes resulted in the following mean extracted dye amounts and % relative standard deviations: C.I. Acid Yellow 49, 0.15 ± 0.02ng (13.22%); C.I. Acid Red 337, 0.36 ± 0.04ng (10.95%); and, C.I. Acid Blue 281, 0.19 ± 0.03ng (18.34%). Linear calibrations based on five concentration levels of dye standards produced coefficients of determination (R^2 values) ranging from 0983 to 0.999. A miniature guillotine for improving the reproducibly of cut fiber length was designed. However, the difficulty involved in cutting sub-mm fiber lengths reproducibly is the primary reason that percent relative standard deviations for extracted dye amounts from replicate 0.5 mm fibers is relatively high. Further LC/MS validation work and technology transfer is also in progress in collaboration with the Forensic Services Laboratory of the State Law Enforcement Division (SLED), Columbia, SC.

In summary, analysis of dye extracts from single acrylic, nylon, and polyester fibers of 0.5mm lengths has been achieved. In tandem MS, two or more stages of mass analysis are combined in one experiment. Each stage provides an added dimension in terms of specificity of structural information characteristic of the target analyte. Multiple reaction monitoring is a common LC/MS/MS detection mode in which pairs of target parent ions and unique fragment ions are used for quick and accurate identification of target analytes. MRM detection enables high discrimination between different dyes because transitions to a characteristic fragment ion are unique to the molecular structure of the parent ion. The specificity of analysis allows simultaneous identification and quantitation at exquisitely low detection limits (e.g., 0.1ng or less for acid dyes extracted from nylon). Using the collection of several hundred textile dyes in the laboratory, infusion of dye standards can establish an MRM transition library. Routine LC/MS/MS screening with an MRM library has the potential to provide unambiguous identification for those dyes. For dyes not in the library, MS/MS analysis can still provide discrimination based on molecular structure differences.

This project was supported by Award No. 2010-DN-BX-K245 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the author(s) and do not necessarily reflect those of the Department of Justice.

Trace Fiber Examination, Textile Dye Analysis, Liquid Chromatography/ Mass Spectrometry

A152 Use of Computer Controlled Scanning Electron Microscopy (CCSEM) Methods for the Analysis of Small Particles Adhering to Carpet Fiber Surfaces

David A. Stoney, PhD, Stoney Forensic Incorporated, 6405 Woodland Run Court, Clifton, VA 20124; and Andrew M. Bowen, MS, and Paul L. Stoney, MBA, Stoney Forensic, Incorporated, 14101-G Willard Road, Chantilly, VA 20124*

After attending this presentation, attendees will understand how fine particles, adhering to the surfaces of individual carpet fibers, can be recovered and quantitatively analyzed by SEM/EDS and, in its current state of development, how this capability can be applied and integrated into conventional forensic trace evidence analysis.

This presentation will impact the forensic science community by demonstrating the feasibility of the analysis of these "piggy back" particles, and how they can be used to remove fundamental class-level limitations on the probative value of trace evidence and provide an independent quantitative means to test hypotheses of common origin.

Very small particles are ubiquitous in our environment and are virtually ignored by forensic science (gunshot residue being a notable exception). These particles range in size from an order of magnitude smaller than conventional trace evidence, down to the molecular level (now routinely exploited through DNA analysis). We move around in a soup that is a combination of these very small particles and they represent an extraordinary, largely untapped resource for forensic associations and source attribution. The combinations of these particles are so complex that until recently there was no practical method to identify and interpret these combinations. Particle combination analysis (PCA) is a new capability that focuses on these methods. This project involves the application of PCA as a means to objectively verify and improve traditional trace evidence analysis of fibers.

An innovative instrumental trace evidence analysis approach that applies the PCA concept to the recovery and quantitative SEM/EDS analysis of fine particles found adhering to the surfaces of larger trace evidence particles is described. Ultimately this approach could fundamentally change the probative value of trace evidence from one of class association to one of highly individual, testable associations (akin to those arising from multiple-transfers of uncorrelated traces, or the co-occurrence of independent, highly variable events).

Methods were developed to quantitatively remove fine particles from carpet fiber surfaces and to prepare the particles for SEM/EDS analysis.

To assess within-carpet variability, computer controlled SEM analyses (CCSEM) were conducted on fine particles removed from three different areas from each of nine carpets (three domestic, three automobile, and three commercial carpets). From each of the three areas on each of the nine carpets, a set of ten carpet fibers was used to define the "known" or target fine particle profile of the carpet itself. Three individual fibers from each of the 27 areas were then used as test fibers, each representing a single recovered transferred fiber. To explore between-item variation, a broader survey of an additional twelve carpet particle profiles was conducted.

Principal findings from these studies were:

- Fine particles are present on the surfaces of individual carpet fibers.
- These particles can be recovered nearly quantitatively for CCSEM analysis by extraction with reagent ethanol.
- Quantities of particles adhering to individual carpet fibers varied from a few hundred to greater than 4000 (the maximum number examined).
- Particle classification schemes currently in use for environmental CCSEM applications are broad compared to variations in elemental composition seen among the individual CCSEM particle spectra.
- Carpets vary widely in the types and quantities of small particles adhering to their fiber surfaces.
- Particle distributions from the individual test fibers could not be explained based on a hypothesis of unbiased statistical sampling from a population defined by the target particle profile.
- Highly characteristic, semi-quantitative patterns of particle types found in target particle profiles were consistently represented in the particle distributions from individual test fibers from the same carpet, and consistently absent among those from different carpets.
- Based on these findings, particle distributions found on carpet fibers can contribute substantially to the weight of evidence linking fibers to a specific carpet.
- Further studies are needed to better understand this type of evidence, including: (a) the sources of within-item variation, (b) the effects of alternative methods of particle classification, and (c) the extent of between-item variation.

This project was supported by Award No. 2010-DN-BX-K244 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Evidence Interpretation, Fiber Analysis, SEM/EDX

A153 Characterization of Vectran LCP Fibers

Thomas J. Hopen, MS, Bureau of Alcohol, Tobacco and Firearms, Forensic Science Laboratory, 2600 Century Parkway, NE, Suite 400, Atlanta, GA 30345; and Natasha Neel, MSFS, Bureau of Alcohol, Tobacco and Firearms, Forensic Science Laboratory, 2600 Century Parkway, Atlanta, GA 30345*

After attending this presentation, attendees will have information for the characterization and identification of Vectran LCP fibers.

This presentation will impact the forensic science community by expanding the knowledge and data on forensic fiber identification.

Vectran liquid crystal polymer (LCP) fibers are a relatively new commercially produced aromatic polyester fiber that was first developed by Celanese Acetate LLC in the 1990s and is now manufactured by the Kuraray Co., Ltd. Liquid crystals (LCs) are a state of matter that have properties between those of a crystalline solid and those of a conventional liquid. Like LCs the LCPs in the liquid state, either dissolved in a solvent or melted, have highly oriented anisotropic-molecular domains like a crystal but they flow like a liquid. A para-substituted aromatic polyamide, is a LCP fiber in the solid state and is wet spun from dissolved polymer in a liquid (lyotropic liquid-crystal polymer). Unlike conventional polyester that is melt spun from randomly oriented and fixable molecules, Vectran fibers are LCPs in the solid state and are the only LCP fibers being produced today that are melt spun from a highly ordered liquid crystal phase (thermotropic liquid-crystal polymer). Since Vectran fibers, like Kevlar fibers, are spun from a LCP it locks in the oriented crystalline nature and provides the exceptional high performance characteristics of strength, rigidity, and chemical resistance.

Both Kevlar and Vectran LCP fibers, as well as several other fibers, fall into the class of "High Performance Fibers." High performance fibers, as compared to commodity fibers, are "fibers that fall into special technical functions that require special properties unique to these fibers." These special functions may include chemical resistance, tensile strength, operating temperature, limiting oxygen index, and a modulus value. It should be noted that all high performance fibers are not classified as "High Temperature Resistant Fibers." A good example of this is high density polyethylene Spectra® fiber that is gel extruded and classified as a high performance fiber but not high temperature resistant fiber due to its low melting point of 250° F (121° C). A general definition of high temperature resistant fiber is "a synthetic fiber with a continuous operating temperature ranging from 375° F to 600° F (190° C to 316° C)" but this definition may vary depending on the end use of the fiber. Three types of Vectran fibers are being commercially produced by Kuraray Co, Ltd.: Vectran HT; Vectran NT; and, Vectran UM. Airbags made with Vectran woven fabric were used by NASA on the Mars Pathfinder spacecraft. A more down to earth use of Vectran fibers in everyday products include rope/cordage made of Vectran HT fiber or Vectran NT fiber; protective clothing made from Vectran NT fiber which is sometimes blended with another type of fiber; and fiber optic cables reinforced with Vectran UM fibers.

Therefore, Vectran fibers, especially HT and NT, may be encountered in forensic fiber evidence in casework. A review of literature commonly relied on by forensic fiber analysts failed to find identification characteristics for Vectran fibers. To fill this void, the microscopic optical properties, physical characteristics, as well as infrared and Raman data will be presented for the characterization and identification of Vectran fibers. Various equipment was used to determine this data.

Vectran LCP Fibers, Liquid Crystal Polymers, High Performance Fibers

A154 Raman Spectroscopy Offers a Great Potential for Non-Destructive Confirmatory Identification of Body Fluid Traces

Vitali Sikirzhytski, MS, Aliaksandra Sikirzhytskaya, MS, Gregory McLaughlin, MS, and Aliea Afnan, BS, University at Albany, State University of New York, Department of Chemistry, 1400 Washington Avenue, Albany, NY 12222; and Igor K. Lednev, PhD, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will have a better understanding of body fluid identification range of problems and advantages of Raman spectroscopic method as compared to conventional forensic methods employed for the identification.

This presentation will impact the forensic science community by providing information about a novel method of the fast nondestructive confirmatory identification of body fluids found at a crime scene.

The identification of traces of body fluids discovered at a crime scene is a major part of forensic investigation today.[1] The three most common fluids found are blood, semen, and saliva. Several methods are currently used to distinguish one from another. Blood can be presumptively tested using different color spot tests; these tests are destructive to the sample and can also yield false positives. Semen can be presumptively tested using destructive presumptive and confirmatory tests. However, saliva, has no confirmatory tests. Most presumptive tests can be performed in the field, but some sample preparation, such as extraction, is often necessary. Most confirmatory tests must be done in the laboratory. The main problem with these tests is the destruction of the sample. The forensic community is in great need of a reliable, non-destructive, on-field method for identification of all common body fluids.

Raman spectroscopy is a technique increasing in popularity among the different disciplines of forensic science. Some examples involve the identification of drugs, lipsticks, fibers, paint, and ink. The theory behind Raman spectroscopy is based on the inelastic scattering of low-intensity, nondestructive laser light by a solid, liquid or gas sample. Very little or no sample preparation is needed, and the required amount of material tested with a Raman microscope can be as low as several picograms or femtoliters. A typical Raman spectrum consists of several narrow bands and provides a unique vibrational signature of the material. Typically, nonresonance Raman spectroscopic measurements do not damage the sample. The stain could be tested on the field and still be available for further use in the laboratory for DNA analysis. A portable Raman spectrometer is a reality now that should allow the identification of body fluids at the crime scene.

The development of a new method for identification of body fluid traces using Raman spectroscopy combined with advanced statistics is reported.[2,3] Dry traces of semen, vaginal fluid, sweat, saliva, and blood were analyzed using confocal Raman microscopy with a 785-nm excitation.[4-6] Dry samples of these body fluids are intrinsically heterogeneous. A library of multidimensional Raman spectroscopic signatures that allowed differentiating the traces of body fluids with high confidence was developed. In addition, traces of human and animal blood could be distinguished.[7,8] Overall, this preliminary study demonstrates the great potential of Raman spectroscopy for nondestructive, confirmatory identification of body fluids for forensic purposes.

This project was supported by Award No. 2009-DN-BX-K196 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

A155 Application of Surface Enhanced Raman Spectroscopy to the Forensic Analysis of Blood

Samantha J. Boyd, BS, Virginia Commonwealth University, Department of Forensic Science, 1020 West Main Street, Richmond, VA 23284-3079; Dexian Ye, PhD, and Massimo F. Bertino, PhD, Virginia Commonwealth University, Department of Physics, 701 West Grace Street, Richmond, VA 23284-3079; and Sarah J. Seashols, MS, Virginia Commonwealth University, Department of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will understand the current applications of surface enhanced Raman spectroscopy (SERS) to the forensic analysis of body fluids, specifically blood. This will include the dissemination of the results of the research conducted, as well as an explanation of the mechanisms behind SERS theory and relevant literature review concerning the utilization of SERS.

This presentation will impact the forensic science community by highlighting the benefits of surface enhanced Raman spectroscopy to the forensic analysis of blood through the comparison of techniques commonly used at crime scenes and in forensic laboratories.

Raman spectroscopy is in the defining stages of determination of application in the forensic arena for the identification of unknown materials. Already it has been used to identify various samples, including automotive paint, condom lubricants, gel pen ink, and contraband drugs. Its potential has been recently extended to the analysis of body fluids. Studies have shown that it is possible to achieve a Raman signature of blood that is characteristic of, and unique to blood, even between people. That, in addition to the advent of the handheld Raman spectrometer, makes this instrument an attractive tool for on-scene confirmatory analysis of physical evidence.

Previously, the dilution limitation detection of blood with the Raman spectrometer was investigated and found to be approximately 1:250, using an excitation power of 2mW at the sample plane. This was comparable to presumptive tests for blood performed on scene with swabs, but not comparable to detection limits of luminol and fluorescein. Analysis of blood samples using SERS and Raman Spectroscopy was investigated and was shown to greatly enhance signals coming from samples. The results of the research have demonstrated a SERS tip (nickel rods on a silicon plate, dusted with silver) allows for a new dilution limit of detection of approximately 1:100,000.

In addition to investigating the limit of blood detection with SERS, dried blood was also reconstituted from fabrics and tested using SERS. Blood was swabbed from fabrics and then rubbed on the SERS tips. Reconstituted blood was found to show signal enhancement; however, no appreciable enhancement seen from the swabs rubbed against the SERS tips. Finally, various plant and chemical material known to give false positives during presumptive tests were examined using Raman spectroscopy. The Raman signatures produced were compared to the Raman signature of blood. Distinct spectra for all tested material were produced, showing Raman spectroscopy has the potential to be used as a confirmatory analysis tool.

In conclusion, SERS can be applied to the forensic analysis of blood, both from blood dilutions and reconstituted blood. Swabs of blood can be analyzed using a Raman spectrometer, but as of yet, no significant enhancement has been achieved using the swabs and SERS. Since Raman spectroscopy produces Raman signatures based on the chemical bonds present in the material tested, unique spectra are produced, leading to the possibility that this instrument may be used as a confirmatory analysis tool.

Raman Spectroscopy, Blood, SERS

A156 Comparison of an Automated Image Analysis Software Versus Visual Examination to Search for Fluorescently-Stained Spermatozoa in Sexual Assault Cases

Anick De Moors, MSc, Royal Canadian Mounted Police, Forensic Science and Identification Services, 1200 Vanier Parkway, Ottawa, ON K1G 3M8, CANADA*

After attending this presentation, attendees will have a better understanding of one image analysis software optimized and validated to automate the search for human spermatozoa stained using a fluorescently-based assay and how it compared to visual examination to count spermatozoa.

This presentation will impact the forensic science community by providing an alternative to visual counting of spermatozoa. A routine approach can be developed to automate the scoring of human spermatozoa in sexual assault exhibits. This can enhance case throughput, increase assay sensitivity, and standardize the search for spermatozoa.

The image analysis software was purchased in the hope of developing an automated method of counting fluorescently stained spermatozoa. The fluorescence-based staining assay was first optimized and validated as a replacement to the current human spermatozoa detection method based on phase contrast microscopy. In this assay, the mouse monoclonal antibody specific for human sperm heads is linked with Alexa 488, which fluoresces in green using a FITC filter. A second dye will appear blue when nucleated cells are present using a DAPI filter.

The development of appropriate classifiers within the software was challenging but essential to teach the system to specifically recognize human spermatozoa. As part of the optimization, different minimum and maximum integration times (exposure times) were tested in order to reduce the background without missing any human spermatozoa.

Optimized classifiers were tested/validated using a diverse sample of slides prepared from mock sexual assault samples containing a limited or a large number of human spermatozoa (fecal swabs, vaginal swabs, all mixed with different semen dilutions in addition to urine, blood, and yeasts for a subset of those swabs, contaminated with lubricants, spermicides, medicated creams, and non-human semen). Automated spermatozoa counts were compared to visual spermatozoa scoring. The performance of the image analysis software was recorded with respect to missed spermatozoa, false positives (rejected counts) and time required for the detection of human spermatozoa in each sample.

An excellent concordance was noted between automated and manual counts. Some human spermatozoa were missed by the image analysis software due to their location at the periphery of a classify field (area of search) or outside the predefined circle for searching. False positives or

rejected counts were caused by high DAPI or FITC background in that area and red dots (positive in FITC but negative in DAPI). Most false positives in the image analysis software were quickly rejected by visualizing the gallery (captured cells) on the computer screen. Ambiguous signals/cells were accepted or rejected by visual examination using both the FITC and DAPI filters. Manual scoring of human spermatozoa and the setting up of the image analysis software took the same amount of time. While the image analysis software carries out the automated scoring of human spermatozoa, other tasks can be performed. A major advantage when counting multiple slides is the elimination of eye strain as reviewing galleries shown on the large computer screen is an easy and quick step.

The results of this study indicate that automated scoring of fluorescently-stained human spermatozoa in mock sexual assault exhibits can be carried out reliably and reproducibly using well-developed classifiers for the image analysis software system. The automated scoring of spermatozoa combining the fluorescence-based staining assay and the image analysis software is currently being tested on a large number of sexual assault cases as part of a pilot project within an operational setting.

Automated, Spermatozoa, Image Analysis Software

A157 Re-Evaluation of the Seratec® PSA Semiquant Test for Use at the UnitedStates Army Criminal Investigation Laboratory

James M. DiFrancesco, MFS, United States Army, Criminal Investigation Laboratory, 4930 North 31st Street, Building 925, Forest Park, GA 30297-5205; and Joel D. Sutton, MSFS, United States Army, Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297-5205*

After attending this presentation, attendees will be educated regarding the detection of PSA using the Seratec® PSA Semiquant test on samples and how the United States Army Criminal Investigation Laboratory (USACIL) has addressed low levels of PSA present in casework.

This presentation will impact the forensic science community by increasing awareness about false positive PSA results using the Seratec® PSA Semiquant test when performing the test on evidentiary samples. Knowing what substances can be attributed to false positive reactions to the Seratec® PSA Semiquant test, and how to dilute them from the sample without compromising the examiner's ability to identify semen, would help to improve confidence in the results that are presented in court.

It is known that semen contains a high concentration of PSA, making PSA a useful biological marker to identify semen. The Seratec® PSA Semiquant test has been determined to be a valid and reliable method for detecting semen in biological stains. The test works by detecting PSA using two monoclonal antibodies that combine with the PSA to form a complex which is visualized as a red line on a membrane. The sample is extracted in a buffered solution to maintain a constant pH and to help it travel through the test strip. It is also well documented that a small chance of false positive PSA results in the absence of semen. Sometimes these results are from elevated PSA due to a biological phenomenon in an individual. Other times this is a result of non-biological material mimicking a positive result on the test strip. In the literature it has been noted that a change in pH due to the addition of organic acids (citric acid, acetic acid, and oxalic acid) can cause a false positive band on the Seratec® PSA Semiquant card. Examiners at USACIL perform Acid Phosphatase (AP), PSA, and microscopic examinations on a sample to determine if semen is present. Sometimes all three tests are performed on the same cutting. If a sample is only PSA positive an immunological indication of semen is reported. A review of cases at the USACIL has noted the presence of weak positive PSA results with no male DNA detected in multiple samples from different cases. In order to determine if a case sample is truly positive for semen, a study was performed to test various non-biological samples in order to isolate any that may show a false positive PSA result. Diet soda, alcoholic beverages, tooth paste, lubricants, douche, mouthwash, and various other substances were tested. During preliminary studies it was found that diet sodas gave false positive results when diluted one to one in PBS. The effects of AP reagent on the Seratec® PSA Semiquant test were also examined to determine if there was any interference occurring. Various dilutions were performed to determine if any changes to the current USACIL protocol can help eliminate these false positive results while still being able to detect low levels of PSA from semen.

Seratec®, PSA, False Positive

A158 The Microscopic Characteristics of Antemortem and Postmortem Hairs at the Root End

Stephen D. Shaw, MS, Linda Otterstatter, BS, and Candie Shegogue, MS, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA; Karen M. Korsberg Lowe, MA, Federal Bureau of Investigation Laboratory, Trace Evidence Unit, 2502 Investigation Parkway, Quantico, VA 22135; Sandra Koch, MFS, Federal Bureau of Investigation Laboratory, Trace Evidence Unit, 2501 Investigation Parkway, Quantico, VA 22135; and Joshua Friedman, MFS, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will see how the microscopic effects various environmental conditions may have on hairs that have been removed antemortem. This presentation will also demonstrate how to microscopically distinguish these hairs from hairs that have undergone postmortem changes.

This study will benefit the forensic science community by providing information on the microscopic characteristics that may be caused by environmental exposure and how these characteristics differ from postmortem banding. Postmortem banding and putrid roots are microscopic characteristics commonly observed in hairs that have undergone postmortem changes. Based on the experience of hair examiners, postmortem banding is generally accepted throughout the forensic hair community as a reliable indication of hair removal during the postmortem process. However, few research studies have been conducted to address the possibility that these characteristics may be observed in hairs removed antemortem.

Results from a study involving 600 hairs collected from fifteen living individuals will be presented. These hairs were exposed to various environments including indoors on a windowsill, submerged in water, buried in potting soil, outdoors on the ground surface, and inside vehicles. The hairs were subsequently microscopically examined at the root end to determine the type of changes that may have occurred as a result of storage in these conditions. Any changes at the root end were then compared to hairs removed from deceased individuals.

The majority of hairs studied (97%) contained roots in the actively growing anagen phase. Hairs in the anagen phase are not completely keratinized and thus more susceptible to changes due to environmental conditions. Two-hundred and fifty hairs were stored in vehicles or indoors on a windowsill for time periods ranging between nine days and 230 days. Two-hundred and fifty hairs were stored outdoors on the ground surface in shaded and non-shaded areas for time periods ranging between seven days and 106 days. One-hundred hairs were submerged in water or buried in potting soil for time periods ranging

between fifteen days and 100 days. No hairs stored indoors on the windowsill and no hairs stored in the vehicles exhibited characteristics of decomposition. Some of the hairs stored outdoors, most of the hairs submerged in water, and most of the hairs buried in potting soil exhibited characteristics of decomposition. Some of these characteristics are similar to characteristics observed in hairs removed postmortem. However, no hairs in this study exhibited characteristics of postmortem banding.

The results from a blind test on the identification of postmortem banding will be presented. The test consisted of over 200 hairs that included all hairs in the presented study with possible changes at the root end as well as hairs known to have been removed from deceased individuals. Initial analysis by the two examiners that completed the test resulted in greater than 99.5% accuracy in identifying postmortem banding. Following a confirmation process whereby each examiner reviewed the initial results, accuracy was increased to 100%.

Results from this study contribute towards the reliability that hairs exhibiting characteristics of postmortem banding are consistent with having been removed postmortem. This study also demonstrates the need for proper training and good quality assurance procedures when identifying postmortem banding.

Hair, Postmortem, Banding

A159 The Evaluation of Possible False Positives With Detergents When Performing Amylase Serological Testing on Clothing

Nicole M. Novroski, HBSc, 58 Dufferin Avenue, Trenton, ON K8V 5C9, CANADA; and Andrea L. Feia, MA, 1430 Maryland Avenue East, Saint Paul, MN 55106*

After attending this presentation, attendees will know that false positive detection of □-amylases is not possible when testing clothing laundered in detergents containing a-amylases to screen for the presumptive presence of saliva on evidentiary clothing.

This presentation will impact the forensic science community by increasing the understanding of presumptive saliva screening methods, and will clarify any misconceptions between the scientific and legal communities regarding the sensitivity and specificity limitations of the Phadebas® and RSID™-Saliva screening methods employed for the detection of α-amylase on evidentiary samples.

Amylase detection has become a very useful tool in the screening process for possible saliva stains on forensic evidence. In particular, α-amylase detection using commercially available tests such as RSID-Saliva or Phadebas® Amylase Test are two ways in which the forensic scientist is able to determine if saliva is presumptively present on an evidentiary sample.

The enzyme α-amylase is naturally occurring in many species of bacteria, fungi, plants, and animals. As a result, the presence of two α-amylase isoenzymes in humans has led to some difficulty in reporting the presence of salivary α-amylase versus pancreatic α-amylase in forensic casework. Moreover, there has been recent speculation from legal professionals that the α-amylases present in common household laundry detergents may be contributing to positive detection of α-amylase on evidentiary samples during forensic presumptive screening procedures.

For almost 40 years, detergent companies have been adding enzymes such as proteases, celluloses, and amylases to their products as a more effective method of breaking down tough stains created by polysaccharides and proteins. To determine whether or not α-amylase detection is possible following routine clothing laundering, unworn, unwashed fabrics of different compositions were laundered in a variety of detergents and stain removing agents. Two assays, RSID™-Saliva (Independent Forensics, Hillside, IL) and Phadebas® Amylase Test (Magle Life Sciences, Lund, Sweden), that use different methods of detecting α-amylase, were used to investigate whether detergent α-amylases in laundered clothing are detectable. RSID-Saliva detects human salivary α-amylase via anti-salivary amylase monoclonal antibodies whereas the Phadebas® assay takes advantage of the enzymatic properties of α-amylase present in a given sample. Thus, when using a screening method such as the Phadebas® Amylase Test, a positive amylase result is only suggestive, and not confirmatory, for the presence of human saliva.

Five fabric swatches were washed in a volume of laundry detergent pre-determined for a light load wash cycle, exceeding what would typically be required to launder five fabric swatches. This was employed in an attempt to maximize the retention of detergent and detergent additives in the laundered clothing. Nevertheless, all garments tested negative in response to alternate light source, Phadebas®, and RSID-Saliva. These findings suggest that at some point during the laundering cycle, the enzymes were damaged, degraded, or removed. The causes of a-amylase loss during laundering were not examined; however, the data support that detergent enzymes should not contribute to a misidentification of a saliva stain using a presumptive screening method.

Additionally, unlike laundered clothing, undiluted detergents do contain detectable levels of α-amylase, but these findings were only observed using the Phadebas® Amylase Test.

Amylase, Saliva Screening, Serology

A160 Capturing the Moment: Photographing Low Level Signals From Serological Testing of Swabs and Cartridges

Francesca M. Daher, BA, Michael A. Donley, MS, and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will have learned how to photograph, in a single image, multiple DNA swabs, or cartridge tests with varying levels of signal intensity from presumptive color tests or from cartridge tests for blood or semen.

This presentation will impact the forensic science community by providing an optimal way to photograph the results of time-sensitive Serological tests of varying signal intensities in order to document the findings of a Forensic Genetics analyst.

To photograph the results of presumptive color tests on swabs or the results of blood or semen cartridge tests, the photographs must be taken at specific time interval after the test is completed. The photograph must accurately capture what the analyst observes even when the results are faint. The Forensic Imaging Division and the Forensic Genetics Laboratory of the Harris County Institute of Forensic Sciences conducted a study to establish photographic standards and procedures that would accurately capture and corroborate the results observed by the analyst within the time constraints. This interdisciplinary effort was designed to identify and validate a photographic method so that the images could be used for verification of the analyst's work. These results are intended to provide guidance to other agencies in establishing and validating photographic methods in order that photographs may become a standard and useful part of the case record.

A Nikon D5000 camera with a Nikkor 85mm macro lens was used to perform the tests with an ISO of 200, a shutter speed of 1/125th of a second and an aperture setting of *f*/22. Due to the fact that several swabs or cartridges are often collected at the same time, these settings had to be able to accurately portray all levels of signal intensity in a single shot. For the swabs, a series of tests on various colored backgrounds, exposure settings, and lighting angles was conducted. Settings were validated by changing one variable at a time and holding the others variables constant. Successful results were observed at -0.3 exposure compensation on an 18% neutral gray background with direct lighting. This proved to yield an image that captured a wide range of signal levels on several different swabs within a single image.

For the cartridges, another series of images was photographed using more extensive exposure compensation settings and lighting angles. Since the cartridges completely fill the frame, there was no need to experiment with different colored backgrounds; however, due to the reflective nature of the cartridge material, additional exposure compensation settings were needed. These images were photographed by changing only one variable at a time in order identify the best settings for the test. The most favorable results were achieved at an exposure compensation setting of -1.7 with direct lighting.

Presumptive color tests of Serological swabs as well as blood and semen testing on cartridges are integral parts of the Forensic Genetics Laboratory. It is the opinion that all results of visual tests should be photographically documented for verification. Photographs of faint results can be challenging, but a photograph taken under the right conditions can provide a permanent and accurate record of the test results. The tests done in this study will allow for time-sensitive test results to be successfully photographed and verified and will provide guidance for others to achieve the same results.

Photography, Presumptive Tests, Serology

A161 To Freeze or Not to Freeze?: Science-Based Guidance for Preserving Biological Evidence

Shannan R. Williams, BA, MPP, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; Dennis Davenport, BA, 7887 East 60th Avenue, Commerce City, CO 80022; Margaret C. Kline, MS*, National Institute of Standards and Technology, 100 Bureau Drive, Building 227 Room B226, Mailstop 8314, Gaithersburg, MD 20899-8314; and Yvette Sanchez-Owens, BA*, Los Angeles Police Department, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032*

After attending this presentation, attendees will gain an understanding of research to date that provides guidance on how biological evidence can be best preserved. Further, this presentation will provide an overview of Technical Working Group on the Preservation of Biological Evidence activities to date and preliminary recommendations.

This presentation will impact the forensic science community by bringing awareness to issues in evidence storage and the solutions being proposed by the working group. The administrative burden of evidence management and storage has increased as advances in DNA technology enable better results with less material and more states enact post-conviction testing legislation. Recent DNA stability studies reveal conflicting justifications for biological evidence storage conditions. Crime labs and property and evidence rooms have different purposes, yet coordination is required among both in order to ensure that evidence is properly collected, analyzed, and preserved.

In August of 2010, the National Institute of Justice (NIJ) and the National Institute of Standards and Technology's Law Enforcement Standards Office (OLES) convened the first meeting of the *Technical Working Group on the Preservation of Biological Evidence Preservation.* The primary objective of the working group is to establish best practices, based in science, to reduce the premature destruction and degradation of biological evidence, thus ensuring its availability for future analysis. After conducting an analysis of the state of biological evidence storage, the group determined that a key barrier to adequate management of biological evidence is the lack of communication and standardized protocols between property and evidence clerks and forensic scientists.

Recent headlines have highlighted significant problems with the storage of potentially exculpatory biological evidence in property and evidence storage units across the country. Court orders for the location of evidence have demonstrated inadequacies in the packaging, storage, and tracking process of some evidence. Investigations into these inadequacies reveal underlying factors such as: capacity of the storage facility, laboratory backlog, materials available for packaging, geographic distance between the collecting and storage facility, and the selected tracking system. The disposition of evidence is a key consideration as the majority of evidence stored is of questionable probative value. Management of evidence in many long term storage locations is lacking, thus jurisdictions must develop standardized protocols to identify what evidence to keep, how to keep it, and for how long. This presentation will focus on describing ways that forensics scientists, in particular, can mitigate these issues.

The group's key deliverables will include a handbook outlining best practices and standardized protocols for property and evidence clerks, a report on legislative considerations, a report discussing current technological trends and possible applications, and a web-based clearinghouse for biological evidence handlers in the property rooms, courts, and law enforcement agencies.

DNA, Evidence, Storage

A162 Mixed DNA Analysis

Matthew J. Bohn, PhD, Analytic Services, Incorporated, 1330 Inverness Drive, Colorado Springs, CO 80910; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will learn how statistically significant information can be extracted from mixed DNA samples. Some statistical techniques are relatively simple to implement such as making random match probabilities on a mixed DNA sample given an individual's DNA profile. Other more difficult techniques will be interesting to the warfighter attempting to capture a terrorist cell or a narcotics unit attempting to track a drug gang. These more sophisticated techniques extract minor commonalities in the DNA profiles using the techniques of Principal Component Analysis (PCA) and clustering algorithms.

This presentation will impact the forensic science community by demonstrating mathematical techniques that can be used to extract information from DNA samples containing more than one contributor.

Currently, mixed DNA samples face difficulties linking an individual to a crime scene or location. However, in an expeditionary environment faced by a military force, evidence linking a group of individuals could be of monumental importance. As a hypothetical example, a recently confiscated cell phone contains DNA from three individuals of al-Qaida and a mixture of four random, innocent individuals can be found to be statistically similar to a mixed DNA sample found on an IED. Cluster analysis can be used to separate the group of al-Qaida members from the random, innocent individuals. In addition, statistics can be used to ascertain the random match probability of an individual in the group. For example, the warfighter could ascertain with what probability the individual holding the cell phone is a member of the al-Qaida group that built the IED.

Analysis techniques will be discussed for mixed DNA from crime scenes, confiscated material, and opportunistic collections. A wealth of intelligence information hidden exists within mixed DNA samples. World-wide analysis and databasing of DNA mixtures will lead to increased awareness of the world-wide threat while simultaneously providing actionable intelligence to the commander in a local environment. Statistical analysis of mixed DNA samples using Principal Component Analysis (PCA) and cluster analysis enables tracking, group identification, and probability analysis of individuals in the group. Computer simulations will be presented demonstrating the exciting potential for the use of DNA mixtures. Based on a NIST database, a computer program was developed to generate random DNA profiles representative of the allelic frequencies in the database. These profiles could then be mixed and a random match probability of a random individual to the group calculated. The random match probability is then plotted versus the number of contributors. One example from the data is that with ten contributors to a mixed profile, the probability of a random individual's profile appearing in the mixture is one out of ten. With four contributors, the random match probability drops to one in 3,333. Obviously these numbers are far from the typical one in five billion random match probabilities for a single profile; however in an expeditionary setting, they may help to uncover a terrorist cell.

Given sufficient data, groups can also be identified and tracked in mixed DNA samples. A collection of 60 computer generated samples were analyzed. The 60 samples consisted of three groups: (1) completely random; (2) four random profiles plus three consistent profiles; and, (3) four random profiles plus three different, consistent profiles. The concept being modeled is that three members of a terrorist cell or drug gang might all touch a cell phone, which is then thrown away and touched by four innocent individuals. This leads to an aggregate DNA sample that contains a mixture of seven individuals. Can these groups be identified and separated? Yes, with reasonable probability, the method of PCA coupled with cluster analysis can separate the groups. In addition, the total number of alleles in these mixtures was analyzed using a Monte Carlo technique and depending on the total number of alleles, an estimate can be made on the total number of contributors.

Mixed DNA, Principal Component Analysis, Cluster Analysis

A163 The Partial Match Process in New York City

Noelle J. Umback, PhD, New York City, Office of Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016; Emily D. Head, MS, 2251 Eisenhower Avenue, Apartment 501, Alexandria, VA 22314; Jennifer D'Andrea, MSFS, New York City, Office of Chief Medical Examiner, 421 East 26th Street, New York, NY 10016; and Christopher M. Kamnik, JD, and Marie Samples, MS, New York City, Office of Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016*

After attending this presentation, attendees will be introduced to a functioning, large-scale partial match operation. The presentation will illustrate how the SWGDAM recommendations for partial matches have been put into practice within the State and City of New York.

This program will impact the forensic science community by addressing the uses of DNA to generate investigative leads when there have been no direct matches to a profile.

In early 2008, the FBI hosted a conference for CODIS laboratories and other interested parties about partial matches, familial searching, and the various ramifications thereof. The SWGDAM Interim Plan for Partial Matches was introduced (and subsequently adopted), which makes recommendations to the community but leaves policy decisions to each state. Shortly thereafter, the New York State Commission on Forensic Sciences, DNA Subcommittee also took up the discussion. In anticipation of a statewide policy, the New York City Office of Chief Medical Examiner (OCME) Department of Forensic Biology began to review potential partial matches to be pursued when the policy took effect.

Partial matches are inadvertently discovered—for instance, moderate stringency matches in CODIS during a routine search, or an evaluation of profiles within a case. These exclude the person brought forward in CODIS as a candidate match as being the actual source of the forensic profile, but there is a chance that a close relative could be the source.

Partial matches are NOT familial searches. Familial searches are deliberate searches seeking similarities between a forensic sample in a database and an offender. Searches of this sort require specific non-CODIS software and are only conducted in a few jurisdictions at this time. In order for a profile to be considered for partial match evaluation in New York City, there are some basic criteria that must be met before even performing any calculations. First, it must be a previously unmatched forensic profile of ≥10 loci. Second, it must be a clean (or fully-deconvoluted) profile—there can be no partially-determined loci, even though such profiles are eligible to be entered into CODIS. At the local level there is a distinction between partial matches obtained through a database search or within a case. At the state and national search levels, only forensic-to-offender partial matches are considered.

The next screening step is to determine how many alleles are shared between the two profiles. For a parent-offspring relationship, the threshold is 50%, because there only needs to be one allele in common at every locus. At any given locus, siblings are not required to share any alleles at all; even when they are the offspring of the same two parents (most siblings have around half in common). Conversely, some siblings share a high percentage of alleles, and these are the siblings for which partial matches may be useful. Based on results from the literature, it was determined that having ≥70% shared alleles maximizes the probability of a sibling relationship between two profiles, while minimizing the probability of more distant relatives, or of unrelated persons. Any pair of profiles fulfilling one or both of these scenarios is evaluated using the CODIS PopStats tool. Further testing (Y-STR or mitochondrial DNA testing) could be undertaken to confirm or refute the possible partial match between two local cases or samples if necessary.

For potential matches involving offender samples from SDIS or NDIS, the New York City Police Department (NYPD) and the appropriate District Attorney's Office (DAO) are queried regarding their interest in the case. Both entities must commit to pursue further investigation of the case if the name of the offender (potential relative) is released and to provide follow-up information to the New York State Division of Criminal Justice Services regarding the outcome. Only after affirmative responses are received from both NYPD and DAO will the OCME formally request the name of the partially-matched offender from the offender database. For non-New York requests, the process is also dependent on the CODIS unit (FBI) deeming it valid to pass along to the offender laboratory and whether that state will release offender names for partial matches.

For those requests from local labs within New York State, the SDIS staff at the New York State Police performs additional kinship calculations for the expected match ratio (EMR) and expected kinship ratio (EKR) as defined in the SWGDAM Interim Plan for Partial Matches. If the results meet their threshold, they advise the databank coordinators to release the name to the local lab. The name is then reported to the NYPD and DAO.

The partial match process began in the spring of 2011. Results regarding the outcomes for the partial match process are expected by early 2012.

Partial Match, DNA Database, Kinship Calculations

A164 Combining DNA Evidence for Greater Match Information

Mark W. Perlin, PhD, MD, Cybergenetics, 160 North Craig Street, Suite 210, Pittsburgh, PA 15213*

Most fields of scientific enquiry routinely combine data from multiple experiments. These experiments can be repetitions drawn from one item, or involve different items entirely. The motivation is to elicit maximal information from an experimental design. The statistical mechanism is the joint likelihood function.

DNA evidence is often challenging to interpret. When a DNA sample has low quantities, is degraded, or contains several individuals mixed together, no single allele pair may be able to explain the STR data. Multiple allele pair possibilities then become feasible, with an associated loss of identification information. It can then become important to use all the available experiment data in order to restore information.

In forensic DNA science, human data interpretation is usually performed on data derived from just one item. This practice is a natural consequence of "thresholds" – applying a preset peak height level to quantitative peak height data in order to simplify human data interpretation, which creates artificial all-or-none qualitative allele possibilities. However, the resulting genetic profiles cannot be mathematically combined. Some groups may heuristically combine profiles after data interpretation to form a "consensus" profile, but this practice has little statistical justification.

Quantitative computer interpretation of continuous electrophoretic STR data signals, however, has no such artificial limitation. It is therefore

natural to mathematically preserve identification information by inferring a genotype using a joint likelihood function that examines all the independent data simultaneously.[1]

A likelihood function mathematically quantifies how well alternative hypotheses explain a fixed data result. A joint likelihood function assesses these hypotheses on multiple data items simultaneously. Typically, the data are drawn from independent experiments. Therefore, the joint likelihood simply multiplies together the likelihood numbers from separate experiments, jointly conditioned on a common explanatory hypothesis.

This talk describes the joint interpretation of DNA evidence. It is shown how likelihood functions can be used to rigorously explain DNA evidence, and how joint likelihood functions can combine evidence. Results that show how the number of assumed contributors affects the inferred result, and why appropriately constructed likelihood ratios (LR) do not overstate the inferred DNA match information will be presented. These concepts on representative DNA mixture criminal cases and experiments will be illustrated.

In particular, using a joint likelihood function on DNA mixtures, we show:

- How a joint examination of the data signals from 10% and 50% mixtures can infer a highly informative genotype, with a combined LR match statistic a million times greater than either separate analysis;
- A criminal case where none of the three data signals from a low-template three person mixture was informative in isolation, but when jointly examined they together produced a DNA match statistic LR over a million; and
- Strategies for effectively combining the data signals of differen mixture evidence (from one or more items) in a joint interpretation that retains more DNA identification information.

Forensic DNA is an information science that centers on inferring genotypes. More informative genotypes can lead to greater match information. By combining DNA evidence, as taught in this presentation, a practitioner can extract more information from their existing data, and make more accurate DNA identifications.

Combining Evidence, DNA Mixture, Likelihood Ratio

A165 A Study of the Effects of Database Size and Loci Number on the Potential for Successful Familial Searches in Databases of STR Profiles

Rick W. Staub, PhD, Orchid Cellmark Incorporated, 13988 Diplomat Drive, Suite 100, Dallas, TX 75234; Dmitry Maschenski, MS, Orchid Cellmark Incorporated, 13988 Diplomat Drive, Suite 100, Dallas, TX 75234; Carlos Baena, BS, Orchid Cellmark Incorporated, 13988 Diplomat Drive, Suite 100, Dallas, TX 75234; Pedro Reinoso, BS, Orchid Cellmark Incorporated, 13988 Diplomat Drive, Suite 100, Dallas, TX 75234; Sid Sinha, MBA, Orchid Cellmark Incorporated, 13988 Diplomat Drive, Suite 100, Dallas, TX 75234*

After attending this presentation, attendees will understand the logic used to perform familial searches and how results are influenced by methodologies, database size, and genetic loci utilized.

This presentation will impact the forensic science community by clarifying potential problems involved with familial searches and how to best overcome them through the use of optimal scientific methods.

Over the past several years, the utilization of familial searching tools by law enforcement to locate relatives of the perpetrators of violent crimes has received a good deal of publicity in the media. This has initiated a good deal of public debate over potential violation of civil rights of those individuals in DNA databases who are identified by familial searches as "persons of interest." There is a legitimate potential for several individuals completely unrelated to perpetrators of violent crimes to arise as persons of interest when database searches are performed, particularly if the searching technique used does not have a strong discrimination power for locating relatives. Even when optimal methodologies are used to carry out familial searches, the number of false positive and false negative results in familial searches will be affected by the number of loci used and the number of profiles in searched databases.

A generally accepted methodology for assessing putative kinship is via the utilization of a Kinship Index (KI), which is a likelihood ratio comparing the likelihood of obtaining genetic results from individuals that are biologically related to the likelihood of obtaining the same genetic results from unrelated individuals. A less robust method of assessing kinship is via allele sharing (identical by descent in biological relatives vs. identical by chance in non-related individuals). In this study we compute KIs and number of shared alleles in comparisons of STR profiles from simulated evidence items to databases of varying size that also contain profiles of known relatives of the donor of the simulated evidence profile. In making these comparisons, the number of loci in the evidence profile is also varied to obtain data on the likelihood of successful searches based on loci used in the search. These data provide the practitioner of familial searches with a reasonable framework within which to establish guidelines to optimize the chances for carrying out successful searches in the future. Additionally, they illuminate the impact of database size on the frequency of false positive hits when performing familial searches. This presentation will examine possible means to reduce false negative and false positive hits that arise, such as the comparison of Y-STR haplotypes for male samples in databases, or comparison of most likely race of evidence and database profiles.

All databases used in these studies were generated from simulated profiles based on an algorithm that utilizes input STR allele frequencies from published data. Profiles of biologically related individuals for search purposes were either obtained from families of known racial/ethnic origin or generated from profiles in databases using rules of Mendelian inheritance.

Familial Search, DNA Profile Database, Y-STR Haplotype

A166 Alternative Sexual Assault Kit Processing

Michael A. Donley, MS, and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Christy Smejkal, MS, Harris County Medical Examiner's Office, Forensic Biology Section, 1885 Old Spanish Trail, Houston, TX 77054; and Michal L. Pierce, MS, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand the pros and cons of an alternative approach to processing sexual assault kits. This presentation will aid attendees in deciding the method to use when processing sexual assault kits. Presented here are the results after implementing the alternative processing method and its comparison to the traditional method.

This presentation will impact the forensic science community by demonstrating an alternative method of processing sexual assault kits and the impact it will have on the evidence being processed.

In 2010, the Harris County Institute of Forensic Sciences Forensic Genetics Laboratory (HCIFS) initiated the use of an alternate processing scheme for sexual assault kits. A portion of each available swab is cut and sent directly to differential extraction without presumptive or confirmatory testing for semen or saliva. This is done regardless of the information in the complainant's narrative. Vaginal, anal, oral, debris swabs (i.e., breast, neck), and swabs of fingernail scrapings are cut and sent directly to

differential DNA extraction. The new method simplifies the activities in Serology while greatly increasing the number of samples needing differential extraction. The HCIFS DNA Lab utilizes high capacity robots for DNA extraction, quantitation reaction set-up, sample normalization, and STR reaction set-up, making the large increase in the number of differential extractions possible.

After eight months of processing kits with this method, the results were evaluated for oral swabs, neck swabs, breast swabs, and swabs of fingernail scrapings – locations where semen is not typically present. Vaginal and anal swabs were not evaluated because semen, if present, is typically found on these swabs. Oral swabs from 153 cases were examined. In 131 cases, the samples were terminated (i.e., testing was halted after quantitation) due to a lack of male DNA. Of 22 cases which were amplified, 18 cases were from a male complainant and in all but one of the cases from a female complainant, only the complainant's profile was observed. In the one instance of a male profile in the male fraction of an oral swab, the narrative indicated that an oral assault had occurred. Differential extraction of these swabs does not appear to be necessary.

Differential extraction from neck and breast swabs is not necessary to observe male profiles. In the traditional method (without differential extraction), 50-70% of these samples yielded foreign male profiles. With the new method where debris swabs were tested only by differential extraction, all of the sperm fractions were terminated after quantitation due to a lack of male DNA. For neck swabs, 80% of the non-sperm fractions were amplified and all revealed mixtures that included male profiles. Similar results were seen in swabs from fingernail scrapings. Again, this indicates that differential extraction of these samples is not helpful since semen is not typically present on these swabs.

These results suggest a combination approach. Vaginal and anal swabs should continue to be tested without screening in Serology - testing for PSA and for sperm will continue to be conducted during DNA extraction. Oral, neck and fingernail swabs should be subjected to regular, not differential extraction unless the female complainant states in the narrative that the suspect ejaculated on her breast, neck, thigh, etc. If the female complainant reports the suspect licked her breast, neck, thigh, etc. then the swabs should be test by regular extraction. As an alternative, all such swabs could be screened for PSA. Those that are positive could be differentially extracted.

In any case, the handling will still be more efficient than conducting a full screen in Serology, although a change will increase the work on the Serology lab. Each laboratory can decide which method (traditional, alternative, or a combination) is best suited for their laboratory.

Sexual Assault Kit, DNA Extraction, Processing Time

A167 Update on DNA-PROKIDS: Fighting Human Trafficking With DNA Analysis

Jose A. Lorente, MD, PhD, University of Granada, Department of Forensic Medicine, Granada, 18012, SPAIN; Maria J. Alvarez-Cubero, MS, University of Granada, Department of Legal Medicine, Faculty of Medicine, GRANADA, 18012, SPAIN; J. Carlos Alvarez, PhD, University of Granada, Department of Legal Medicine, GRANADA, 18071, SPAIN; Maria Saiz-Guinaldo, BS, University of Granada, Department of Legal Medicine, Faculty of Medicine, Granada, 18071, SPAIN; Miguel Lorente, PhD, University of Granada, Department of Legal Medicine, Granada, 18012, SPAIN; Bruce Budowle, PhD, University of North Texas Health Science Center, Forensic & Investigative Genetic, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107; and Arthur J. Eisenberg, PhD, University of North Texas Health Science Center, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107*

After attending this presentation, attendees will know about the impact and success of the DNA-PROKIDS program that has generated databases in more than ten countries and has solved over 350 cases of child trafficking and illegal adoptions.

This presentation will impact the forensic science community by showing how human trafficking and illegal child adoptions are closely related, and how DNA analysis has shown to be an invaluable tool to fight these crimes.

Human trafficking has become one of the main criminal problems throughout the world, and it is rapidly becoming the primary crime in economic terms. One forensic science-based approach that can assist in the effort to combat human trafficking is through the use of the tools for human identity testing. DNA analysis can play an important role in verifying alleged kinship relationships. Forensic DNA testing for identification of human remains and routine casework is used throughout the world and is a technology that is readily accessible. Nevertheless, the use of DNA analysis is not used extensively in the efforts to address the epidemic of missing children. More than one million children are reported as actively "missing," and likely this number is grossly underestimated. Many of these missing children have been separated from their families and are being trafficked for various exploitations. DNA typing of these children and alleged relatives can verify or refute biological relationships that could be extremely useful in securing trafficked and exploited children and in assisting law enforcement in identifying traffickers and their networks. Moreover, database of DNA profiles from parents who report missing children and children who are offered for adoption or abandoned will facilitate the identification process on national and international scales. In 2006, the University of Granada, Spain, initiated the DNA-PROKIDS Program, and in 2009 the Center for Human Identification, University of North Texas Health Sciences Center, joined in the program as a primary partner. In addition to providing a DNA analysis service, DNA-PROKIDS is a program that develops DNA collection kits, protocols, methodologies, software, and educational materials for the use of DNA typing of these trafficked and abandoned children, and to assist in combating trafficking. This program has been able to function by support from the Spanish Government, several large Spanish banks including BBVA, Santander and CajaGranada-BMN, and donations from the Life Technologies Foundation.

Two databases are needed to form a functional search capability for child identification. One is a Reference Database (RD) of DNA profiles (composed primarily of autosomal STRs, and may include Y-STRs and mtDNA markers) obtained from biological samples (buccal swabs) voluntarily provided by mothers and other family members of missing children. The other database is a Questioned Database (QD) of DNA profiles (composed of the same genetic markers used for profile generation for RD) obtained from children who have been found without their families, are being exploited, or are known to be victims of human trafficking. Each country that has agreed to be part of the DNA-PROKIDS network maintains its own RD and QD. The DNA profiles are searched within and between a country's databases in an effort to identify missing children within the country. International sharing is performed on a case-by-case basis and currently is a manual process. DNA-PROKIDS has partnered with and has supported the development of such DNA databases in six of the countries within Latin America (Mexico, Guatemala, El Salvador, Paraguay, Peru, and the Dominican Republic) and within four of the countries in Asia (the Philippines, Thailand, Sri-Lanka, and Indonesia).

To date, over 2,500 samples have been collected by the different participating countries, and over 330 positive identifications have been made. Some experiences and notable cases will be described. In September 2010, Guatemala passed the Alba-Keneth Law that requires mandatory collection and analysis of biological samples from all children found without relatives and offers, by law, all relatives of missing children the opportunity to donate a biological sample for the DNA-PROKIDS Guatemalan database. It is believed that this is the first law of its kind throughout the world. The database is coordinated in Guatemala through its National Institute of Forensic Sciences (INACIF).

A greater global coordinated effort is needed to continue to identify trafficked and exploited children and to dramatically increase the success

that these DNA-PROKID pilots have experienced. The initial results and experiences obtained by DNA-PROKIDS clearly demonstrate the application of forensic DNA analyses and its supporting technical infrastructure can play an important role as a deterrent of this terrible crime.

DNA-PROKIDS, Human Rights, DNA Databases

A168 Evaluating the Probative Value of Sexual Assault Evidence Collected From Suspects

Chani Sentiwany, MS, Oakland Police Department, 455 7th Street, 6th Floor, Oakland, CA 94607; William M. Green, MD, University of California Davis, Medical Center, 2315 Stockton Boulevard, Sacramento, CA 95817; Jennifer S. Mihalovich, MPH, Oakland Police Department, Criminalistics Division, 455 7th Street, Room 608, Oakland, CA 94607; Edward A. Panacek, MD, University of California Davis, Medical Center, 2315 Stockton Boulevard, Sacramento, CA 95817; and George Sensabaugh, DCrim, University of California - Berkeley, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720*

After attending this presentation, attendees will appreciate the value of collecting suspect sexual assault kits on a regular basis and of the use of a standard sexual assault kit format.

This presentation will impact the forensic science community by introducing how victim DNA can be obtained from sexual assault suspects. Demonstrations on how victim DNA can be detected on penile swabs and finger swabs collected from sexual assault suspects up to and at least 28 hours after the alleged assault.

Over 80,000 forcible rapes are reported in the U.S. annually. Many states have established protocols for the medical forensic examination of sexual assault victims and a national protocol was published by the President's DNA Initiative in 2004. It is believed that only California has a standardized protocol with instructional guidelines, along with a forensic medical report form, for the collection of evidence from suspects. When a sexual assault suspect is known and available, collection of evidence from this suspect in a timely fashion may aid in corroborating the victim's report.

The objective of this study was to evaluate the probative nature of evidence obtained during forensic exams of suspects in sexual assault cases. This retrospective study reviewed findings from 106 suspect sexual assault kits (encompassing 102 cases) collected in the City of Oakland, California from 2000 through 2009. This included review of 49 suspect sexual assault kits collected at a county designated hospital prior to February 2006 and 57 kits collected by a contract service at the county jail after February 2006. Data from the California suspect forensic medical report (CalEMA 2-950 form) was collated with the appropriate data from the corresponding victim kit forensic medical report (CalEMA 2-923/930 forms). The data and relevant information were translated into a database structure. Information from the Oakland Police Department Criminalistics Laboratory analyst case notes including the victim and suspect kit inventory, examination notes, microscopic examination form, and genotyping data table(s) was integrated into the database.

The sample collection protocols differed between the two collection agencies. Prior to 2006, during collection at the county hospital, a single swab was used to collect from the suspect's penile glans and shaft. Scrotal swabs, separate glans and shaft penile swabs, and finger swabs were not collected on a consistent basis. After 2006, a procedural change occurred as collection was shifted to the county jail: finger swabs, separate swabs for penile glans and shafts, and scrotal swabs were collected on a regular basis. For this study, of the 106 kits examined, 104 kits contained genital swabs and 54 contained finger swabs. In total, DNA profiling was performed on 130 genital swabs and 94 finger swabs. No DNA typing was done on 18 of the kits based on analyst discretion, failure to detect epithelial cells, or redundancy of samples.

A standard protocol was used for the examination of the swabs. The swabs were extracted and the extracts were examined microscopically for cellular material. Typically, samples with epithelial cells or sperm were taken to DNA typing. In some cases, based on analyst discretion, samples without epithelial cells were also taken to DNA typing. Prior to September 2007, amplification was performed with the AmpFlSTR Profiler Plus® typing kit. For cases after September 2007, samples were amplified with the AmpFlSTR Identifiler® typing kit. DNA profiles containing DNA from someone other than the suspect were classified as having "Foreign DNA." Profiles with foreign DNA were categorized as "Probative" if the victim could not be eliminated as a possible source. The post assault interval (PAI) time was determined for each kit using date and time of the alleged sexual assault stated on the victim forensic medical report or police report and the date and time of penile swab collection noted in the suspect forensic medical report.

Probative DNA typing results were obtained from at least one genital swab in 42% of cases (44 of 104) or finger swab in 30% of cases (16 of 54). Half or more of the possible victim's DNA profile was detected on at least one genital swab in 24% (25 of 104) and on at least one finger swab in 17% (9 of 54) of cases. Full victim DNA profiles were obtained on at least one genital swab in 17% (17 of 104) or finger swab in 11% (6 of 54). A full victim DNA profile was obtained from a genital and a finger swab out to 18 hours and a 60% DNA profile on a genital swab was obtained at 28 hours.

Suspects, Sexual Assault, DNA Profiling

A169 Retrospective Study of 150 Sexual Assault Cases

Shannon C. Cavness, MS, Oakland Police Department, 455 7th Street, Room 608, Oakland, CA 94607; William M. Green, MD, PO Box 800, Shingle Springs, CA 95682; Jennifer S. Mihalovich, MPH, Oakland Police Department, Criminalistics Division, 455 7th Street, Room 608, Oakland, CA 94607; Edward A. Panacek, MD, University of California Davis, Medical Center, 2315 Stockton Boulevard, Sacramento, CA 95817; and George F. Sensabaugh, DCrim, University of California - Berkeley, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720*

After attending this presentation, attendees will have an understanding of the importance of blind collection of potential oral contact site swabs, the possible discrepancy between vaginal smear slide results obtained by forensic medical examiners versus the forensic laboratory scientist and the importance of proper collection of rectal swabs. Additionally, overall DNA typing results of these cases will be reported.

This presentation will impact the forensic science community by adding to the practical knowledge of the laboratory scientist and forensic medical examiner and potentially affecting policy change with respect to sample collection post sexual assault.

According to the Bureau of Justice Statistics, approximately one in five women is sexually assaulted during their lives. DNA technology in combination with CODIS databases is a powerful tool for the identification of sexual assailants. However, without proper evidence collection, DNA typing from sexual assault cases could not be conducted. Thus the individuals responsible for the crimes would not be identified. In that vein, it is absolutely imperative to discern the best methods of evidence collection, preservation, and analysis.

The evaluation of 150 sexual assault cases collected by medical practitioners at Highland Hospital in Oakland California and examined by Criminalists at the Oakland Police Department (OPD) Criminalistics Laboratory was conducted. Cases assigned the California penal code: 261 and analyzed by the Criminalistics Laboratory between August 2003 and October 2007 were examined. No other penal code cases were utilized. These cases include only sexual assault examination of female victims aged 14 years and older and were selected from approximately 300 forcible rapes per annum from the same time period.

Microscopic examination of the vaginal smear slides by the forensic medical examiner resulted in observation of sperm 13% of the time. When the examiner observed sperm, the crime laboratory scientist also observed sperm on the corresponding vaginal swab 100% of the time. Of the 119

cases which were sperm negative when examined by the forensic medical examiner and the nine cases in which no wet mounts were prepared, subsequent examination of x-mas stained slides in the forensic laboratory detected sperm in 57 cases, a yield of 48%. Of these 57 cases, complete foreign DNA profiles were obtained in 37 cases (65%), partial profiles with sufficient data for upload to CODIS were obtained in 10 cases, and few alleles were obtained for six cases. The evaluation of these 150 cases resulted in probative DNA profiles being obtained from 100 cases. Oral contact samples yielded the only probative DNA profiles in 10% of cases. Twenty victims reported a lapse of consciousness. Potential oral contact samples from these victims were not ubiquitously collected. Policy should be implemented such that neck, face and breast swabs are routinely collected from victims.

There are 21 kits with reported penile anal penetration. One case had no anal or rectal swabs collected even though there was a report of anal penetration. Eleven (52%) cases had anal swabs collected and 10 (48%) cases had rectal swabs collected (one of these cases had anal and rectal swabs collected with an anoscope used for the rectal swab collection). Seven (33%) cases had rectal swabs collected using an anoscope. An additional case may have had an anoscope used for the collection of the rectal swab; however, the writing on the sexual assault medical report was illegible. This means, including the report with the illegible writing, rectal swabs were collected improperly (without the use of an anoscope) for four cases and no rectal swabs were collected for 10 cases. Rectal swabs need to be collected via anoscopy for all reports of anal penetration.

Sexual Assault, Forensic Evidence, Oral Contact

A170 The Analysis of Sexual Assault Kit Backlogs: Scientific Results and Criminal Case Dispositions

Joseph L. Peterson, DCrim, California State University, Los Angeles, School of Criminal Justice and Criminalistics, 5151 State University Drive, Los Angeles, CA 90032-8163; Donald Johnson, MS, California State University, Los Angeles, School of Criminal Justice, 5151 State University Drive, Los Angeles, CA 90032; and Denise Herz, PhD, Lisa Graziano, PhD, and Taly Oehler, MS, California State University, Los Angeles, School of Criminal Justice and Criminalistics, 5151 State University Drive, Los Angeles, CA 90032-8163*

After attending this presentation, attendees will be familiar with the scientific results from the testing of backlogged sexual assault kits, the success in uploading DNA profiles into CODIS, and the criminal justice dispositions of a sample of backlogged cases vs. a sample of sexual assaults that were tested currently.

This presentation will impact the forensic science community by increasing awareness of a growing national problem and how the role and impact of forensic science in backlogged sexual assault kit cases is mediated by the relationship between the assailant and victim and associated demographic and investigative variables.

Backlogged and untested sexual assault kits (SAKs) are a major problem facing forensic crime laboratories and law enforcement agencies throughout the United States. The combined untested SAKs from the Los Angeles Sheriff's Department (LASD) and Los Angeles Police Department (LAPD) reached 10,895 cases in the fall of 2008. The chief executives of both agencies announced that all backlogged kits would be tested, using outside private DNA testing laboratories. The Sexual Assault Kit Backlog Project was funded by the National Institute of Justice (NIJ) to: (1) evaluate the results of scientific tests performed on outsourced backlogged sexual assault kits; (2) review the sexual assault case processing literature; (3) determine the criminal justice dispositions of backlogged and nonbacklogged cases before and after kit testing; and, (4) identify case and evidence characteristics useful in prioritizing sexual assault evidence submitted in the future.

Researchers from California State University, Los Angeles collected a 20% random sample (1,948 cases) of backlogged cases from the more than 10,000 tested cases in order to evaluate the scientific results. The study design also included a smaller subsample of 742 backlogged and nonbacklogged cases to determine final criminal justice dispositions, before and after testing. The research design also included a review of the sexual assault case processing literature and focus groups with sexual assault investigators, prosecuting attorneys, and criminalists to discuss the role SAK evidence plays in resolving both stranger and nonstranger sexual assaults.

Data from tested SAKs were drawn from crime laboratory files and revealed 93% of victims were female, two-thirds knew their assailants, almost half reported they were intoxicated with alcohol or drugs at the time of the assault, and more than three-quarters (77.3%) sustained one or more injuries. The average post coital interval between the time of the assault and victim exam was 23.3 hours, three-quarters reported vaginal penetration, and more than one-quarter thought the assailant had ejaculated.

Laboratory results included screening tests to find different biological markers (sperm, P30, Y chromosome, acid phosphatase, amylase, and epithelial cells) from various orifices and in dried secretions on the body. Semen screening tests and Y chromosome tests were successful 40% to 50% of the time on samples from the vaginal and external genitalia areas and varied widely on samples from other areas. Y chromosome tests were also successful about 50% of the time for dried secretions. STR analyses found male DNA in about 80% of attempts with samples from the vagina and two-thirds of samples from external genitalia and dried secretions. Full DNA profiles were determined in two-thirds of DNA samples taken from the vaginal area, but in a lesser percent from other body regions. Success in finding foreign DNA and achieving CODIS Uploads decreased as post coital interval (PCI) increased.

The crime labs were successful in uploading profiles to CODIS almost 60% of the time and in achieving offender "hits" in about 45% of inquiries and case to case hits in less than 3%. For the SAK backlog sample (n=371), no new arrests occurred after SAK testing occurred, but one filing and two convictions did. Almost 40% of these sampled cases had previously resulted in arrests and 18% convictions without the benefit of a SAK analysis. For the matched sample of 371 nonbacklogged cases, almost the same percentage of cases resulted in arrest, filing, and conviction prior to SAK testing. After the tests, however, a modest percent of new cases resulted in arrest (2%), filing (5%), and conviction (12%). Focus group participants felt that testing of kits should not be mandatory and that future kits testing must reflect investigator evaluation. Many cases in the backlog were those where identity was not an issue and the alleged crime was a question of consent. A system of priorities needs to be established to determine which cases (and which evidence within the kits) need to be tested and recognize that forensic resources are limited. DNA can contribute to both stranger and nonstranger cases, but the SAK and the case at hand require evaluation before testing. Also, although uploading DNA profiles into CODIS may also have value in the long term, many of the backlog "hits" that occur are those where the assailant's DNA profile has already been entered (upon his arrest or conviction) on the same case and is redundant. A priority scheme with scientific, investigator and prosecutor input should be devised and implemented.

Sexual Assault Kits, Case Backlogs, Criminal Dispositions

A171 Assessment of Acidified Hydrogen Peroxide vs. Cyanoacrylate Ester/Rhodamine 6G Processing for Developing Latent Fingerprints on Brass Cartridge Cases

Denae' Hodge, Clayton State University, 2000 Clayton State Boulevard, Morrow, GA 30260; Henry Swofford, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Shauna M. Steffan, MS, United States Army Criminal Investigation Laboratory, Latent Print Branch, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will have an understanding of the comparative performance of Acidified Hydrogen Peroxide vs. Cyanoacrylate Ester/Rhodamine 6G for developing latent fingerprints on brass cartridge cases.

This presentation will impact the forensic science community by discussing which processing method develops latent fingerprints with higher quality (Acidified Hydrogen Peroxide vs. Cyanoacrylate Ester/Rhodamine 6G).

Cyanoacrylate Ester (CA) fuming followed by Rhodamine 6G (R6G) fluorescent dye stain is a common processing technique for latent prints on non-porous evidence. The latent print residue will initiate the polymerization of the CA monomers forming a white, fibrous material thus developing the latent print. R6G fluorescent dye stain can then be applied which will absorb into the fibrous matrix of the CA polymer. The latent print can then be visualized at 532nm using a LASER or alternate light source. Another common method for developing latent prints, specifically on brass cartridge cases, is Acidified Hydrogen Peroxide (AHP). Fired cartridge cases typically appear dark in color due to the firing process. AHP will oxidize the brass cartridge case in all areas except where the latent print residue protects the brass resulting in a light colored appearance except in those areas below the latent print residue. The latent print can then be visualized under ambient lighting conditions. These two processes may also be used in sequence when processing cartridge cases (CA/R6G followed by AHP). Because AHP is an irreversible reaction, there may be a potential for the process to corrode the brass and interfere with forensic firearms examinations. Because of this, consideration should be given to determine the success of this technique over other non-destructive processing methods available. This research, therefore, seeks to understand the severity of potential corrosion to the brass and which of these processing methods (CA/R6G vs. AHP) develop latent prints with higher quality.

A total of 225 brass cartridge cases were used in this evaluation which was comprised of three different processing methods and using two types of latent print matrix standards (sebaceous and eccrine). One latent print was placed on each of the sixty 9mm cartridge cases, sixty .556 cartridge cases, and forty-five M16 cartridge cases using the sebaceous latent print matrix standard. Additionally, one latent print was placed on each of the sixty .556 cartridge cases using the eccrine latent print matrix standard. For each set of cartridge cases, one-third was processed with CA/R6G, one-third was processed with AHP, and one-third was processed with CA/R6G followed by AHP. All CA processing lasted approximately fifteen minutes followed by a ten minute vent sequence then rinsed with R6G. All AHP processing lasted until a latent print developed (range 29 – 75 seconds). All latent prints were photographed and the development times for all cartridge cases developed with AHP were recorded. Fifteen of each set of latent prints were digitally presented to a certified Latent Print Examiner for evaluation. The Latent Print Examiner rated the quality of development according to a numeric rating scale (0 to 5) corresponding to the quality of the friction ridges developed. Data was evaluated according to which processing method developed latent prints with higher quality, whether the results varied according to the type of cartridge case used, and whether the results varied according to the latent print matrix standard used.

Results indicate CA/R6G and CA/R6G followed by AHP consistently developed higher quality latent prints than AHP alone for all types of cartridge cases and latent print matrix standards ($p<0.001$). Statistical differences were observed between types of cartridge cases and the processing methods with CA/R6G developing higher quality latent prints on the M16 cartridge cases and AHP developing higher quality latent prints on both the .556 and M16 cartridge cases compared to the 9mm ($p<0.01$). The quality of latent print development for each processing method appears to be dependent on the type of latent print matrix with AHP developing higher quality latent prints using the sebaceous matrix and CA/R6G and CA/R6G followed by AHP developing higher quality latent prints using the eccrine matrix ($p<0.001$). Results also indicate no difference in the time of latent print development using AHP only vs. AHP following CA/R6G. Lastly, results indicate CA/R6G develops at a much quicker rate when using the eccrine matrix, but further research is warranted to better understand whether this time difference is significant. These results warrant further research to better understand how time and normal environmental degradation will impact the quality of the latent prints developed using these methods and using other types of cartridge cases.

Forensic Science, Cartridge Cases, Fingerprint Development

A172 Latent Print Development Using Low Pressure Sublimation Vapor Deposition: Evaluation of a Prototype System

Henry Swofford, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; Calvin Knaggs, BS*, Linde Canada Limited, 5860 Chedworth Way, Mississauga, ON L5R0A2, CANADA; and Josh Ballard, BS, Chipper Beegle, BS, and Sarah Harbin, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will be introduced to novel technology designed to improve the process of developing latent fingerprints using many of the traditional chemical and physical development methods while eliminating the need for the use of any hazardous and destructive chemical solvents.

This presentation will impact the forensic science community by discussing the mechanical operation of the system; the results of a performance evaluation comparing the quality of latent fingerprints developed using this system to traditional processing methods, and other improvements this system may provide over traditional processing methods for the development of latent fingerprints.

Numerous and various processing methods for the development of latent fingerprints have been introduced over the years, but many require costly hazardous and destructive chemical solvents to yield successful results. Chemical solvents are the most significant contributor to the destructive nature of latent print examinations. Because of this, laboratory examinations of evidence must adhere to specific processing sequences through the various forensic science disciplines in order to minimize or eliminate the potential loss of evidence as a result of a particular examination method. Novel technology involving a sublimation gas injection delivery system into a low pressure chamber environment has been developed in a prototype form to eliminate the use of chemical solvents for many of the most common processing methods for the development of latent prints. Each of the current processing methods can be achieved using this technology.

The performance of this prototype system was evaluated by comparing the quality of latent fingerprints developed using seven common traditional processes: (1) Cyanoacrylate Ester; (2) Cyanoacrylate Ester/Rhodamine 6G; (3) Cyanoacrylate Ester/Fluorescent Powder; (4)

Fluorescent Powder; (5) Iodine; (6) 1,2-Indanedione; and, (7) Ninhydrin. Eleven different substrates were used in this evaluation consisting of porous, non-porous and semi-porous substrates (including some with thermosensitive layers). Three latent fingerprints were deposited on each substrate sample using the appropriate latent print standard matrix. Each latent fingerprint was cut in half and processed separately using the comparable processing method (i.e. Cyanoacrylate ester, Ninhydrin, etc.). One half was processed according to established procedures for each traditional processing method and the other half was processed with the comparable processing method using the prototype system. The halves of each latent fingerprint were re-joined and photographed. Each image was digitally processed to convert the images to gray-scale to maintain anonymity of the processing method and minimize potential interpretation bias during the evaluation of each latent fingerprint. Each latent fingerprint was digitally presented to six Latent Print Examiners to evaluate whether one half of the latent print contained friction ridges that developed with higher quality and clarity or whether there was no distinguishable difference in the quality and clarity of development. Further examinations were carried out to determine if the processing regime using this low pressure system had any negative effect on other forensic examinations (Drug Chemistry, Forensic Document, and DNA). The Drug Chemistry evaluation consisted of placing a known sample of cocaine on sheets of multi-purpose office paper (20lb), cutting the samples in half and processing one half through each latent print processing method while retaining the other half as a standard control. Cocaine was used as a representative drug sample since it approximates the analytical behavior of most other drugs. Following the latent print processing, all samples and controls were analyzed using a GC-MSD. The Forensic Document evaluation consisted of an analytical comparison of six different ink marks and one pencil mark placed on a standard sheet of multi-purpose office paper (20lb). One set of samples were processed using each of the latent print processing methods in the low pressure system. One set of samples remained unprocessed as a control. Following the latent print processing, six different analytical methods were employed to detect chemical differences in the ink and pencil samples as a result of the latent print processing method. The DNA evaluation consisted of placing a sample of saliva on sheets of mult-purpose office paper (20lb), cutting the samples in half and processing one half through each latent print processing method while retaining the other half as a standard control. Following the latent print processing, saliva samples were evaluated to determine if DNA inhibition and/or degradation was present.

The overall results of the quality of developed latent prints were comparable to traditional processing methods. The Drug Chemistry results were analyzed and revealed conclusive results for cocaine with no apparent interference from any of the latent print processing methods using the low pressure system. The Forensic Document results were analyzed with variable results. For all latent print processes using the low pressure system, except for 1,2-Indanedione, one or more of the Forensic Document analytical methods indicated the latent print processing method negatively affected one or more of the ink and pencil samples. The DNA results were analyzed and revealed full DNA profiles from all samples with no apparent inhibition or degradation.

The results of this study indicate this method of developing latent prints using a low pressure sublimation vapor deposition system may provide improvements over traditional processing methods. In addition to the overall quality of developed latent prints being comparable to traditional processing methods, other improvements are related to the process, cost, and safety of developing latent fingerprints on multiple forms of evidence (porous, non-porous, semi-porous), no known interference with drug chemistry and DNA examinations, elimination of hazardous and destructive chemical solvents due to the dry process, standardized processing regimens programmed into the system computer, and the ability to rely on the single system for many of the most common processing methods for the development of latent prints.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Forensic Science, Low Pressure Deposition, Fingerprint Development

A173 Assessing the Performance of Silver as a Post-Gold/Zinc Process for Vacuum Metal Deposition

Mary Nguyen-Quan, BS, Clayton State University, 2000 Clayton State Boulevard, Morrow, GA 30260; Henry Swofford, BS, and Mandi A. Hornickel, MFS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will understand the performance of silver as an effective post-gold/zinc process for vacuum metal deposition.

This presentation will impact the forensic science community by demonstrating the ability of silver to develop more and higher quality latent prints when used as a post-gold/zinc vacuum metal deposition process than the traditional gold/zinc process alone.

Vacuum Metal Deposition (VMD) using gold/zinc is a process which may be used to develop latent prints on many types of non-porous and semi-porous substrates. VMD has been found to be successful when other traditional processing methods have failed, such as with older latent prints and those previously exposed to water and other environmental conditions. The effectiveness of the gold/zinc VMD process relies heavily on the composition and surface contamination of the substrate and latent print residue. Variations in the composition and surface contamination of substrates may prevent successful development of latent prints using the gold/zinc process producing no or poor quality latent prints. Further research has suggested silver may be used as a post-gold/zinc VMD process having the potential to improve poorly developed latent prints and develop additional latent prints which were not developed using the gold/zinc VMD process alone. However, the amount of research demonstrating the performance of silver as an effective post-gold/zinc VMD process is limited. This research, therefore, seeks to better understand the performance of gold/zinc VMD process alone compared to the performance of silver as a post-gold/zinc VMD process on various types of substrates.

Nine different types of non-porous and semi-porous substrates were used in this evaluation, which included: Duct tape, packaging tape, pressure sensitive tape, adhesive tape, masking tape, cardboard, photo-paper, plastic sandwich bag, and thick plastic wrap. The ability of the gold/zinc VMD process to develop latent prints on the non-adhesive side of many types of tapes has been demonstrated in the literature, but research is limited on the success of developing latent prints on the adhesive side. Because of this limited research, this evaluation focuses on the ability to successfully develop latent fingerprints on the adhesive side of tapes. Each substrate contained a depletion series of five fingerprints using a sebaceous standard fingerprint matrix and a depletion series of five fingerprints using natural sebaceous fingerprint matrix obtained from the study coordinator's forehead. All fingerprints were deposited under controlled conditions on each substrate surface. Four sets of each substrate were used to evaluate the gold/zinc and silver VMD processes with fresh, one week, two week, and three week old fingerprints yielding a total of 360 fingerprints processed by each VMD process. All substrates were stored in controlled laboratory conditions until being processed. Following the VMD processing, each fingerprint was photographed and digitally presented to a certified Latent Print Examiner for evaluation. The Latent Print Examiner rated the quality of development according to a numeric rating scale (zero to five) corresponding to the quality of friction ridges which developed. Data were

evaluated according to the quality of fingerprints developed with the gold/zinc VMD process, the quality of additional fingerprints developed and those further enhanced with the silver VMD process, and whether the type of fingerprint matrix used, the age of the fingerprints, and depletion series impacted the ability of the gold/zinc and silver VMD processes to develop quality fingerprint impressions.

The gold/zinc VMD process consistently yielded poor quality results on the adhesive side of the tapes and plastic substrates; however, successful results were obtained on both the cardboard and photo-paper substrates. The silver VMD process yielded positive results on many substrates in which the gold/zinc VMD process failed or developed poor quality fingerprints. The quality of fingerprints developed using silver as a post-gold/zinc VMD process were greatly improved compared to the quality of fingerprints developed using the gold/zinc VMD process alone ($p<0.001$). Further analysis revealed no statistical differences in the quality of the fingerprints developed using the different fingerprint matrices and the fingerprint ages; however, those fingerprints having more matrix (deposition #1 in the depletion series of five fingerprints) yielded higher quality results when compared to the fingerprints having less matrix (deposition #5 in the depletion series of five fingerprints). These results suggest silver is an effective post-gold/zinc VMD process having the ability to develop additional fingerprints and further enhance those previously developed using the gold/zinc VMD process alone. Further research is warranted, however, to better understand the performance of the various VMD processes on other substrates, fingerprint matrices, and ages.

Forensic Science, Vacuum Metal Deposition, Silver

A174 Shape Measurement Tools in Footwear Evidence: An Investigation to Determine Size Without Scale

H. David Sheets, PhD, Canisius College, Department of Physics, 2001 Main Street, Buffalo, NY 14208; Susan Gross, MSFS, and Glenn M. Langenburg, MS, Minnesota Bureau of Criminal Apprehension, 1430 Maryland Ave East, Saint Paul, MN 55106; Anne Torres, MS, King County Sheriff's Office, 7300 Perimeter Road South, Seattle, WA 98108; Peter J. Bush, BS, SUNY at Buffalo, Laboratory for Forensic Odontology Research, School of Dental Medicine, B1 Squire Hall, South Campus, Buffalo, NY 14214; and Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214*

The goal of this presentation is to examine the ability to use shape measurement tools to determine the class characteristic of shoe size without a scale in place on an image.

This presentation will impact the forensic science community by providing a method to allow for sizing of a shoe in circumstances when a scale is not included in the image, aiding the area of footwear impression evidence. This method also has potential applications in impression evidence in cases where key images lack a scale.

When footwear evidence is collected at a crime scene, inclusion of a scale in photographed images is necessary to determine the size of the shoe. If no scale is used, the evidentiary value can be lowered. The goal of this project was to explore the use of shape measurement methods with footwear impression evidence to determine if shape change alone, in element differences in the soles of different brands of shoes, can predict shoe size. These methods provide robust statistical approaches to shape comparison that do not require a scale.

One method that may be used to determine size without scale is geometric morphometic analysis (GM). This technique is used widely in other fields and is often used to describe change in the fossil record in evolutionary biology, in fisheries research and in addressing a range of ecological questions. GM methods involve the placement of a series of landmarks on digital images, positioned on the image as to capture shape information of a structure of interest. These landmarks are then extract and analyzed statistically as a unit. This allows for quantitative evaluation of large datasets.

The landmarks can be plotted in Procrustes superimposition, a method of optimally matching one shape to another. This allows for visualization of shape information and is a measure of the closeness in shape of superimposed specimens. Procrustes distances can be used to express the degree of similarity of individual specimens, means of populations, to summarize variations in populations, or to search for matches between specimens. Procrustes distances provide a general metric of shape distance, and allow for a wide range of statistical and data processing tasks to be readily carried out, including Principal Component Analysis (PCA). This allows for determination of which shape aspect is responsible for the most variation.

A size series of different brands of shoes were utilized from a local shoe store. The shoes were scanned on a flatbed scanner at 300dpi with an ABFO scale in place. Landmarks were placed on the repeatable locations on elements seen on the soles, specifically at the outer edges. It was noted that there were detectable and predictable shape differences between the sizes in several models of shoes examined, but not all. Results indicated that as the element altered shape and/or position, size could be determined even with no scale in place. Distances from a suspect shoe to each of the shoes in a measured size series of shoes could be used to assign the suspect shoe to a specific size, without use of the scale information. The error level was roughly one half shoe size as could be expected due to variation in manufacturing processes.

The ability to use this method will be brand dependent as not all brands may have repeatable elements relative to size. The method does require a reference set of shoes of varying sizes by which a suspect shoe may be matched. Landmark selection and placement was highly critical in success of this method.

Forensic Science, Footwear Impressions, Geometric Morphometric Analysis

A175 Defining a Reliable Human Decomposition Odor Profile for Forensic Canine Investigations

Brian Eckenrode, PhD, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; Douglas Beussman, PhD, Oak Ridge Institute for Science and Education, Federal Bureau of Investigation Laboratory, Quantico, VA 22135; Patricia T. Caldwell, PhD, 1757 River Bend Way, Apartment 2012, Woodbridge, VA 22192; David Cho, PhD, Oak Ridge Institute for Science and Education, Federal Bureau of Investigation Academy, Quantico, VA 22135; Lauryn DeGreeff, PhD, Oak Ridge Institute for Science and Education, 4437 Duke Street, #403, Alexandria, VA 22304; Deanna Snyder, MS, Oak Ridge Institute for Science and Education, Federal Bureau of Investigation Academy, 2501 Investigation Parkway, Quantico, VA 22135; Sarah J. Milam, BS, 2204 West Grace Street, Apartment 1A, Richmond, VA 23220; Rex Stockham, MS, Evidence Response Team Unit Federal Bureau of Investigation, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Nishan Dulgerian, MS, Evidence Response Team Unit, Federal Bureau of Investigation, Federal Bureau of Investigation Laboratory, Quantico, VA 22135; Martin Grime, BS, GSS International, Botley Road Romsey, Hampshire, S051 5SW, UNITED KINGDOM; and Wynn Warren, BS, and Christopher Tipple, PhD, Federal Bureau of Investigation, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will discuss on-going research in determining the distinct volatile organic compounds and their relative ratios as they relate to the discovery of clandestine human burials.

This presentation will impact the forensic science community by providing insights into the difficulty of adequately and accurately

measuring the distinct components that will be used in canine training aids to assist in field investigations.

This presentation will provide a better understanding of the challenges facing forensic canine specialists in both locating clandestine burials as well as the challenges facing forensic research chemists in defining a reliable volatile organic chemical (VOC) composition profile from which to train their canines. There are several key issues that need to be addressed, most importantly determining and optimizing the set of volatiles that accurately represent human decomposition and reduce or eliminate associations to other odors resulting from background and/or non-human sources. Surface and sub-surface VOC comparative analyses could be important to adequately delineate any differences in odor profiles for investigations. Determination of this set of volatiles will allow for more appropriate training of victim recovery canines across the forensics community. If canines can be trained using a common training aid, the overall location accuracy of clandestine burials should improve.

This presentation will impact the forensic community by enlightening a wider audience as to these issues, which in turn may lead to advances in research and development to address these key issues. As a result, a greater number of well trained, efficient canines would be available to consistently locate clandestine burials (i.e., buried or concealed human remains).

The use of canines in law enforcement and military applications is well-known. Among their many uses, canines are used to screen for drugs and explosives, to locate missing persons, to associate crime scene evidence with a suspect, and to locate victims of violent crimes. Qualitative and quantitative characterization of the VOCs resulting from human decomposition (i.e., odor) has been elusive. Determining the relevant VOCs amidst a wide array of potential markers for human evidence, both living and deceased, has not been adequately achieved. For example, locating a clandestine burial efficiently and independent of the time since death has long been a significant challenge for canines due to the wide range of chemicals measured, as well as the number of chemicals that are similar from a variety of confounding decomposing matrices or sources. Traditional air sampling techniques, new sampling devices, human surrogate testing, chemical mimics, and new analysis tools have been developed over the years to assist in addressing these questions. The overall goal of this research is to improve the detection and characterization of the most relevant VOCs for forensic investigative reasons, as well as to improve training models for cases such as these.

Air sampling via solid phase microextraction (SPME) and 400-mL canisters has been performed in two biotopes: Knoxville, Tennessee (Anthropological Research Facility, (ARF)) and Boston, Massachusetts. A GC×GC TOFMS system with a preconcentrator was used for measurements of human materials (e.g., tissue or clothing) both fresh and decomposing. A GC/MS system was used for SPME sample analysis and also whole air samples when this system was interfaced to a dual preconcentrator thermal desorption system. An existing and a new hand-held preconcentrator have been computer modeled with flow simulations based on recent experiments with a baseline prototype device under high sampling air flow conditions. Chemical mimic development and testing was performed with a variety of mixtures and actual field trials were performed using canines. Bloodhounds and Springer Spaniels were used to test mimic performance and to test human decomposition and suspect scent hypotheses.

Prior research in human decomposition has shown that there could be over 450 different VOCs emanating from human subjects buried at the ARF in TN. Subsequent research supports focusing on a manageable 50 based on a variety of factors including a systematic statistical analysis. Further narrowing of this list is currently underway with careful consideration of biotope controls and the analytical results therein. Comparison of these reduced lists to a variety of currently available research studies and those performed in this laboratory using human surrogates such as pigs, has indicated that commercially available mimics may not be acceptable for efficient canine human decomposition training based on the GC/MS and GC×GC TOFMS data. Research into understanding canine olfactory capabilities has also influenced the development of improved VOC collection devices and computational fluid dynamic simulations of a baseline system prototype, which indicates that a newly designed hand-held device once fabricated should be up to 40 times more sensitive for VOCs, once fabricated. This presentation will provide an overview of the many avenues of investigation involved in human (living/deceased) odor profile studies that are on-going in the research unit and in conjunction with the evidence response team unit's canine program.

Human, Decomposition, Volatiles

A176 Imaging Using Synchrotron Radiation: A New Tool for Forensic Science

Aldo A. Mattei, PhD, RIS Carabinieri, S.S. 114 km 6,400, Messina, 98128, ITALY; Federico Cervelli, PhD*, and Sergio Carrato, PhD, Univeristy of Trieste, Via Valerio 10, Trieste, 34100, ITALY; Martino Jerian, MS, AMPED S.r.L, Area Science Park, Padriciano 99, Trieste, 34149, ITALY; Luca Benevoli, PhD, Elettra sincrotrone trieste SCpA, Area Science Park, s.s. 14 km 163.5, Trieste, Italy 34100, ITALY; Lucia Mancini, PhD, Elettra sincrotrone trieste SCpA, Sincrotrone Trieste S.C.p.A., Area Science Park, Basovizza, Trieste, 34149, ITALY; Giuliana Aquilanti, PhD, Elettra sincrotrone trieste SCpA, Sincrotrone Trieste, s.s. 14 km 163.5, Basovizza, Trieste, 34149, ITALY; Andrea Perucchi, PhD, Elettra sincrotrone trieste SCpA, Area science Park, Trieste, 34100, ITALY; Lisa Vaccari, PhD, Elettra sincrotrone Trieste SCpA, Area science park, Trieste, 34100, ITALY; and Franco Zanini, PhD, Elettra sincrotrone trieste SCpA, Sincrotrone Trieste, S.S. 14 - km 163,5, Trieste, 34149, ITALY*

After attending this presentation, attendees will learn a different approach to latent fingerprint development which allows determining complete friction ridge details and important additional information regarding origin, chemical composition, and potential contaminants of the finger deposit, facilitating subsequent DNA analysis.

This presentation will impact the forensic science community by providing a new powerful tool for personal identification in high profile cases by means of Synchrotron Radiation facilities, particularly useful in the analysis of IED fragments.

Forensic science has experienced an increasing interest in research activities: all paths that allow the investigators to obtain more information about major crimes are tracked to solve offenses related to national security like terrorists attacks. The goal of the research, established in the framework of a project funded by the Italian Interior Ministry, by "Fondo Trieste" fund, is to adopt a multi-technique approach based on conventional and Synchrotron Radiation (SR) techniques, and to study latent fingerprints from the morphological and chemical point of view. The main goal of the research is to perform fingerprint analysis by its visualization with a SR source. The ultimate objective is to develop methods of image reconstruction that merge all the information coming from different SR techniques to produce valuable evidence gathered with additional information regarding the chemical nature and the contaminants of the enhanced fingerprint.

The analysis is performed using infrared micro spectroscopy (IRMS) on sweat fingerprints, by X-ray phase contrast (XPC), and by X-ray absorption fine structure analysis (XAFS) on contaminated ones.

Multiple donors, both male and female, were chosen to deposit the fingerprints. Prior to the deposition, each donor behaved normally and hands were not cleaned. Moreover, latent prints were not charged by inducting artificially sweat in any way. Each deposition was performed as a depletion series of eight fingerprints by the same finger, to take into account components abundance and to model, if possible, the real situation. The substrates chosen were silicon wafers and PET sheets. Contaminated fingerprints were realized shooting with a gun, prior to deposit, with the depletion technique.

With the intent to characterize the chemical nature of the fingerprint deposit and to make a chemical imaging of it, IRMS was used. It resembles

hyper spectral imaging: the fingerprint sample of interest is analyzed (either in parallel or serially) with a broad spectrum IR light source, ranging from 4000 cm^{-1} to 500 cm^{-1} (Mid IR region). Then, spectra are collected by a single-element detector. Each picture element is not characterized by a unique intensity value, but by a full spectrum in the same band mentioned above.

The broad methyl and methylene stretch bands (from 3000 cm^{-1} to 2800 cm^{-1}) can be found in all donors spectra. In the 1800 cm^{-1} to 1400 cm^{-1} range some donors show an intense carboxylate band signal around 1590 cm^{-1}, while others are characterized by the amide I (around 1650 cm^{-1}) and amide II (around 1540 cm^{-1}) stretching bands. Each donor shows different spectral shapes, with different relative intensities in the same bands, due to the different proportions of the fingerprint components. The ability to solve the amide I and amide II contributions in the 1800–1400 cm^{-1} band, decoupling those from the intense carboxylate signal around 1590 cm^{-1}, will allow the analysis of the fingerprint.

With the goal to characterize the contaminated fingerprints on silicon, XPC technique was used. This technique exploits the phase difference caused by the sample in the X-ray's path from the source to the acquiring sensor. The energy values chosen ranged from 8 keV to 35 keV. The analysis made on contaminated fingerprints with the XAFS technique showed the presence of metals, thus several images were taken with XPC just above or below the absorption of these elements. In practice, suitable preprocessing algorithm will have to be used to improve the signal-to-noise ratio which is very low due to the small quantities of contaminants and, consequently, to their low absorptions.

While being in its early stage, the research seems promising in visualizing latent fingerprints. Moreover, the added value of giving a complete morphological and chemical characterization of the fingerprint and its contaminants could enrich the classical approach with key additional information, facilitating also subsequent DNA analysis so as to identify the perpetrator.

Synchrotron Radiation, Trace Analysis, Latent Fingerprints

A177 Analytical Profile of 4-Methyl GHB, 4-Phenyl GHB, GVL, and Gamma-Phenyl GBL

Yuriy Uvaydov, MS, Drug Enforcement Administration Northeast Laboratory, 99 Tenth Avenue, Suite 721, New York, NY 10011; and Tara N. Rossy, BS, Drug Enforcement Administration Northeast Laboratory, 99 Tenth Avenue, Suite 721, New York, NY 10011*

After attending this presentation, attendees will better understand the impact of the internet on current trends concerning the synthesis of "designer" drugs. Additionally, analytical data for several analogs and precursors of GHB will be provided for use/reference in the proper identification of this class of compounds.

This presentation will impact the forensic science community as it will discuss analogs of GHB that are extremely easy to synthesize and are currently being discussed on internet message boards by illicit drug users.

Illicit drug users are continuously searching for alternative ways to reach the biological effects of drugs which are federally controlled in an attempt to circumvent federal and state drug regulation laws. When γ-hydroxybutyric acid (GHB) was regulated as a Schedule I controlled substance in 2000, illicit drug users began to use 1,4-butanediol and γ-buterolactone (GBL) as these drugs were shown to have similar sedative effects. As a result, the government made it increasingly difficult to obtain these compounds, classifying GBL and 1,4-butanediol as List I chemicals. Federal and state laws also made it illegal for stores and online websites to sell products marketed as heath supplements, sleep aids, and cleaning products that contain the precursors of GHB.

Recent literature and internet searches have revealed additional analogs of GHB that drug users are synthesizing. Several internet message boards and websites contain concise instructions for synthesizing analogs, chemicals needed, narratives describing the biological effects and users' experiences, and published scientific research regarding the efficacy of these analogs in mice. Scientific research suggests not only are certain analogs more potent than their original drugs, but that they are also more toxic. These websites provide a forum for users who are trying to stay one step ahead of the law by producing analogs that forensic laboratories have not yet seen. Two GHB analogs, γ-hydroxyvaleric acid (4-methyl GHB) and 4-hydroxy-4-phenylbutanoic acid (4-phenyl GHB), are among the newer GHB analogs that have caught the attention of illicit drug users. There has been little work done on these compounds regarding their identification, making it difficult for forensic laboratories to determine whether samples coming in for analysis are newer analogs or precursors to these analogs.

The analysis of GHB and its analogs is problematic due to their chemical properties. Conventional methods of analysis utilizing gas chromatography-mass spectrometry (GC/MS) have shown interconversion between analogs and their precursors, making the differentiation challenging. Due to their small molecular weights and polarity, GHB and its analogs are also difficult to analyze utilizing liquid chromatography-mass spectrometry (LC/MS) as they are not easily retained on column for analysis.

In this study, 4-methyl GHB and 4-phenyl GHB were synthesized using γ-valerolactone (GVL) and γ-phenyl-γ-butyrolactone (γ-phenyl GBL), respectively. Preliminary results have indicated that the compounds can be separated by high performance liquid chromatography (HPLC) using (A) 10 mM sodium phosphate buffer (NaH2PO4/NaHPO4, pH~7.3) and (B) acetonitrile, at 2% (B) isocratic for two minutes followed by a linear gradient to 40% (B) over eight minutes. The components were separated using HPLC columns 4.6 x 50mm, 1.8 µm column. UV detection was performed at 215nm. Confirmation of the GHB analogs was also achieved using GC/MS derivatization via trifluoroacetic anhydride (TFA) and bis(trimethylsilyl)trifluoroacetamide (BSTFA, 99% with 1% TMCS). LCMS/MS linear ion trap results indicated that optimal detection of 4-phenyl GHB can be achieved in negative mode requiring chromatographic separation from its precursor, γ-phenyl GBL. In addition, the presentation will discuss results using standard color tests and Fourier transform infrared spectroscopy-attenuated total reflectance (FTIR-ATR).

GHB Analogs, Precursors, Mass Spectrometry

A178 Spectral Analysis of the of Gamma-Hydroxybutyrate (GHB) and Gamma-Butyrolactone (GBL) Using Near Infrared Spectroscopy in Varying Beverage Matrices

Kristen J. Johnson, BS, and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 10104; and Bharat Lakhkar, MS, Westchester County Forensic Science Laboratory, 10 Dana Road, Valhalla, NY 10595*

After attending this presentation, attendees will have a better understanding of the use of Near Infrared Spectroscopy (NIRS) to study the chemistry and equilibrium of gamma-hydroxybutyrate (GHB) and gamma-butyrolactone (GBL) in different beverage matrices.

This presentation will impact the forensic science community by serving to provide a critical understanding how GHB and GBL behave in typical sample matrices of common beverages that may be involved in a drug-facilitated sexual assault.

GHB is a central nervous system depressant classified as a sedative-hypnotic and abused for its euphoric, sedative, and anabolic effects. GHB can be studied using the spectroscopic technique of NIRS because it is a quick non-destructive technique that allows for the measurement of organic compounds with vibrational overtones between 700nm and 2500nm, similar to mid-IR. GHB is classified as a federal Schedule I drug as an illicit substance, but can also be obtained in prescription form. GHB commonly cyclizes into a lactone, GBL, with the equilibrium dependent on

the matrix conditions. The equilibrium ratio between GHB and GBL can vary with the pH of the medium as well as the temperature of the matrix. The equilibrium reactions can be measured accurately using NIRS in the transmittance mode. Due to the solutions being essentially clear and colorless, the transmittance mode is most appropriate for this beverage study. The unique changes in the carbon-hydrogen groups can be used as the main parameter of comparison in shape, size, and intensity of each spectrum resulting in an understanding of how GHB and GBL behave in beverage matrices. All beverage samples were spiked with GHB or GBL at a concentration of 3.00g per serving. Either GHB or GBL was dissolved directly in the beverage, and measured in a cuvette (2mm) using NIRS. Thirty two scans for each sample were taken and the intensity was measured as it occurred at a given concentration. To standardize the spectral data all spectra were analyzed using multivariable mathematical software provided with the instrument.

The results show that GHB and GBL can be correctly identified in spiked samples versus unadulterated samples. When GHB or GBL is added to the beverage matrix, temperature controlled, there is a clear distinction between the two. Calibration curves of each of the eight beverages yield a straight line with R^2>0.98 for each beverage. A calibration curve made from similar beverages using spectral correction has been shown to accurately yield concentration information. A similar beverage composition can be used to quantitate the GHB in solution; the exact beverage is not needed. The GHB and GBL in a beverage matrix has also been shown to be stable in concentration and composition over a period of greater than ten days, even after freezing the sample and defrosting it. Confirmation of concentration of GHB in the beverage matricides was achieved using LC/MS. Results from an equilibrium study was also completed for GHB and GBL coupled with the beverage study yielding data consistent with Ciolino.[1] All relative percentages and equilibrium times using GHB and GBL in buffered solutions agree with previous reports.[1]

Forensic Science, GHB, GBL

A179 Objective Discrimination of *Salvia divinorum* From Related Salvia Species Using Chromatographic Techniques and Multivariate Statistical Procedures

Monica L. Bugeja, BS, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; Victoria L. McGuffin, PhD, Michigan State University, Department of Chemistry, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

The goal of this presentation is to demonstrate statistical differentiation of the hallucinogenic plant, *Salvia divinorum*, from related Salvia species based on chemical profiles obtained using both gas chromatography-mass spectrometry (GC/MS), and liquid chromatography-mass spectrometry (LC/MS).

This presentation will impact the forensic science community by providing an objective methodology for the differentiation of S. divinorum from four related Salvia species using a combination of chromatographic techniques and multivariate statistical procedures. The application of such statistical procedures directly addresses one of the recommendations highlighted in the 2009 *National Academy of Sciences Report*; that is, the need for statistical evaluation of forensic comparisons.

Salvia divinorum is a hallucinogenic herb that is currently regulated in 25 states in the United States. Although there are over 900 Salvia species, *S. divinorum* is the only one known to contain the hallucinogen, salvinorin A. As such, forensic identification of *S. divinorum* currently relies on the extraction and identification of salvinorin A in the plant, typically using GC/MS. Despite being more widely available in forensic laboratories, GC/MS is limited to the analysis of sufficiently volatile compounds that do not thermally degrade at the high operating temperatures used during analysis. In contrast, LC/MS is more suited to the analysis of non-volatile compounds and hence, may offer additional discriminatory information.

In this research, five different Salvia species were investigated: *S. divinorum*, *S. guaranitica*, *S. nemorosa*, *S. splendens*, and *S. officinalis*. Dried leaves from each species were extracted in triplicate for 16 hours, using a rotary agitation procedure. For GC/MS, the extraction solvent was dichloromethane while, for LC/MS, acetonitrile was used. All extracts were analyzed in triplicate using the appropriate chromatographic technique and, following analysis, two separate data sets were formed: one containing total ion chromatograms (TICs) obtained from GC/MS and the second containing TICs from LC/MS. Compounds present in extracts of each species were identified through mass spectral interpretation.

Prior to data analysis, TICs in each data set were subjected to various preprocessing procedures to remove instrumental sources of variance. This is necessary to ensure that subsequent data analysis procedures do not identify these non-chemical sources of variance as differences within the data set. Various preprocessing procedures were investigated for each data set, including background correction, smoothing, retention time alignment, and normalization. Background correction was used to minimize differences in background signal, while smoothing was used to minimize random variations in noise. Chromatograms were then retention time aligned, to account for retention time drift during analyses, and normalized, to account for variation in injection volume.

The pretreated data sets were then separately subjected to principal components analysis (PCA) to investigate differentiation of *S. divinorum* from the other four Salvia species based on the chemical profiles. Principal components analysis is an unsupervised statistical procedure that identifies groupings of samples within a data set. The procedure is termed "unsupervised" since no prior knowledge of groupings within the data set is required. The two outputs from PCA are a scores plot and loadings plots. The former is a scatter plot in which samples that are chemically similar are clustered closely, while chemically different samples are distinct. For both GC/MS and LC/MS analysis, *S. divinorum* was differentiated from the other four Salvia species in the corresponding scores plots. Student's t-tests were then used to statistically assess the positioning of the samples in the scores plots. Additionally, the PCA loadings plots were used to identify those compounds contributing most to the variance among the Salvia species. These compounds have potential use as chemical markers for the discrimination of Salvia species.

Using a combination of statistical procedures, discrimination of *S. divinorum* from four related Salvia species was demonstrated based on profiles of both the volatile compounds, obtained by GC/MS, and the non-volatile compounds, obtained by LC/MS.

***Salvia Divinorum*, Chromatographic Techniques, Multivariate Statistical Procedures**

A180 Assessment of Methods for the Chemical Identification of the Psychoactive Plant Kanna *(Sceletium tortuosum)*

Jillian Yeakel, MS, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; Wendy M. Vent, MS, 14349 Township Highway 108, Upper Sandusky, OH 43351; Karen R. Marcucci, MS, 5 Green Valley Drive, Churchville, PA 18966; Heather L. Harris, MFS, JD, 2401 Lombard Street, Suite 1, Philadelphia, PA 19146; and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe analytical techniques for the chemical identification of the alkaloids present in the Kanna plant *(Sceletium tortuosum)*.

This presentation will impact the forensic science community by providing information to allow the identification of the plant material using forensic testing techniques that follow SWGDRUG recommendations and standard testing protocols.

Kanna is a ground cover plant that grows in the arid climate of South Africa. Kanna contains the primary alkaloids mesembrine, mesembranol, mesembrenone, hordenine, sceletenone, sceletium A4 among many others. Some of these alkaloids have pharmacological properties reported to elevate mood and decrease stress in addition to calming anxiety and producing euphoric effects. These effects, commonly sought after by drug users, add to the overall appeal of the plant as a substance to abuse. The drugs are not controlled by the federal government so it is important to be able to distinguish these alkaloids from other vegetable material submitted for forensic examination and analysis. Kanna is featured as a natural alternative to traditional anti-depressants on many online sites that describe psychoactive experiences with the drug, and as a result of its uncontrolled status it is easy to purchase online as capsules, powders, tinctures, and seeds.

This presentation describes the evaluation of the content and characteristics of commercial Kanna preparations using common chemical color tests and thin layer chromatography (TLC), with confirmation by gas chromatography/mass spectrometry (GC/MS). The following materials were purchased from an online supplier: *Sceletium tortuosum* (Kanna) finely shredded plant material; Herb Spirits Kanna 5:1 liquid extract; Kanna whole white leaf; and Kanna 5:1 powdered extract.

A basic extraction optimized for the recovery of mesembrine along with a methanolic extraction was performed on each of the four commercially available products. Color tests including Cobalt Thiocyanate, Dille-Kopanyi, Dragondorff, Froehde, Janovsky, Liebermann, Mandelins, Marquis, Mecke, and Simons were applied to the plant material and the above extracts. A Duquenois-Levine test was performed on the Kanna whole white leaf. Color tests showed positive reactions with the optimized extraction method, but produced non-specific reactions with the methanolic extracts. The color tests that yielded the most distinguishing results included Cobalt Thiocyanate, Janovsky, Dille-Kopanyi, Dragondorff, Mecke, and Liebermann.

Extracts of all products were compared using TLC. The solvent system was a mixture of ethyl acetate, methylene chloride, methanol, and concentrated ammonium hydroxide (74:72:12:4). TLC bands were visualized using short and long ultraviolet radiation and with both acidified iodoplatinate and Dragondorff reagents. This technique produced distinctive and characteristic results from the extracts of the Kanna products. Mesembrine, mesembranol, and mesembrenone were confirmed in three of the four Kanna products analyzed; hordenine was identified in two of the products, while sceletenone and sceletium A4 were each identified in one of the products. One of the products contained no Sceletium alkaloids.

Together this battery of forensic techniques proved effective in the characterization of Kanna and used SWGDRUG compliant testing options. Analysis of commercial Kanna products showed that their content was highly variable and counterfeit products containing no alkaloids are being sold as Kanna.

Forensic Science, Kanna, *Sceletium Tortuosum*

A181 Chemical Characterization of Kratom and Associated Alkaloids

Theresa Scott, BS, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; Jillian Yeakel, MSFS, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; and Barry K. Logan, PhD, and G. John DiGregorio, MD, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to identify the most prevalent and unique alkaloid, mitragynine, present in the plant Kratom and various commercial preparations, using standard forensic chemical testing procedures that meet SWDRUG recommendations.

This presentation will impact the forensic science community by raising awareness of the existence of mitragynine containing products when they are submitted for analysis.

Kratom (*Mitragyna speciosa*) is a tree found mainly in Asian countries whose leaves, when consumed in low doses, provides both a stimulant and analgesic effect. When consumed in high doses, Kratom has a depressant effect and its major alkaloid, mitragynine, has been found in combination with other CNS depressant drugs in a number of fatalities. Although use of Kratom and mitragynine products is not yet widespread in the United States, the alkaloid has been detected in "legal high" products. Increasing numbers of internet sites market a number of different Kratom products including liquid extracts, dried leaves, powdered leaves, and the plants themselves.

An analytical standard of the alkaloid mitragynine was obtained commercially and characterized using various chemical color tests. The tests did not work well when applied directly to the plant material consequently a simple methanolic extraction was required. The botanical material caused the methanol to be tinted green and after addition of the reagents, the colors seen were natural botanical colors (such as greens and browns) making a color change caused by the reaction difficult to visualize. Therefore, the color tests tested thus far are not ideal presumptive tests to utilize for mitragynine.

Following methanolic extraction, Kratom related products were also analyzed by thin layer chromatography (TLC) using a 9:1 chloroform to methanol solvent system which yielded good separation of the components of the botanical material. Viewing under short wave ultra violet light allowed visualization of the mitragynine and final development with iodoplatinate spray produced a mitragynine band initially purple in color, then turning yellow shortly after, and finally turning orange overnight. Retention factors of the bands produced from the methanol extraction of the purchased products were compared to the bands from the standard mitragynine and found to be similar.

Following a mitragynine optimized extraction, confirmatory analysis was performed by gas chromatography/mass spectrometry (GC/MS). Mitragynine has a base peak of 214 and distinctive and prominent fragments of 398, 397, and 383 m/z, and was consistent with the mass spectrum in various mass spectral databases.

Analysis of several commercial products, six products labeled as "Kratom," as well as various products that were believed to be Kratom through appearance, confirmed the presence of mitragynine. Of the thirteen samples for this study, six were purchased over the internet by our laboratory and seven were obtained as evidence submitted to the lab for analysis. The six purchased were obtained from reputable sites from which samples for other research projects have been purchased and all were labeled as Kratom products. Of the seven samples acquired through the lab, one was a bag of capsules each of which contained a green powder, another was a K2 product, and the rest were either silver bags with a zip top or small, plastic containers all appearing to contain a green, botanical powder.

This approach of TLC followed by GCMS meets SWGDRUG requirements for forensic testing and proved suitable for the identification of mitragynine in these products.

Forensic Science, Kratom, Mitragynine

A182 Identification of Methamphetamine and Select Regioisomers

Harry F. Skinner, MS, Southwest Laboratory Drug Enforcement Administration, 2815 Scott Street, Vista, CA 92081; and Sandra Sachs, PhD, Oakland Police Department, Crime Laboratory, 455 7th Street, Room 608, Oakland, CA 94607*

After attending this presentation, attendees will be able to identify methamphetamine and select regioisomers unequivocally from one another by chromatography and mass spectrometry.

This presentation will impact the forensic science community by allowing the forensic scientist to identify methamphetamine from the similar regioisomers.

Regioisomers are positional isomers which vary only in the position of a functional group or other substituent. Positional changes will not only alter a compound's physical, chemical, and physiological properties, but in the case of methamphetamine, variations will also affect the legal status as a controlled substance. Methamphetamine has four regioisomers: N,α-dimethylphenethylamine, α,α-dimethylphenethylamine (phentermine), N,N-dimethylphenethylamine, N-ethylphenethylamine, and α-ethylphenethylamine.

Mass spectral data from these five compounds has been subjected to close scrutiny, since misidentification by using only a library search is a possibility. All four regioisomers have a molecular weight of 149 a.m.u. and have the same m/*z* 58 base peak seen in methamphetamine. The four regioisomers also display similar fragmentation patterns and ratios seen in methamphetamine. Despite these similarities, it has been shown that differentiation of methamphetamine from its various regioisomers is entirely possible, through the use of routine laboratory equipment. Various studies have been performed with methamphetamine and its regioisomers, and it has been shown that methamphetamine can be both chromatographically separated from its regioisomers and accurately characterized by confirmatory analysis.

The gas chromatography separation of the regioisomer mixture on both the non-polar HP-5 and mid-polar DB-17 columns will be discussed. Amphetamine and N,N-dimethylamphetamine was included with the methamphetamine regioisomer mixture as reference. Methamphetamine with a retention time of 1.575 minutes with the HP-5 column and 2.640 minutes with the DB-17 column did not co-elute with any of the four regioisomers.

The LC chromatography separation of the regioisomer mixture is comparable to other work. Methamphetamine had a retention time of 5.101 minutes and did not co-elute with any of the regioisomers. Complete baseline separation of all compounds in the regioisomer mixture was achieved.

The mass spectral data collected from the regioisomers closely match published spectral data. In the analysis of fragmentation patterns of similar compounds such as the regioisomers, it is necessary to expand the spectra in order to show the specific fragments and their abundance ratios. All four regioisomers and methamphetamine have the characteristic m/*z* 58 base peak. Furthermore, the fragmentation patterns are very similar except for a few distinguishing key ions. Sachs and Woo focus on the low mass region (m/*z* 39 – 56) as an area of distinction. In addition to the low mass region, a few unique/key ions are found in some of the compounds that allow for differentiation from methamphetamine and each other. For example, methamphetamine has a significant m/*z* 119:115 ratio not found in any of the regioisomers, which is a unique identifier for methamphetamine in addition to the low mass analysis. Both the nitrogen substituted compounds, N-ethylphenethylamine and N,N-dimethylphenethylamine have a significant m/*z* 105 fragment which would allow exclusion from methamphetamine. The regioisomer, α-ethylphenethylamine contains a uniquely identifying peak at m/*z* 120. Lastly, phentermine can be identified by its strong m/*z* 134 peak and lack of an m/*z* 148/ 149 (contains no alpha hydrogen's). In conclusion, methamphetamine can be distinguished from its regioisomers using chromatographic retention time *or* a thorough evaluation of the mass spectroscopy fragmentation pattern.

Methamphetamine Identification, Regioisomers, Mass Spectrometry

A183 Herbal Incense and Bath Salts Cases in Harris County, Texas

Warren C. Samms, PhD, and Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will learn about the timeline of appearance, case overview, analysis, and reporting of "herbal incense" (cannabinoid receptor agonist) and "bath salts" (methcathinone or pyrovalerone derivative) at the Harris County Institute of Forensic Sciences, located in Houston, TX. Unlike other portions of the Texas Controlled Substances Act (CSA), the subsections referencing these drugs (effective September 1, 2011) are written with broad language. While examples are given in the law for the different types of "herbal incense" and "bath salt" compounds, the list is not all-inclusive. As attorneys have no direct manner of correlating some of these chemical names with the Texas CSA, Harris County Institute of Forensic Sciences (HCIFS) Drug Chemistry Laboratory (DCL) provides additional information on the laboratory reports for these types of results.

This presentation will impact the forensic science community by communicating the analytical experience the DCL has had with regards to these two classes of designer drugs. It is hoped that the case history, compounds encountered, types of exhibits, and methods of reporting may be beneficial to other laboratories and agencies, especially in the Northeastern and Western United States, areas identified by the National Forensic Laboratory Information System (NFLIS) as having very low occurrences of these substances compared to the rest of the country.

The HCIFS DCL received its first encounter with "herbal incense" type substances in May 2010 – a foil pouch of "Space Blend" herbal incense which was found to contain the substance JWH-018. Since then, exhibits have been submitted on a near-exponential frequency in both opened and unopened commercial pouches, unlabeled plastic bags, in hand-rolled cigarettes, and mixed in with marijuana. Around that same time, the DCL also received an exhibit consisting of approximately 25 grams of JWH-018 powder, having an appearance similar to cocaine. Approximately three months later in August 2010, a suspected ecstasy tablet was analyzed by GC-FID, GC-MS, and DART-TOF, and found to contain 3,4-methylenedioxypyrovalerone (MDPV), m-trifluoromethylphenylpiperazine (m-TFMPP), and caffeine, marking the first appearance of a "bath salt" compound at the HCIFS. As of August 2011, the DCL is currently capable of confirming 22 "herbal incense" and six "bath salt" compounds, with others being added as analytical standards become available. The DCL is also able to distinguish between 3-and 4-fluoromethcathinone isomers.

During the 2011 session, the Texas Legislature passed two separate bills relating to these designer drugs, using general language as opposed to an all-inclusive list of substances. Senate Bill 331 authored by Senator Florence Shapiro of Plano, TX, controls herbal incense as "any quantity of a synthetic chemical compound that is a cannabinoid receptor agonist and mimics the pharmacological effect of naturally occurring cannabinoids." Seven major structural classes are listed, and examples are given for each, listed by systematic name (ex. JWH-018, AM-2201). Penalties for possession are analogous to those of marihuana. House Bill 2118, authored by Rep. Garnet Coleman of Houston, TX, controls bath salts as "any compound structurally derived from 2-aminopropanal by substitution at the 1-position with any monocyclic or fused-polycyclic ring system." including subsequent modifications. This bill also gives examples of some applicable compounds, listed by chemical name. The language of both bills was based on the general language added to the United Kingdom's Misuse of Drugs Act in 2010, regarding these substances.

As substances, therefore, may be controlled without being listed by name, when reporting a result containing a cannabinoid receptor agonist, the DCL uses the systematic name and adds the following result statement: "This compound is also known as [chemical name]. It is a cannabinoid receptor agonist classified as a [structural class]." In order to refer to a substance as a "cannabinoid receptor agonist," the DCL requires peer-

reviewed scientific literature on file discussing the compound's cannabinomimetic properties. Upon reporting a methcathinone or pyrovalerone derivatives, the following statement is added, as appropriate: "This compound is also known as [common name]. It is a structural derivative of 2-aminopropanal."

Designer Drug, Herbal Incense, Bath Salts

A184 Analysis of Synthetic Cannabinoid (AM2201) by LC/MS/MS and GC/MS: A SPE Approach

Jeffery Hackett, PhD, United Chemical Technologies, Incorporated, 2731 Bartram Road, Bristol, PA 19007; Albert A. Elian, MS, 59 Horse Pond Road, Sudbury, MA 01776; and Michael J. Telepchak, MBA, United Chemical Technologies, Incorporated, 2731 Bartram Road, Bristol, PA 19007*

After attending this presentation, attendees will learn about the analysis of a new synthetic cannabinoid (AM2201) from seized material using readily available solid phase extraction (SPE) cartridges and gas chromatography/mass spectrometry (GC/MS) liquid chromatography/mass spectrometry (LC/MS/MS). Use of this SPE method will permit analysts to provide data on this compound in samples

This presentation will impact the forensic science community by offering analysts in forensic facilities a method that permits samples of synthetic cannabinoids to be analyzed in a clean format with minimal matrix effects and excellent analytical characteristics in terms of SPE and GC/MS/ LC/MS/MS.

Method: Extraction (SPE) was performed on a mixed mode column (C8/WAX) conditioned with methanol, deionized water, and 0.1 M phosphate buffer (pH 6 (3mL, 3mL and 1mL, respectively)) prior to sample loading. Methanolic extracts of seized material (1mL) were adjusted to pH 6 with 0.1 M phosphate buffer (5mL) and an internal standard added (THC-d3). After loading the sample, the sorbent was washed with deionized water and a solution of the phosphate buffer containing 20% by volume of acetonitrile (3mL). After drying each SPE column was eluted with 3 mL of a solvent consisting of ethyl acetate containing 10% methanol (two x 3mL). The individual eluates were collected, evaporated to dryness and dissolved in mobile phase. These solutions were combined for analysis by LC/MS/MS in positive multiple reaction monitoring (MRM) mode. Data is presented for MRM's of AM2201 and THC-d3 respectively. For GC/MS analysis, after evaporation, the eluates were dissolved in 50µL of ethyl acetate/ BSTFA (containing 1% TCMS) and heated prior to injection.
Liquid chromatography was performed in gradient mode employing a 50 x 2.1 mm C18 analytical column and a mobile phase consisting of acetontitrile and 0.1% aqueous formic acid. The gradient was programmed to run from 5% to 90% acetonitrile in 4.0 minutes and then back to 5% for re-injection. The total run time for each analysis was less than 5 minutes. In terms of GC/MS, a temperature program starting at 100ºC for one minute rising to 310ºC at 40 ºC/ minute was used employing a 30m x 0.25mm (250 µm) capillary column. Mass spectrometry was performed in selected ion monitoring/full scan mode (50- 500 m/z). In this presentation, representative chromatograms are shown to illustrate the efficiency of the chromatography and analysis.

Results: The limits of detection/quantification for this method were determined to be 50ng/g and 100ng/g, respectively for both. The method was found to be linear from 100 ng/ g to 2000 ng/ g (r2>0.999). Data is presented to show that recoveries of AM2201were found to be greater than 85%. Interday and Intraday analysis of AM2201 were found to < 5% and < 8%, respectively. Matrix effects were determined to be < 6%. Details of genuine samples are given at the presentation.

Conclusion: The use of this new procedure for the analysis of a synthetic cannabinoid (AM2201) will be of great use to analysts in the field of forensic drugs analysis as the concentrations of this can now to be reported rather by either GC/MS or LC/MS/MS techniques.

Spice, LC/MS/MS, SPE

A185 Synthetic Cannabinoid Colorimetric Detection

Danielle Green, Albany State University, 504 College Drive, Albany, GA 31705; Candice Bridge, PhD, and Sue Lenhard, MS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will learn what a synthetic cannabinoid is, how they were originally used, and the detection of marijuana and synthetic cannabinoids.

This presentation will impact the forensic science community by providing a field test specific to detecting synthetic cannabinoids.

Marijuana is illegal and highly abused used due to the psychoactive effects that the user would experience. The active component in marijuana is tetrahydrocannabinol (THC) which is what gives the psychoactive properties.[1] In the last 40 years compounds known as synthetic cannabinoids(SC) have been developed in an effort to research the possible medical uses of marijuana without having the consequences of the negative unwanted side effects.[2] Synthetic cannabinoids are able to produce similar effects to the body as THC because they bind to the same receptor sites however they do not have a similar structure.[3]

In 2004 an herbal mixture of plant material called "Spice" came into the drug community.[4] The plant material was believed to give a similar or a more potent "high" as THC. In truth, "Spice" is a combination of plant material that has been sprayed with one or more SCs and then passed as an herbal drug. Synthetic cannabinoids were not detected in "Spice" until late 2008 by a German pharmaceutical company called THC Pharm. The first reported death due to "Spice" occurred in 2010 in Iowa and since the identification in 2008 many hospital cases across the globe have been reported. Currently there is no ban placed on all SCs, only a few specific cannabinoids have been banned in numerous countries. Little research and literature is available on the detection of SCs in the field and this study will lead to exponential progress in that area.

Recently, a colorimetric field test has been developed that positively identifies the THC compound and claims to positively identify SCs. There are two tests marketed: a general screening test and a THC specific test. To conduct this study test samples were broken up into two different sections: known positives and known negatives. These groups would determine the test's specificity toward SCs. The positive samples were comprised of SC standards, THC standards, and "Spice" samples that had tested positive for SCs. The known negatives had samples of "Spice" that had tested negative for known SCs and household items that would not contain SCs like sugar, flour, oregano, and tobacco paper. "Spice" samples and known negative samples were tested as a solid and in solution for the presence of SCs. A 1mg/mL solution was prepared and tested to determine if there was a positive reaction. A positive reaction for identification occurs when the test solution in contact with the sample turns red.

The study yielded a range of results. In regards to the known positive samples only THC; CP-47, 497; and HU-210 had positive results for both tests when analyzed in the solid form and in a solution form. The other SCs and most of the true negatives did not have a color change for both the general screening test and the cannabis specific test. A few of the "Spice" samples had faintly positive results for both the tests. The study did yield some ambiguities including a lack of consistency in tests results depending on the physical state of the sample when tested. Some samples had a positive result in the solid test but did not have the same result while in liquid form. The test shows signs of movement in a positive path in regards to field detection. It is able to detect classic cannabinoids as well as THC which is a necessity in field detection.

Synthetic Cannabinoids, Spice, THC

A186 Differentiation of Isomers of Synthetic Cannabinoids

Christina England, United States Air Force Academy, 2304 Cadet Drive, USAF Academy, CO 80841; Sara Roper, BS*, and Lee Fadness, BS, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will be familiar with the combination of analytical procedures that are necessary and sufficient to conclusively identify synthetic cannabinoids and preclude the possibility of false positives. This will be accomplished by outlining, for each of fourteen commonly encountered synthetic cannabinoids, the specific combinations of tests that can differentiate the particular cannabinoid from a series of its structural isomers.

This presentation will impact the forensic science community by describing a rational approach to the analysis and positive identification of an important and growing class of abused compounds.

The first herbal smoking blends laced with synthetic cannabinoids are believed to have been produced about six years ago. Sold in foil packets with a distinctive glinting eye logo, "Spice" was the forerunner of hundreds of similar products that have been sold in head shops and on the Internet under various names. In late 2008 and early 2009, JWH-018 and cannabicyclohexanol were identified as the active ingredients in Spice. Since then, a bewildering array of synthetic cannabinoids has been encountered by forensic laboratories. The purpose of this presentation is to introduce data and analytical schemes that will allow forensic laboratories to confidently identify many of these compounds.

In this two-part presentation, attendees will be introduced to the commonly encountered synthetic cannabinoids and will be presented with direct instrumental data comparisons of isomers of these compounds. All of the analyzed compounds were synthesized by Cayman Chemical Company.

Part one of the presentation will discuss the following compounds: the 3- and 4-methoxy isomers of JWH-250, the 3- and 4-chloro isomers of JWH-203, the 2- and 3-methoxy isomers of RCS-4, the 3- and 4-methoxy isomers of RCS-8, the 3- and 4-iodo isomers of AM-694, and the 2-naphthyl isomer of JWH-200.

Part two of the presentation will discuss the following compounds: fifteen structural isomers of JWH-018 formed by pentyl chain rearrangements and 1- and 2-naphthyl linkages, seven structural isomers of JWH-073 formed by pentyl chain rearrangements and 1- and 2-napthyl linkages, the six isomers of JWH-081 as determined by the six possible positions of the methoxy group on the naphthyl ring, the six isomers of JWH-122 as determined by the six possible positions of the methyl group on the naphthyl ring, the six isomers of JWH-210 as determined by the six possible positions of the ethyl group on the naphthyl ring, the six isomers of JWH-398 as determined by the six possible positions of the chloro group on the naphthyl ring, the 3- and 4-methyl isomers of JWH-251, and the 2-, 3-, and 4-fluoropentyl isomers of AM-2201.

The compounds listed were analyzed by GC/MS, GC/IRD, LC/UV/MS, and NMR. The chromatographic and spectral data revealed adequate separation and/or distinguishable spectral features among all the samples. The necessary and sufficient tests to discriminate between the parent compounds and their respective isomers will be discussed.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Cannabinoids, Isomers, Spice

A187 Differentiation of MDMA Exhibits Using Liquid-Liquid Extraction, Headspace Solid Phase Microextraction, and Gas Chromatography-Mass Spectrometry

Karlie M. McManaman, BA, 89 South Dietz Road, Webberville, MI 48892; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will have learned about impurity profiling procedures for 3,4-methylenedioxymethamphetamine (MDMA). This research compares liquid-liquid extraction and headspace solid phase microextraction procedures, as well as different GC temperature programs.

This presentation will impact the forensic science community by investigating the effect of extraction procedure and GC temperature program on the association and discrimination of MDMA tablets based on organic impurities. Determining the more effective extraction procedure and GC temperature program would be a step towards standardizing the procedures used in forensic laboratories for this application. This would allow better comparison of data collected in different laboratories which will be necessary for the successful identification of drug trafficking routes.

MDMA is a Schedule I controlled substance, which is often found as an active ingredient in ecstasy tablets. Surveys such as the 2010 Monitoring the Future Survey indicate that abuse of controlled substances, including MDMA, continues to be a growing trend in the United States, with a significant increase in MDMA use for all ages questioned since the previous study five years prior. This increase has created a greater need for quick and easy identification methods for illicit tablets, as well as improved methods for the identification and prevention of drug trafficking.

Impurity profiling can be used to determine the synthesis method of MDMA in illicit tablets, potentially linking tablets to a common production source, based on the impurities present. Profiling is conventionally done using liquid-liquid extraction (LLE) and gas chromatography-mass spectrometry (GC/MS), but recent literature has also shown the potential benefits of using headspace solid phase microextraction (HS-SPME) as an alternative extraction procedure. However, reports in the literature use different GC temperature programs to analyze extracts and different statistical methods are used to evaluate the impurity profiles.

The objective of this research is to investigate the effect of the extraction procedure and GC temperature program on the association and discrimination of MDMA tablets based on the organic impurities. Determining the more effective extraction procedure and GC temperature program would be a step towards standardizing the procedures used in forensic laboratories for this application. This would allow better comparison of data collected in different laboratories, which will be necessary for the successful identification of drug trafficking routes.

Three different MDMA exhibits were used for this preliminary study. Tablets from each exhibit were homogenized to minimize variation within each exhibit due to the clandestine manufacturing process. Samples from each exhibit were extracted using both LLE and HS-SPME. Extracts were then analyzed in replicate (n=5) using four different GC temperature programs that ranged in the number of temperature ramps (one-, two-, and three-step ramps), as well as the total analysis time (36-53 minutes).

The resulting total ion chromatograms from each extraction/GC temperature program combination were treated as separate data sets and subjected to principal components analysis (PCA). This multivariate statistical procedure is used to identify sources of variance within a data set, while reducing dimensionality to allow simpler visualization. In this case, the PCA scores plots were used to assess association of replicates of the same exhibit and discrimination among exhibits. In addition, the PCA loadings plots were also used to identify those impurities contributing most to the variance in the data set. Such impurities are potentially useful chemical markers for discrimination of MDMA exhibits. Additional statistical procedures, such as Pearson product moment correlation (PPMC) coefficients and student t-tests, were used to evaluate the association and discrimination of exhibits observed in the PCA scores plots. Association of replicates from the same exhibit and discrimination among exhibits was possible irrespective of GC temperature program and extraction procedure.

MDMA, Impurity Profiling, Multivariate Statistics

A188 Investigation Into the Influence of Precursor Chemicals on the Chemical Profiling of Methylamphetamine

Saravana K. Jayaram, MSc, University of Strathclyde, Centre for Forensic Science, Department of Pure and Applied Chemistry, Royal College Building, 204 George Street, Glasgow, Scotland G1 1XW, UNITED KINGDOM; Niamh Nic Daeid, PhD, University of Strathclyde, Centre for Forensic Science, 204 George Street, Glasgow, Scotland G1 1XW, UNITED KINGDOM; and William J. Kerr, PhD, University of Strathclyde, Department of Pure and Applied Chemistry, 204 George Street, Glasgow, Scotland G1 1XW, UNITED KINGDOM*

After attending this presentation, attendees will understand the basic principles of gas chromatography Mass spectroscopy analysis and how it is used in the chemical profiling of methylamphetamine. The paper will discuss the eight routes employed in the clandestine synthesis of methylamphetamine and the precursors used in the manufacture (e.g., ephedrine, pseudoephedrine, and phenyl-2-propanone (P2P)).

This presentation will impact the forensic science community by providing useful insight in the identification key route specific impurities of two popular clandestine synthetic routes of methylamphetamine: (1) Moscow; and, (2) Hypophosphorous routes. This research explores differences in impurity profiles extracted from samples prepared from pure grade materials and batches of methylamphetamine synthesized from precursors extracted from cold medication using different solvents and other pharmaceutical grade essential chemicals, i.e. iodine tinctures, hydrogen peroxide.

The goal of this research is to synthesize methylamphetamine using *pseudo*ephedrine hydrochloride extracted from decongestant tablets which are available in pharmacies in Glasgow, United Kingdom. This precursor was extracted from the decongestant tablets with three different solvents. The three different solvents used in the extraction were ethanol, laboratory prepared methylated spirits, and commercial methylated spirits. Two synthetic routes were investigated in this research: (a) Moscow route; and, (b) Hypophosphorous route. The mentioned routes are popular in clandestine synthesis of methylamphetamine due to its simple process in a large scale production. The mentioned routes are variations of the Nagai route. In both of these routes, hydroiodic acid is made *in situ* during the reaction process. These modifications are most likely to have occurred as a result of the difficulty of obtaining the hydroiodic acid in the market. In the Moscow Route, hydroiodic acid is made "*in situ*" by adding red phosphorous, iodine and water. For the hyphophosphorous route or "Hypo route," hydroiodic acid is made "*in situ*" by adding hypophosphorous acid and iodine. This route does not require any red phosphorous in the reaction because hypophosphorous acid itself acts as the reducing agent and can be used as an alternative to red phosphorous. The two routes were chosen due to their popularity in clandestine synthesis of methylamphetamine.

Other key catalysts such as red phosphorous were extracted from matchbooks and iodine crystals derived from iodine tinctures using hydrogen peroxide. Most of the methodology of the extraction of the precursor and extracting the essential chemicals were obtained from the clandestine literature. The methylamphetamine synthesized from the two routes was analyzed by gas chromatography mass spectrometry (GC/MS) and the route specific impurities elucidated. The determination of an optimized impurity extraction method and gas chromatography mass spectrometry is essential in the investigation related to the profiling of route specific impurities of methylamphetamine. This presentation will demonstrate an ideal extraction method that will efficiently extract the maximum number of route specific impurities from two mentioned routes and optimum gas chromatography mass spectrometry conditions that produced chromatograms with well resolved peaks.

This work forms part of a wider investigation into the ability of other analytical technique to discriminate the inter and intra batch variation of methylamphetamine synthesized from the two popular clandestine routes, focusing in particular on stable isotope analysis at natural abundance level of the elements C, N, and H by Isotope Ratio Mass Spectrometry (IRMS) for this purpose.

Methylamphetamine, Illicit Synthesis, GCMS

A189 The Effect of Season and Soil Type on the Microbial Degradation of Gasoline

John V. Goodpaster, PhD, and Dee A. Turner, BS, Indiana University-Purdue University Indianapolis, 402 North Blackford Street, LD326, Indianapolis, IN 46202*

After attending this presentation, attendees will understand the concept of microbial degradation of gasoline and the effects of soil type and season on this process.

This presentation will impact the forensic science community and the justice system by highlighting seasonal and soil type differences in the microbial degradation of gasoline.

Substrates rich in organic matter such as soil provide an excellent source of carbon and therefore contain a high bacterial load. Since ignitable liquids are comprised of various hydrocarbons, the bacteria can utilize these fuels as a carbon source. In particular, common soil bacteria have been shown to selectively metabolize lower substituted alkylbenzenes (e.g., toluene, ethylbenzene, and propylbenzene) and normal alkanes (e.g., n-octane, n-nonane and n-decane). Previous work completed on various ignitable liquids (e.g., petroleum distillates, gasoline, isoparaffinic, and naphthenic-paraffinic products) has shown a significant loss of normal alkanes in the range of C_9 to C_{16}. Branched alkanes appear to be more resistant to degradation than normal alkanes. In addition the degree of degradation was positively correlated to the length of the alkyl chain on the mono-substituted alkylbenzenes. Also, the position of the alkyl branches plays a significant role in the ability for the bacteria to metabolize the alkylbenzenes. This is problematic for fire debris analysis as samples often sit for many weeks before they are analyzed due to case backlog. As a result, selective loss of key components due to bacterial metabolism can make identifying and classifying ignitable liquid residues by their chemical composition and boiling point range very difficult.

Of interest to this study are the effects of soil type (e.g., residential, industrial or agricultural) as well as the physical and chemical characteristics of soil on bacterial populations. These characteristics

include the pH, nitrogen and phosphorus content, total organic carbon (TOC), and the soil composition (e.g., silt, clay, or sand). In addition, the season (e.g., fall, winter, spring, or summer) can strongly influence the nature and activity of some bacteria. Overall, these variables (soil type and season) could impact the degree of microbial degradation observed in fire debris samples containing soil substrates. Therefore, the microbial degradation of gasoline in agricultural, industrial, and residential soils was monitored for up to 30 days over four different seasons. The top two inches of these soils were collected from specific areas in Northern Indiana each season. Degradation studies were carried out by spiking these soils in quart-sized paint cans with 20µL gasoline and stored for analysis after 0, 2, 4, 7, 11, 15, 22, and 30 days. These samples were then subjected to passive headspace concentration and GC-MS analysis.

The chromatographic profiles showed that residential soil was the most active and the industrial soil was the least active in terms of the microbial degradation of gasoline. Furthermore, a positive correlation was noted between the outdoor temperature when the soil was collected and the degree of degradation. It was noted that storage at ambient conditions upon collection prior to degradation studies had no apparent effect on the rate of degradation of the gasoline.

Principal Components Analysis was also utilized to elucidate trends of microbial degradation among the different soil types and seasons. These trends showed clear differences in the overall rate of degradation of the ignitable liquid in the different types of soil as well as over the various seasons. In particular, the industrial soil lagged significantly behind the agricultural and residential soils. Even though gasoline was degraded more slowly, by 30 days the chromatographic profile was significantly altered. The aromatic profile became very important for PCA, particularly for the C_3-alkylbenzenes. It was noted that as degradation progressed, the chromatographic resolution was lost between 3-ethyltoluene and 4-ethyltoluene. This was due to benzaldehyde (a possible hydrocarbon metabolite) becoming more abundant relative to the other components being degraded. Benzaldehyde has major ions of 77 and 105 in its mass spectrum. Therefore, the previously used aromatic profile which included m/z 91, 105, and 119 was adjusted to include only m/z 91 and 120. This allowed for the exclusion of benzaldehyde while still allowing toluene, the C_2- and the C_3-alkylbenzenes to be captured.

Fire Debris, Ignitable Liquid, Principal Components Analysis

A190 The Association and Discrimination of Gasoline and Lighter Fluid Using Multivariate Statistical Procedures in the Presence of Evaporation, Thermal Degradation, and Matrix Interferences From Surface-Treated Wood

Suzanne Towner, BS, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824; Victoria McGuffin, PhD, Michigan State University, Department of Chemistry, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will have an understanding of an objective method that may be used to identify the presence of an ignitable liquid extracted from wood in simulated fire debris. Principal components analysis (PCA) and Pearson product moment correlation (PPMC) coefficients are used to associate an ignitable liquid residue to the corresponding standard, in the presence of interferences from untreated and surface-treated wood, despite evaporation and thermal degradation effects.

This presentation will impact the forensic science community in two ways. First, the compounds inherent to combinations of treated or untreated and burned or unburned wood will be characterized. This may allow analysts to determine if compounds in a chromatogram of fire debris originate from the wood matrix and/or its surface treatment. Secondly, an objective method for identifying the presence of an ignitable liquid will be demonstrated. It has become increasingly important to establish methods in which objectivity replaces subjectivity, especially in light of the National Academy of Sciences report from 2009.

In order to characterize the inherent interference compounds, samples of untreated/unburned and surface- treated/unburned wood were sealed in nylon bags and extracted at 80°C using a passive headspace extraction with activated charcoal strips. Each extract was then analyzed using gas chromatography-mass spectrometry (GC-MS). Separate untreated and surface-treated wood samples were also burned for different periods of time to determine the optimal burn time that generated the maximum amount of matrix interferences. These samples were analyzed in an identical manner to identify the compounds introduced during the burning process.

Next, two ignitable liquids (gasoline and lighter fluid) at four different evaporation levels were individually spiked onto unburned wood samples that were either untreated or surface treated. This allowed the data collected to take into account the effect of evaporation of the liquid. The liquids were also spiked onto burned wood samples that were either untreated or surface treated, which allowed the data to reflect the effects of the matrix interferences as well as the evaporation of the ignitable liquid. Lastly, fire debris was simulated by spiking the liquids onto the unburned wood (untreated and surface treated), which was then burned. This last data set took into account thermal degradation of the sample in addition to evaporation and matrix interferences.

The association of the ignitable liquid residues extracted from the wood to the ignitable liquid standards was assessed using PCA in combination with PPMC coefficients. Principal components analysis identifies the variance among samples and will cluster chemically similar samples accordingly in the scores plot. The PPMC coefficients provide a pairwise comparison between chromatograms and produce a value, which describes the similarity between the chromatograms. Multivariate statistical procedures were used to objectively associate the ignitable liquid residue extracted from the wood to the corresponding standard in spite of evaporation, matrix interferences, and thermal degradation.

Ignitable Liquids, Wood Fire Debris, Multivariate Statistical Procedures

A191 The Persistence of Gasoline on Fabrics Constructed of Natural and Manufactured Fibers

Melanie L. McMillin, MS, Bureau of Alcohol, Tobacco, Firearms and Explosives, 6000 Ammendale Road, Beltsville, MD 20705; and Thomas Kubic, JD, PhD, John Jay College of Criminal Justice, City University of New York, 445 West 59th Street, Room 4503N, New York, NY 10019*

After attending this presentation, attendees will understand that it is imperative to collect and secure fabric samples in vapor-proof packaging within 24-hours of the gasoline deposition to ensure the highest potential of detection and identification. Furthermore, the fabric fiber type and the environmental conditions to which the fabric was exposed must be known in order to predict the elapsed time since deposition of the gasoline.

This presentation will impact the forensic science community by describing some of the challenges associated with the detection and identification of gasoline on fabrics and demonstrating the impact of environmental factors on the prediction of the elapsed time between the deposition of an ignitable liquid and the detection of the residue on fabrics.

This study examined the persistence of gasoline on single-component fabrics constructed of the natural fibers cotton and silk and the manufactured fibers acetate, acrylic, nylon, polyester, olefin, and rayon. The study was designed to determine if the type of fabric affected the detection of evaporated gasoline and if that information could be used to predict the length of time between the deposition of the gasoline to the collection and analysis of the material. The persistence was evaluated with constant and variable airflow, humidity, and temperatures ranging from 34°F to 87°F. All samples were placed in vapor-proof nylon bags and

extracted using the passive headspace concentration method (ASTM E1412). One-half of an activated charcoal strip (ACS) was placed in the bag with each fabric. The bag was resealed and heated at 80°C for 16 hours. Each half strip was eluted with carbon disulfide and analyzed by gas chromatography-mass spectrometry (ASTM E1618). The extracted ion chromatograms (EIC) for the molecular ion 105 of the gasoline-spiked substrates were compared to the C3 akylbenzenes profile of gasoline which consists of m-ethyltoluene (1-methyl-3-ethylbenzene), p-ethyltoluene (1-methyl-4-ethylbenzene), o-ethyltoluene (1-methyl-2-ethylbenzene), and 1, 2, 4-trimethylbenzene (pseudodocumene). The plots of the selected ion total peak areas versus time for these compounds demonstrated the subjectivity of gasoline evaporation from the different types of fabric substrates when exposed to various environmental conditions. Generally, there was an inverse relationship between the exposure temperature and the time interval that gasoline remained detectable on the fabrics. The results for the constant and variable environment conditions were not consistent among the fabrics tested. For example, cotton retained gasoline for up to five days in the EIC at a temperature of 76°F and constant airflow. However, with variable conditions, gasoline was only detectable in the EIC for up to 24 hours. Gasoline could be detected in the EIC for nylon, olefin, and polyester for up to five days after deposition depending upon the conditions. In contrast, gasoline was identifiable in the total ion chromatogram for acetate for up to five days after deposition in both constant and variable conditions. The fabrics that were least retentive of gasoline were acrylic, rayon, and silk. Given the results of this study, it is imperative to collect and secure fabric samples in vapor-proof packaging within 24 hours of the gasoline deposition to ensure the highest potential of detection and identification. Furthermore, this study shows that the environmental conditions to which the fabric was exposed must be known in order to predict the elapsed time since deposition of the gasoline.

Gasoline, Fire Debris, Fibers

A192 NIST Trace Explosives Test Bed

Marcela Najarro, MFS, and Greg Gillen, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mailstop 8371, Gaithersburg, MD 20899*

After attending this presentation, attendees will learn about the laboratory research being conducted at NIST in the area of trace explosives detection and the efforts in transitioning research findings into real-world applications.

This presentation will impact the forensic science community by reporting test bed evaluations to critical stakeholders for the potential modification of explosive trace detection protocols.

There is a critical need to protect government infrastructure from potential terrorist threats. Government agencies have expanded security measures by increasing surveillance, manpower, and threat detection capabilities. The National Institute of Standards and Technology (NIST), Surface and Microanalysis Science Division, focuses on the development of measurements and standards that facilitate improvements in the reliability and effectiveness of currently deployed explosives trace detectors (ETDs) and next-generation detection technologies. Ion mobility spectrometers (IMS) - based ETDs are widely used for the rapid screening of trace explosives and narcotics residues collected by physical swiping of a suspect surface. In this technique, residues collected on a sampling swipe are thermally desorbed by rapid heating to produce neutral vapor molecules that are subsequently ionized with a ^{63}Ni source at atmospheric pressure. Although extensive research is focused on the development of next-generation technology, long-term evaluation of instrument field performance is a need in the area of trace explosives detection.

New efforts have focused in the development of a NIST Trace Explosives Ted Bed. The goal of this field test bed is to test NIST laboratory findings in real-world field conditions to determine end-user utility and provide stakeholders with operation improvement recommendations (OIRs). The development of the test bed has involved the deployment of trace detection systems throughout the NIST campus. In addition, a training program has been developed and implemented for NIST Physical Security. Laboratory research findings have been integrated into the training program including standard operating procedures for proper instrument operation and best practices for sample collection and alarm resolution. To date, over 40 NIST security clerks/police officers have been trained in the daily operation and maintenance of explosives trace detectors. Field experiments with our trained officers have yielded data supporting the improvement of collection media (swabs) as well as hand-held wands used to harvest a sample. In addition, researchers provide field screeners with well-characterized explosives test materials used daily to validate instrument performance under operational environmental conditions. Inkjet printing technology capable of depositing a known mass of explosive with better than one percent precision is used to produce the quality assurance/quality control (QA/QC) test materials. The stability of the test materials as well as testing different storage methods to establish sample shelf-life is being evaluated. Analytical figures of merit such as measurement repeatability and instrument sensitivity are evaluated as part of the analysis. Preliminary QA/QC results of ETDs deployed at the NIST test bed show typical measurement repeatability of approximately 10% RSD, when n = five using these high-level test materials. In summary, the ability to compare field data versus laboratory data allows us to compare factors such instrument drift, environmental effects, test material stability in the field, monitor need for maintenance of the detectors, as well as compare instrument response and measurement repeatability. Operational improvement recommendations developed through the test bed are now being leveraged by stakeholders in a series of pilot studies to determine their value for airport security screening. In the future the test bed will be expanded to take advantage of other resources available such as an explosives canine team and a cargo-screening facility.

Trace, Explosives, Test Bed

A193 Evaporation Rates of Unconfined Explosive Liquids

Kelley M. Kitts, MS, Indiana University Purdue University Indianapolis, 402 North Blackford Street, LD 326, Indianapolis, IN 46202; and John V. Goodpaster, PhD, Indiana University Purdue University Indianapolis, FIS Program, 402 North Blackford Street, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will understand the evaporative trends of various nitrated explosives and their relation compounds, under unconfined conditions. Attendees will also understand how evaporative theories (Langmuir, Deegan, Berry) hold up in experimental conditions; ultimately a mathematical model to be used to describe the evaporation of unconfined explosive liquids is suggested.

This presentation will impact the forensic science community by helping understand how explosives behave under different conditions and how this behavior affects a canine's ability to detect and alert to an explosive compound.

Although canines are regularly utilized by law enforcement agencies to detect explosives, the mechanism by which canines respond to explosive vapors is not well understood. In particular the factors that govern the amount of explosive vapor available for canine sampling are often confused, leading to difficulties in canine training and testing. For example, it is a common misconception that the amount of explosive itself is the chief contributor to the amount of odor available to a canine. In fact, the concept of odor availability is decidedly more complex in that it depends very little on the amount of explosive material present. More importantly, it is known that the amount of vapor generated from explosive compounds is dependent upon several factors including sample amount, vapor pressure, rate of transport, and the degree of confinement. Underlying these factors are the

basic processes of evaporation of unconfined explosives, which are crucial to understanding how their vapors behave in other, more confined, systems.

The concept of odor availability remains controversial in the explosive-detecting canine community because the quantity of explosive used for canine testing and/or training is easily measured while the degree of confinement and the amount of vapor available for sampling is not. It has also been shown that vapors emanating from certain nitrated explosives tend to adsorb unto surrounding surfaces. Ultimately, odor availability is dependent upon evaporation rates, or the rate at which the mass of explosive material is decreases over time. Because evaporation involves both heat and mass transfer, the unconfined evaporation of an explosive must be modeled in order to fully account for odor availability. In this study, evaporation rates were determined for several explosive liquids using an analytical balance. These rates were compared to one another as well as to theoretical models for the evaporation of small liquid pools.

In general and as expected, the mass of explosive liquid decreased linearly with time with evaporation rates ranging from -9.57 x 10^{-6} mol/sec to -9.09 x 10^{-8} mol/sec for the most and least volatile species, respectively. Furthermore, it was shown that sample amount (i.e. surface area) and vapor pressure (as reflected in the boiling point of the substance) were determining factors in the evaporation of unconfined, nitrated liquids. For example, the mass loss of nitromethane ranged from 0.024 mg/sec (for 10µL) to 0.16 mg/sec (for 10mL) and the evaporation of nitromethane (374°C) proceeded approximately three times faster than nitropropane (405°C). The overall trend for the nitroalkane and nitroaromatic species was an exponential decrease in evaporation rate with increasing boiling point.

Overall, it was determined that the evaporation of unconfined nitrated liquids, exposed to open air, can be described by Deegan's model for the evaporation of liquid drops on flat surfaces, where the determining variables are the surface area of the pool and the vapor pressure of the substance. While several examples of solvent "pinning" on a metal surface (Deegan) were observed, these phenomena may be attributed to surface abnormalities in the container (i.e., unflatten surface and/or surface irregularities) as Deegan's model specifies the need for a completely flat surface.

Explosives, Evaporation Rate, Canine Detection

A194 Further Studies Investigating Zeolites for the Recovery of Oxygenated Compounds From Fire Debris Samples

Corissa L. Rodgers, BA, Boston University School of Medicine, 72 East Concord Street, Boston, MA 02118; Kathryne St. Pierre, MS, Boston Police Crime Laboratory, One Schroeder Plaza, Boston, MA 02120; Vincent J. Desiderio, MS, New Jersey State Police, Central Laboratory, 1200 Negron Road, Hamilton, NJ 08691; and Adam B. Hall, MS, Boston University, 72 East Concord Street, L-1004, Boston, MA 02118*

After attending this presentation, attendees will have gained knowledge of further studies into the use of zeolites for improved recovery of oxygenated compounds from fire debris samples which may supplement the activated carbon strip technique for recovering petroleum-based products.

This presentation will impact the forensic science community by demonstrating the feasibility for implementing zeolites into forensic casework as a viable technique in fire debris analysis for the recovery of oxygenated ignitable liquids.

Heated passive headspace concentration is presently the most commonly utilized technique for the extraction of ignitable liquid residues from fire debris evidence. This process, introduced by William Dietz in 1991, typically involves suspending an activated charcoal strip within an airtight container such as a metal can and incubating the sample for a period of time. ASTM Standard Practice E 1412-07 advises heating the sample for 2 to 24 hours at a temperature of 50 to 80° Celsius. Subsequently, the compounds are easily eluted from the adsorbent with a suitable solvent, often carbon disulfide, and analyzed using gas chromatography/mass spectrometry (GC/MS) for the potential identification of any ignitable liquid residues. It is a simple, sensitive, and nondestructive method, and can often be performed within the original sample packaging. The activated charcoal strip, which does not interact with water or nitrogen, is advantageous in its affinity for hydrocarbons and resistance to oxidation. The technique is highly efficient for recovering petroleum-based ignitable liquids, however, it has had limited success with adsorbing and concentrating oxygenated species.

In an effort to improve the recovery of ignitable liquids containing oxygenated compounds, previous studies have suggested zeolites are a suitable adsorbent for the recovery of acetone through heated passive headspace concentration. Zeolites are inorganic, microcrystalline materials that have a well-defined internal structure and uniform pore size. Most frequently aluminosilicate with cations dispersed internally, zeolite beads attract small organic molecules including alcohols. Their high thermal and chemical stability make them ideal adsorbents for heated passive headspace applications. An additional advantage to utilizing zeolite beads involves selective adsorption of small organic molecules due to their pore size. Molecular modeling has shown that the 13X zeolites were effective for recovering analytes smaller than 10 Å, such as acetone (6.3 Å). Any compound with a molecular diameter greater than the pore size may not gain access to the internal zeolite channels, and thus may not be adsorbed.

The primary aim of this study was to further optimize the conditions for implementing zeolites as a viable extraction technique within fire debris casework, complementing the activated charcoal strip method. Extraction time and temperature, desorption solvent, and GC parameters were all examined to provide for the most efficient recovery of oxygenated volatile compounds, including (but not limited to) ethanol, 1-propanol, 1-butanol and isopropanol. For example, approximately a 900% increase in recovery was observed for 1-butanol by the use of zeolites in comparison to an activated charcoal strip. This is in accordance with previous studies that reported a 300% improvement in acetone recovery by utilizing zeolites. In an effort to evaluate the ability of zeolites to selectively adsorb oxygenated volatile compounds, comparative recoveries of mixtures of petroleum and alcohol-based ignitable liquids were studied utilizing both activated charcoal strips and zeolites. In the presence of both adsorption media within the same can, 100% of three major components of gasoline (toluene, 1,2,4-trimethylbenzene, and naphthalene) selectively adsorbed to an activated charcoal strip, while approximately 90% of isopropanol adsorbed to zeolites. This phenomenon may be attributed to the size exclusion properties and polarity of the zeolites. An ideal technique for the analysis of ignitable liquids would allow for the efficient recovery of both petroleum-based and oxygenated products in a single concentration procedure.

Zeolites, Volatiles, Fire Debris Analysis

A195 Pattern Recognition Based Library Searching Techniques for IR Spectra of Clear Coat Paint Smears

Barry Lavine, PhD, Nikhil Mirjankar, BS, and Ayuba Fasasu, PhD, Oklahoma State University, Department of Chemistry, 107 Physical Sciences, Stillwater, OK 74078; and Mark Sandercock, PhD, Royal Canadian Mounted Police, Forensic Science and Identification Services, 15707-118th Avenue, Edmonton, AB T5V 1B7, CANADA*

After attending this presentation, attendees will understand the principles of pattern recognition techniques, advantages of preprocessing and deconvolving vibrational spectra using the wavelet transform, and the importance of coupling search prefilters with library searching algorithms to improve the accuracy of IR spectral searches in the PDQ database.

This presentation will impact the forensic science community by being aware of modern automotive paints using thinner undercoat and color coat layers, but a thicker clear coat layer. All too often, a clear coat paint smear

is the only layer of paint left at the scene of a hit and run accident where damage to vehicles or injury or death, especially of the pedestrian, has occurred. In these cases, the text-based portion of the PDQ database will not be able to identify the motor vehicle as to the manufacturer and model. However, crucial investigative lead information from infrared spectra of clear coat paint smears can be extracted from wavelet-transformed spectra using pattern recognition techniques.

Applying a wavelet packet tree to de-noise and deconvolve infrared absorbance spectra of clear coats by decomposing each spectrum into wavelet coefficients which represent the sample's constituent frequency, a genetic algorithm for pattern recognition and feature selection has been used to identify wavelet coefficients characteristic of the manufacturer and model of the automobile from which the clear coat paint sample was obtained. Wavelet coefficients characteristic of the manufacturer and model of the automobile are formulated into search prefilters. Even in challenging trials where the samples evaluated were all the same model (Chrysler or General Motors) with a limited production year range, the respective manufacturing plants could be correctly identified using a search prefilter.

Utilizing search prefilters, many of the problems encountered in library searching can be addressed. Most spectral comparisons performed during a search are of little use because the spectra in question are very dissimilar. A prefilter can quickly spot dissimilar spectra, thereby avoiding a complete spectral comparison. Prefilters allow for more sophisticated and correspondingly more time-consuming algorithms to be used for spectral matching since the size of the library is culled down for a specific match.

Searches currently performed using the PDQ database often generate a large number of hits because the chemical information in the current PDQ database is only described in terms of generic chemical formulations. The major advantage of using the pattern recognition approach to identify paint samples is an increase in search accuracy because spectra from the entire database are searched. Improving discrimination capability between spectra in the database using the wavelet packet transform for spectral preprocessing and the pattern recognition GA to identify informative coefficients permits inter-comparison of original equipment material (OEM) automotive paint layer systems using the infrared spectra alone. This allows comparison of all possible pairs in the database, reducing dependence on the text-based portion of the database, resulting in improved ease of use and fewer errors. By coupling the proposed pattern recognition searches with a library search algorithm that utilizes the cross correlation function, it will be possible to perform similarity searches (i.e. identify spectra in the library that are similar but are not identical to the unknown). If a paint sample is not contained in the PDQ library, similarity searching is crucial for a tentative identification. Currently, there are no algorithms commercially available to perform similarity searching, so this feature is expected to have significant impact in the field of spectral library searching.

Library Matching, Search Prefilters, Spectral Pattern Recognition

A196 Determination of Unique Fracture Patterns in Glass and Glassy Polymers

Allison C. Baca, BS, Frederic A. Tulleners, MA, and John Thornton, DCrim, University of California-Davis, Forensic Science Graduate Program, 1333 Research Park Drive, Davis, CA 95618*

After attending this presentation, attendees will gain information on current research in the field of fracture pattern analysis. Particular attention will be given to the uniqueness of each fracture pattern. A statistical treatment of observed data will be presented, together with a discussion of potential error rate and measurement uncertainty.

This research will impact the forensic science community by providing information relevant to the reliability of physical match and fracture pattern interpretation. In particular, the issue of coincidental fracture duplication will be addressed.

Not infrequently, investigators ask if two glass fragments collected from different locations fit together in a manner demonstrating their former adjacency in a now fragmented glass object. Clearly, the evidentiary value of such a fit depends on the reliability of methods that demonstrate the uniqueness of fractured glass surfaces and the physical properties of glass itself. But fracture mechanisms, not uniqueness of fracture patterns, have been the focus of research in the forensic science community. The goal has been to understand such mechanisms and to reveal ways of identifying the fracture mechanism in any given situation. Thus one does not know how unique fracture patterns may be or how reproducible they are.

Also, within the forensic sciences, the uniqueness of fracture margins of glass and other brittle solids has been assumed. While there is empirical evidence of this, there has been little effort to develop a rigorous fundamental basis to support this assumption. Much of the forensic literature dealing with glass and glassy polymer evidence has spoken of the mechanisms of fracture propagation rather than fracture uniqueness. The present work has focused on the issue of uniqueness.

Fractures were initiated using two different methods, velocity impact and static pressure. For the velocity impact method, a drop weight was released at a predetermined velocity to initiate the fractures in glass window panes and glass bottles. Ten of each item was fractured for each of the three interchangeable tips used in the drop weight. The three tips used included a round tip, a sharp tip, and a blunt tip. These three tip types were chosen to determine if the type of surface that impacted the glass had any effect on the fracture pattern.

For the static pressure method, a hydraulic press was used to apply pressure to the glass window panes and glass bottles until fractures were obtained. Again, ten of each item was fractured for each of the three tips used in the hydraulic press. The round, sharp, and blunt tip types were again used to determine if the type of surface that impacted the glass had any effect on the fracture pattern. Once all fracture experiments were complete, the fracture patterns were converted to digital images and an inter-comparison analysis was completed to determine the uniqueness of each fracture pattern.

It was found that in an inter-comparison of the sixty glass window pane fractures, none of the 3,600 comparisons were determined to be duplicate fracture patterns. In an inter-comparison of the sixty glass bottle fractures, it was also determined that none of the 3,600 comparisons were found to be duplicate fracture patterns.

Glass Fracture, Physical Match, Fracture Pattern

A197 Glass Analysis by Laser Ablation Inductively Coupled Plasma Mass Spectrometry: Casework Experience

David Ruddell, PhD, Brenda Burton, MBA, Hendrik Dorn, PhD, and Alexander Heydon, BSc, Centre of Forensic Sciences, 25 Grosvenor Street, Toronto, ON M7A 2G8, CANADA*

After attending this presentation, attendees will have a better appreciation of how elemental analysis works in real cases. They will also be able to acquire software that will assist in reporting of results and in research.

This presentation will have an impact on the forensic science community by demonstrating the utility of Laser Ablation Inductively Coupled Plasma Mass Spectrometry in forensic casework.

The use of Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS) for the analysis of glass has been the subject of a great deal of research; however, reports of the use of this technique in casework are lacking. This presentation will examine the use of elemental analysis of glass from samples collected since 2009. In that time, of the cases where elemental analysis had potential to be useful (i.e., excluding

cases with no questioned glass recovered, or where the questioned glass was different in refractive index or thickness), 64% had sufficiently large questioned samples to perform LA-ICP-MS analysis.

A total of 82 glass samples from cases submitted to the CFS have been analyzed with LA-ICP-MS, with the following trace elements used for discrimination: 49Ti, 55Mn, 85Rb, 88Sr, 90Zr, 137Ba, 139La, 140Ce, 146Nd, and 208Pb. Using pairwise comparison analysis (3321 pairs) with a modified ± four standard deviation match criterion, three Type II errors were found, giving a false inclusion rate of approximately one in 1000. Further analysis of the casework samples has shown little correlation between refractive index and the concentration of any of the ten trace elements that are used for comparison (the largest R2 value among the ten elements is for 49Ti, at 0.19). Given this, it is not unreasonable to assume that the trace element concentration and refractive index are independent. Using this assumption, along with the observation that in typical cases, the refractive index range for a known sample will match 1-4% of the samples in the CFS database, the coincidental match probability can be estimated. For two unrelated pieces of glass, when refractive index, thermal history, and elemental concentration have been determined, this is approximately one in 25,000-100,000.

In order to present the results of the elemental analysis in a more readily understandable form, a spreadsheet has been developed that not only determines if samples are indistinguishable from one another, it also presents the information in a clear manner, suitable for reviewers or presentation in court. A related spreadsheet has also been developed that can perform pairwise comparisons for up to 500 samples (124,750 comparisons). This has great utility in determining Type I and Type II error rates. Both spreadsheets are freely available to interested parties.

Two interesting cases will be discussed. The first had questioned and known sources that were indistinguishable in refractive index, but differed in elemental concentration. This is the first case seen at the CFS where samples indistinguishable in refractive index were distinguished by elemental analysis. The second case, a "smash and grab" at a jewelry store, had four known samples from one location. Questioned glass was indistinguishable from all four known samples in refractive index, and indistinguishable from three of the known samples in elemental concentration. One known sample was different in just one element.

Glass, Elemental Analysis, ICP-MS

A198 Nonparametric Permutation Hypothesis Testing: Applications to Physical Evidence

Michael E. Sigman, PhD, and Caitlin Rinke, BS, University of Central Florida, PO Box 162367, Orlando, FL; Liqiang Ni, PhD, University of Central Florida, Department of Statistics, 4000 Central Florida Boulevard, Orlando, FL 32816; and Katie M. White, MS, University of Central Florida, PO Box 162367, Orlando, FL 32816*

The goal of this presentation is to introduce the audience to nonparametric permutation testing which frees the analyst from distributional assumptions, and to demonstrate the application of the method to physical evidence evaluation.

This presentation will impact the forensic science community by demonstrating methods in which physical evidence is evaluated in the laboratory and presented in court.

This presentation will provide an overview of a nonparametric permutation hypothesis testing methodology and demonstrate the application of the method to laser-induced breakdown spectroscopy (LIBS) analysis of paint and glass samples, and analysis of fiber evidence by microspectrophotometry.[1-3] Research results will be presented and a method for reduction to practice will be described. The methodology described in this presentation directly addresses the need for improved statistical assessment of physical evidence.

Parametric statistical tests often rely on the assumption of normality which frequently does not hold for experimental data and the robust nature of the statistical test is relied upon to insure reliable results.

Nonparametric tests free the analyst from rigid distributional assumptions. The nonparametric permutation test exhibits excellent discriminating power for the physical evidence analyses mentioned above and rigorously holds the actual size of the Type I error at the nominal level.

The nonparametric permutation test has been applied to multivariate data sets comprised of spectral profile representations of the samples. Multiple spectra from each of two samples are compared through a similarity metric (i.e., Fisher transformations of Pearson product moment correlation coefficients). The difference between the sums of the similarity metric within spectral groups and between spectral groups, W_n, is calculated for all *n* permutations of the set of spectra. The fraction of W_n greater than or equal to the original spectral grouping, W_0, is a measure of the p-value for the test.

Results from laboratory tests of glass, paint and fiber analyses show that the test is sensitive enough to detect within-sample variations at a prescribed significance level (i.e., $\alpha = 0.05$). An example of LIBS analyses of glass samples is shown in Figure 1. Analyses were conducted in five different areas on each of ten different automobile side windows. Twenty comparisons each were made between all same window-same area (SWSA), same window – different area (SWDA) and different window (DW) samples, for a total of 4,100 comparisons. The distributions of the p-values for each set of comparisons are shown as box plots in Figure 1. The SWSA p-values are randomly drawn from a uniform distribution with 3.5% of the values less than or equal to 0.05 (i.e., 3.5% Type I error which is near the nominal $\alpha = 0.05$). A total of 54.8% of the SWDA p-values fell below 0.05, indicating a significant discrimination between different areas of the same window. Substantial variation of elemental concentration within float glass panes has been reported based on LA-ICP-MS analyses.[4] A total of 98.7% of the DW comparisons gave p-values below 0.05 (i.e., a 1.3% Type II error rate), reflecting the excellent power of the test. A methodology will be described which combines the nonparametric permutation test with a Wilcoxon rank sum test to allow the nonparametric permutation method to be effectively applied to casework samples.

All calculations were performed using software written in-house.

This work was supported under award number 2006-DN-BX-K251 from the Office of Justice Programs, National Institute of Justice, Department of Justice. Points of view in this document are those of the authors and do not necessarily represent the official position of the U.S. Department of Justice. Ni's research was supported in part by grant DMS-0885409 from the National Science Foundation.

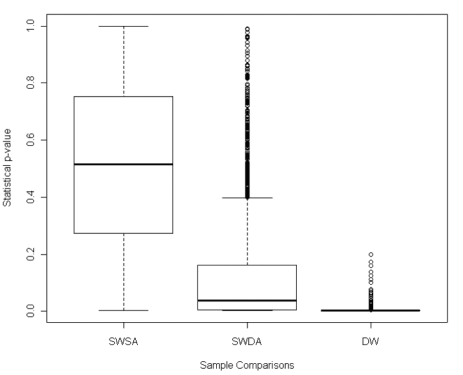

Figure 2. Statistical p-value distributions from the comparison of LIBS spectra taken from the same window-same area (SWSA), same window-different area (SWDA) and different windows of automotive side windows.

Hypothesis Testing, Nonparametric Permutation Methods, Physical Evidence

B1 Scientific Validation of Digital Forensics Tools: A Case Study

Marcus Rogers, PhD, 401 North Grant Street, West Lafayette, IN 47907; and Philip Craiger, PhD, Daytona State College, Advanced Technology Campus, 1770 Technology Boulevard, Daytona Beach, FL 32117*

After attending this presentation, attendees will: (1) become familiar with the importance of digital forensics tool validation; (2) will be provided an overview of a large-scale study demonstrating digital forensics tool validation process; and, (3) will be presented lessons learned from a validation study.

This presentation will impact the forensic science community by showing how scientific validations of digital forensic tools are important. Anecdotal evidence; however, suggests that the tools do not appear to undergo the same scrutiny as forensic tools in other more established disciplines. Therefore, it is important that examiners (some of whom may not have a good background in computing) understand the tool validation process and how the lack thereof may affect the interpretation of the results.

As with all other forensic disciplines, the results obtained from digital forensics tools must meet basic evidentiary and scientific standards to be allowed as evidence in legal proceedings. In the United States, the requirements for the admissibility of scientific evidence and expert opinion were outlined in the precedent setting U.S. Supreme Court decision *Daubert vs. Merrell Dow Pharmaceuticals, Inc., 509 U.S. 579*. The U.S. Supreme Court found that evidence or opinion derived from scientific or technical activities must derive from methods that are proven to be "scientifically valid" to be admissible in a court of law. The term "scientifically valid" suggests that the tools and methods are capable of being proven correct through empirical testing. In the context of digital forensics, this means that the tools and techniques used in the collection and analysis of digital evidence must be validated and proven to meet scientific standards.

The recent case of *State of Florida vs. Casey Anthony* underscores the importance of tool validation. Examiners conducted an initial analysis of the family computer and found that someone had performed an internet search for the keyword "chloroform," and that the same user (apparently) visited a web page — a single time — that contained information on "how to make chloroform." A subsequent analysis with a different tool indicated the same web page had been visited ***84 times*** within a few minutes. Such a discrepancy between tool results clearly indicates a problem with the validity of one, if not both, tools.

This presentation presents an overview of a large-scale digital forensics tool validation study consisting of over 150 validation tests, as well as lessons learned. Funded by the National Institute of Justice, the purpose of the study was to validate several popular digital forensics tool suites with respect to the most commonly employed functions (e.g., keyword search, identifying deleted files, file recovery, hashing, internet history, etc.), across multiple versions of operating systems as well as across multiple file systems. The validation protocol described in the *Scientific Working Group on Digital Evidence's Recommended Guidelines for Validation Testing (Version 1.1)* was used for each validation test. Testing protocols required the creation of multiple source evidence sets for a crossed design (e.g., XP-FAT32; Vista-FAT32, Vista-FAT32, XP-NTFS, Vista-NTFS, 7-NTFS, etc.). Evidence creation scripts were developed and used to create sample evidence for each experimental "cell" (combination of operating system and file system where appropriate).

Although a few anomalies were identified, in general, the results of validation testing suggested that the digital forensic tools were capable of accurately performing the functions tested. Operating system version did not appear to affect accuracy of the tools, nor did file system type (e.g., FAT32 vs. NTFS). One interesting finding was that the user manuals for the tools occasionally did not precisely specify the limitations of a particular function, which could affect the results and consequently an examiner's interpretation of the results. This may be of some consequence if examiners are unfamiliar with the tools, and have little knowledge or experience with validation testing.

Digital Forensics, Tool Validation, Scientific Validation

B2 An Alternate Methodology for Validating Hardware Write Block Devices

Benjamin R. Livelsberger, MS, National Institute of Standards and Technology, 100 Bureau Drive, Stop 8970, Gaithersburg, MD 20899-8970*

The goal of this presentation is to show how the Computer Forensics Tool Testing (CFTT) project at National Institute of Standards and Technology has developed an alternate methodology for validating Hardware Write Block (HWB) devices. After attending this presentation, attendees will be familiar with this methodology and the benefits it offers.

This presentation will impact the forensic science community by showing how the current methods used to validate HWBs have an inherent weakness. This presentation will have the impact of educating the community to the nature of this weakness and to introduce an alternate NIST-developed method that seeks to account for it.

Before being used in an investigation, the correct functioning of a forensic tool must first be established. For Hardware Write Block tools this involves testing: (1) that the HWB allows informational and read commands to be passed to the drive and their responses to be returned to a host computer; and, (2) that it blocks modifying commands from reaching the protected drive.

The current commonly used method for validating a HWB involves using forensics tools and/or common operating system utilities and operations to attempt to read and write to a protected drive. There is a weakness inherent in this approach, namely that it only tests a small subset of the commands that could be used to read from or write to a drive. For example, testing a HWB's ability to block modifying commands by attempting a file copy operation to a protected ATA drive using an operating system that implements the WRITE DMA EXT command for ATA devices will only test the hardware write block's ability to block the WRITE DMA EXT command; it will not test whether the HWB blocks the WRITE SECTORS EXT or WRITE MULTIPLE EXT commands. In this scenario, a malfunctioning HWB that incorrectly allows the WRITE MULTIPLE EXT command to be passed to protected drives will not be identified as faulty. A more thorough approach, one that tests the HWB's behavior with a broader range of commands than those implemented by a given operating system is desirable.

The Computer Forensics Tool Testing (CFTT) project has developed an alternate methodology for validating HWBs. With this methodology, testing is not limited by the subset of commands implemented by the operating system being used. HWBs are instead tested with all read and write commands as defined in ATA specs 4-8 and SCSI Block Commands-2 and as implemented by an extended version of the ATAraw Linux library written by Kyle Sanders and Simson Garfinkel of the Naval Post Graduate School. Three Linux programs were written to implement the CFTT methodology. These programs tie into the ATAraw library to send ATA or SCSI commands to devices via the Linux SCSI Generic driver. The three programs are:

try_read sends all defined SCSI or ATA read commands to a drive;

try_write sends all defined SCSI or ATA write commands to a drive, and;

write_verify measures whether any hard drive sectors have been successfully written to.

Using these programs, a HWB tool may be validated in the following manner:

1. For each hard drive interface supported by the HWB, initialize a drive with known content.
2. Calculate a before reference hash for each drive.
3. For each permutation of host-to-blocker and blocker-to-drive interfaces execute the try_read and try_write programs.
4. Calculate an after reference hash for each drive.
5. Use write_verify and a comparison of the reference hashes to measure whether any sectors on the test drives have changed.

Digital Forensics, Hardware Write Block, Tool Validation

B3 Creating Deleted File Recovery Tool Testing Images

James R. Lyle, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8970, Gaithersburg, MD 20899*

After attending the presentation, attendees will be made aware of some of the issues in the creation of test data for testing computer forensic tools used to recover deleted files from digital evidence and strategies used by the Computer Forensics Tool Testing (CFTT) project to address the issues.

The presentation will impact the forensic science community by increasing awareness of what impact tool test strategies have on the ability to reveal anomalies in tool behavior. The presentation will aid the forensic practitioner in the preparation of test data sets for testing forensic tool capabilities for the recovery of deleted files.

The CFTT project at the National Institute of Standards and Technology develops methodologies for testing computer forensic tools. This presentation covers creating test data images for testing digital forensics tools that recover deleted files using residual meta-data after a file is deleted to recover file name and file content.

A file system is used to store data for access by a computer. This data is normally stored within a tree-structured hierarchy of directories and files. When a file or directory is deleted from a file system, the associated *metadata* entry and the stored data are no longer directly accessible to the user and appear to be completely removed. However, in many file systems, e.g., FAT, neither the metadata associated with the file nor the actual content is completely removed. This creates a situation where there is *residual metadata* (metadata remaining after a delete has occurred) that is still accessible by direct access outside the usual operating system methods and can be used to reconstruct deleted files. Many forensic tools exploit the behavior exhibited by file systems of leaving metadata behind after a file is deleted to attempt to recover these deleted files. Metadata-based deleted file recovery should not be confused with *file carving*, i.e., scanning unallocated memory for the file signatures present within a file itself to identify a deleted file. The scope of this presentation is limited to metadata-based deleted file recovery tools that use file system metadata from file system structures such as directories or i-nodes to identify recoverable deleted files.

The basic approach to creating a test image is as follows:

- Create a file system on a secondary storage device.
- Create some files.
- Delete some of the created files.
- Image the storage device.
- Use the tool under test to attempt to recover the deleted files.

This basic approach requires refinement so that the tool testing can produce verifiable results; the following issues need to be addressed:

1. The content of the image file needs to be documented. In particular, the following should be noted:
   - Active files and blocks allocated to each active file
   - Deleted files and content history for blocks allocated to a deleted file and time of file deletion
   - MAC (modify, access & create) times for each file
   - File attributes
   - Each operation (create, append or delete) on files.
2. Identification of conditions within a file system that are relevant to tool behavior and should be present in test images.
3. Development of techniques to bring about the relevant conditions.

Four programs were created to aid documentation of image file content as follows:

- **not-used** writes the text message "not used" to each sector of the storage device. This is run as a first step before the file system is created.
- **mk-file** is used to create files. Each block of the file is tagged with the file name and a sequence number. Blocks allocated to a file are easy to identify and track.
- **ap-file** is used to append to an existing file. This appends blocks to the file already created and continues the block numbering where it left off.
- **layout** scans an image file and classifies blocks as files, metadata or not used.

These four programs simplify classification of blocks from an image file as either *allocated to a file*, *never been used* or *file system metadata*.

This presentation gives an overview of the issues in creating deleted file recovery test images and techniques that can be used to address the issues.

Digital Evidence, Software Testing, Deleted File

B4 The Role of Global Telecommunications Providers in Tracking and Investigating Information Security Incidents

Christopher W. Day, BS, 2 South Biscayne Boulevard, Suite 2800, Miami, FL 33131*

After attending this presentation, attendees will have a better understanding of how global telecommunications providers can provide assistance to digital forensic investigators investigating a host of information security breaches and incidents. Global providers have a vested interest in tracking and mitigating many forms of information threats such as so-called advanced persistent threats, organized crime activity, botnets, child pornographers, and so on. Many providers offer their customer base various services against these threats, while others are compelled by their national governments to maintain certain records for law enforcement use. All are interested in protecting their infrastructure from today's increasingly sophisticated threats. The types of information potentially available to those investigating an information incident may include extensive flow records (including multi-hop, multi-jurisdictional data), access logs, reputational statistics for IP blocks and addresses, peering data, and many others. In certain limited circumstances, even captured packet data may be available.

This presentation will impact the forensic community by providing practitioners with awareness of the types of information that may be available from global telecommunications providers, how the information can provide evidence to support an investigation, and how to go about requesting and preserving the evidence. There are also a number of formats in use today for reporting incidents as well as requesting support from a provider for an investigation. A number of case examples will be discussed to better demonstrate how the various types of data have been used in this study to investigate a wide array of computer intrusions and incidents in the past. Finally, various legal frameworks and privacy issues that come into

play when requesting and utilizing this sort of information will be discussed. As well as a number of industry initiatives to capture, utilize, and normalize data submission. This useful data in an appropriate manner for investigation purposes while preserving and protecting privacy and civil liberties will be shared.

Many incidents today involve multiple systems in various international jurisdictions. Piecing together the evidence to not only understand the scope of the incident, but also determine attribution of the perpetrators, can be a daunting and time-consuming process. In many cases, investigators are not aware of what types of information may be available to them from a given provider. In some scenarios, access to a known-malicious host, in its entirety, has been made available for forensic analysis. In certain limited circumstances, even captured packet data may be available under the appropriate legal frameworks. Additionally, with the ever-growing movement of computing workloads into various cloud computing infrastructures, many owned and operated by telecommunications providers, investigators must be cognizant of what types of evidence and information cloud providers are maintaining to support their businesses and how that information can be useful to an investigation. The presentation will also discuss issues relating to the scale of the evidence acquisition problem brought about by increases in bandwidth, system memory, data storage, and the elasticity of today's cloud computing environments. Investigators must be prepared to receive and process potentially massive amounts of data (possibly on the order of terabytes) when requesting incident information from large providers.

Telecommunications, Global, Investigation

B5 Hand Identification Based on Skin Characteristics

Meredith Dilley, United States Air Force Academy, 2304 Cadet Drive, USAF Academy, CO 80841; Christina A. Malone, MFS*, United States Army Criminal Investigation Laboratory, Digital Evidence, 4930 North 31st Street, Building 925, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will understand inter- and intra-observer reliability when counting commonly found skin features of the hand that may be used in photographic hand comparisons.

This presentation will impact the forensic science community by determining if different examiners see the same features on the same hands, and if the same examiner sees the same features in the same hands. A second goal of this study is to examine how observer reliability is correlated with examiner experience in pattern recognition.

The markers used in this project include moles, freckles, sunspots, and scars. These dermatological features vary in appearance and are a potentially valuable resource for establishing individuality. As these features may form throughout an individual's life, current data and relatively recent photographs are essential. In general, these markings are constant, and such observable skin features have been useful for facial identification; however, oftentimes a suspect's face is not present in a photograph. Hands are a useful alternative, as they may be depicted in images of crimes such as: kidnappings, trophy killings, sexual assault, and child pornography.

Previous research suggests the use of a method for conducting photographic comparisons of the dorsal surface of the hand using fourteen regions. The current research consisted of examining inter-/intra- rater reliability of observers assessing a series of images of the right hand and counting the number of markers in each of these fourteen regions of the hand. Three of the thirty-four images were repeated three times, creating a total of forty images. The sets of images were examined by individuals with various experience levels in pattern recognition and dermatology. It was hypothesized that examiners with more experience would have similar results and that the three repeated hands would have closely correlated values.

Raw data was compared by examiner, region, hand, and repeated hands. The values were cross-correlated to determine the similarity between results for each examiner and for each hand. The results show that high correlation values were obtained for different examiners comparing the same hands, while slightly lower correlation values were obtained when comparing different hands. In general, those examiners with more experience had more correlated results than those with less experience. The repeated hands had comparable values to one another. Further, it seemed that some hands were particularly difficult to examine based on their high ranges and standard deviations across all examiners.

Using hands for identification of an individual will give investigators another tool to use in identifying suspects. Improvements are needed, but this method shows promise for future research and demonstrates the need for experience in image analysis and pattern recognition when conducting photographic comparisons of the hand.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Inter-/Intra- Observer, Identification, Photographic Comparison

B6 Photographic Analyses Using Skin Detail of the Hand: A Methodology and Statistical Evaluation

Christina A. Malone, MFS, United States Army Criminal Investigation Laboratory, Digital Evidence, 4930 North 31st Street, Building 925, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will understand a method for examining micro-level skin detail of the dorsal surface of the hand in photographic comparisons. Such comparisons have been conducted worldwide by experts in image analysis and human variation, using skin features to demonstrate unique aspects of unknown individuals.

This presentation will impact the forensic science community by demonstrating a method which can be easily employed to assess the distribution and frequency of commonly found skin features on the dorsal surface of the hand.

Lesions, scars, marks, tattoos, and other imprints on the skin can aid in the identification of unknown individuals and have been employed by law enforcement agencies for suspect and victim identification. The importance of hand analysis has arisen in recent forensic image comparison casework, including sexual assault and child exploitation cases, where images have been submitted in which the individual's face was not present in the image.

This research utilizes a database of 128 hands collected from employees of the U.S. Army Criminal Investigation Laboratory to examine the frequency and distribution of micro-level skin detail on the dorsa of the hand. To assess the location of features, the hand was segmented into fourteen regions using readily discernable anatomical landmarks. Each hand was assessed for the number of features found in each region. Pigmented lesions were observed in 14/14 regions, and scars or injuries were observed in 13/14 of the regions. Overall, 2,618 pigmented lesions and ninety-two scars or injuries were documented.

Descriptive statistics (range, mean, and variance) were calculated to compare each of the regions to one another. Additional statistical techniques were employed to determine which regions of the hand demonstrated significant difference in the distribution of features. When the location of pigmented lesions was considered, Region Thirteen expressed the most pigmented lesions per hand, and Region One demonstrated the least pigmented lesions per hand. When evaluating the location of scars and injuries, Region Eleven exhibited the most

scars/injuries per hand, and Region One showed the least scars/injuries per hand. The quantity of lesions present and how they were distributed across regions provided information on how the hands could be differentiated from one another.

Through the assessment of skin detail in this study, an examiner has another tool that can be employed when performing photographic comparisons and when explaining findings in a courtroom. With the increased demand for photographic comparisons of skin and the expanded availability of digital cameras, the current study presents a set of data and calls for the implementation of further research.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Photographic Comparisons, Image Analysis, Forensic Identification

B7 A New Technique for Photo Skull Superimposition Using CT and Presentation Software

Brandon Nichols, MD, University of South Alabama Medical Center, 2451 Fillingim Street, Mobile, AL 36617; B.G. Brogdon, MD, University of South Alabama Medical Center, Department of Radiology, 2451 Fillingim Street, Mobile, AL 36617; and James A. Bailey, PhD, University of North Carolina Wilmington, 601 South College Road, Wilmington, NC 28403*

After attending this presentation, attendees will learn about a new technique for rapid superimposition of a skull and facial photograph for postmortem identification with standard software, following simple steps, on almost any personal computer.

This presentation will impact the forensic science community by illustrating this new method which, using universal technology, quickly and simply replicates the results obtained by the widely accepted but complicated and time-consuming video sequencing process.

The technique of using complex video setups with film editing techniques can be greatly simplified with custom modern CT technology and PowerPoint® presentation software including custom animation.

The validity and usefulness of craniofacial superimposition in identification cases has been demonstrated for decades.[1] When the anatomical features of the skull do not align with the photograph, a match is eliminated. However, when there is alignment between the anatomical features or anomalies, it offers strong evidence of identity, even though the evidence is circumstantial. In cases with unusual cranial morphology, alignment between the skull and photograph is even more compelling evidence.

Craniofacial superimpositions were initially made by using tracings of skull and faces from photographs. Since these early attempts, other craniofacial superimposition techniques have been developed. Early photographic comparison of a skull and a facial photograph required scaling and orientation of the skull photograph to match the precise pose of the head when photographed.[2] Clyde Snow, in 1976, may have been the first to use video superimposition, which has become the method of choice since the early 1980s.[3] It has often appeared to be the best solution for correcting the many variables encountered: the most difficult being the scaling and orientation of the skull image since the photograph of the person in question is unalterable.

A modern video superimposition laboratory is described as requiring several people and substantial equipment.[1] Two video cameras are needed; one is directed at the photograph, the other at the skull, which must be supported in some fashion to permit altering its orientation in three planes. The two images thus acquired are superimposed and blended on a third monitor while correcting for scale.

Given the remarkable advances of 3D reconstruction of CT generated images, this process can be simplified. This paper defines the technique of using 3D rendering software and PowerPoint® presentation software to produce quickly and simply the same image sequences rendered by video superimposition techniques. This can be accomplished using almost any personal computer and modern CT equipment with minimal manpower. Further, a great advantage of this new technique is that it does not require defleshing a skull, thus permitting examination of a live subject who is unrecognizable due to injury, or a partially decomposed decedent.

With this new technique, unlimited skull orientation is accommodated using 3D reconstruction software available with any modern diagnostic CT software or DICOM viewer software. Standard features built into presentation software permit easy scaling and superimposition of both images. Using these techniques, standard video sequences— fades, sweeps, and box sweeps — can be replicated quickly and with minimal effort.

A real-time sample case demonstrating this new technique will compare traditional concordant craniometric landmarks on a skull to cephalometric landmarks of two individuals of same sex and ethnicity, similar age and body stature.[4,5] Possible match or exclusion will derive from superimposition of such landmarks as: skull to face proportion; cranium width to forehead; eyebrows to superorbital margin; eye/pupil to orbit; external nose; and, nasal ala to nasal aperture.

In conclusion, this craniofacial superimposition technique offers an expedient method for comparing unidentified skulls to photographs for purposes of identification. This innovative technique was devised to meet the challenge of matching a skull to one of three robbers involved in the infamous 1876 Northfield Bank Robbery.

Identification, CT, Superimposition

B8 Heart Beat Detection in Snuff Movies

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; and Dirk Jan Elzinga, MSc, TU Delft, Laan van Ypenburg 6, Den Haag, 2497 GB, NETHERLANDS*

After attending this presentation, attendees will have an insight into the forensic possibilities for the determination of the presence and rate of a heart beat from video.

This presentation will impact the forensic science community by investigating snuff movies and determining if a heartbeat is measurable from the veins in the face with ordinary webcams or video to help determine if a person is dead or alive.

Experiments are conducted to obtain the heart rate from a movie for forensic use in, for example, snuff movies. The approach is based on the principle of photoplethysmography. This means that volumetric changes are measured with the aid of a light source. Here, the changes of interest are the volumetric changes of the blood vessels and the light source used is ambient light.

The heart rate obtained from a movie is compared with the heart rate measured with a finger pulse oximeter and the two methods are used for the comparison. The first method is the root mean squared error and the second is based on the, so-called, Bland-Altman statistics.

Results are obtained from movies of the facial area (recorded with a digital camera and a webcam), an arm (inside and outside, digital camera), a hand (inside and outside, digital camera), and a leg (outside, digital camera).

The maximum obtained root mean squared error is 2.69 beats per minute (hand inside) and the maximum Bland-Altman standard deviation is 2.44 beats per minute (hand inside). Therefore, it can be concluded that the heart rate determined from movies as well as the heart rate measured with the finger pulse oximeter do not differ significantly.

In the experiments that examine the facial area, a face tracker is used. The region of interest is a centered rectangle. The agreement, between video and finger pulse oximeter, might be further improved by using a different region of interest, e.g., the forehead or cheek area. No tracker is used in the experiments with the arm, hand, or leg. Introducing a tracker in these experiments will likely reduce errors caused by motion artifacts.

The parameters used to analyze the photoplethysmographic signal extracted from a movie are determined with a genetic algorithm. Changing the parameters from their optimal values has a great impact on the determined heart rate. This aspect seemed not present in the results reported by Poh of MIT.[1] It is assumed that the difference is caused by the presence of an additional light source. Extra experiments have been performed to validate this assumption.

Additional experiments showed that decreasing the resolution of the movie as well as compression of the movie both increase the root mean squared error and the Bland-Altman standard deviation.

In current implementation, the algorithm always selects a frequency in the range of interest (0.75-4.00 Hz). Therefore, the implementation needs to be modified in order to apply it to snuff movies. A possible approach is to examine the photoplethysmographic signal obtained from the video) for typical photoplethysmographic features. A good feature could be the standard deviation and a standard deviation lower than normal could indicate a subject without a pulse. Validation of the method is necessary before it is applied in casework.

Heart Beat, Measurement, Video

B9 Implementation of the Likelihood Ratio Framework for Camera Identification Based on Sensor Noise Patterns

Wiger Van Houten, MS, Criminal Investigation Unit North, Schweitzerlaan 2, Groningen, NETHERLANDS; Ivo Alberink, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, 2497 GB, NETHERLANDS; and Zeno J. Geradts, PhD, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, 2497 GB, NETHERLANDS*

After attending this presentation, attendees will understand some of the typical problems that may arise when applying the Bayesian framework of evidence evaluation to camera identification based on sensor noise patterns.

This presentation will impact the forensic science community by illustrating practical issues when the Bayesian framework of evidence evaluation is applied based on similarity scores between traces.

In digital forensics, the question of which particular camera was used to make a certain photograph may arise, e.g., in child pornography casework where an accused is suspected of producing photographs in addition to possessing them. Instead of looking at metadata, one may look at identifying characteristics present directly in the image due to small deviations in the image sensor itself. These small deviations in the image sensor mostly arise from the pixels in the image sensor having non-uniform sizes, and hence capture more or less light, even when all pixels are under the same illumination. This phenomenon is called photo response non-uniformity, or PRNU, and can be used as an identifying characteristic. Therefore, camera identification comes down to verifying whether the PRNU pattern from a questioned image corresponds to the PRNU pattern from reference images from a camera.

Extraction of PRNU patterns can be done effectively and efficiently with state of the art methods. The similarity between patterns is calculated using Pearson's correlation coefficient, which will increase if the similarity increases. The goal of the presentation is the assessment of the strength of the evidence of eventual similarity of PRNU patterns. Assessing the similarity between two sources, i.e., individualizing the sources, is classically approached by using a verbal scale (e.g., "strong support" for a certain hypothesis). This scale may be based on estimations of probabilities or on thresholds set by the expert. It is clear that both approaches are to a certain extent subjective: it likely depends on the amount of experience of the investigator and may vary from investigator to investigator. In forensics, a framework gaining popularity to assess the value of the evidence is the likelihood ratio (LR) framework under a Bayesian reasoning approach; from here on: "LR framework." The goal of the LR framework is to accurately assess the strength of evidence in the light of clearly defined opposing hypotheses, and not to comment on the probability of traces being from a common source, which is considered principally impossible. Furthermore, it should harmonize the value of the evidence and ease the interpretation of the evidence in different disciplines.

In Nordgaard and Hoglund, the LR framework is implemented for PRNU-based camera identification, where the focus is on the measurement uncertainty of the strength of evidence.[1] The current presentation focuses on general problems that are encountered when interpretation of results is performed in the LR framework. In two (fictive) case examples, namely for a mobile phone camera and a good quality Sony DSC-S500 camera, the results of the LR approach are described. It turns out to be very possible to obtain statistical distributions underlying the reference data for both "matching" and "non-matching" comparisons, for both types of cameras. Based on these, LRs can be calculated. For the mobile phone cameras, it turns out that in the tail of the distributions problems will emerge: the LR decreases as a function of the correlation between PRNU patterns, which is nonsensical. For the Sony camera this point is even clearer. Again the LR function is not increasing on the whole range of correlations encountered. Moreover, LRs under Hp are absurdly high. The reason for this is that the statistical fit of the distribution for "non-matches" is constantly evaluated in a range where there is no reference data. Clearly the numbers that are being returned cannot be trusted. The problem is that extrapolation takes place in the tail of the fit for correlation scores under H_d, which is a bad statistical procedure. All in all, under these circumstances it is not possible to come up with reliable LRs, and the reason for this is that the correlation scores under both hypotheses are separated too well.

The issue of widely separated distributions, and the resulting unreliable LRs is not a problem that is unique for PRNU-based comparison: if the informative value of any forensic comparison (be it fingerprints, speech, glass particles, etc.) is high, the problem emerges. Although this may be considered to be a problem of luxury, the question remains how to deal with it. The alternative of checking whether comparison scores are larger or smaller than some threshold value yields LRs that are smaller but more reliable.

Camera Identification, Bayesian Framework, Likelihood Ratios

B10 Analysis of Corrupt Video Files With Open Source Initiative Defraser

Zeno J. Geradts, PhD, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; and Rikkert Zoun, MS, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, 2497 GB, NETHERLANDS*

After attending this presentation attendees will explore the forensic possibilities to analyze and restore video from files that are broken.

This presentation will impact the forensic science community by demonstrating the possibilities to investigate broken and partial video files and restoring them properly with less time compared to other methods.

Cameras may be seen in many places, recording persons and events. Sometimes the recordings are helpful as forensic evidence in court, providing insight into what happened at a crime scene, or which scenarios are possible. Also people often record videos of crimes with the purpose of assisting the police, or to record what has happened for other reasons. Sometimes people try to erase the video before it is given to or seized by the police, or the data storage may get corrupted, and the video is not playable anymore. Also, in cases such as lawful internet interception only parts of a video file may be recoverable. Slack space and unallocated clusters on a hard drive may also contain partial video files.

In these cases, the data carriers or damaged files can be examined and fragments that are found may be repaired with a hex editor and the specifications of the video file format. This usually involves a lot of reverse engineering and comparison with reference files from the same recording device or storage device.

For this type of examination the Netherlands Forensic Institute developed the software Defraser (abbreviation for Digital Evidence Fragment Search & Rescue). It helps the digital forensic investigator by searching for fragments of video files and displaying metadata such as recording time and video resolution. In the current version the user can view any valid keyframes that are found. It also allows creating new files by combining syntactic elements (headers) of video file fragments by dragging and dropping. This way, a broken video file can be repaired using headers from valid reference video files that have the same settings. Ideally, such reference files are recorded with the same camera type as the one under investigation. Defraser also has a wizard to help with header replacement. The software can log the links between the output of the software and the source evidence files. In court, such information can be used to completely reconstruct any resulting video files from the source evidence material.

The knowledge about video file formats is stored in plug-ins. Currently there are plug-ins available for the AVI, MPEG-1, 2, & 4, 3GPP/QuickTime/MP4, and ASF/WMV video file formats. A plug-in for H.264 is currently being developed. The software is developed in .NET and C#; and on the software engineering side, the structure is such that new plug-ins can be developed easily without too much rework by software engineers, reducing development time. The software is open source, so it can be downloaded for free from *http://sourceforge.net/projects/defraser*.

The benefits to making it an open source program are to give reviewers and other experts the possibility to do a code review of the forensic software as well as writing new plug-ins for other video formats, and also give vendors the possibility to include it in their software for further development. In practice, the code review does not often happen, since in general codes of thousands of lines are not easy to follow, even if there are many comments included on what exactly happens.

In practice, Defraser has proven to be useful in an increasing number of forensic cases. The approach saves time compared to reverse engineering and working with hex editors. The most notable advantage of Defraser over other recovery software is that it recognizes fragments of video files, as opposed to just full video files.

In this presentation several examples of where it works will be shown, but also cases in which the approach could not be used, as well as guidelines for carving of video files. Examples include cameras that have been used in skimming devices for banking cards and partially erased video files from mobile phones.

Defraser, Video, Multimedia

B11 Quantifying Phase Changes in Audio Authenticity Examinations

Kenneth Marr, MS, David J. Snyder, BS*, and Andrew Galotti, BS*, Federal Bureau of Investigation, Engineering Research Facility, Forensic Audio, Video and Image Analysis Unit, Building 27958A, Quantico, VA 22135*

After attending this presentation, attendees will be presented testing results of automatic methods for detecting phase changes in forensic audio recordings when conducting audio authenticity examinations. Additionally, attendees will learn to compare the results of different automatic phase detection programs used in this series of tests.

This presentation will impact the forensic science community by exploring how phase changes by themselves may not provide insight as to whether an event is an alteration or not, but show promise as a method to correlate multiple events. If the accuracy of detecting phase changes is unreliable, this will also impact the value of it being used as potential method for forensic audio authentication.

Hypothesis: To determine whether a phase change in a forensic audio recording can accurately be identified as an alteration or edit and develop criteria or parameters classifying the event as such.

Synopsis: A series of test recordings that include various digital formats containing both altered and unaltered recordings will be analyzed by two different automatic phase detection systems. The test recordings will consist of reference tones recorded at various amplitudes as well as background environments consistent with forensic recordings. Testing results will address the question: Is a phase change in an audio file synonymous with alterations; and, can they accurately be detected?

The use of changes in phase is not a new analysis method for forensic audio authenticity examinations. Interest in expanding its role to detecting edits in digital recordings has increased in the last several years. Several concerns accompany this increased interest. Automatic detection of phase shifts can help speed a cumbersome time-consuming process of manually locating events, but the accuracy and thresholds of such detection methods are not widely known. Even if events are detected accurately, there is no specific criteria to determine whether the phase shift is the result of an alteration or naturally occurring event during the time of recording.

Test recordings will be produced to include reference tones at various amplitudes to determine if changing the amplitude of the reference tone will directly impact the accuracy of automatic phase detection systems. The test recordings will also contain a range of naturally occurring events and files with various alterations. The use of several common digital formats that represent the type of audio being received for examination and the method in which they are recorded may show that some formats may or may not maintain phase. An automatic detection system may falsely identify phase changes that may be inherent to the recording process, format, or recording environment and not necessarily the result of an edit or alteration. It may also identify phase changes where they do not exist or not identify them at all. Being able to accurately account for the number of phase changes detected or not detected is important.

The second part of this presentation will attempt to clarify what a phase change means to the authenticity of an audio recording. Even if the detection of phase changes is accurate, what correlation does a phase change have to an alteration or edit? Examination of known events may help correlate phase changes caused by edits or naturally occurring ones. Criteria is lacking for establishing which phase changes are the result of an alteration and which ones are not. This problem is similar to identifying events as pauses or as voice-activated for analog recorders. Both of these events are caused by stopping the transport of the recorder without disengaging the record and erase heads. A pause event is generally

associated with a potential alteration, where as a voice-activated event is generally not. Often the events are identified through testing the operation of the analog recorder. This analog analysis method does not translate to digital analysis of record events.

Digital Audio, Authenticity, Data Analysis

B12 Strategies for the Forensic Collection of Digital Evidence From Shared Storage and Virtualized Environments

Danielle M. Desfosses, MFS, 3152 Covewood Court, Unit K, Falls Church, VA 22042; and Brian D. Nunamaker, BS*, and Paul Cibas, BS, Drug Enforcement Administration, 10555 Furnace Road, Lorton, VA 22079*

After attending this presentation, attendees will gain a basic understanding of proposed strategies to obtain digital evidence from shared storage technologies such as, iSCSI, Fiber Channel (FC), and Network Attached Storage (NAS), which are commonly used with virtualization.

This presentation will impact the forensic science community by empowering digital forensic examiners with strategies involved in acquiring, investigating, and preserving digital evidence from shared storage technologies and virtualized environments that have become increasingly prevalent.

With the increase of virtualization being adopted by the IT industry, coupled with the continued decrease in data storage costs per gigabyte, shared storage technologies have become more prevalent. The advantages of shared storage technologies are vast. They allow for extremely large amounts of data to be disseminated to both individual computers and servers. These storage areas can then be presented to the individual computers and servers as local disks. With only a few clicks of the mouse and with no additional physical hardware changes, these disks can be re-sized, moved, added, and deleted with ease. Furthermore, the centralization of these storage technologies allows for easier management and secure segregation of data within a business enterprise. As a result, significant performance gains can be achieved by spreading data across multiple drives.

The traditional computer forensic examiner who is comfortable with locating and preserving evidence from stand-alone computers that have locally attached hard drives may have difficulty in finding and preserving digital evidence located on shared storage technologies. In the case of encountering shared storage, a forensic examiner must first be able to identify the type of technology being utilized. For example, the presence of a host bus adapter card physically attached to the computer hardware will indicate to the forensic examiner that FC technology is being employed. Additionally, a forensic examiner must be able to develop a concise and practical strategy to obtain digital evidence from storage arrays, which may consist of terabytes or even petabytes of data; and may possibly need to be obtained without the assistance or knowledge of the local system administrator. As a result, the strategy developed must encompass the ability to target specific data, as it may be impractical and too time-consuming to duplicate the entire shared storage array.

Because shared storage technologies are often affiliated with virtualized environments, a forensic examiner must be able to identify and locate the virtual computer(s). The forensic examiner must have an understanding of the types of files generated, managed, and saved by each virtualized environment. For example, VMWare uses "VHD" virtual disk files to store virtual machine(s). A forensic examiner also must be able to identify specific information they are seeking, even if it is encapsulated within a virtual disk.

The purpose of this presentation is to address all of the above listed needs. An overview of the most commonly used virtualization software packages, including VMWare's VSphere, Microsoft's Hyper-V, and Linux solutions such as XEN, and the system requirements for implementing shared storage technologies, will be provided. This overview will cover specific hardware and software configurations affiliated with each shared storage technology, how to identify them, and proposed strategies for gaining access to the shared storage areas. Based on the type of virtualization environment, proposed strategies will be identified and presented for the recovery of digital evidence from the associated virtual machines.

At the conclusion of the presentation, attendees will be more familiar with virtualization, shared storage, and strategies for recovering digital evidence from these environments.

Shared Storage, Virtualization, Digital Evidence

B13 Understanding Issues in Cloud Forensics: Two Hypothetical Case Studies

Josiah Dykstra, MS, 1739 Carriage Lamp Court, Severn, MD 21144; and Alan T. Sherman, PhD, University of Maryland, 1000 Hilltop Circle, Baltimore, MD 21250*

After attending this presentation, attendees will understand how cloud computing poses unique forensic challenges that require new methods of forensic acquisition, evidence preservation and chain of custody, and open problems for continued research.

This presentation will impact the forensic science community by laying out the significant issues associated with digital forensics for cloud computing and preparing the way for forensic investigation of the inevitable criminal targeting of cloud environments.

Crime committed using cloud computing resources and against cloud infrastructures is inevitable. Though real incidents have already taken place against cloud providers including Google, an absence of documentation indicates that no crimes using the cloud or targeting it directly have been publicized nor litigated thus far. Forensic investigators must understand that current tools and techniques are inadequate in the cloud environment where acquisition, examination and analysis will be in practice executed very differently than is done today. To illustrate these issues, two hypothetical crimes are fabricated and the forensic investigation is deconstructed against them.

Companies are embracing cloud technology to offload some of the cost, upkeep, and growth of equipment that they would otherwise have purchased themselves. Cloud infrastructure, with exceptional bandwidth, storage and computing power, offers an attractive prize for hackers. While many people have lamented how the users of the cloud and their data are protected, few of these discussions have considered the difficulty of responding to security breaches, including forensics and criminal prosecution. Furthermore, no case law exists on which to extrapolate the desire of the courts on the matter. Garfinkel recently suggested that "cloud computing in particular may make it impossible to perform basic forensic steps of data preservation and isolation on systems of forensic interest."[1]

To provide an update about the state of digital forensics for cloud-related crimes, the investigative response and forensic process of two hypothetical, but plausible, case studies of crimes tied to cloud computing are considered. While fictional, they describe computer crimes that are not uncommon today. Case Study one uses the cloud as an accessory to a crime. In this case, a criminal stores and distributes child pornography using the cloud. Case Study two targets the crime against the cloud. In this case, a criminal hacks into a cloud-based website and installs malicious code. These common crimes require a reinterpretation when set in a cloud computing environment. In both scenarios, the following themes emerge that differentiate these investigations from traditional digital forensics:

- Acquisition of forensic data is more difficult.
- Cooperation from cloud providers is paramount.
- Current forensic tools appear unsuited to process cloud data.
- Cloud data may lack key forensic metadata.

• Chain of custody is more complex.

These two case studies illustrate larger issues that exist beyond the scope of the specific examples. Forensic acquisition is a renewed challenge, one unsuited for today's tools, which will possibly be addressed by a combination of technological and legal approaches. We have begun to evaluate the ability of popular forensic tools to obtain evidence from a cloud environment. Cooperation with providers will empower consumers to understand their risks and give them leverage to prosecute crimes. The preservation and availability of forensically relevant metadata remains an open problem.

The issues of common crimes that vary from today only in their use of the cloud have been evaluated. This technology alone introduces peculiarities and open problems that demand immediate attention. Shown in this presentation are deficiencies in both law and technology can be addressed with proper advances.

Cloud Computing, Digital Forensics, Case Studies

B14 Facebook®: Do You Leave a Trace? A Forensic Analysis of Facebook® Artifacts

Katherine Helenek, BS, Joshua L. Brunty, MS, Chris Vance, BS, and Terry Fenger, PhD, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will learn where Facebook® chat artifacts are stored in different browsers and what the specific format means. Furthermore, attendees will understand how Facebook® message artifacts are saved and which browsers keep full messages.

This presentation will impact the forensic science community by demonstrating how forensic scientists, specifically the digital forensics community, can obtain potential evidence quickly and effectively from Facebook® artifacts.

As the use of technological devices has increased and become widespread, the internet has become mainstream for global communications used by persons, informal groups, public organizations, corporations, and governments.[1] In turn, social networks have increased in popularity as a means of contact and communication. The generic structure involves creating a profile, making connections with existing friends, and meeting new people through the site.[2] In addition, social networks allow the user to upload photos, describe their interests, explain their work and education history, post a relationship status, reveal personal stories and activities, give their current location, and even plan events.[2,3]

Facebook® was originally designed in 2004 as a social networking site specifically for Harvard University students, but has been developed throughout the years for any user over the age of thirteen.[3] Presently, Facebook® is available for general use with more than 750 million active users, half of whom log on at least once every day.[4] It is up to the users to set their own privacy settings in order to control others' access to their personal profiles; and their choices in the resulting levels of privacy are based upon their trust of the website and their trust of other users.[3]

As society has become more technologically developed, crime has transitioned from the corporate world into the digitized world of cyberspace. Law enforcement agencies claim that at least 50% of cases have a digital component, and that the number is currently rising. In 2009, the internet Crime Complaint Center (IC3) reported 336,665 complaints of internet offenses. Since 2000, the number of complaints has been increasing each year by 24.5%. The internet is a method of communication that consists of noncommittal interactions; this facet creates an easy means to take advantage of users.[5] A variety of online assaults and crimes occur every day; bullying, harassment, theft of personal information, sexual grooming, encouragement to harm others and the self, racist attacks, financial crimes, and fraud are just some of the various internet crimes that exist.[5,6]

Disclosure of certain personal information online, combined with other tools available for use on the internet, such as reverse directories, can aid fraudsters to obtain home phone numbers, full addresses, ages, and genders. These few pieces of information provide a means to acquire identity based information such as credit cards and driver's licenses, and in some cases make it possible to forge even more critical legal documents like passports.[3] It is important to recognize that these digital artifacts are contained within sources such as web pages, computer logs, internet newsgroups, and online chat rooms.[1]

A vast amount of the global population uses the internet and Facebook® each day for their activities. Unfortunately, some people are using these common places of communication for malicious and nefarious purposes. It is necessary for forensic investigators to have the ability to quickly and easily extract information from these sources so that evidence may be acquired as efficiently as possible. It should be feasible to recover Facebook® chat artifacts and discern a common pattern in order to quickly search for any previous chats. Furthermore, Facebook® messages may be able to be recovered, or parts of messages, in order to attain some information or at least create an apparent link between users.

In order to start off with pure profiles, three new user profiles were created on Facebook®. This was performed by first setting up three Gmail™ accounts from Google©; it was then possible to use these email addresses to create Facebook® profiles. Three virtual machines (VMs) were created (one per profile) for each browser that was to be tested. The "Windows 7 Original" VM was cloned and Internet Explorer® 8 was used to download each additional browser to be examined. This process was followed to set up three virtual machines each for Windows® Internet Explorer® 9, Mozilla Firefox® 4, Mozilla Firefox® 5, Google© Chrome 11, Google© Chrome 12, and Apple© Safari 5, totaling twenty-one virtual machines to use for the analysis. A *Single Chat Study*, a *Simultaneous Chat Study*, and a *Sent Message, New Inbox Message, and Already Read Message Study* were performed. A forensic duplicate image was taken from each VM using FTK® Imager and loaded into Forensic Toolkit® for examination.

B15 Homicide: The Effects of Fraudulent Social Network Accounts

Adanna N. Smith, MA, 1300 East Lafatette, Apartment 109-110, Detroit, MI 48207*

After attending the presentation, attendees will be able to see the effect of fraudulent social network accounts (such as Facebook and Twitter) leading to child homicide and/or rape homicide as a result of meeting in

person for social purposes, prostitution, to buy drugs and other types of criminal acts.

This presentation will impact the forensic science community by highlighting, through research and comparative analyses, the demographics (race, socioeconomic status, location, religion, sexual preference, and other trends) that may be most affected by predators. The presentation will discuss and critique patterned escalation of deviant behavior of convicted sex offenders as well.

While most of the issues surrounding this new type of predator are still being researched and categorized, this session will identify some causes, effects, and impacts these predators have on the subset of targeted population evaluated in this study.

The presentation introduces computer forensics to attendees to provide the foundation for the chain of events leading the collection of evidence for homicides. Evidence such as fingerprints, pictures, and DNA will be discussed as additional mechanisms utilized to obtain a positive identification of the predators. The comparison of the systems in place to monitor child activity on the internet such as parental controls will be examined as well.

A differentiation between computer forensics and mobile phone forensics will be provided. It is important to examine forensic artifacts, such as exchanged e-mails, notifications received, and picture uploads to social sites or via MMS (Multimedia Messaging Service) from mobile phones that can lead to a meeting that results in homicide. Recent studies have shown that mobile phones are now being analyzed in investigations because many people check and respond to e-mails on their mobile phones. Because of this, investigators are unable to locate messages that could show insight on illegal activities on laptops or hard drives when they are confiscated.

This presentation acknowledges historical data related to chat rooms as they provide the framework of the evolution of social network use. It is important to note that data collection pertaining to investigations of crimes related to fraudulent social network accounts is still in the early stages of development. Because of this, there is a call for technological advances to assist law enforcement agencies to combat these types of deviant behavior.

Attendees will gain a fundamental appreciation and understanding of how multimedia can reveal pertinent information on homicide investigation. By studying demographics affected, attendees will obtain greater insight on the subset of targeted population through cognitive research and comparative analyses. The presentation will provide a description of how the advent of new multimedia technology affects the way homicide investigations are presently conducted. Useful information that can assist in both domestic and global homicide investigation by exploring how they intertwine will be provided. Collaborative efforts between domestic and global jurisdictions will be necessary to investigate and prosecute the predators. Finally, the collaboration between traditional forensic investigation and technological forensic investigation will be examined.

Homicide, Fraudulent, Social Media

B16 TracHac: Non-Smartphone First Responder Forensic Tool

Marcus Rogers, PhD, Purdue University, Cyber Forensic Lab, 401 North Grant Street, West Lafayette, IN 47907; and Robert Winkworth, MSc, 656 Oval Drive, West Lafayette, IN 47907*

After attending this presentation, attendees will become familiar with the current state of mobile forensics of non-smart phones and will be briefed on a custom hardware/firmware tool developed by the Purdue Cyber Forensic Lab for use with this class of mobile phones.

This presentation will impact the forensic scientific community by detailing the ability to acquire and analyze the data contained within mobile/cellphones. By presenting details regarding the development of a tool to deal with the most commonly used disposable cellphones, the area of mobile phone forensics will be further matured.

The use of disposable cellphones by various criminals and terrorist groups is becoming increasingly more common. This should not be surprising, as this technology has outpaced any other class of technology including personal computers. Criminals and terrorists are very aware that law enforcement considers cellphones to be an important source of evidence and intelligence. As such, the use of low cost, non-contract, disposable cellphones are becoming increasingly common. It is assumed that these devices will be very difficult for law enforcement to connect to the criminal or terrorist and they will contain either a minimum of evidence or be impervious to the current automated cellphone forensic tools. As a result, government and law enforcement are struggling to develop low cost tools and procedures to deal with disposable cellphones. This task is further complicated by the need for these tools to be used in the field to close the gap between the discovery of actionable intelligence or evidence, and the interview of the suspect(s) involved.

This presentation is an overview of a research project conducted at Purdue University that was designed to investigate the feasibility of developing a tool that focused on low cost disposable cellphones (aka, TracFones®). The functional limitations of the tool were determined by the sponsoring agency. The tool was limited to being used with non-smart phones, being non-invasive and automated enough to be used by first responders with only a limited amount of digital forensic training.

These low cost disposable phones often have the limited functionality and as such they fall under the radar of most of the industry standard automated mobile forensic tools. The current project surveyed law enforcement in the southwest region of the USA regarding the most commonly seized disposable mobile phones. The results where then used to purchase a sample of these phones that ranged in price from $20 - $50. These phones were populated with known data and then tested against industry standard automated tools.

The results indicate that the automated tools could not process most of the phones as they did not appear in the tools list of supported phones. A proof of concept first responder hardware/firmware prototype for dealing with these phones was fabricated and tested. This presentation will discuss the specific results and procedures for testing the TracFones® against common industry mobile forensic tools as well as details of the fabrication and development of the Purdue Cyber Forensic TracHac tool itself.

Mobile Phones, Disposable Cellphones, TracFone®

B17 Applied Predictive Behavioral Modeling: The Role of Behavioral Sciences in Digital Forensics

Marcus Rogers, PhD, and Kathryn C. Seigfried-Spellar, PhD*, Purdue University, College of Technology, Knoy Hall of Technology, 401 North Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will be familiar with the current state of predictive modeling of cyber adversaries and cyber criminals using behavioral indicators and personality risk likelihood models. It will also provide those interested with a procedure and method to further this type of research.

This presentation will impact the forensic science community by providing understanding of the role that behavioral models can play in predicting adversarial behavior; digital forensics will be better able to take advantage of discoveries and tools from the other forensic sciences. It is also important policy decisions and responses are based on valid real world empirical evidence and not solely on theoretical abstract models that lack any real world credibility.

It has become obvious that purely technical solutions to try and deal with cyber adversaries in a *post hoc* fashion have failed. Business and

governments spend more money on cyber security than ever before, yet, if the most recent surveys are believed, the rate of cyber crime and other adversarial attacks is at an all time high. With the current economic crisis budgets are tight and as such it has become increasingly important that any technology expenditures be judged on their Return on Investment (ROI). This shift to an economic model has highlighted that technology alone will not mitigate the risk of cyber crime or cyber attacks.

The fields of predictive analysis and behavioral predictive modeling are now being applied to cyber security and cyber crime space. Several models have developed that, while appearing to be valid from an internal consistency approach, have failed when tested in real world settings. Most of these failed models rely on synthetic data sets, have improper factor loading and issues related to multicolinearity. Even more disturbing is the fact that these failed models are being used to inform government policy and to draft anticipated responses to cyber related events. A further disturbing finding is that in most cases the models were developed with little or no input from behavioral scientists and were based on the fallacy of game theory and behavioral economic: that people are logical rational actors. Human behavior is far more complex than envisioned in these rudimentary models and is more similar to the problem set used for Chaos theory namely irrational behavior.

The current project provides a meta-analysis of behavioral predictive analysis from the areas of insider threat modeling, hacker profiling and cyber terrorism/infowar. The research project focuses on a specific category of cyber criminal behavior (child pornography) and using real world data sets from law enforcement, tested various models to determine their goodness of fit and predictive validity. The Rogers-Seigfried (RS) predictive model was then tested against the same data sets to determine its fit and validity (research ongoing at time of submission)

The results of this research will be presented as well as suggestions for its investigative use and further development of the RS model. The meta-analytic procedure used in the study will also be discussed in order for other researchers to conduct similar studies.

Cyber Crime, Behavioral, Predictive Modeling

B18 Should We Fear Peer-to-Peer? Some Basics in Peer-to-Peer Investigation

Walter T. Hart, MBA, 149 Hamerton Avenue, San Francisco, CA 94131*

After attending this presentation attendees will gain a better understanding of peer-to-peer file-sharing application installation options and artifacts, possible uses of the applications, artifacts created during use, and approaches to investigating cases involving the use of peer-to-peer file-sharing applications.

This presentation will impact the forensic science community by providing a basic understanding of peer-to-peer file-sharing in investigations involving digital evidence including risks, vulnerabilities, and opportunities.

Peer-to-peer networking and other file sharing programs have become increasingly popular with users of the internet for sharing both large and small files. Many small organizations will use the capabilities of peer-to-peer file-sharing to effectively share information about their organization without having to maintain a centralized server. These could include families, bowling leagues, social organizations, and virtually any other groups of individuals sharing the same interests or a need to access the same data. Larger organizations utilize peer-to-peer file-sharing to economically and rapidly deploy very large datasets. There are a number of legitimate business uses for peer-to-peer networking and distributed file sharing including rapid dissemination of patches for software and new distributions of games and their data.

Peer-to-peer file sharing has also become popular with distributors and others sharing illegal files or illegally sharing legal files such as intellectual property rights protected software and media including movies, television shows, music, and almost any other copyrighted material that can be stored in a digital format. With rapid and widespread distribution of files, it is also possible to distribute viruses and other malware unchecked quickly. Without proper controls, this could provide entry into otherwise secure networks by unwitting users. These illegal uses of peer-to-peer networking have created a challenge in the digital forensic community due to the volume and perceived anonymity of the process. The number of available peer-to-peer applications and incredible volume of data being shared could easily overwhelm digital forensic examiners.

As is the case with many software applications, there are similarities between the many peer-to-peer applications but the differences and the forensic artifacts created are significant. This presentation will discuss many of these applications and some differences in the artifacts created. Examples will be given of the installation, configuration, and use of some common peer-to-peer file-sharing applications. This will include some of the standard, default installation options that both hamper and help investigators in these cases. Some general approaches to peer to peer investigative cases will be examined as well as the use of available tools to assist these cases. While generally accepted investigative techniques will uncover the presence of peer-to-peer installations, there are some specific tools directed specifically at investigating these products.

The presentation will also discuss smaller subset of file sharing applications appropriately called friend to friend as opposed to peer-to-peer as they are a group of applications that employs the ability to have some level of access control before users can share or download files. This subset of file sharing applications, while using some similar processes and technology, presents even greater challenges to the investigator as users frequently must “buy” their way into the group.

Peer-to-Peer, File Sharing, Friend-to-Friend

B19 Look Ma! No Wires: Challenges Wireless Networking Presents to Investigators

Walter T. Hart, MBA, 149 Hamerton Avenue, San Francisco, CA 94131*

After attending this presentation, attendees will gain an understand of the scope of wireless networking technology, potential problems it creates for investigators, and what methods can be employed to help account for the presence of wireless networking technology in the field.

This presentation will impact the forensic science community by providing a basic understanding of the principles and challenges faced by investigators because of the widespread use of wireless networking technology.

Wireless networking is everywhere around us from our phones, our computers, our printers, our storage devices, and even our cars. While this makes life for most very convenient, it presents many challenges to network security managers and to investigators of wrongdoing using digital devices. In virtually all types of digital investigations, investigators must plan for, and account for the presence of wireless devices. These devices provide vulnerability, opportunity, as well as possible defenses to allegations of wrongdoing involving digital evidence. Wireless technology provides both a way in and a way out of what might otherwise be a controlled network environment. Many businesses both large and small, households, and government installations, may have wireless access points. Many of these may have multiple wireless access points with varying levels of security on each. While this makes access to the network resources, including the internet, very easy, it also provides possible access to unauthorized persons or organizations to internal resources and/or the internet. Securing a network while providing a convenient level of wireless access has proved to be challenging, even for experienced network administrators. Many home users, unaware of the need to secure their home network, do not even attempt to do so, leaving themselves at risk to the loss of personal data and/or unauthorized access to their resources.

Additionally, many resources within a network can now be accessed wirelessly such as printers, scanners, phone systems, and internal data servers. While convenient to be able to use these resources without having physical infrastructure in place, this also provides an opportunity for data compromise.

Basic examples will be given of wireless network scanning resources, how they can be utilized, when they might be utilized, and precautions and pitfalls to using these tools. This will include mapping of the wireless network environment while conducting an investigation. The manufacturing of inexpensive wireless network scanning equipment that can be utilized in investigations as well as an introduction to the capabilities of some commercially available equipment will be briefly discussed. While an effective wireless investigators kit may not require any of these, some basic understanding of the capability is beneficial. Examples will be given of the use of this technology in investigations as well as investigations where it was not employed, but might have been.

A brief discussion about wireless security in the home, home office, and/or small business environment will highlight the basics of what might be done to help secure these networks. Some typical wireless installation options for common home or home office type wireless equipment will be used as examples. This will allow an investigator to possibly ask better probative questions during interviews of network administrators, home office users, and/or subjects of the investigation.

Wireless, Network Vulnerability, Wi-Fi

C1 Study on the Effects of Surface Roughness on Blood Patterns

Chan-Seong Park, PhD, and Nam-Soo Cho, PhD, National Forensic Service, Central District Office, Daejeon, 305-348, KOREA; and Young-Shik Choi, PhD, National Forensic Service, Division of Forensic Medicine, Seoul, 158-707, KOREA*

After attending this presentation, attendees will understand the feasibility of using a contact angle as a parameter to represent the surface characteristic at the blood impact velocity estimation.

This presentation will impact the forensic science community by introducing a new parameter capable of representing surface characteristic at the blood impact velocity estimation.

Blood impact velocity estimation plays an important role in crime scene reconstruction, and it is mainly studied by correlating the impact velocity to the number of spines radiating from the periphery of circular blood stains and the droplet volume. Paper, drywall, wood, etc. have been considered regarding the surfaces that blood impacts without introducing quantitative parameters that represent surface characteristics. This study focuses on the effects of the surface condition on the blood pattern by introducing the contact angle as a parameter to represent the surface.

The surface roughness of six stainless steel specimens used for blood impact tests was altered using a sand blasting process. The ten point roughness R_Z of the specimens is 16.3μm, 17.5μm, 19.6μm, 24.5μm, 29.3μm, and 38.1μm. The contact angle of each specimen was measured by using a sessile drop method and maintaining blood temperature at 37°C. Maintaining the blood temperature at 37°C through a thermal bath, the viscosity of the test blood was measured with a cone plate type viscometer. The blood was dropped vertically by using a syringe with an adjusted droplet volume of 20μl. The syringe was mounted onto an adjustable laboratory stand to allow for variation in release height from 10cm to 100cm. A computerized fluid dynamic (CFD) analysis was performed to study the mechanism of spine formation by using the Flow-3D program, which finds the boundary of two phases by the volume of fluid (VOF) method. The surface of the specimens was scanned using an ATOS-III system. The scanned surface image of the specimen was used as a boundary wall in the CFD analysis to study the surface effects on the blood pattern.

The measurement results of blood viscosity showed the shear thinning characteristic of a non-Newtonian fluid; that is, the viscosity decreases as the shear rate increases. The results showed deviation in comparison with the results yielded by the viscosity model equations of Carreau and Kensey due to individual differences in the blood composition. Additional study is required to determine whether individual deviations of blood can be generalized by introducing multiple variables acquired by many blood samples including the results of bio-chemical analyses. The contact angle increased linearly as the roughness increased, and variation among the blood samples was also observed. The spread factor was calculated as the ratio of the stain and the droplet diameter and was represented as a Reynolds number. It increased as the Reynolds number increased but decreased as roughness increased. From these observations, it was concluded that roughness affects the contact angle and the spread factor through flow resistance. This tendency was more clearly pronounced when the momentum of the droplet was less. From the droplet impact experiments and the CFD analysis, the difference in the spread factor of specimen R_Z = 0 μm with the other specimens becoming larger as the Reynolds number decreased. There was no spine formation for the specimen of R_Z = 0 μm and R_Z = 17.5 μm but with the specimen of R_Z = 38.1 μm at the droplet release height of 0.5 m. As the release height increased, there was spine formation for the specimen of R_Z = 17.5 μm but not with the specimen of R_Z = 0 μm. In the case of the specimen of R_Z = 0 μm, there was no spine formation throughout the range of release height. From these observations, it could be concluded that the spine formation depended on the droplet velocity as well as on the surface roughness. The contact angle can be an additional parameter to represent the droplet impact velocity together with the spine number and spread factor. Experiments to make a general equation to describe the blood impact velocity by introducing the parameter of the contact angle for various surfaces were prepared.

Blood Pattern, Contact Angle, VOF

C2 The Role of a Federally Funded Research Development Center (FFRDC) in Advancing Forensic Sciences

Donald J. Rudy, PhD, and Alan M. Foonberg, MS*, The Aerospace Corporation, 2310 East El Segundo Boulevard, El Segundo, CA 90245; and Robert Pentz, BS*, and Matthew Begert, MA*, The Aerospace Corporation, 2350 East El Segundo Boulevard, El Segundo, CA 90245-4609*

After attending this presentation, attendees will learn the history of support and contribution to the engineering forensic sciences field by Aerospace Corporation personnel. The Aerospace Corporation (Aerospace) operates a Federally Funded Research and Development Center (FFRDC) that was chartered to support national security space (NSS) for over 50 years. This presentation will explain how the practical application of knowledge and experience derived from technically complex space-related problem solving has contributed specific evolutionary and revolutionary advances to support engineering and multijurisdictional forensic sciences.

This presentation will impact the forensic science community by highlighting how Aerospace will continue to play an important role in the development of new forensic procedures and investigation methodologies.

Because Aerospace is an engineering firm, much of the work is to protect and prevent as well as support case work and incident response. Specific examples of case-based technical support will illustrate the capability to work with criminalists and the potential to contribute expertise when the solution set requires specific knowledge, equipment, or instruments not resident in a mainstream, accredited forensic laboratory.

Aerospace has a history of support to the federal government in the fields of law enforcement and public safety. Aerospace personnel were involved in the re-investigation of the assassination of President Kennedy as well as other high profile cases. Methods for the recovery of the video from tapes that have been soaked in solvent and had parts melted have been developed. Aerospace developed one of the first “gunshot residue” tests and has contributed substantially to the “less than lethal” weapon and body armor fields. Methods for remotely detecting “drug cooks” have been developed and field-tested. This technology was used to support post 9/11 terrorist attack analyses. A hyperspectral instrument was flown over the site in an effort to confirm or refute the presence of asbestos in and around the wreckage area as well as the landfill where the debris was deposited. Because of Aerospace’s assistance in the investigation of launch failures, there are Subject Matter Experts (SME) in the fields of explosives and the damage to various materials caused by explosions. This includes metallurgical analysis of failed materials, electron microscopy, and x-ray

analysis. Mass spectrometry analysis of bullet fragments has also been provided to various law enforcement agencies.

Aerospace ran a regional criminal justice technology support center that was operated for the DOJ. This center helped transition DOD technology to local agencies. Video tapes were processed by the Center's Imagery Exploitation Facility, leading to several arrests. Audio evidence was processed to extract voices from noisy audio tapes, including difficult dialects and computer aided voice identification. These cases covered a wide spectrum of criminal activity, ranging from employee theft to child molestation to murder. Aerospace personnel also implemented a computer crime facility to assist law enforcement in recovering, enhancing, and evaluating computer information. This facility is used to decipher evidence from confiscated computers – evidence often thought to be unretrievable. In addition, Aerospace helped develop GPS for the Air Force. This space based technology, small enough to be hidden, provides pin-point accuracy in tracking.

This support continues with the development of expertise in real-time forensics. Real-time forensics is a new field where rapid analyses support in-real-time situational awareness enables multijurisdictional decision making in excessively costly or life-and-death situations. This is becoming especially important in the area of Improvised Explosive Devices (IED)—both in their detection and their handling.

A proactive approach to real-time engineering forensics will be put forth. Combining real-time forensics with emerging concepts, and based upon lessons learned, will advance the capability to develop site-specific safety and security features that facilitate post-event response, recovery, and evidence collection, as well as to deter crime.

The presentation will conclude with a delineation of the path forward for using Aerospace's technical and process capability in alignment with recommendations of the National Academy of Sciences.[1]

Space Related Problem Solving, Rapid Analysis, Real Time Forensics

C3 Finding the Genie in a Bottle

Michael C. Hadka, PhD, Trillium Inc., 520 Peck Road, Downingtown, PA 19335; and James S. Smith, PhD, Trillium, Inc., 28 Graces Drive, Coatesville, PA 19320-1206*

The goal of this presentation is to describe how to use forensic science investigation/evaluation approaches on environmental release work where soil was impacted by past dumping practices.

This presentation will impact the forensic science community, by adding to the arsenal of petroleum hydrocarbon release site investigation techniques, using typically available or easily obtainable chemical analysis data to investigate the release. This technique has direct impact on who is the liable party for the release.

In 1994 during the removal of an underground heating oil tank behind a gasoline service station, a light non-aqueous phase liquid (LNAPL) described as a black viscous oil, was discovered floating on top of the groundwater. The service station at this location has been in operation since the 1930's. The underground heating oil tank, used to supply fuel for heating the station building, did not appear to be leaking when it was removed. Other potential sources of the LNAPL were the gasoline, diesel fuel, and kerosene stored in underground storage tanks (USTs) and dispensed at the service station. The service station building, USTs, and dispensers are located in the southeast corner of the property. About 100 yards of empty land separates the service station building from a tidal creek along the western boundary. The property is prone to flooding during extremely high tides. The groundwater is only about three feet below the ground surface. In the past, fill material was added to the east and north sides of the service station to raise the elevation of the property. Additional LNAPL was found in twenty-two test pits located within this fill material.

Samples of the LNAPL were submitted for gas chromatographic analysis using a flame ionization detector (GC/FID). The GC/FID chromatogram of the LNAPL collected from a pit in the southwestern corner of the property is shown in Figure 1. The chromatogram is a lubrication-type oil (i.e., mineral oil) with the center of the unresolved complex mixture (UCM) in the C_{22} to C_{23} n-alkane retention window. The n-alkanes C_{17} and C_{18} are present in the chromatogram along with the isoprenoids pristane and phytane. LNAPL samples from the eastern portion of the site do not have the C_{17} and C_{18} n-alkanes indicating that more aerobic biodegradation has taken place. Finding the lubrication-type oil next to the service station would lead one to suspect that this oil was used crankcase oil from oil changes that were performed at the station; however, zinc, lead, chromium, and copper were either not detected or were present at only a few parts per million in the oil. Zinc compounds are added to motor oil for antiwear and anticorrosion properties. Lead, chromium, and copper are wear metals from the engine that contaminates used crankcase oils. The concentrations of these metals in the LNAPL were too low to be considered used crankcase oil.

Other indicators that the LNAPL was not used crankcase oil was the polynuclear aromatic hydrocarbons (PAHs) content. There are two sources of PAHs in used crankcase oil, petrogenic and pyrogenic. Petrogenic PAHs are from the crude oil used to refine the oil while pyrogenic PAHs are formed from combustion. For pyrogenic PAHs, the unsubstituted parent PAH predominates over the alkylated PAHs of the parent and the abundance of the alkylated PAHs decreases with the increasing level of alkylation. For petrogenic PAHs, the alkylated PAHs predominate over the parent PAH. In used crankcase oil, there will be an increase in pyrogenic PAHs as the result of combustion blow-by in the engine.[1] In the LNAPL samples, the alkylated PAHs predominated over the parent PAH indicating that the source of the PAHs was petrogenic and not from combustion.

The LNAPL found at the site was co-located with fill material containing trash, glass bottles, glass shards, and documents from a nearby glass bottle manufacturer. One of the documents found dated back to 1940. Other material identified in the fill that was associated glass bottle manufacturing including bottle molds, bottle slugs, mold swabs, bottle brushes, and oil cans used to squirt oil into the molds. The trademark molded into the bottom of the intact bottles belonged to the same glass bottle manufacturer identified in the documents found in the fill. Research into glass bottle manufacturing practices revealed that the molds used to form the glass bottles are coated with a releasing agent called a mold dope before the molten glass is added. A mold dope is an oil containing a small percentage of other materials such as sulfur, graphite, rubber, and even old shoe heels.[2] The oil used in commercial mold dopes is mineral oil.[3] The GC/FID chromatogram of one commercial mold dope contains mineral oil similar to the LNAPL including the n-alkanes, pristane and phytane. The mold dope entered the waste stream of the glass manufacturer from drippings collected in pans and on absorbents, in sweepings, from used mold swabs, rags, and discarded mold oil containers. Workers from the glass manufacturer transported these wastes along with general trash, used bricks from the ovens, and unusable glass in dump trucks where it was used as fill in the marsh next to the service station.

Environmental Forensics, Lubricating Oil, LNAPL

C4 Attorneys, Journalists, Environmental Forensic Scientists, and Four Words

James S. Smith, PhD, Trillium, Inc., 28 Graces Drive, Coatesville, PA 19320-1206*

After attending this presentation, attendees will better understand the meanings of the terms theory and possibility as used by each of the experts involved in an environmental case.

This presentation will impact the forensic science community by highlighting the fact that scientific disciplines use different meanings for the same terms, which will cause confusion for the trier of fact.

In the realm of environmental forensic science, attorneys, journalists, forensic geologists, hydrogeologists, chemists, engineers, environmental scientists, and many other experts do not speak the same language. Yes, it is English; however, we define words differently which does not clarify the issue for the trier of fact. Instead it creates smoke and fosters junk science.

How often has the phrase, "it is the plaintiff's or defendant's theory been heard." A theory is a formula derived by inference from scientific data that explains a principle operating in nature. A theory implies a greater range of evidence and a greater likelihood of truth than a hypothesis. A theory allows one to make a prediction with a good chance of being correct. Environmental forensic science rarely, if ever, reaches this level of predictability.

Normally, environmental forensic science begins with a hypothesis. A hypothesis is a tentative assumption made in order to draw out and test its logical or empirical consequences. Environmental "whodunits" usually have insufficient evidence to provide more than a tentative explanation. Joseph P. Bono, MA, in the President's Message in the *Academy News*, September 2010, Volume 40, Issue 5, page 3, states "The six most questionable words used to formulate the justification for a conclusion by any forensic analyst are 'Based on my TRAINING AND EXPERIENCE.'" Numerous attorneys have been told that when those words are spoken at a deposition or in trial, they can count on the fact that the remaining portion of the sentence is being made up at the time. In other words, they are about to hear speculation. This brings me to two additional words to be defined.

It has been asked "isn't it possible?" more times than can be remembered. This word possible, should be eliminated from forensics. "Possible" is in the realm of expertise of a philosopher or a person of religion. As a forensic scientist, we do not have the expertise to determine the "possibility" of an explanation, hypothesis, or theory without testing to determine the probability of the hypothesis being asked.

It is the opinion "reasonable" means that the conclusion is based on logic, references, supported by and derived from a tested hypothesis, so that there is a good probability the hypothesis is correct or, at least, consistent with the facts. Instead, more often a lot of speculation is heard in the courtroom or, as some describe it, the "throw it against the wall and hope some of it sticks, and if it doesn't stick, throw some more" approach. Yes, we are back to "In my experience...." and "possibilities."

As a first step toward improving the situation, the deletion of the words "theory" and "possibility" in the language of environmental forensic science is recommended.

Possibilities and Probabilities, Hypothesis, Theory

C5 The Use of Regulations, Codes, Standards, and Acceptable Practice in Forensic Architecture and Engineering

Mark I. Marpet, PhD, PE, 14 Cowie Road, Chester, NJ 07930-9715*

After attending this presentation, attendees will understand the proper (and improper) use of regulations, codes, standards, and acceptable practices in the evaluation and analysis of hazards and defects, with emphasis on premises liability.

This presentation will impact the forensic science community by showing how codes, standards, regulations, and the more amorphous "accepted practice" forms the corpus that allows a practitioner to evaluate whether the hazard of a particular feature is or is not acceptable. Those who attend the presentation will be in a better position to underpin any such evaluations with reasonable certainty, in a manner that can better withstand *Daubert* and *Frye* challenges.

In establishing a breach of duty between parties, it is essential to understand just what duty one party owes to another. One way to establish that is to look at what has been codified in the technical literature. This presentation discusses the use of Regulations, Codes, Standards, and Accepted Practice (RCSAP) in establishing duties between parties and discusses how they should be used and are misused by forensic engineers and architects.

There exist two ways in which RCSAP can be used: (a) directly, by showing a violation of a legally mandated and on-point RCSAP provision, generally the violation of a Regulation; and, (b) indirectly, by showing a non-binding but on-point violation of acceptable practice.

This paper will use staircase elements as examples.

Definitions:

Regulations - A Regulation[1] has the force of law behind it. It can be international, federal, state, or municipal in origin. Generally speaking, violations of state and federal statutes can be used to show a violation of duty or, at least, evidence of such a violation. (Check the case law in your venue.) International treaties and municipal ordinances are not generally considered to be capable of generating negligence but can be an element of a violation of acceptable practice.

Codes - A code is a document generated by and under a committee of interested parties. For example, the International Building Code has been developed under the auspices of the International Code Counsel, Inc. Codes are generally far more comprehensive than are standards. There are many different types of codes. For example, building codes relate to construction and alteration of a structure; existing structures codes relate to the maintenance of an already built structure. The violation of a temporally-appropriate code is evidence of a violation of acceptable practice. If the code is incorporated by reference into a regulation, it can also be a direct violation of a regulation.

Standards - A standard is a document generated by a group of interested parties. The typical raison d'être for standards is to assist in commerce. Standards are generally narrow in scope and standards can range from company-wide to industry-wide to international. Standards are voluntary unless the parties involved agree to be bound by them or the standard is incorporated by reference into a statute or regulation. Standards having the most impact are known as full-consensus standards, meaning that all interested stakeholders are allowed input and substantial agreement must be reached on all of the provisions. On-point temporally-appropriate but non-binding standards may well be evidence of acceptable practice.

Acceptable Practice - Acceptable practice is the concrete manifestation of the way things should have been done in the time period and geographical area of interest. It is a catch-all category. The absence of on-point regulations, codes, and standards does not and cannot suggest that anything goes. For example, if a building had been built before the existence of a building code for the geographic area, that doesn't suggest that anything is acceptable. One must look to acceptable practice.

Appropriate use of RCSAP - For a regulation code, or standard to be directly used, it must be strictly applied, temporally appropriate and on-point. To show a direct violation, Regulations Codes, and Standards (RCS) must be strictly applied. The use of the document must fall within the ambit of the scope of the document. The timeframe of the RCS must match that of the object under study. Given all of that, violations of not-mandated standards and codes are not *per se* regulatory violations. Unless mandated by law, no one is required to follow a standard or code; however, non-binding documents can give insight into acceptable practice.

Acceptable practice can be developed using (temporally and geographically) "nearby" building codes, by age-appropriate textbooks, by an architectural survey of similar-age buildings, and anything else that can place the analyst into the time and practice mindset of a competent practitioner. Acceptable practice is a more amorphous concept than are RCSs. The thing about Acceptable Practice is that it is far more flexible than is RCS, but requires one to do one's homework.

Here's an example. When one looks at the apartment buildings in New York City built in the early twentieth century, it is clear that the main exits, which typically have one or two steps down to the sidewalk, were simply not built with handrails as the code of the era would appear to require. (The 1916 Building Code of the City of New York states that (§154) exterior stairways "shall conform … to the requirements … for interior stairs." Interior-stair requirements (§153.6) requires handrails on both sides" of a stairwell). But if an architectural element is evident in many or most of the built-in-the-same-era buildings, that strongly suggests how that element had been parsed in that era. (It is often the case that neighborhoods develop quickly after the infrastructural elements: water, sewers, electricity, and roads, fall into place. Thus, many of the original buildings in the same neighborhood are architecturally similar). It is clear that the architectural grammar of the teens and twenties of the twentieth century did not require handrails on the main entrances of buildings, notwithstanding what the literal wording of the code suggests. It's not that architects were ignoring the code; rather, architects did not consider the one or two steps at main entrance of an apartment building to be an exterior staircase.

What acceptable practice is not is something that is based upon "in my experience." In my experience doesn't reach the level that *Frye* or *Daubert* requires: as one's experience in isolation lacks both "general acceptance" and reproducibility. If there is no research backing up an opinion, no discussion in the literature of practice, nothing save someone's opinion, that opinion should be looked at with circumspection. One obvious issue; how on earth can any person practicing today talk about "in my experience" with respect to a building built in the 1920s?

Misuse of RCSAP: *Conflating A Violation With Causality* - One thing that is important to understand is that a "violation" of a regulation, a code provision, or a standard, is not in-and-of-itself tantamount to negligence. One must also establish that the violation is causal in any damages. A classic example of conflation of a violation of a code provision with the issue of negligence concerns handrails in stairs. Specifically, building codes, which were originally developed to ensure fire safety, placed early emphasis on the need to have handrails on both sides of all but the narrowest of stairs, and intermediate handrails on wider stairs. The intermediate handrails are both to channel downward (eliminating side-to-side traffic) rushing-down-the-steps-in-emergency crowds of pedestrians and to provide handrails for at least half of the stair users. But one or two people exiting a building do not need intermediate handrails, because one or two pedestrians can simply avail themselves—if they choose to—of the handrails at the edges of the stair.

Using Generic Standards To Establish A Specific Violation - Most building codes have somewhere a section that states that a building must be "reasonably safe and without nuisance." You must not rationalize that what you think is a hazard, therefore, violates that generic provision. In other words, because you think something is a hazard that doesn't per se cause a violation of that generic "keep things safe" provision of a code. In short, the RCS should not be used merely to wrap your ideas in the mantle, the imprimatur, of Standard or Code. What you think is a hazard may well be a hazard; but it does not become a hazard by citing to a generic "keep-things-hazard-free" RCS citation.

Equating Quantity With Quality - One does not need large numbers of RCS citations to prove a point. The experience here is that there is an inverse correlation between the quantity of standards cited and the relevance and utility of those standards. The plain fact is, two, two dozen, or two hundred not-on-point citations are not-at-all equal to one on-point citation. That said, if one is trying to show the state of accepted practice, the more temporally-appropriate citations, the better. If you are trying to show that large, square newel posts at the top and bottom of a staircase was the custom in 1900, one citation is good, two are better, and three are even better. If the citations are both local and geographically distant, that would be better yet.

Asserting that the absence of an on-point, temporally-appropriate standard implies that "anything goes" is nonsense. Dimensional rules that define how a staircase should be constructed date back to the late 1600s. There has been much written in the early practicum on stair dimensions. Carpentry texts from the late 1800s give suggested dimensions for risers and corresponding treads. Thus, the idea that, before codes had been published, any riser and tread dimensions would be acceptable is cynical nonsense. Again, in the absence of on-point RCS, acceptable practice must be researched. (Do your homework!)

Being Dogmatic In Areas Of RCSAP Flux Is Counterproductive
From at least the 1930s through the 1980s, handrail heights were set at 30–34 inches above stair nosings. From the 1980s, based upon research by Brian Maki, handrail heights were raised to 34–38 inches. Handrails that also serve as stair guards are allowed to be 42 inches high. Given all that, it is absurd to assert that a building built in, say, 1950, is defective because its handrails were 36 inches tall. It is arguably problematic to suggest that a building designed in 2000 that has 33 inch handrail heights, is hazardous because it violates the 2000 building code. It is a code violation, to be sure. But it was acceptable for over fifty years, so it would be hard indeed to establish that handrail height as a causal element in a stair accident.

Similar situations exist when looking at riser and tread dimensions, stair widths, and so forth. Architectural elements that change over time imply that it is no "right" or "optimal" answer. In a situation where codes have changed over time, and within reason (that is, the parameter under discussion is within the range of variation of code and/or acceptable practice), a "code violation" doesn't per se suggest a hazard.

C6 Apportionment of CERCLA Liability - A Case Study

Marc Zeppetello, JD, Barg Coffin Lewis & Trap, LLP, 350 California Street, 22nd Floor, San Francisco, CA 94104-1435*

After attending this presentation, attendees will understand how CERCLA liability was apportioned following trial in one case, in a decision affirmed by the U.S. Supreme Court, as well as the implications of that case for demonstrating a reasonable basis for apportionment.

This presentation will impact the forensic science community by illustrating how relevant data are used by the courts.

Burlington Northern v. United States, 129 S.Ct. 1870 (2009), was the first CERCLA action in which a district court determined the degree to which different parties contributed to the contamination at a site and apportioned liability accordingly.

In 1960, Brown & Bryant (B&B) opened an agricultural chemical facility on its 3.8-acre parcel. B&B carried two soil fumigants, D-D and Nemagon, manufactured by Shell Oil Company (Shell), and a weed killer, dinoseb, made by Dow Chemical.

In 1975, B&B leased an adjacent 0.9-acre parcel from the predecessors of BNSF Railway Company and Union Pacific Railroad Company (the Railroads), on which they parked application rigs, kept dinoseb cans, and stored empty Nemagon containers.

The site made the National Priorities List in 1989. In 1996, the United States and California Department of Toxic Substances Control filed cost recovery actions against B&B, the Railroads, and Shell. A major focus of the trial was whether the environmental harm was capable of apportionment, including the underlying analytical data regarding contamination on the railroad parcel.

Restatement (Second) of Torts Section 433A provides that damages are to be apportioned among two or more causes where there are distinct harms, or where there is a reasonable basis for determining individual contributions to a single harm. The Railroads argued that either the limited soil contamination on their parcel was a separate harm from the extensive soil and groundwater contamination on B&B's property, or the site contamination constituted a single harm that could be apportioned based on the relative mass of contaminants in groundwater attributable to each parcel. The Railroads submitted expert testimony to support this basis for apportionment.

The government argued the contamination constituted an indivisible harm that could not be apportioned, claiming releases on the Railroad parcel contributed to the groundwater contamination. Because the evidence was too uncertain to quantify the respective contributions from the two parcels, the Railroads were arguably jointly and severally liable.

The government also argued that apportionment is discretionary, and to avoid injustice to the plaintiff agencies, the court should allocate (insolvent) B&B's orphan share to the other defendants.

Shell argued any D-D contamination associated with product deliveries had not impacted groundwater and that it was not liable for the "hot spot" of dinoseb contamination because dinoseb was not its product.

The district court found the soil and groundwater contamination at the site was a single harm. While acknowledging the Railroads' evidence for apportionment, the court did not find that evidence to be helpful because it was unable to translate the expert's formula for apportioning the harm into usable data. Instead, the court's approach considered the size of the Railroad parcel relative to the total site area, the length of time it was leased to B&B, and that releases of dinoseb and Nemagon on the Railroad parcel contributed to the contamination. The court calculated the Railroads' divisible share to be 6%, then added a 50% allowance for calculation errors and concluded the Railroads' divisible share was not more than 9% of the total site response costs.[1]

Citing evidence as to the estimated quantities of various types of D-D spills, the district court apportioned 6% of total site response costs to Shell.

Finally, the district court concluded that reallocating B&B's orphan share would be "manifestly inequitable."[2]

On appeal, the Ninth Circuit reversed the district court's apportionment rulings and imposed joint and several liability on the Railroads and Shell. While agreeing that, conceptually and with adequate information, the contamination traceable to the parties could be apportioned, the Ninth Circuit found that the numbers used by the district court bore an insufficient logical connection to the pertinent issue and lacked the necessary precision.

The Supreme Court reversed the Ninth Circuit and held that the district court's apportionment of 9% of the harm to the Railroads was supported by the evidence and consistent with applicable principles, concluding "that the facts contained in the record reasonably supported the apportionment of liability."[3]

The Court acknowledged the Ninth Circuit's criticisms, but determined that "it was reasonable for the court to use the size of the leased parcel and the duration of the lease as the starting point for its analysis."[4] The Court also found any miscalculation due to the district court's conclusion that Nemagon and dinoseb accounted for two-thirds of the contamination was harmless since the final apportionment determination included a 50% margin of error. Had the court limited its apportionment calculation to the amount of time B&B used the Railroad parcel and that parcel's percentage of total site area, it would have reached the same result.

The Supreme Court applied a clearly erroneous standard of review to the district court's apportionment of liability to the Railroads, as reflected by how the Court framed the issue – whether the record provided a reasonable basis for the district court's decision.

The Court's decision demonstrates that a CERCLA defendant may meet its burden of proving a reasonable basis for apportionment by introducing evidence sufficient for the district court, as fact finder, to determine the degree to which different parties contributed to the harm, even while not accepting the defendant's own arguments and expert testimony as factual bases for apportionment.

Affirming the district court's apportionment determination as a reasonable approximation of the Railroads' contribution to the harm, the Court rejected the Ninth Circuit's demand for "sufficient data to establish the precise proportion of contamination" attributable to the Railroad parcel.[5]

The Ninth Circuit agreed with other courts that, with adequate information, divisibility may be established by volumetric, chronological, geographic, or other types of evidence.[6] The Supreme Court's decision establishes that such "simplest of considerations" may be sufficient to provide a reasonable basis for apportionment,[7] affirming that a calculation limited to the amount of time B&B used the Railroad parcel and that parcel's percentage of the site area adequately supported the district court's apportionment determination.

Courts have long acknowledged that CERCLA allows for apportionment while almost always imposing joint and several liability. *Burlington Northern* demonstrates that a district court has considerable discretion to weigh the evidence relevant to a defendant's contribution to site contamination and find that such evidence provides a reasonable basis for apportionment.

C7 A Really Big Corrosion Litigation

Robert N. Anderson, PhD, RNA Consulting, Inc., 27820 Saddle Court, Los Altos Hills, CA 94022*

After attending this presentation, attendees will learn the basis of metal corrosion and the dezincification phenomena that occurs with some types of brass fittings. This presentation also will address how a very large corrosion litigation matter was successfully handled.

This presentation will impact the forensic science community by identifying a large and growing area of litigation brought on by the changing nature, due to materials costs, of the brass fittings.

In one housing area, 34,000 homes suffered or were going to suffer severe water leaks due to failure of their plumbing system. A number of corrosion engineers were employed by various parties including tubing and fitting manufacturers, building contractors, plumbers, insurance companies, and homeowners. The plumbing system in question used Kitec brass fittings in conjunction with PEX tubing. The PEX tubing is made by cross linking high density polyethylene. The tubing was PEX-Al-PEX with a layer of aluminum sandwiched between PEX layers to prevent diffusion of oxygen into the water system and, hopefully, prevent corrosion from occurring.

The brass fittings are attached to the PEX tubing by compression rings or clamps. The plumbing system failures involved uniform layer type dezincification, as opposed to pitting type dezincification, with subsequent loss of strength of the brass fittings.

In dezincification, the zinc leaches out, leaving behind a porous copper sponge. The resulting sponge fitting leaks at the connection points. The leached zinc causes build up of bulky mounds of zinc oxide in the water fitting, resulting in constricting and choking the normal water flow. This is referred to as meringue dezincification.

The failed brass fittings were manufactured from a high zinc duplex alloy of 35 - 40% Zinc. The potable water in that area was considered non-corrosive and had a neutral Langelier index, but it appeared to be aggressive to the high zinc brass fittings.

The brass fittings were failing and leaks were occurring in three to six years. Factors that increase dezincification:

- High temperature
- Low water speed (stagnant water)
- Low aeration
- Zn concentrations above 15% in the brass
- High chloride content in the water

The litigation issues focused on the following:

- The plumbing installation was approved by the governing agency.
- The zinc content at 35% was unusually high in the failed fittings.
- The water was considered non-corrosive.
- Fitting manufacturing processes were questionable.
- Poor plumbing installation practices causing physical stress on the fittings.
- The use of an aluminum layer in the tubing was a problem.

Examination of the Cu-Zn phase diagram showed that an intermetallic compound of Cu-Zn formed at high concentrations of Zn. The intermetallic compound was susceptible to dezincification under certain water conditions that normally were not considered corrosive to other metals.

An empirical plot developed in 1961 that correlated water composition in various parts of England with the occurrence of dezincification of brass fittings was found to provide an explanation of the corrosive nature of the water in the housing area of failures.

The "Turner Diagram" plotted chloride concentration versus $CaCO_3$ hardness, and showed that the water used in the area of the homes in litigation was aggressive to brass. The water, in combination with the high zinc content in the fittings, was the cause of the dezincification.

Because copper costs four times more than zinc, more high zinc brasses will be found on the market. These "yellow" brasses will be susceptible to dezincification failure, in particular with soft water containing more than 40ppm chloride.

Corrosion, Dezincification, Brass Fittings

C8 Being Significant and Watching Your Figures

Denise A. Shepperd, BS, Trillium, Inc., 2014 Carol Drive, Wilmington, DE 19808*

After attending this presentation, attendees will better understand the importance of the relationship between the accuracy of a measurement system and the number of significant figures used to report the results.

This presentation will impact the forensic science community by demonstrating the relationship between the demonstrable accuracy of a result and the defensibility of the data in legal proceedings.

A Google search of the term "significant digits" offers up a variety of definitions. They all boil down to this: significant digits are those digits in a number that can be defended based on the accuracy of the measurement system used to generate them.

Every analytical chemistry course includes a unit on precision and accuracy and a lesson about significant figures. Students are taught what they are, how to use them, and why they are important. When this lesson is forgotten, the illusion of greater accuracy than the analytical methods can produce is proliferated. For instance, when using a calibration equation to calculate a result, any number of digits and decimals can be produced, but only those that are representative of the method's accuracy can be defended.

No analytical result can be more accurate than the factors used to determine it. In other words, if a balance that is accurate to 0.1 g is used to weigh a sample, a result of 0.11g cannot be defended because that result implies greater accuracy and precision than it was possible to achieve with the measurement system. Likewise, a calibration curve produced by analyzing standards at concentrations of 5.0, 10, 50, 100, and 200pg/mL cannot produce a defensible calculated result of 5.005pg/mL.

The last significant figure in an analytical measurement is the only figure that should express variance. For instance, a result of 1.6 reflects two significant figures and an error term of 0.1, meaning that the result could be 1.5, 1.6, or 1.7. The error term is expressed as 62 parts per thousand or 6.2%. If the same result is reported with three significant figures, as 1.62, a smaller error term is expressed (6.2 parts per thousand or 0.62%), meaning that the result could be 1.61, 1.62, or 1.63, but not 1.5 or 1.7. Supporting this level of accuracy and precision at this concentration range would require that the laboratory can routinely and demonstrably analyze two portions of a project-specific sample with duplicate agreement of less than one relative percent difference (RPD).

The second of the four non-exclusive factors that make up the criteria used to judge the validity of an expert opinion in a *Daubert* test asks, "Is there a known error rate or variability?." [1]

Every measurement has an error term. Any measurement system will produce a range of results for a single sample when that sample is repeatedly measured for a given analyte. The known or potential error term is a statistical measure of how similar (or different) these results are likely to be. In analytical chemistry, the method includes the entire analytical procedure used to identify and measure the concentration of an analyte in a sample matrix. Some sources of error are unavoidable, while some sources can be minimized by following good analytical practices and sound quality control procedures. The objective of any experimental process should be to produce the most accurate result possible, i.e., a result with the smallest possible error term. The use of good laboratory practices and sound quality control procedures is essential in a laboratory's effort to reduce the error term, but it cannot be eliminated. This measurement uncertainty is reflected in the number of significant figures used to report the results. It is critical to present results using only the significant figures that are appropriate to the data set. The error term implied by the significant figures must be supported by the available data and documentation and must be demonstrated to be repeatable for the results in the data set.

Significant Figure, Error Term, Defensibility

C9 Why Current Detection and Reporting Limits are Useless in Low Level Data Evaluation

Michele W. Sanders, BS, and Jack R. Hall, BS, Materials and Chemistry Laboratory, Inc., East Tennessee Technology Park, Building K-1006, 2010 Highway 58, Suite 1000, Oak Ridge, TN 37830*

After attending this presentation, attendees will have a better understanding of the basis of laboratory detection and reporting limits, and how those limits fail to provide the information necessary to evaluate low level data with a high degree of confidence.

This presentation will impact the forensic science community by providing data users reasons for the inadequacies of the current complex series of terms used for detection and reporting limits.

Currently, the environmental field is plagued with a number of acronyms for both detection limits (DL) and reporting limits (RL). For example, method detection limit (MDL), minimum quantitation limit (ML), level of detection (LD), limit of quantitation (LQ), estimated detection limit (EDL), practical quantitation limit (PQL), contract required quantitation limit (CRQL), etc. These are all derived either statistically, by contract, or from regulatory limits. None of the terms used are based on results from real world samples. The environmental laboratory industry is being required to report results down to the DL without justification or proof; thus reporting non-defendable data which the user may misinterpret. Laboratories have even been judged based on their MDLs (labs with lower DLs are better!). DLs and RLs are not the same and the terms should not be used interchangeably. The DL should be the concentration at which one can state with a known confidence level that an analyte is present. The RL should be the lowest concentration at which the analyte is determined within a known precision and accuracy range. Unfortunately, RLs in most cases are calculated as a factor times the DL, with no requirement to confirm for a specific sample. For example, a statistical approach (MDL) was originally developed by the USEPA to demonstrate that the methods being promulgated for regulated analytes had detection limits below the regulatory levels in discharge permits of Publicly Owned Waste Treatment facilities (POWTs) and receiving water bodies. The formula is MDL = 3.143 times the standard deviation of the measured analyte concentration of seven replicate spiked laboratory water solutions. The USEPA minimum level of quantification (ML) was originally stated as ten times the standard deviation used to calculate the MDL in the described way. The ML is also commonly calculated as 3.1 times the MDL.

The original intent of the USEPA was to use the MDL procedure to determine detection limits of analyte(s) in the method user's samples. Instead, the MDL requirement has been interpreted such that the environmental laboratory industry is required to determine MDLS on all analytes, general matrix types, and instruments used, but not on specific samples.

This approach has led to unbelievably low DLs and RLs in laboratory reports and subsequently in project databases. How does one defend a beryllium in soil result of <0.01mg/kg when the associated matrix spike (MS) and matrix spike duplicate (MSD) data has 15% and 12% recovery with spiking at the 1mg/kg level? The laboratory flagged the low recovery MS and MSD data as a matrix effect. This implies that the sample itself interferes with recovery of beryllium. Using the reporting limit of <0.01mg/kg would be in error and if the regulatory limit was 0.05mg/kg, one would be reporting non-defendable data that truly is wrong. The data show that one can only state with any certainty a reporting limit of 1 mg/kg.

Now, if the same data in the above example were reported for the analysis of hexavalent chromium by Ion Chromatography in soil, then the results would be understandable and defendable. Hexavalent chromium is converted to trivalent chromium by this sample matrix and thus gives low recoveries for MS and MSD samples. This can be proven by having acceptable recovery of a post digestion spike sample.

Other examples of the pitfalls of DLs and RLs and their application will be presented. Recommendations will be made on a more realistic approach to a reporting limit and its confirmation, using appropriate quality control samples, what information should be provided to the laboratory to achieve useful data and most importantly, what questions to ask the laboratory to better understand the data.

Detection Limits, Reporting Limits, Quantitation Limits

C10 On Confidence Intervals Used to Determine Background Concentrations

Willem A. Schreuder, PhD, Principia Mathematica Inc., 445 Union Boulevard, Suite 230, Lakewood, CO 80228*

The goal of this presentation is to make attendees aware of the consequences of including and excluding outliers including non-detects when determining background concentrations.

This presentation will impact the forensic science community by showing what confidence intervals represent.

Determination of a background concentration is often a controversial exercise. It is further complicated by noisy data which requires a statistical expression of what the background concentration measurements mean, typically expressed as using a confidence interval.

A confidence interval simply expresses to probability that the mean value of the measurements will be less than a given value. When a finite set of measurements of the same quantity (background concentration in this instance) is made, the mean value represents the most likely (expected) value of that quantity. It is possible, however, that the mean value of a finite set of measurements does not represent the true mean of the entire population, in this instance all the possible samples that could be taken. To express the certainty with which we can say that the set of samples we do have represents the true value you would find with a much larger (or infinite) set of samples, it is customary to express the result in terms of a confidence interval.

When the measurements are consistent, that is, the standard deviation of the measurements are small, the confidence intervals are narrow. Specifically, if all the measurements are exactly the same, the standard deviation is zero, and it is extrapolated that no matter how many more samples are taken, the measured value would always remain the same. However, when the data are noisy and have a large standard deviation, the confidence intervals can be very large. For such data, the actual population of concentrations vary and exactly which subset of all the possible subsets we measure could give very different answers for the mean. As such, the large confidence interval expresses the fact that the true mean of the entire population may be poorly captured by the actual subset of measurements taken.

Special care should be taken with the treatment of extreme values, sometimes called outliers, as such values would increase the standard deviation of the data and hence the confidence intervals. On the low end of the concentration range are often non-detected values, while at the high end there may be outliers which may actually be the result of sample contamination or influence by the source being investigated.

Where background concentrations are relatively low, it is common to find a number of non-detects in the data set. Since concentrations are strictly positive and often show a log-normal distribution, selecting the specific concentration to use for the non-detect is very important. Half the detection limit is often used; however, when the detection limit varies among the samples, this may introduce an artificial variation in the sample set since the detection limit simply expresses an upper bound on the true concentration, while the actual concentration may show little variation among samples. Conversely, it is possible that the actual concentration varies greatly among the samples, but that this concentration is below the detection limit and that the same detection limit is reported for many samples. This would artificially reduce the variability.

This presentation discusses the statistical basis of confidence intervals, and demonstrates using examples the consequences of different ways used to treat these outliers.

Confidence Interval, Background Concentrations, Statistics

C11 Application of a Monte Carlo Analysis to the Johnson and Ettinger Soil Vapor Intrusion Model

Todd R. Crawford, BA, Crawford Independent Analysts, 16 Wintergreen Road, Queensbury, NY 12804*

After attending this presentation attendees will be able to recognize the forensic distinctions between applying a Monte Carlo analysis to estimate the most likely impact of soil vapor intrusion as opposed to calculating unique solutions to the Johnson & Ettinger Vapor Intrusion model.

This presentation will impact the forensic science community by providing understanding of how models are often used to develop the justification for forensic investigations and actions. In order to apply the models correctly, the users must recognize when a Monte Carlo analysis is appropriate.

Models are used in environmental investigations to describe the site conditions using the best available data. Known values are combined with estimates of unknown values to develop a representation of the historical or current or future site conditions. Confidence in the model may be increased as the site description improves, either by acquiring more data, or by improving the sophistication of the model. However, an environmental model should be as simple as possible to utilize or else its complexity will overwhelm practitioners.

Federal guidance and many state regulations cite the Johnson and Ettinger soil vapor intrusion model to describe the interactions of environmental factors which could influence the migration of a volatile chemical in groundwater into soil vapor and thence into the indoor air of a building. The Johnson and Ettinger (J&E) model calculates an attenuation factor, α, for the ratio of the subsurface soil vapor concentration versus the indoor air concentration due to vapor intrusion. Some of the J&E model inputs include chemical reference values, scientifically derived characteristic values, measured site specific values, and estimated site information. The J&E model's complexity is suggested by publications intended to simplify its use.[1] Confidence in the representativeness of the model is generally low when it is tested against a small number of samples from a site, but for large sites the average value of the modeled α has been shown to approximately represent the average attenuation factor for large numbers of samples.[2]

The failure of the J&E model to represent site conditions for small numbers of samples may be due to short-term fluctuations in some site factors that have very large effects on the model, but may not represent the average conditions found when analyzing many samples from the same site. The measured attenuation factors for a pair of samples could be predicted with choice selections of parameters in the J&E model, but using EPA recommended parameters probably will not generate a comparable result.

A Monte Carlo analysis using parameters from EPA and API vapor intrusion guidance gives a probability distribution for α. Single determinations of α may vary by several orders of magnitude depending on the values selected for the J&E model parameters, but the central tendency of the Monte Carlo probability distribution for α has a much smaller range. As critical input factors for the model are varied, the overall impact on the central tendency of α is less than the variation predicted from unique determinations of the model.

EPA has compiled a vapor intrusion database (http://www.epa.gov/oswer/vaporintrusion/vi_data.html) which was queried for the average attenuation factor for all results for trichloroethylene detected in soil gas versus indoor air. The average attenuation factor calculated from the database (N=75) was $1.8x10^{-3}$ and the 50th percentile was $1.2x10^{-4}$ (range $9.7x10^{-7}$ to $5.5x10^{-2}$). A Monte Carlo simulation for TCE vapor intrusion using the J&E model gave an average α of $2.3x10^{-4}$ which also was the same value as the 50th percentile of 20,000 iterations (range $1.3x10^{-5}$ to $8.1x10^{-4}$).

The Monte Carlo analysis gives a much narrower range of attenuation factors than are found in the EPA database of field measurements. However, the range of possible values of site specific parameters is limited for the Monte Carlo analysis, which tends to limit the range of values generated by the calculations. The mean value of the Monte Carlo analysis is comparable to the mean of all values in the EPA database, which is more precise than the range of estimated attenuation factors calculated in the EPA reference guidance.

A Monte Carlo analysis of the J&E model with a defined set of site specific characteristics will predict a small range of reasonable values of α, while a deterministic approach to using the model to describe vapor intrusion at a site might not be any more accurate than a best guess. The Monte Carlo analysis can be used to predict the most likely site conditions.

C12 Standardization of Risk Assessment: Why It Doesn't Always Work

James S. Smith, PhD, Oak Creek, Inc., 60 Oak Creek, Buxton, ME 04093-6616*

After attending this presentation, attendees will become aware the potential pitfalls of using a standardized risk assessment approach in the characterization of human health risk at hazardous waste sites.

This presentation will impact the forensic science community by providing attendees with an appreciation for the potential shortcomings inherent in the use of a standardized approach to risk assessment at hazardous waste sites.

Over the last two decades, state and federal regulators have been working to standardize the conduct of human health risk assessments at hazardous waste sites. Regulators have long sought a process of human health risk assessment that is, quick, efficient, consistent, and easy to understand. The application of a standardized approach to risk assessment, however, does not always provide human health risk information that is useful to risk managers. This is because standardization of this process relies on the use of generic exposure parameters, equations, and other information in preference to site-specific information.

Actions taken to clean up Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Superfund sites are designed to be protective of human health and the environment. At such sites, a

baseline assessment of human health risk is an integral part of the Remedial Investigation/Feasibility Study (RI/FS). The goal of the RI/FS is to gather information sufficient to support an informed risk management decision regarding which remedy appears to be the most appropriate for reducing health risks. Specific U.S. EPA guidance relating to the performance of baseline risk assessments identifies them as "site-specific" assessments of human health risk that can "vary in both the detail and the extent to which qualitative and quantitative analyses are used," characterizing the complexity and particular circumstances of a site. U.S. EPA experience has shown that Superfund sites are complex, characterized by heterogonous wastes, extreme variability in contamination levels, and a variety of environmental settings and potential exposure pathways. Because the complete characterization of a site, necessary to reduce uncertainty, is not feasible or cost-effective, U.S. EPA adopted a streamlined approach to the RI/FS and the selection of appropriate remedies, making a policy decision "to use, wherever appropriate, standardized assumptions, equations, and values in the human health evaluation." According to the U.S. EPA, this policy "has the added benefit of making the human health risk assessment easier to review, easier to understand, and more consistent from site to site." The inherent problem of such streamlined standardized approach to assessment of human health risk is that it may not always provide useful information to risk managers about which remedy is most appropriate for reducing human health risk.

The Massachusetts Department of Environmental Protection (MassDEP) has taken a similar approach to the conduct of human health risk assessment with its ShortForms. Provided as a "shortcut" or "streamlined method for evaluating potential human health risk at hazardous waste sites" MassDEP provides ShortForms (i.e., computer spreadsheets) to calculate human health risk associated receptor exposure to environmental media. These ShortForms only require the operator to input an appropriate exposure point concentration (EPC) for the media of interest in order to quantify human health risks. Similar to other standardized approaches to human health risk assessment, the resulting estimates of human health risk may not always provide useful information to risk managers about which remedy is most appropriate for reducing human health risk.

While anyone might use a standardized approach to perform risk assessment, only qualified professionals are capable of determining whether the resulting health risk estimates are useful to risk managers in the selection of appropriate remedies. In this presentation, the potential for several standardized approaches to human health risk assessment used by state and federal regulators to result in inappropriate risk management decisions will be examined.

Risk, Assessment, Standardization

C13 The Analysis of Gun Shot Residue Using Transmission Electron Microscopy

Whitney B. Hill, MS, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Suite 400, Duluth, GA 30096*

The goal of this presentation is to present to the forensic community information about how Transmission Electron Microscopy (TEM) coupled with Energy Dispersive X-ray Spectroscopy (EDS) can be instrumental in the analysis of nano-sized gun-shot residue (GSR).

This presentation will impact the forensic science community by showing the advantages of using TEM-EDS to identify nano-sized GSR particles released during the discharge of a firearm.

Routine GSR analysis is normally performed by Scanning Electron Microscopy (SEM). Classic GSR particles are usually defined as spherical particles, 1um in size and larger, containing three main components, which are Pb, Ba, and Sb. Therefore, particles less than 1um in size are usually overlooked during routine analysis for GSR by SEM.

For this presentation, an experiment was done using TEM-EDS to characterize the particles released during the discharge of a firearm. Samples of GSR were generated by firing five rounds of Browning High Powered Sellier and Bellot ammunition from a 9mm handgun in an enclosed facility. Air samples were collected simultaneously with the firing of each round of ammunition. The air pumps were set up adjacent to the muzzle and ejection port of the handgun. An ambient air sample was collected 12 hours after firing the initial five rounds of ammunition. A second set of GSR samples was generated by firing three rounds of Winclean ammunition also from a 9mm handgun in an enclosed facility. Air samples were also collected simultaneously with the firing of each round of the Winclean ammunition. The GSR samples were collected on 0.45 µm pore sized, 25mm diameter, Mixed Cellulose Ester (MCE) filters and prepared according to procedures described in the NIOSH 7402 method for TEM. TEM-EDS analysis of the filters showed that particles, both spherical and non-spherical, of varying sizes and elemental compositions, were released into the atmosphere during the discharge of each round of ammunition. A significant amount of the particles observed by TEM-EDS were less than 1µm in size. However, the spherical GSR particles containing Pb, Ba, and Sb, analyzed by TEM-EDS, ranged in size from greater than 1µm to less than 100nm. Analysis of the ambient air sample showed that nano-sized, spherical GSR particles containing Pb, Ba, and Sb were still suspended in the air 12 hours after the initial rounds of ammunition were discharged.

This study confirmed that many GSR particles less than 1µm in size are released into the atmosphere during the discharge of a firearm and these particles tend to remain suspended in the air for longer periods of time than the larger particles. Therefore, TEM-EDS can be instrumental in the analysis of nano-sized GSR particles especially in the absence of those greater than 1µm in size. Future research involves determining how long and under what conditions, nano-sized GSR particles can remain suspended in the air.

GSR, TEM, Nanoparticles

C14 Chemistry Ignored — A Case Study

Carol A. Erikson, MSPH, Trillium, Inc., 356 Farragut Crossing Drive, Knoxville, TN 37934; and James S. Smith, PhD, Trillium, Inc., 28 Graces Drive, Coatesville, PA 19320-1206*

After attending this presentation, attendees will understand how the evaluation of chemical tracers in ground water can play an important role in a site investigation.

This presentation will impact the forensic science community by illustrating a valid and useful means of evaluating ground water data to interpret the source and migration of contaminant plumes that is readily available but not routinely used.

In an all too familiar scenario, drinking water wells in a residential neighborhood were found to be contaminated with low concentrations of chlorinated solvents; 1,1-dichloroethene (11DCE) was the initial red flag. A chemical release from a neighboring manufacturing facility (Facility A) was alleged, and, in the subsequent toxic tort litigation, the facility was named as a source of the contamination. After multiple site investigations were performed by at least five different consultants, the analytical data were compiled into a single data base. Evaluation of these data yielded an unexpected result: two plumes were identified, and only one was linked to Facility A.

While it was clear that both a "Northern Plume" and a "Southern Plume" were present, it was not clear where, or if, they overlapped. Since both plumes contained chlorinated solvents and ultimately migrated toward the affected neighborhood (Neighborhood A), this was an important determination. Initially the request was to review isotopic analysis data to determine if the plumes could be differentiated on this basis, but since isotopic data were only available for Facility A, there was nothing to

compare. Instead, the entire set of ground water data was reviewed with a focus on chlorinated solvent chemistry, and used the biodegradation and hydrolysis daughter products of the source contaminants as chemical tracers to map the plumes.

Results for three source contaminants (1,1,1-trichloroethane [TCA], trichloroethene [TCE], and tetrachloroethene [PCE]) and four degradation products (11DCE, 1,1-dichloroethane [11DCA], 1,2-dichloroethane [12DCA], and cis-1,2-dichloroethene [c12DCE]) were plotted separately. For simplicity, the plotted result for each sample location was estimated as an average over time and depth. From this first set of maps, several things were clear: (1) there was a significant source (Facility B) of PCE south and west of Facility A; (2) no PCE was detected above 10 ppb at Facility A; and, (3) both Facility A and Facility B were significant sources of 111TCA and 11DCA in the ground water. 111TCA was looked at more clearly.

111TCA hydrolyzes to form 11DCE. Because biodegradation is not involved, this chemical reaction in ground water affords an opportunity to estimate the age of the 111TCA (i.e., how long it has been dissolved in the ground water at that location) based on the relative concentrations of these two analytes, the temperature of the ground water, and the kinetics of the hydrolysis process. At the likely source of the Southern Plume, estimated 111TCA ages ranged from 14-20 years; immediately down gradient of this source (Neighborhood B), ages were estimated at 26-41 years. At Facility A, there were not enough data to calculate any 111TCA ages, but estimates ranging from 22-39 years, were calculated for Neighborhood A. A plot of the estimated ages shows a plume that travels east, then curves to the northeast, skirting Facility A entirely. This trend did not; however, convince the clients. So, it was tried again.

111TCA biodegrades in ground water to form 11DCA. The ratio of the 11DCA concentration to the total calculated 111TCA concentration (measured 111TCA + measured 11DCA + [4.545 x measured 11DCE]) allows us to evaluate the relative amount of 111TCA biodegradation that has occurred at each sample location. This plot showed a clear distinction between the two plumes: at Facility A, the ratios ranged from 0.27 to 0.62, while at Facility B they ranged from 0 to 0.08. Clearly, the 111TCA at Facility A is more biodegraded than the 111TCA at Facility B. At Neighborhood A, the ratios were a striking match to the 111TCA from Facility B, and it was concluded that Facility A (the Northern Plume) did not contribute to the contamination in Neighborhood A.

Unfortunately, the clients were not comfortable with the approach and conclusion, partly because results less than 10 parts per billion were excluded, where analytical error is highest, and partly because this was not a standard approach to using ground water tracers. Remaining confident; however, that the chemistry of chlorinated solvents in ground water is a reliable and readily available means of mapping plumes and identifying sources of contamination.

Chlorinated Solvents, Groundwater, Chemical Tracer

C15 The Road to the Supreme Court

James S. Smith, PhD, Trillium, Inc., 28 Graces Drive, Coatesville, PA 19320-1206*

After this presentation, attendees will understand the chemistry behind the contamination at a contaminated railroad and agricultural chemical site and the reliability, or lack thereof, of the analytical data presented to the court.

This presentation will impact the forensic science community by illustrating the questionable nature of one set of data that was presented to, and ultimately used by, the court in apportioning CERCLA liability.

Burlington Northern v. United States, 129 S.Ct. 1870 (2009) was the first CERCLA action in which a district court determined, using the data presented as evidence, the degree to which the parties contributed to the contamination at a site and apportioned liability accordingly. In 1995, the railroad companies requested an evaluation of the analytical chemistry and the fate and transport of agricultural chemicals at a site in Arvin, California. The chemicals of concern were:

- Dinoseb - a herbicide used for potato crops
- 1,2-Dichloropropane (1,2-DCP) - a nematocide used for root crops
- cis- and trans-1,3-Dichloropropene (1,3-DCPe) - a nematocide used for root crops
- 1,2,3-Trichloropropane (1,2,3-TCP) - an impurity in both 1,2-DCP and 1,3-DCPe

A small portion of the site was leased from the railroads by the agricultural commodity provider. Since the owners of the leased site were without funds, the USEPA, as plaintiff, was suing the railroads and the manufacturers of the chemicals of concern for investigative costs and remediation expenses.

The USEPA conducted a majority of the investigative sampling and analysis activities of soils and groundwater on and adjacent to the site. The analytical results for soils and groundwater indicated widespread contamination by the chemicals of concern. However, the soil results for the leased property contained only a few "hits" of relatively low concentration. The main difficulty with the EPA data was that its validity was highly questionable. There were two fundamental reasons for the EPA data to be of questionable value for their investigative purposes:

1. Sampling highly contaminated soil immediately prior to sampling a supposedly contaminant-free background soil boring. For example, a sample 400 feet off site at 45 feet below ground surface (bgs) contained dinoseb at 1,100ug/kg (ppb), but there were non-detects at 25 and 35 feet below the surface. The boring that was sampled prior to the background boring was in the most highly dinoseb-contaminated area of the site.
2. Analytical chemistry for the analysis of 1,2,3-TCP was done by the EPA with an on-site laboratory utilizing a gas chromatograph (GC). The calibration of the GC and the detection of 1,2,3-TCP in pure water blanks indicated that the reported values for 1,2,3-TCP in soils were unreliable at values below 100 ppb.

With the best data, there were only two soil samples containing dinoseb that were found on the railroad property. Both of these "hits" were not valid because the GC retention times were different from the calibration retention times. Thus, EPA did not have any valid data demonstrating contamination emanating from the railroad property.

Groundwater was about 70 feet bgs and moved southwest in the 1990s when these investigations were being done. The site's unlined wash basin was the main avenue for dissolved chemicals to be transported to the groundwater. Mounding of the groundwater beneath this wash basin and a down-gradient potato shipping wash basin pushed some of the chemicals of concern to the west and beneath the railroad property. This location of the chemicals in the groundwater was exploited by the EPA during trial, along with the language of "joint and several," all the way to the Supreme Court.

CERCLA, Apportionment, Chemistry

C16 Free Product Determination Using Ethylbenzene to Total Xylenes Ratio

Grant W. DeWitt, BA, MS, PM Environmental, Inc., 4080 West Eleven Mile Road, Berkley, MI 48072; and James S. Smith, PhD, Trillium, Incorporated, 28 Graces Drive, Coatesville, PA 19320-1206*

After attending this presentation, attendees will understand a complimentary method to determine whether or not a petroleum free product is in the soil.

This presentation will impact the forensic science community by putting another tool in attendees toolbox for use at petroleum-contaminated sites.

During a 2005 kerosene UST assessment, concentrations of diesel range organics (DRO) (140,000 - 4,900,000 ug/kg) were reported in the

shallow samples. However, the absence or generally low levels of polynuclear aromatic hydrocarbons (PNAs) and volatile organic compounds (VOCs) associated with these samples do not support an association with free phase conditions.

During the 2009 and 2010 supplemental soil boring sampling activities, selected samples in which total VOCs did not exceed 75,000ug.kg were additionally analyzed for gasoline range organics (GRO) (C-6 to C-10). Based on the available data, however, no specific data trend or correlation of total VOCs versus GRO was identified. Because of the absence or very low levels of PNAs reported in these soil samples, no additional DRO analysis was deemed necessary in order to assess for diesel range free phase conditions.

An evaluation using the Ethylbenzene/Xylenes Ratio (EXR) Method (DeWitt, Smith, and Hoitash, 2008) determined that the residual contaminant levels reported in soil samples do not represent free phase conditions. Gasoline and middle distillates (ie., diesel, kerosene, and fuel oils) have composition ethylbenzene/xylenes ratios (EXRs) of approximately 0.20±0.05. Long term sources of contamination will continue to supply contaminants to the environment and replace those which are transported away from the source area, are biodegraded, or removed through remediation (Alexander, 1999). Upon a release, bacteria rapidly uses available oxygen, driving the release environment anaerobic. Anaerobic biodegradation removes xylenes faster than ethylbenzene (Reinhard, Hopkins, and LeBron, 2005), thus EXRs increase with time. An EXR of approximately 0.25 or greater indicates anaerobic biodegradation (Smith and DeWitt, 2006). Release areas can act as continuing sources having extremely slow biodegradation resulting in continued elevated contaminants and EXR values typically greater than 0.15 and less than 0.25, but can vary pending site-specific conditions and release compositions. EXR data not showing an increasing trend and remaining near the range anticipated for product can indicate the presence of "free product" and/or significant source material (e.g., free phase conditions).

The EXR values for the cumulative data for the VOCs consistently reported (2005 to 2009) will be presented. In general, for the samples exhibiting benzene concentrations, which would be expected to be present if free phase conditions were acting as a continuing source of contaminants, the EXR values are above 0.25 (i.e., 0.33 to 1.71) indicating that biodegradation is occurring and that free phase conditions cannot be present. The highest VOCs concentrations in this group are represented by the former excavation sidewall sample S-17 (EXR - 0.58) and soil boring sample SB-3 (EXR - 0.35), which might be considered as having free phase conditions. However, the EXR values for samples S-17 and SB-3 and the lower levels of contaminants in the other samples are not representative of free phase conditions.

Based on the above weight of evidence approach and given the volume of removed source soils, it is not probable that free product or free phase conditions are present at the site.

EXR, Free Phase Petroleum Product, Soil

C17 Determining the Primary Source and Time Period of Trichloroethylene Contamination in Groundwater — An Unusual Case History in Which TCE Apparently Moved Faster Than Its Degradation Compounds

John B. Robertson, BS, J.B. Robertson Consulting, 40107 North 3rd Street, Desert Hills, AZ 85086*

The goal of this presentation is to show that some of the conventional thinking about the relative mobility of trichloroethylene and its degradation products in groundwater does not always apply.

This presentation will impact the forensic science community by showing how investigators sometimes need to think "out of the box" to determine relative timing and locations of groundwater contamination sources.

A large area of trichloroethylene (TCE) contamination was discovered in groundwater in 1989 at a former industrial facility rural Kansas. The facility served as an Army Air Base during World War II (WWII) where heavy bombers were prepared for final deployment to European and Pacific war theaters. After the War, the facility was turned over to a local municipality and converted to a municipal airport and industrial park. A major aircraft manufacturing company then leased much of the property and conducted various manufacturing and assembly operations at the site from 1950 to the early 1960s.

After the discovery of groundwater contamination at the site in 1989, regulatory authorities determined that the aircraft manufacturing company was responsible, at least in part, for the contamination and ordered the company to characterize the extent of contamination and to implement appropriate remedial actions. The primary contaminant is the industrial chlorinated solvent TCE, but its chemical biodegradation products, 1,2-dichloroethene (DCE) and vinyl chloride (VC) are also significant contaminants. The groundwater contamination plume extends several miles down-gradient from the source areas. The contaminated aquifers are composed of three, relatively thin, flat-lying limestone strata.

During the course of conducting remedial investigations and cleanup actions, the aircraft manufacturing company filed a law suit against the federal government under the terms of Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), claiming that the U.S. Army caused a significant portion of the contamination during its activities at the base during WWII. Serving as an expert for the government to determine what portion, if any, of the contamination could be reasonably attributed to the Army's activities.

An unusual aspect of the groundwater contamination plume was the fact that in the most distant, down-gradient portion of the plume, TCE is the dominant contaminant, with very little of the degradation products, DCE and VC. In contrast, near one of the two primary source areas, the degradation products are the dominant contaminants. This is unusual because in many aquifers, DCE and VC are more mobile than TCE and move faster because TCE is more retarded by adsorption to solid organic carbon matter in the aquifer matrix.

There were two primary source areas where TCE was initially released: a large hanger area called Hangar A and another larger hangar area, Hangar B. The plaintiff's expert in this case argued that the explanation for the TCE-dominant contamination at the leading edge of the plume was caused by early releases of clean TCE during the Army's activities at one of the two source areas (Hangar A) and that the DCE/VC dominance at that source area was due to the later releases of non-chlorinated solvents, fuels, and paint strippers probably during the aircraft manufacturing company's activities. The aircraft company conducted TCE vapor degreasing operations at both hangar sites. No credible evidence could be found that the Army ever conducted TCE degreasing operations or other significant use of TCE at the site during its WWII operations.

After careful analysis it was shown that the unusual distribution of TCE, DCE and VC was due to the release of relatively clean TCE at Hangar B by the aircraft company and that undegraded TCE constituted the contamination at the leading edged of the plume. Later releases of TCE mingled with petroleum hydrocarbons by the aircraft company at Hangar A caused the DCE/VC-dominated contamination near that source area. Another factor effecting the contaminant distributions is the fact that matrix diffusion in the fractured limestone aquifers favor greater mobility of TCE over DCE and VC (the opposite effect of adsorptive retardation).

At trial, the court concurred with my analysis and concluded that the federal government had no liability for the contamination.

Groundwater, Contamination, Trichloroethylene

C18 Molecular Level Compositional and Structural Characterization for the Deepwater Horizon Oil Spill By GC-GC and FT-ICR Mass Spectrometry

Ryan P. Rodgers, PhD, and; Amy M. McKennna, PhD, National High Magnetic Field Lab, 1800 East Paul Dirac Drive, Tallahassee, FL 32310; Robert K. Nelson, BS, and Christopher M. Reddy, PhD, Woods Hole Oceanographic Institute, 266 Woods Hole Road, Woods Hole, MA 02543; and Alan G. Marshall, PhD, Florida State University, 1800 East Paul Dirac Drive, Tallahassee, FL 32310*

The goal of the presentation is to provide information on the first compositionally comprehensive inventory of the Deepwater Horizon crude oil, and monitor molecular level changes in the crude as a function of biotic and abiotic modifications from the wellhead to terminal point in the environment.

This presentation will impact the forensic science community by understanding how Ultrahigh-resolution Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS) enables detailed compositional characterization of complex petroleum samples (all acidic, basic, aromatic and aliphatic species) at the level of molecular formula assignment. Comprehensive 2D gas chromatography (GCxGC) provides exhaustive structural characterization of nonpolar oil components below a carbon number of ~35. Such information is critical for source appointment and quantification of water washing and evaporative losses. Combined, the two techniques provide a wealth of compositional information that provides forensic fingerprinting of petroleum releases and monitors compositional changes at the molecular level. For the first time, comprehensive 2D GC and ultrahigh-resolution FT-ICR MS are combined to provide molecular level information on a real world oil spill.

An oil spill changes its chemical composition continuously, due to evaporation and dissolution. Furthermore, "weathering" (biotic and abiotic modifications) changes the composition of a crude oil and increases the relative abundance of polar species that are readily addressed by FT-ICR MS, but that are problematic for GC separations (requiring chemical derivatization prior to analysis). In work completed under an NSF RAPID Grant (#CHE-1049753), we have resolved and identified 72,000 acidic, basic, and nonpolar species in the Deepwater Horizon parent crude oil. Subsequent fractionations by micro-distillation and HPLC-2 have revealed thousands more species as well as structural information not provided by high resolution mass spectrometry alone and provide relevant fractions for more detailed analysis by FT-ICR MS and GC x GC. Collectively, the compositional results provided a detailed fingerprint and inventory of species released into the Gulf of Mexico. Water washing experiments have revealed water-soluble species that cannot be directly analyzed by gas chromatographic methods. Collaborative efforts reveal acidic/basic species compositional changes from the wellhead to being washed ashore in Pensacola, FL, where the compositional complexity of the basic species increased by 50%. Compositional analysis of tidal beach sediments at various depths exposes compositional changes due to weathering and sea water solubility, critical for enhanced model development. Most notably, the carbon number and aromaticity (double bond equivalents = rings plus double bonds to carbon) for the species identified below the initial oil contamination zone are lower than for the primary oiled sediment layer. Such compositional changes have been previously documented by our research in simulated oil spills performed in the laboratory (Stanford *et al.*, 2005). FT-ICR MS enables access to high boiling, polar species that have eluded environmental studies in the past due to their complexity and acidic/basic nature. That very character can now be exploited and combined with the highest performance FT-ICR mass spectrometry, to provide detailed compositional information for tens of thousands of acidic, basic and nonpolar species that lie within and far beyond the range of state-of-the-art gas chromatographic techniques. However, the resolution and structural analysis of lower boiling, nonpolar species (less than 35 carbons) is critical to determine the identity of suspect crude oils and measure weathering phenomena of volatile/semi-volatile species not easily analyzed by FT-ICR MS. Work supported by NSF (CHE-10-49753 and DMR-06-54118).

GC-GC, High Resolution Mass Spectrometry, Deepwater Horizon Oil Spill

C19 Corrosion Evaluation of Lock and Dam Structure

Charles K. Clarke, PhD, Metallurgical Consulting, 1146 Leroy Stevens Road, Suite A, Mobile, AL 36695; Peter Peterson, PhD, Ivium Technologies USA, 961687 Gateway Boulevard, Suite 201D, Fernandina Beach, FL 32034; and Don Halimunanda, MS, Metallurgical Consulting, 1146 Leroy Steven Road, Suite A, Mobile, AL 36695*

After attending this presentation, attendees will understand the concept of using research type electrochemical techniques for rapid evaluation of corrosion problems involving steel and coatings in lock and dam structures.

The presentation will impact the forensic science community by providing forensic engineers with the ability to rapidly acquire corrosion and/or coating behavior data under the actual conditions of interest.

Literature research revealed the possibility of thermal sprayed coatings providing significant improvements over currently used vinyl coatings for U.S. Corps of Engineers locks and dams. This was confirmed by the following tests:

Electrochemical corrosion methods can be used to rapidly acquire data on the performance of metals and coatings in corrosive environments. Corrosion of metals involves transport of ions and electrons. DC current methods can measure corrosion rate and evaluate pitting and cracking tendencies in metals. Barrier type paint coatings produce a capacitor situation when placed on a steel substrate immersed in water. AC current techniques (electrochemical impedance spectroscopy or EIS) can utilize the effect to monitor moisture transport through coating and ultimately coating break down. Research using these techniques is almost always conducted in controlled laboratory environments. A lock miter gate is exposed to muddy, turbulent, and aerated river water. Tests using both DC and AC electrochemical techniques on actual muddy river water produced some startling results in the area of the current vinyl coatings behavior. Tests were conducted with samples of both vinyl (the current coating) and thermal sprayed coatings immersed in barrels containing aerated, intermittently agitated, muddy river water. (Clear river water was used for some samples.) Previous reported work has utilized small cylinders containing artificial sea water without aeration.

Steel plates coated with 20mil (500 micron) thick layers of thermally applied zinc, aluminum, and zinc -15% aluminum (125 micron surface profile were supplied by two separate contractors and placed into a 55 gallon (210L) drum on a PVC pipe rack. Similar samples of three coat (51 microns) vinyl coat with vinyl zinc rich primer were also provided. One set of the vinyl samples was fully cured. A second set was placed into the water at 24 hour intervals after application to test the effect of not meeting cure requirements.

The AC EIS results on the vinyl coatings were surprising in how fast they exhibited total coating failure. Fully cured samples failed at a slower rate than freshly painted samples but they failed. Failure was indicated in the EIS tests by a drop of several orders of magnitude in measured impedance of the coating. This is evidence for moisture saturation of the coating. The vinyl zinc primer also failed to provide any protection potential. These observations raise serious concern for all of the coated steel structures using these vinyl coating systems.

Thermal spray coatings exhibited no attack or degradation during the tests. Corrosion rates were low thus confirming published work. Both the zinc and zinc-15 aluminum coatings provided good protection potentials to the steel substrate while the aluminum coating was marginal in this regard.

Separate corrosion tests on bare steel in the intermittently stirred, muddy, aerated river water produced very high corrosion rates. Tests on clear river water revealed lower corrosion rates. Prior work suggests that this was the result of iron bacteria.

These results show that thermally sprayed zinc and zinc-15 aluminum are attractive candidates for replacing the current vinyl coatings. Thermal sprayed coatings have no VOC's and are reported to yield at least three times the service life of vinyl coatings. Test results suggest that the vinyl coatings may not provide near the protection expected from them in locks/waters with heavy traffic and water turbulence. Replacing the vinyl coatings with thermal spray coatings has the potential to save enormous amounts of money because shutting a lock down for recoating shuts down the navigable river in many cases. Increasing recoat time by at least three times saves maintenance costs and lost revenue from river traffic.

The electrochemical techniques used for this work can be used in most applications where corrosion is a problem. They have been successfully used in cooling water systems, chemical processes, and other coating studies. They provide the forensic engineers with the ability to rapidly acquire corrosion and/or coating behavior data under the actual conditions of interest.

Corrosion, Corrosion Tests, Infrastructure

C20 The Application of Scanning Electron Microscopy and Energy Dispersive Spectroscopy for Forensic and Failure Investigations

Gregory J. Wagner, PhD, Materials and Chemistry Laboratory, Inc., East Tennessee Technology Park, Building K-1006, 2010 Highway 58, Suite 1000, Oak Ridge, TN 37830; and Bonnie Zimmerman, MS, Materials and Chemistry Laboratory, Inc., PO Box 5808, Oak Ridge, TN 73831*

After attending this presentation, attendees will have a better understanding of the use and value of using SEM with EDS in investigating component and industrial and chemical process failures.

This presentation will impact the forensic science community by providing examples of approaches to use in failure investigations in a timely manner.

Scanning Electron Microscopy (SEM) with associated Energy Dispersive Spectroscopy (EDS) has been used extensively for industrial forensic applications at Materials and Chemistry Laboratory, Inc. (MCLinc), particularly to evaluate causes of failure in manufacturing and chemical processes. Failure investigations are typically initiated with a client interview to establish alloy type of the failed component, operating conditions, process excursions, and other historical data. The region of failure is then visual inspected. Proper collection and conditioning of samples for shipping has been found to be essential for preserving sample integrity prior to analysis. After visual inspection and photography, coupon sections are mapped out and separated to allow for comparison of sections near the region of failure and those isolated from the region of failure. The coupons are then embedded in epoxy in a 1.25 inch diameter mold, cured, and polished to 0.3µm. The mounts are then examined by Reflective Optical Microscopy and SEM. The polished cross sections are typically etched during the examinations to expose the grain structure of the alloys. Optical Microscopy is conducted to determine the general grain structure and/or inclusions while Electron Microscopy is used to examine fine details at higher magnification and obtain general chemistry and chemistry of features and/or precipitates within the grain boundaries. The grain structure observed in the failure region provides insight into the failure mechanism. Observed failures include thermal granular growth, intergranular attack, and general corrosive attack.

A recent investigation included the examination of a 3/8 inch Inconel 600 vessel which failed in hydrogen fluoride service. The results of the investigation demonstrated that sulfidation was the cause of the failure. It was determined that a process variable caused the sulfur concentration in the feed stream to be higher than typical. Moreover, a mechanical issue involving a defective heater element caused elevated temperature at the failure region, hence, accelerating the rate of sulfidation. The low oxygen content of the process also contributed to the accelerated sulfidation. Photomicrographs and EDS spectra revealed a breakdown of the Cr_2O_3 layer with the resulting transport of sulfur within the bulk alloy. Ni-S, Cr-S, and Cr depleted regions were also observed. This observation was consistent with published literature on sulfidation. Results of this investigation provided a mechanism for failure that is consistent with the operating conditions.

Failure Investigations, SEM-EDS, Chemical Processes

C21 *In-Situ* Hardening of a Steel Tank: Carbon Diffusion Over 35 Years at Ambient Temperatures

Anastasia Micheals, MS, Forensic Materials Consulting, 1784 Sanchez Street, San Francisco, CA 94131-2741*

After attending this presentation, attendees will understand the importance of diffusion in materials, particularly in surface hardening of steel.

This presentation will impact the forensic science community by presenting a case study where low temperature diffusion has a large impact on the properties of steel.

Municipal water storage tanks are reservoirs that ensure both adequate supply and pressure to customers during low and high usage periods. Typical materials used in ground-located water tank are environmentally robust materials such as fiberglass, plastic, or stainless steel. Corrosion-sensitive carbon steel is also used. Modern methods to protect tanks from corrosion include silica glass coatings, applied to panels, processed at high temperature and then assembled. Historically, the choice for protecting carbon steel tanks from the combination of water and air that cause corrosion was a coating of coal tar pitch epoxy. Coal tar pitch is the semi-solid that remains after distillation of the coal tar by-product of coal gasification. Fairly inexpensive, it is water-resistant and long lasting. However, being a fossil fuel derivative, it is composed of a number of long chain hydrocarbons, phenols, and polycyclic aromatic hydrocarbons (PAH). Exact composition depends on the coal source material. Various PAHs are known carcinogens, mutagens and teratogens, so protective equipment must be used when applying or removing coal tar pitch.

During recoating of the interior of a 35-year old, 1.2 MG municipal water tank, the interior coal tar pitch epoxy coating was being removed by sandblasting; the goal was a white metal, or SSPC-SP 5, finish, so that a new coating could be applied to clean metal. Initial sandblasting was performed with silica, which resulted in unexpectedly low removal rates. Time was of the essence, as the tank needed to be on-line within a specified timeline, so the abrasive was switched to steel abrasive, a more expensive material. The blasting still took much longer than scheduled and anticipated.

A three inch diameter, $^{7}/_{32}$ inches thick disk was cut from the roof of the tank. This disk was cut in half; ***Piece A*** was not cleaned in any way, and ***Piece B*** was sweep blasted with the steel abrasive. Optical microscopy, scanning electron microscopy (SEM) and energy dispersive x-ray spectroscopy (EDS) was performed on both ***A*** and ***B***.

Under the optical microscope, a cracked, black coal tar pitch epoxy coating was observed on un-cleaned ***A*** (Figure 1). In some areas, the coating had spalled away, and, in the presence of both air and water, red iron oxide scale formed. ***A*** was then examined by scanning electron microscopy, in a region containing both coating and corrosion (Figure 2). The corrosion has an appearance typical of iron oxide (Figure 3). The coal tar coating (Figure 4) shows some surface deposits. It also shows a typical surface crack in the coating.

Elemental analysis of ***A*** by EDS was unremarkable. Carbon, iron, and oxygen were the major elements present. Minor elements were silicon, aluminum, potassium, magnesium, calcium, sulfur and chlorine. The major elements are from the coal tar coating and steel tank material; the minor elements are likely deposits from the well water held in the tank.

Optical microscopy of ***B*** showed that the sweep blasting, while incomplete, had removed most of the coal tar coating (Figure 4). Residual red iron oxide was observed, as well as some black regions that were consistent in shape and density with the coal tar coating seen on the un-cleaned piece. ***B*** was examined in the SEM. The surface was somewhat rough, indicating incomplete sweep blasting. EDS of the area again revealed no unexpected elements.

Spot elemental analysis was performed on an area of sweep blasted ***B***, where a cross-section from the pitch coating to the bare steel was visible (Figure 6). Elemental measurements were made at three locations; pitch coating, mid coating, and bare steel. The analysis results are summarized in Table 1. The additional elements detected, likely deposits from groundwater, are silicon, calcium, aluminum, magnesium, potassium, sulfur, and chlorine.

Element	Atomic %		
	Spot 1	Spot 2	Spot 3
Carbon	50.1	33.2	1.7
Oxygen	34.9	31.8	22.6
Iron	0.4	30.1	65.3
Additional elements	14.6	4.9	10.4

Table 1. Concentration of elements found at three different spots on a cross-section of ***Piece B***.

At Spot 1, the top of the coating, carbon from the coal tar pitch epoxy was detected. Hydrogen is also likely present, although the EDS technique cannot detect it. At Spot 2, a significant amount of iron was detected, in addition to carbon and oxygen. The ratio of iron to oxygen is approximately 1:1, which suggests iron oxide of the form FeO, a black oxide. The presence of carbon suggests carbon diffusion into the iron oxide. At Spot 3, the primary element present is iron. The oxygen present may be due to debris from the sweep blasting process. A very small amount of carbon is present as well.

Piece A is representative of the present condition of this 35-year-old tank and coal tar coating. Its condition is reasonable considering the age and environmental history of the system. With time and temperature fluctuations, volatile organic compounds evaporated from the pitch, causing it to lose elasticity. Cracks in the coating were then initiated and grew in the stiffened coating, as the pitch shrunk due to the loss of the volatile material, and as the steel substrate expanded or contracted with changing ambient temperature. Water then penetrated through the cracks to the steel, and formed ferrous oxide (FeO), the iron corrosion that forms in limited-oxygen environments. The corrosion propagated underneath the coating (Figure 7); the corrosion continued underneath the coating, allowing pieces to spall off. The iron, then exposed to oxygen from the air, converted from black FeO to red Fe_2O_3.

Piece B reveals a second process occurring, that of carbon diffusion. Carbon will readily diffuse into iron, at a rate dependent on temperature. The carbon gradient discovered in Piece B indicates that the carbon diffusion process has been taking place over the 35-year lifetime of the tank. Although the maximum ambient temperature was relatively low (~100º F), the long time allowed significant carbon diffusion to occur, causing surface hardening of the low carbon steel. This diffusion rate was verified by Fick's Second Law.

The goal of sandblasting was to remove the pitch layer, and the top surface of the steel, leaving a clean steel surface for recoating. The increase in hardness, from that of the expected low carbon steel material, to a high carbon steel of around 2.5%, resulted in exceptionally low material removal rates by sand blasting.

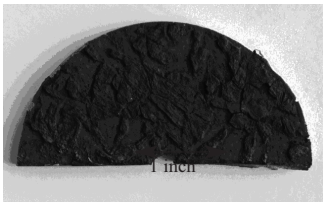

Figure 1. Water tank specimen, ***Piece A***, no cleaning.

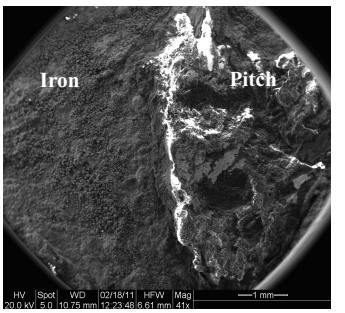

Figure 2. Electron micrograph of ***A***, in a region with both red iron oxide corrosion and pitch epoxy coating.

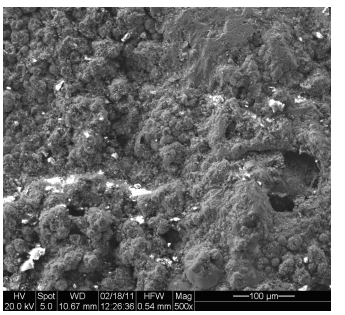

Figure 3. Electron micrograph of corrosion from ***A***. The bubbles are typical of rust; EDS analysis confirmed the composition of the rust to be Fe_2O_3.

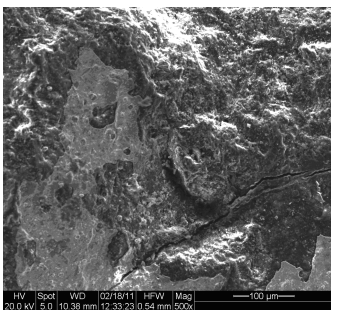

Figure 4. Electron micrograph of the pitch epoxy coating from ***A***. The light areas are surface deposits. The crack is typical of those found in the coating.

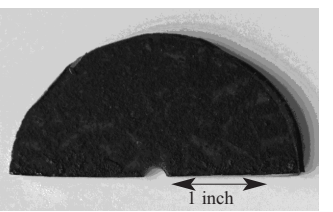

Figure 4. Water tank specimen, ***Piece B***, sweep blasted.

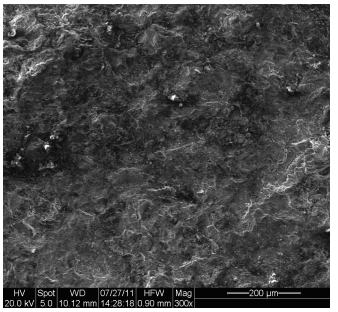

Figure 5. Electron micrograph of ***B***. The rough surface is a result of sweep blasting with steel abrasive, which did not penetrate to the steel substrate.

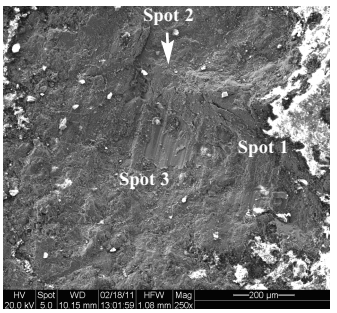

Figure 6. Area of EDS analysis.

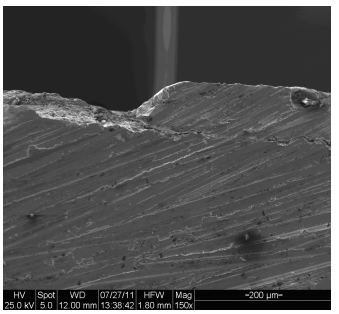

Figure 7. This cross section shows the propagation of corrosion beneath the coating.

Diffusion of Carbon in Steel, Oxidation, Corrosion

C22 Review and Analysis of a Bowstring Wood Truss Roof Collapse During a Snow Event

Daniel M. Honig, PE, Structures Consulting Engineers, PO Box 125, Swarthmore, PA 19081*

After attending this presentation, attendees will be introduced to a case where roof trusses in a renovated building collapsed at the time of an ice and snow event. The investigation into the cause of the collapse and the recommendation for remediation will be described.

This presentation will impact the forensic science community by illustrating the necessity of a proper and reasonable structural engineer review and evaluation of existing building conditions prior to a renovation project.

Distress often develops in individual truss members during normal load service because of the cumulative damage effects of the long-term loadings over the structure's life. Overstress issues due to inadequate allowances for accumulations of rain or drifting snow need to be reviewed and properly addressed when investigating bowstring roof trusses.

A building was affected by an ice and snow event, which occurred during a recent winter season. During the 1998/99 timeframe, a single story prior use supermarket was renovated, upgraded, and enlarged as a medical and professional office building. The construction type of the original structure consisted of brick masonry bearing walls supporting heavy timber bowstring profile wood trusses. These trusses supported conventional wood framing bearing on the truss top chords, with ceiling joists supported by the truss bottom chords.

During the course of the significant winter precipitation event, three of the trusses located towards the middle of the original building section structurally failed and began to collapse. These roof trusses, which remained in place, were found to have had long term deflections, thereby causing some of the bottom chord split ring connectors to develop significant gaps between the connectors and the bottom chord elements.

Significant additional structural loadings were placed on the existing truss system as a result of the building renovation. A new roof profile created new snow drift zones adjacent to the intersection of a new rear two-story area and the existing bowstring truss roof as well as at new valleys on either side of a new semicircular entrance. Given the uniform profile of the bowstring trusses prior to the alterations, the existing bowstring wood trusses were not designed to support the additional loading created at the new snow drift zones.

The minimum due diligence of the design team, including the architect and structural engineer of record, during the modification of the existing building profile included taking into account any new additional loads. This required the design team to complete a detailed structural review of the existing building system. This structural review was not properly performed during the 1998/99 renovation work, and as a result additional loads and snow drift profiles were added to the existing roof without any structural reinforcement or alteration.

Based on computer analysis of a typical truss loading after the renovation project, some truss members had significant overloading stresses that exceeded those allowable under the uniform snow load, unbalanced snow load, and drifted snow load cases. Based on the analysis, the trusses were found to be significantly overloaded under the maximum anticipated service loads, as defined by the 2000 edition of the International Building Code and the ASCE-7 Subcode. In addition, top chord shear stresses were found to exceed allowable stresses, and the four longest diagonal struts were found to be too slender for the compressive forces.

Based upon field observations, evaluation, and follow-up structural analysis, it was confirmed that long term wood deterioration, shrinkage, and movement of the southern bottom chord ends must have occurred, thereby permitting the southern wall to shift outward and the roof trusses to move downward under the additional loading caused by uneven snow drifting. The trusses required strengthening in place by increasing the tensile capacity of the bottom chords, the shear capacity of the top chords at panel points, and the area of the slender diagonals.

Given that a proper structural survey and inventory was not completed prior to the building alterations, significant areas of concern during the renovation design phase were neglected. These renovation design omissions led to the collapse during the winter storm events.

A proper and complete structural evaluation of the bowstring wood truss framing system prior to the structural and building renovation program would have determined the scope of the structural deficiencies, and the overstress of the bowstring truss members then could have been addressed from a structural engineering standpoint. Given that far more severe storm events occurred prior to the renovation and collapse, it is reasonable to conclude that the renovation was made without the proper and expected structural engineering review and evaluation of the existing bowstring wood trusses.

Bowstring Wood Trusses, Snow Load, Structural Analysis

C23 Hazards of Volcanic Eruption to Aviation

Richard S. Brown, MS, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Suite 400, Duluth, GA 30096-893; Raymond K. Hart, PhD, JD, 145 Grogan's Lake Drive, Sandy Springs, GA 30350-3115; and Whitney B. Hill, MS, and William R. Boltin, MS, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Suite 400, Duluth, GA 30096*

The goal of this presentation is to provide information on both the chemical and physical properties of the ash plume from Eyjafjoll volcano. Information on the potential and actual hazards of ingesting volcanic particles into modern jet-turbine engines will be considered.

This presentation will impact the forensic science community by presenting recently determined scientific data on the chemical and physical nature of volcanic ash. That information will be valuable in litigating mechanical failures in aircraft jet engines.

Commercial aviation has been striving in recent years to improve the efficiency of their jet-turbine engines, especially after fuel costs have continued to sky-rocket. In order to offset the high cost of fuel, aircraft engine manufacturers have been striving to produce jet turbines that are more thermodynamically efficient.

The efficiency of a jet-turbine engine equals $T_1 - T_2 / T_1$ where T_1 and T_2 are the absolute temperatures in the hot chamber and cold chamber respectively. The upper temperature limit in the combustion gas is dictated by the maximum temperature that the high-temperature turbine blades were designed to operate in. If the high temperature turbine blades are exposed to higher than the maximum design temperature, the blade alloy will be subjected to an "overtemp" condition, in which incipient melting of grain boundary metal will occur, and carbon will be solutioned in the metal grains. Incipient melting in superalloys usually starts at about 100°C below the alloy's actual melting point.

In order to obtain a more efficient engine performance, the blades in the first two high-pressure turbine discs are fabricated with hollow cores and numerous small air holes, approximately 1mm in diameter. Those small holes can direct a layer of highly pressurized cold air across the airfoil of those blades and thus permit the turbine blades to safely operate in combustion gas at an appreciably higher temperature. Unfortunately, if those engines are operated in dust-ridden conditions, such as sand storms or high concentrations of volcanic ash, those small air holes in the blade's airfoil can easily become blocked. Should blockage occur, it will then cause the operating temperature of HPT-1 and HPT-2 turbine blades to rapidly rise to an unsafe operating level.

Particulate matter, that is larger than that which can either pass through or block air holes in the turbine blades, can do appreciable damage to metal parts in jet turbine engines and lead to severe structural damage.

High-temperature oxidation of superalloys in "clean" combustion gas will produce mixed oxides of their major metal components, which are usually nickel and chromium. When the combustion gas carries extraneous gas and/or low melting point particulate material to the heated surface, a deposit-modified oxidation process will occur: called "hot corrosion."

To characterize the ash plume from the Eyjafjoll volcano, which erupted in Southern Iceland from April 14, 2010 to May 23, 2010, a sampling of volcanic ash was collected on April 30, 2010 from Thorvaldseyri Farm, which is located approximately 40 kilometers west of the city Vik. The actual eruption site was approximately 4.5 kilometers north of the farm.

Approximately 29 grams of volcanic ash was sieved and analyzed using a combination of polarized light microscopy (PLM), scanning electron microscopy-energy dispersive x-ray spectrometry (SEM-EDS) and transmission electron microscopy coupled with select area electron diffraction an energy dispersive x-ray spectrometry (AEM). PLM examination of the <63µm fraction reveals abundant volcanic glass fragments with mineral inclusions. The glass ranges from frothy colorless pumice particles to brown fragments, some exhibiting vesicular texture. Many fragments are magnetic, apparently due to the presence of microscopic inclusions of magnetite; ilmenite and/or titanomagnetite are also indicated by SEM-EDS analysis of inclusions in the glass. Plagioclase, olivine and clinopyroxene are present as individual grains and as inclusions within the glass. SEM and AEM analysis were used to support the PLM analysis.

Volcanic Ash, Jet Engine, Microscopy

C24 BioMedical Engineering Methodological Protocol for Testing Real World Helmet Performance

Laura L. Liptai, PhD, BioMedical Forensics, 1660 School Street, #103, Moraga, CA 94556*

After attending this presentation, attendees will understand how to objectively investigate helmet impacts and utilize proven protocols and techniques to test motorcycle helmets beyond standardized testing. The objective is to quantitatively compare and analyze impact performance of three types of DOT approved helmets and three types of Non-DOT approved helmets in real world impacts.

This presentation will impact the forensic science community by quantifying the dynamic differences between helmet choices in real world impacts beyond standardized testing methods. By increasing the knowledge base of engineers and scientists, helmets can be better designed to be most effective for the intended use.

Motorcyclists suffer serious trauma to the head more often than automotive occupants, primarily due to contact with non-yielding surfaces, such as asphalt and concrete, and/or direct impact from other motorized vehicles. A motorcycle helmet is the principal protection to the head from an impact once the occupant is ejected. In the United States, consumer helmets are initially divided into two distinct categories: DOT (Department of Transportation) approved and non-DOT approved (sometimes referred to as novelty helmets). For a helmet to be approved by the Department of Transportation it must pass a series of tests administered by the Department of Transportation, and once done so, the helmet will display a "DOT" sticker. DOT approved helmets must meet a series of performance testing requirements including impact, penetration, and retention tests. In terms of impact performance testing, the motorcycle helmet is dropped in a guided freefall at a set range of velocities onto a hemispherical or flat steel anvil, where data collected must not exceed critical accelerations of 400 g's maximum, 200 g's for two milliseconds, and 150 g's for four milliseconds. (Federal Motor Vehicle Safety Standard (FMVSS) No. 218). The testing methods used in this research project differ from the above because the helmet performance testing is conducted at higher impact velocities, different principal directions of force, and impact onto real world surfaces compared to the standardized testing.

To quantitatively compare the impact performance of the motorcycle helmets, including the energy dissipation characteristics, the forensic engineering method was utilized. The forensic engineering method is composed of five steps: (1) occurrence of precedent event; (2) define forensic engineering problem; (3) collect data; (4) analyze data; and, (5) develop and evaluate findings. The dynamics of the real world incident is studied thoroughly using longstanding forensic methods. The remaining four steps are then iteratively evaluated. The engineering problem definition in this instance is to quantitatively compare the impact performance, including the energy dissipation characteristics, of a sample of DOT approved helmets and a sample of non-DOT helmets at real world energy levels.

Six helmet types were tested; three types of DOT approved helmets and three types of non-DOT helmets. The impact tests were conducted using an inverted pendulum system with a helmeted Hybrid-III head-form. When dropped, the helmets contacted the exemplar surface (helmet performance can potentially be altered by the properties of the contact surface). Accelerometer data was acquired with a data acquisition system. The data from the sensors was filtered in accordance with SAE standard J211.

Four exemplars were tested for each of the six helmet types at two different velocities, yielding a total of 48 impact tests. For each test, a new helmet was fitted to the Hybrid III head-form and the chinstrap of the helmet was secured per the manufacturer's instructions. The real world principal direction of force can be utilized in the experimental design to replicate the subject head impact region. To initiate each test, an inverted pendulum protocol with Hybrid III head-form and helmet was raised to replicate the subject impact velocity ranges. Helmet performance was revealed.

The results quantify the performance by category and model, and proved to be consistent with the principals of rotational and translational energy, collinear contact of two bodies, and impact deformation. The higher delta t resulted in substantially lower peak accelerations for the DOT approved helmets when compared to the non-DOT approved helmets.

Motorcycle, Helmet, Head

C25 How Far Has the Federal Government Advanced Toward Meeting the Recommendations of the National Academy of Sciences (NAS) Report and How Does the United States Effort to Strengthen Forensic Science Compare With That in Other Countries?

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of PA, Erie County Court House, 140 West 6th Street, Room 223, Erie, PA 16501; Peter Alexander, PhD*, , 4934 Wagontrail Court, Parker, CO 80134; Douglas H. Ubelaker, PhD*, Department of Anthropology, NMNH - MRC 112, Smithsonian Institution, Washington, DC 20560; Kenneth E. Melson, JD*, Department of Justice, Office of Legal Policy, 950 Pennsylvania Avenue, HW, Washington, DC 20530; Mark D. Stolorow, MS*, Law Enforcement Standards Office, National Institute of Standards and Technology, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899-8102; Patrick Gallagher, PhD*, National Institutes of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899-8102; Chan Park, JD*, Senate Office Building, 224 Dirksen, Washington, DC 20510; Noah Bookbinder, JD*, United States Senate Judiciary Committee, Senate Office Building, 224 Dirksen, Washington, DC 20510; Anne-Marie Mazza, PhD*, The National Academy of Science, 500 Fifth Street, NW, Washington, DC 20001; Alastair Ross*, National Institute of Forensic Science, Australia New Zealand Policing Advisory Agency, Level 6, Tower 3, World Trade Center, 637 Flinders Street, Melbourne, 3005, AUSTRALIA; Chris Milroy, MD, LLB*, The Ottawa Hospital, 501 Smyth Road, Box 117, 4th Fl CCW, Ottawa, ON K1H 8L6, CANADA; Peter Neufeld, JD*, The Innocence Project, 40 Worth Street, Suite 701, New York, NY 10013; Thomas L. Bohan, PhD, JD*, Medical and Technical Consultants Forensics, 54 Pleasant Avenue, Peaks Island, ME 04108; and Betty Layne DesPortes, JD*, Benjamin & DesPortes, PC, PO Box 2464, Richmond, VA 23218*

After attending this presentation, attendees will be updated regarding Federal efforts in meeting recommendations of the National Academy of Sciences Report.

This presentation will impact the forensic science community by alerting listeners to the progress of efforts to upgrade forensic science in the United States.

Most AAFS members, regardless of our disciplines, will be affected either directly or indirectly by the reverberations flowing from the 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward*. A number of federal entities are working on various initiatives linked to the NAS Report. Among these are: The White House Subcommittee on Forensic Science, the U.S. Senate Judiciary Committee, and the National Institute of Standards and Technology (NIST). These entities will be shaping the future of forensic science, as it is practiced in the United States.

Today's session has been structured in an effort to answer a variety of questions. Among these questions are:

- Who are the participants, what have they done, and what are they going to do?
- What are the relationships between the participants?
- What constructive role can we, AAFS members play in this process?

Presenting in this session will be distinguished speakers from the AAFS, the Senate Judiciary Committee, the White House Subcommittee on Forensic Science, the NIST, the NAS, and the Innocence Project. Descriptions of the experiences of the international community in this area will also be presented. Speakers will describe the forensic science activities in Canada, the United Kingdom, and Australia. There are several issues of keen interest to all:

- How should forensic practitioners be certified? Should they be tested, and if so how and by whom? Should they be grandfathered if they have already been certified by an earlier regime?
- What methodology should be used to accredit forensic laboratories? Who should do the accreditation, the federal government, professional organizations, the Judiciary, or the private sector?
- Will any of the money allocated to the above processes make its way outside the federal system to fund the private sector to help with these activities?

Underlying the above issues is the even more important question of validity. The validity of the procedures currently used in many forensic "practices" (methods) has been called into question. Among these methods are DNA mixture analysis, fingerprint identification, and the analysis of hair, bite marks, fibers, shoeprints, soil, and tool marks. Shaken baby syndrome methods and diagnoses are also being questioned. What procedures will be employed to validate these methods? Will this be done by the Government or outside parties? No matter who does the validation work, how can we be sure that they will be done in a scientifically rigorous manner? In this session one speaker will discuss his disagreement with how many of the above techniques have been applied in the past.

Judge Domitrovich will describe how judges can improve their gatekeeping roles regarding the admissibility of relevant and reliable scientific evidence, as well as what resources are available to educate and train judges?

These issues will suffuse today's proceedings. Each talk will be followed by a 10 minute question & answer period.

AAFS President Dr. Ubelaker will begin the session by describing the respective responsibilities assumed by the disparate federal entities that are addressing the 2009 National Academy of Sciences Report mandated by Congress: *Strengthening Forensic Science in the United States: A Path Forward* (NAS Report). As AAFS spokesperson and as a member himself of the White House Subcommittee on Forensic Sciences, President Ubelaker has had a front-row seat as both an observer and participant in the actions taken by these entities in addressing the NAS Report. His presentation to the Joint Session will summarize his views of what has been accomplished, where he thinks we are headed, and what the AAFS role should be in strengthening forensic science in the United States.

There can be no better source of information regarding the activities of the White House Subcommittee on Forensic Science and of its interactions with other federal agencies than Mr. Melson and Mr. Stolorow. They have been involved in creating within the Executive Branch of the federal government a structure that in some regards tracks the structure that the Leahy bill seeks to create. Of particular interest will be their observations regarding the comparison and contrast of the two approaches, differences that in part reflect the different natures of the Executive and Legislative Branches of the federal government. In addition to these comments, they are expected to also present their own views on validating

practitioners, accrediting laboratories, and determining the validation of forensic theories and techniques. Mr. Melson is the Forensic Science Advisor at the Department of Justice Office of Legal Policy. Mr. Stolorow is Director of the NIST Office of Law Enforcement Standards.

Dr. Gallagher is the Director of the one of the most important scientific bodies within the federal government: the National Institute of Standards and Technology (NIST). Reflecting this, and the bill's intent to emphasize science, the Leahy bill calls on NIST resources and personnel for a major part of the new forensic structure it envisions. It will be of great interest to learn how he expects this expansion to take place and whether he sees NIST as awarding outside grants for forensic research.

Mr. Bookbinder and Mr. Park, senior staff members of the Senate Judiciary Committee chaired by Senator Patrick Leahy. Senator Leahy began working in 2009 on a legislative approach to addressing the issues in forensic science highlighted in the NAS Report. In assisting the Senator to approach this task, Mr. Bookbinder and Mr. Park sought to confer with all segments of the forensic community and, over an 18-month period, sat down, separately and in concert, with forensic scientists, crime lab directors, defense attorneys, law enforcement officials, Innocence Project members, and others. AAFS members were well represented at these gatherings. Through this process and guided by political realities, they developed the bill introduced in January 2011 by Sen. Leahy under the caption *Forensic Science Reform Act of 2011*. Regardless of whether this bill in some form becomes law by the time of the 2012 AAFS Annual Meeting, an account of considerable interest and help to anyone hoping for legislative solutions to the needs of the forensic community will be provided.

Since its creation in 1999, Dr. Mazza has been the Director of the NAS Committee on Science, Technology, and Law, the body that created and oversaw the ad hoc Committee responsible for the NAS Report. Associated with the NAS since 1995, she also worked during 1999-2000 with the White House Office of Science and Technology Policy. With this broad background in science policy and the specific experience involved in taking part in the preparation of the NAS Report, she is in an excellent position to discuss the generation of that report, the history behind it, and the manner in which its findings have been understood and misunderstood, construed and misconstrued.

The key recommendation of the NAS Report is that a National Institute of Forensic Science (NIFS) be created as an independent agency of the federal government. Although the Leahy bill does not go so far as to call for the creation of such an agency, it does envision an Office of Forensic Science within the Department of Justice. Therefore, it should be illuminating to learn the experience of Australia in setting up and operating its National Institute of Forensic Science. Mr. Ross, as one of the creators and presently the Director of the NIFS serving Australia and New Zealand, is an excellent person to describe the problems in creating such an organization, as well as the benefits that it has provided to those it serves. NIFS currently resides within the Australia New Zealand Police Advisory Agency as a Directorate.

Dr. Milroy, a forensic pathologist based in Canada after an extensive career in the United Kingdom, where he was a member of the National Forensic Science Service, has for many years been an active participant in the Evidence-Based Medicine movement. He will address the efforts in the United Kingdom and Canada to police forensic science practitioners and laboratories, including thinking in those countries regarding oversight committees. It is anticipated that he will discuss the recent dismantling of the forensic-practitioner registry developed over many years in the United Kingdom, thereby providing valuable insight to those looking toward the certification of forensic practitioners in other countries.

Mr. Neufeld is co-founder and co-director of the Innocence Project, which, directly or indirectly, has been responsible for the DNA exonerations of more than half of the nearly 300 persons wrongly convicted of homicides and/or sexual assaults in the United States. In most cases these individuals served long sentences for crimes which forensic DNA proved they had not committed. In seventeen cases, they had been sentenced to death. The post conviction DNA exonerations and the revelation that in a substantial number of the underlying trials, forensic analysts called by the prosecution provided invalid testimony at trial, were important factors in the NAS investigation of forensics and cited in the final 2009 NAS Report. As a consequence, Mr. Neufeld and his associates at the Innocence Project have been expected to play a major role, along with other entities, in the government led collaborative undertaking to enhance forensics. He will detail some of forensics' systemic problems and offer appropriate remediation. As a corollary to this, he will comment on various improvements proposed by Congress and agencies of the Executive Branch.

AAFS Board of Directors member Ms. DesPortes and former AAFS President Dr. Bohan plan to provide a summary of the day's proceedings augmented by their own experiences since the release of the NAS Report. They will advise audience members of the opportunities for involvement in the initiatives described by the other program presenters.

Forensic Science, Forensic, NAS

C26 Development of a Scanning Electron Microscopy Screening Method for World Trade Center Dust

Amy M. Bern, MS, United States Environmental Protection Agency, United States EPA/OECA/OCEFT/NEIC, PO Box 25227, Building 25, Denver Federal Center, Denver, CO 80401; Heather A. Lowers, MS, and Gregory P. Meeker, MS, United States Geological Survey, Central Region, Building 20, Denver Federal Center, Denver, CO 80225; and Jacky A. Rosati, PhD, United States Environmental Protection Agency, National Homeland Security Research Center, E-343-06, 109 T.W. Alexander Drive, Research Triangle Park, NC 27711*

After attending this presentation, attendees will be knowledgeable about the procedures and methods used to develop a scanning electron microscopy signature screening method for World Trade Center (WTC) dust.

This presentation will impact the forensic science community by providing a detailed description of an environmental forensic challenge, the methodology used to address the problem, and the results of an inter-laboratory study designed to test a new analytical method.

Dust from the September 11, 2001, collapse of the WTC penetrated indoor areas of lower Manhattan. Apartments, offices, and public buildings were contaminated with the debris. In 2005, in response to continuing public health concerns about dust inhalation, including the "World Trade Center Cough," the U.S. Environmental Protection Agency and the U.S. Geological Survey (USGS) were tasked with developing a screening method to detect low-levels of WTC dust in the presence of indoor dusts from other sources.

The development of a WTC dust signature was complicated by the dilution of the dust by urban background dust accumulated over the period of four years. The composition of the analyzed dust was highly variable because of contributions from a number of sources unrelated to the WTC collapse on September 11, such as building damage, construction debris, and other common urban dust sources. In addition, variations in the composition of the WTC dust over the affected area due to exposure to moisture, distance from the WTC site, and elevation were evaluated.

Analysis performed by USGS by scanning electron microscopy with energy dispersive spectrometry (SEM/EDS) determined that the major components of the less-than-150-micrometer fraction of the WTC dust were gypsum/anhydrite, phases compatible with crushed concrete, and man-made vitreous fibers (MMVF), including a calcium-aluminum-silicon glass, soda-lime glass, rock wool, and slag wool. These components were also present in urban dusts not impacted from the event, but in different ratios than dusts from the WTC. Slag wool, specifically, was found to be present in WTC dust at much higher concentrations (20-25 % by area) than in urban background dusts (10^{-3} to 10^{-5} wt. %). Additionally, the slag wool

identified in the WTC dust was distinguishable from rock wool found in most urban dusts by iron content. The definitions used for slag wool and rock wool were those used by the Thermal Insulation Manufacturer's Association.

A SEM/EDS point counting method was developed to determine the amount of slag wool (fibers/milligram) in collected dusts. The method described a procedure that included splitting, ashing, and sieving the collected dust. From each split, a suspension of the dust in alcohol was prepared and an aliquot was placed on a SEM substrate. Sources of measurement uncertainty were evaluated and the major source of variability was found to be directly related to the small number of slag wool fibers present on the sample stub. Suitable reference materials containing known amounts of characterized WTC dust must be used to obtain accurate results.

A subsequent inter-laboratory evaluation of the method was implemented by eight laboratories analyzing a number of dust samples consisting of background dust and background dust spiked with material affected by the WTC collapse. The inter-laboratory study results illustrated that the method was able to distinguish WTC affected dust at the 5% level by weight from 22 out of 25 background dust samples.

C27 Lessons Learned About Spray Fireproofing Systems From the World Trade Center Collapse

Roger G. Morse, Barch, Morse Zehnter Associates, Rensselaer Technology Park, 165 Jordan Road, Troy, NY 12140*

After attending this presentation, attendees will: (1) understand how to investigate fireproofing systems; (2) will know about the fireproofing failures that contributed to the WTC collapse, standards developed for spray fireproofing; and, (3) will learn about needed changes to building codes and standards for installation of fireproofing materials.

This presentation will impact the forensic science community by improving the understanding of failure modes for spray fireproofing systems.

Over a ten year period, during investigation of the spray fireproofing systems, many spray fireproofing deficiencies were discovered in the World Trade Center (WTC) towers. Failures occurred due to design errors, installation problems, and maintenance issues. Some of the observed failures affected those highly stressed members that failed causing the collapse of the towers including: the connection between the long span joists supporting floors and the outside walls, the long span joists themselves, and interior core columns. It should be remembered that the towers stood despite the damage inflicted by the planes. It was only after the fires started by the planes that burned long enough to weaken the structural steel that the towers fell. This presentation will describe the investigative techniques used and provide photographic documentation of the observed problems. Experiences during application of spray applied materials during construction of the World Trade Center towers, as well as other buildings, led to development of standards regarding the suitability of spray fireproofing materials for use in buildings and their initial installation. Unfortunately, spray fireproofing materials are relatively fragile and become damaged during later construction activities; and then during occupancy of a building. Additional standards are needed to insure the continued utility of fireproofing systems following their initial application. The importance of these issues has been underscored by the WTC collapse.

Mineral fiber spray materials in common use since early in the Twentieth Century as acoustical treatments were made completely from inorganic materials so they were fire-resistant and were also good insulators. In 1917, ASTM developed a full scale fire test, now standard E119, to determine if structural elements would survive a fire, and if so for how long. A vigorous mineral fiber industry, looking for new markets, applied sprayed mineral fiber acoustical materials to structural steel elements and subjected them to the ASTM E119 fire test. It was discovered that when tested, these materials were sufficiently rugged, temperature resistant, and survived a fire long enough to meet building code requirements. This discovery made high rise construction more efficient and less costly helping to spur the post-war high-rise building revolution into high gear, including the building of the World Trade Center towers.

However, all this was not without problems. Serious application problems with spray fireproofing materials existed at the time of construction of the WTC towers. Sometimes spray mineral fiber materials would fail to stick to the surface of the steel members and simply fall off. This happened to the spray material on the core columns, the columns that bucked in Tower one, where the fire protection fell off in story high sheets exposing the naked steel to fire conditions. Sometimes the spray material would be too thin or have insufficient density to adequately insulate and protect the steel from fire. In the WTC towers, spray fireproofing was found to be either completely missing or too thin to protect critical structural members in many locations, such as the highly stressed ends of the long span joists and their connection at the outside walls, the location where the floors in the fire areas of the towers fell helping to initiate a progressive collapse. In 1977, years after the WTC towers were completed; ASTM developed standard E-736 that set forth tests for adhesion and cohesion, and Standard E-605 to measure thickness and density. Had these standards been in place at the time of the WTC construction it is likely that the observed deficiencies would have never occurred.

In 1980, standards were developed to test the suitability of a spray applied material for use for fire protection of steel; however, the work on standards and regulation governing the use of spray fireproofing materials is not complete. Buildings that pre-date the standards, damage during construction and occupancy still need to be addressed.

C28 A Review of the World Trade Center (WTC) Dust Screening Procedure

Richard S. Brown, MS, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Suite 400, Duluth, GA 30096-893*

After attending this presentation, attendees will gain insight into the process used by EPA and others to develop a procedure to screen dust samples for the presence of particles unique to the collapse of the World Trade Center after the September 11, 2001 terrorist attack.

This presentation will impact the forensic science community by showing the practical limitations built into the method and based on the instrumentation chosen to carry out the analysis ultimately prevented the method from being adopted by the EPA.

It was evident during a meeting of experts sponsored by the EPA that a substantial amount of time, labor and resources had been invested in the "Dust Screening Procedure" developed by USGS and EPA scientists and staff in their attempt to produce a cost effective analytical procedure to determine the presence of WTC dust particles in settled dust samples that could be followed by a commercial laboratory. During the day and a half "Dust Screening Procedure" evaluation meeting, the purpose of the procedure, the details of the procedure, and discussions about the procedure were presented. This proved to be an excellent way to reveal any potential problems with the procedure and suggest ways to correct them. A set of 32 samples would ultimately be distributed to the eight participating laboratories, (three government and five commercial) for analysis according to the procedure adopted with any modifications. The results would be reported back to EPA for compilation.

Scanning electron microscopy-energy dispersive x-ray spectrometry (SEM-EDS) was the method of choice. The SEM-EDS analysis was manual and labor intensive, using x-ray maps or to perform quantitative analysis of particles dispersed in a field of view. This technique was based

on an approach that could be applied to polished sections but was not appropriate for the analysis of particulate dispersed on a sample stub. Automated scanning electron microscopy, a technique that has been available to the forensic community for over 25 years, was discussed, but the fact that automated SEM-EDS was not generally available to the participating laboratories prevented its incorporation into the method. Polarized light microscopy (PLM), the work-horse of settled dust sample characterization, was not well represented. Many of the participating laboratories also did not have this capability (government labs included) and there was little confidence within the government agencies that PLM would be able to produce verifiable and reproducible data.

Time requirements of the analytical procedures incorporated into the method were such that collecting the x-ray maps (or x-ray images) required over 6.5 hours of instrument time. This did not include the time required for off line processing of collected digital images, manual SEM-EDS measurement and analysis of any glass fibers that may have been present and the time required to generate a report. The allocation of instrument time, analyst time and sample turnaround time were not well considered in the planning stages of the method development. The procedure that was eventually adopted took well over an eight hour work day to complete a single sample analysis by SEM-EDS. Instruments capable of automated analysis using motorized stages and available software were not an option due to the limited availability of such automated instrumentation in the government labs and in many of the commercial laboratories that participated in the study.

Overall, the study was limited by a singular approach to the analysis of a very complex sample. The "Dust Screening Procedure" was the result of existing USGS capabilities and was limited to the analytical capabilities available at USGS and the experience of the analysts with respect to multi-component dust sample analysis. Had the participating laboratories been allowed the opportunity to modify the procedure based on the sample constituents and known and widely accepted analytical methods, a more streamlined and thus cost-effective procedure may have been produced and ultimately accepted by the EPA.

WTC Dust, SEM-EDS, Microscopy

C29 Update on Dust Particulate Analysis From the World Trade Center Disaster of September 11, 2001

James Millette, PhD, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Suite 400, Duluth, GA 30096*

The goal of this presentation is to provide an update 10 years later to the forensic community on the microscopical analysis of dust particles from the World Trade Center Disaster of September 11, 2001.

This presentation will impact the forensic science community by showing how forensic microscopical studies display the differences between WTC dust and other dusts from other sources in indoor environments thereby helping to provide the scientific information necessary for judicial decisions.

After the September 11, 2001 attack on the World Trade Center buildings in New York City dust samples were collected from a variety of locations both inside and outside of buildings. Microscopical analysis of dust samples showed that the dust was composed primarily of construction debris containing glass fibers, plaster and cement particles as well as soot, wood particles, paper, and cotton fibers.[1-3] Similar findings have been published by the U.S. Geological Survey.

Based on a number of samples and a number of different types of analyses, the general composition of the WTC dust was found to be:

- Glass fibers (primarily mineral wool) - 35 – 40 %,
- Gypsum particles - 25 – 30 %,
- Cement/Calcium-containing particles - 10 – 15 %,
- Cellulose (paper, cotton, wood fibers) - 5 – 10 %,
- Combustion Products (soot and char) - 1 – 10 %,
- Crystalline Silica ~ 6 %,
- Asbestos (primarily chrysotile with some amosite and tremolite) - < 1 – 2 %,
- Other Material Classes (paint, metal, vermiculite, glass shards) - <1 % per class.

Elongated particles of calcium/sulfur/silicon were also found. The source of these particles has not been determined. They may have been generated from wallboard gypsum and ceiling tile mineral wool under high temperature conditions.

All the classes of components in the WTC dust have been found in other residential and office dust samples but the population of small particles containing a combination of a high amount of glass fiber, a high amount of construction debris material (plaster/cement) and obvious presence of combustion product particles (both char and soot) serves as a distinguishing characteristic of WTC dust when compared to most typical residential or office dusts. Pieces of asbestos large enough to be seen with the light microscope are also a characteristic of some WTC dust samples because large asbestos particles are not seen in normal building dust samples. With the exception of the elongated calcium/sulfur/silicon particles, all the types of particles in the WTC dusts have been reported as associated with normal dusts. At this time, no single particle type is accepted by the scientific community as a signature particle for WTC dust.

WTC, Dust, Microscopy

C30 Luminance as a Metric for Accident Reconstruction and Avoidance Analyses of Headlamp-Only Vehicle/Pedestrian Collisions

James B. Hyzer, PhD, Hyzer Research, 1 Parker Place, Suite 330, Janesville, WI 53545-4077*

The goal of this presentation is to present a scientifically-valid luminance-based method for evaluating visibility distance to dark-clad pedestrians under headlamp-only illumination.

This presentation will impact the forensic science community by showing how identification luminance can be used to determine identification distances to pedestrians for the reconstruction and avoidance analyses of many common types of nighttime vehicle/pedestrian collisions.

Photometry is the measurement of quantities associated with light. Two primary quantities of light that can be measured directly are illuminance (measured in footcandles or lux) and luminance (measured in footlamberts or candelas/meter squared). Where illuminance is the density of luminous flux (light) incident on a surface, luminance is the quantity of light reflected or emitted off the surface in a given direction.

For practical forensic applications, the luminance of an object or pedestrian is a function of the amount of light falling onto the surface, the reflectance of the surface, and depending on the type of reflection, the relative orientation and position of the surface with respect to both the light source and the observer. In the case of headlamp-only automobile/pedestrian collisions, light falling onto the pedestrian is exclusively from the headlamps of the colliding vehicle, measured as illuminance.

The illuminance gradient falling on a pedestrian from an approaching vehicle is shown in figures 1a and 1b for a pedestrian standing to the left and right side of the path of the vehicle, respectively, for distances from the approaching vehicle in 50 foot increments from 400 to 100 feet. The figures are demonstrative of how illuminance gradients vary for pedestrians on the left compared with those on the right, as the vehicle approaches.

Whether the pedestrian is visually detected, recognized and then perceived by an approaching driver depends on the extent to which the pedestrian is more or less luminous than the background upon which he is visualized. To detect an object means to discover or determine its presence. A detected object that is also a hazard, however, may not necessarily be recognized as a hazard. To see the object, simply means to perceive it by the eye or by vision. To perceive it means to become aware of its presence through the senses (here by vision). An object is visible if it is capable of being seen. An object is conspicuous if it attracts or tends to attract the attention of an observer so as to be readily discovered by vision. Conversely, an object is inconspicuous if it is not readily noticeable or discoverable by vision. The term conspicuity, then, is the capacity of an object to stand out in relation to its background so as to be readily discovered by vision.

Figures 2a and 2b are cumulative probability plots of identification distance and identification luminance of a dark-clad pedestrian under U.S. low-beam headlamp illumination for pedestrians standing to the left and right of the vehicles path. How these figures were derived is described elsewhere.[1]

The results of this analysis allow the accident reconstructionist to determine visibility distance from luminance measurements or calculations for many common collisions involving vehicles operating with low beam headlamps and dark-clad pedestrians. A luminance-based analysis permits interpolation and extrapolation to be made for different pedestrian positions in the roadway and different clothing reflectance. Additionally, with a luminance-based analysis driver/observer statistics and expectancy considerations can be quantified.

Accident Reconstruction, Visibility, Illumination

C31 Threshold Energy for Vehicle Damage in Rear Impact Collisions

John J. Smith, MSEE, Raymond P. Smith & Associates, 43766 Buckskin Road, Parker, CO 80138; and Bradley B. Boville, HSD, Raymond P. Smith & Associates, 4289 Monroe Drive, Apartment C, Boulder, CO 80303*

After attending this presentation, attendees will have a greater understanding of the relationship between speed, energy, and damage in collisions.

This presentation will impact the forensic science community by enabling attendees to more accurately reconstruct and analyze low-speed no-damage collisions.

Over the last two decades, more than a thousand full scale vehicle-to-vehicle collision tests have been performed by a variety of investigators and organizations. In addition, an even greater number of full scale vehicle-to-barrier crash tests have been performed. These tests have provided substantial amounts of data regarding damage and energy absorption in bumper-to-bumper impacts. The data has revealed that vehicles absorb significant amounts of energy before the onset of visible damage.

For the purposes of this paper, cosmetic damage is defined as scuffing or scraping and can be considered to be similar to minor parking lot contact damage. Bumper damage is defined as damage to the bumper plates, brackets, or assemblies, including bending or misalignment provided it is limited to the bumper assembly. Structural damage is defined as damage to the sheet metal or frame of the vehicle outside the bumper assembly area.

The theoretical background for the investigation is based on the principles of conservation of momentum, conservation of energy, and restitution. The relevant energy into a rear impact is the kinetic energy possessed by the vehicles. Based on conservation of energy, the energy into the collision must be accounted for in the energy transferred to the struck vehicle in the form of increased velocity, the energy dissipated in the components of the vehicles and the kinetic energy retained in the striking vehicle. Additional energy is dissipated in the form of noise and heat but these have not been shown to be significant in terms of reconstructing the impact.

Mathematically, the principle can be represented by:

$$KE\,(V1)_{pre\text{-}impact} + KE\,(V2)_{pre\text{-}impact} = KE\,(V1)_{post\text{-}impact} + KE\,(V2)_{post\text{-}impact} + C_{rush}E_{nergy}\,(V1) + C_{rush}E_{nergy}\,(V2)$$

In addition to the conservation of energy, momentum must also be conserved. The relationship of the final distribution of the momentum between the vehicles is a function of the restitution in the collision. In order to determine the total energy absorbed by the vehicles, the equations for conservation of momentum and kinetic energy were solved simultaneously using the appropriate restitution values.

In the course of the research,[1-15] 15 SAE technical papers, IIHS test data, other fully documented unpublished test results and NHTSA research dealing with full scale bumper impacts were reviewed. Of these, 10 papers were considered to possess sufficient data to perform an analysis of the energy absorption in vehicle-to-vehicle collisions. These papers covered 163 vehicle-to-vehicle, front-to-rear collisions. IIHS and NHTSA crash test data were considered in order to compare vehicle-to-vehicle collisions with vehicle-to-barrier collisions.

Due to test constraints, many of the published tests found used the same vehicles repeatedly. Often the tests were performed with human biomechanical considerations and did not continue until vehicle damage occurred. Additionally, many of the vehicles experienced both front and rear impacts. For the purpose of determining energy absorption, frontal and rear impacts on the same vehicle were considered as separate events although total energy absorption values from all impacts for each vehicle were considered. Table 1 provides a summary of the test data reviewed and the results of each set of collisions.

One concern with the data was the over representation of 1980s and 1990s vehicles. To evaluate the effect of using older vehicles, IIHS barrier impacts were researched.[16-20] Comparing older vehicles with newer models revealed that, in general, the cost of repair in the IIHS crash test has been decreasing since 1995, the earliest year reported. Nineteen vehicles were reported for which direct comparisons of crash test damage between a new model and an older model existed. Six examples were found where repair cost increased for the newer model. Only two of these increases were significant; comparisons between the 1997 and 1999 Mazda Protégé and the 1999 and 2004 Nissan Quest. Both increases correlated with significant model changes. If the vehicles suffered similar damage there would be an escalation expected for inflation. The decrease in repair costs can be attributed to improved vehicle body and bumper structure resulting in greater resistance to damage.

A comparison to barrier impacts revealed that damage to vehicles increased significantly when striking an immovable barrier. Table 2 provides a comparison using NHTSA crash tests for 1982 and 1984 Honda Accords.[21] In this case, a vehicle-to-vehicle collision at 60.1mph. resulted in only 90% of the crush seen in a vehicle-to-barrier collision at 34.8 mph., despite the vehicle-to-vehicle collision having 298% of the kinetic energy of the vehicle-to-barrier collision. The data show that damage to vehicles is much greater when colliding with a barrier rather than another vehicle, even at lower speeds.

Analysis of the data revealed that the onset of damage to the bumper systems beyond minor cosmetic damage typically did not occur until over 10,000 foot pounds of energy had been absorbed. Damage beyond the bumper system typically did not appear until energy values approaching 15,000 foot pounds were dissipated. The highest single impact with no damage dissipated 7,642 foot pounds of energy. These values cannot be considered the upper limit since some vehicles had cumulative energy absorption in excess of 30,000 foot pounds with no damage.

The data revealed that from a reconstruction standpoint, significant amounts of energy are absorbed in vehicle-to-vehicle, bumper-to-bumper collisions before the onset of damage to the vehicles. By using the energy threshold values determined in this paper, it should be possible to determine minimum impact speeds by combining momentum, energy and restitution (MER). MER analysis has been described in the past by some authors,[22-24] but has always been limited by the lack of data regarding the initial threshold energy values.

Bullet Vehicle	Target Vehicle	Total Energy Absorbed (ft-lbs)	Bumper Damage Onset (ft-lbs)	Structural Damage Onset (ft-lbs)
1984 Ford Mustang	1982 Toyota Celica	6,967	No Damage	No Damage

Table 1: Onset of bumper and structural damage for reported collisions

1. Damage was to both vehicles
2. Damage was to Accord. Total absorbed energy for collisions with the 929 was 17,623 with only damage to bumper assembly.
3. Total absorbed energy for collisions with the Mazda 929 was 28,269 ft-lbs with no reported damage.
4. Damage was to the Celebrity. Total absorbed energy for collisions with the Cavalier was 10,053 ft-lbs with no reported damage.
5. Damage was to the Cavalier. Total absorbed energy for collisions with the Cavalier was 14,520 ft-lbs with small buckle to fender.
6. Total absorbed energy for collisions with the 1981 Escort was 20,432 ft-lbs.
7. Total absorbed energy for collisions with the GMC C 1500 was 35,916 ft-lbs with no reported damage.
8. Each of the four vehicles in this series was involved in two collisions. Total absorbed energy for collisions with the 1993 Festiva was 5,508 ft-lbs with no reported damage.
9. Total absorbed energy for collisions with the Dodge was 14,643 ft-lbs with no reported damage and one test omitted.
10. Combining both tests results in 11,692 ft-lbs with no reported damage.
11. Total absorbed energy for collisions with the Buick Regal was 12,819 ft-lbs with no reported damage and one test omitted.
12. Total absorbed energy for collisions with the Ford was 26,027 ft-lbs with no reported damage.
13. Total absorbed energy for collisions with the GMC was 24,203 ft -lbs with no reported damage.

Test Type	Closing Speed in m.p.h.	Average Crush in mm	% Average Crush	% Kinetic Energy
VTB	34.8	637	100	100
VTV	60.1	571	90	298
VTV	55.6	567	89	255
VTV	54.9	570	89	249

Collision, Low Speed, No Damage

C32 Method for Predicting Rear Impact Force Levels Associated with Bumper Override and Sheet Metal Crush

Kenneth J. Saczalski, PhD, Environmental Research and Safety Technologists, 1440 West Bay Avenue, Newport Beach, CA 92661; Todd K. Saczalski, BS, 141 Calle Irena, Sedona, AZ 86336; and Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Suite A, Edgewood, NM 87015*

The goal of this presentation is to provide an accurate analytical reconstruction tool to estimate crash force levels associated with rear-impacts that involve "bumper override" and large "sheet-metal crush damage".

This presentation will impact the forensic science community by providing a simplified means for evaluating "average-peak-G" force levels needed to assess vehicle rear-impact seat performance as related to

occupant loads and injury risk for both front seated adults, and rear seated children located behind, when large amounts of "offset sheet metal override crush" are experienced.

In many rear-impact accidents the front bumper of a large striking vehicle, like a pick-up or tractor-trailer type vehicle, eventually "overrides" the stiffer rear bumper structure of a smaller struck vehicle, like a minivan or sedan, and then induces a significant amount of "less-stiff" "sheet-metal crush" deformation that tends to complicate reconstruction of "average-peak-G" force levels experienced by the struck vehicle. The accuracy of these "average-peak-G" force levels is important in assessing the struck vehicle occupant interactions and performance of safety devices such as "seat systems" and "restraints" needed to hold front occupants securely in place and free from contact impact with rear occupants, like children, or non-yielding structures located behind. Unfortunately, most reconstruction programs and methods rely on high "linear-stiffness" parameters obtained from "moving-rigid-barrier" rear impact tests that simultaneously engage the "stiffer" bumper floor structure and the "less stiff" vehicle body sheet metal structure. The use of such "simultaneously" measured "linear-stiffness" parameters, especially in cases where "bumper override" and larger amounts of offset "sheet-metal" body-crush takes place, tends to "over-estimate" the impacted vehicle "peak force" levels, thus complicating the injury risk assessment of "seat system and restraint" safety performance.

In the current study, both "vehicle-to-vehicle" dynamic crash tests and quasi-static "bumper-override" and offset "sheet-metal" body crush tests were run to delineate and assess the stiffness effects associated with large amounts of offset "sheet-metal" body crush characteristics. The "bumper-override" and offset "sheet-metal" body crush "quasi-static" tests were run on a complete minivan vehicle and a sedan where a "barrier face" simulating the "front of a tractor-trailer vehicle" was laterally offset to overlap only about one-half of the test vehicle and was then slowly pushed into the top edge of the vehicle rear-bumper, causing the vehicle to "squat" on the rear suspension, allowing the "barrier face" to "only engage and crush" the sheet-metal body structure of the test vehicle. The measured forces and deformations from these offset "sheet-metal" body crush tests were used to calculate energy levels that were then compared to energy calculations made using the traditional "linear-stiffness" parameters obtained from "moving-rigid-barrier" rear impact tests. These comparisons indicated that the offset "sheet-metal" body crush energy was actually only about one-half the energy levels obtained from the traditional "linear-stiffness" parameters.

Next, "vehicle-to-vehicle" rear-impact crash tests were run on a popular family minivan and a sedan vehicle where the vehicles were impacted by a 20,000kg tractor-trailer rig traveling at about 40kph and inducing large amounts of offset "sheet-metal" body crush. In addition, "vehicle-to-vehicle" tests were also run on the minivan with impact from a pick-up and a mid-size truck that also induced offset "sheet-metal" body crush. Next, the struck vehicle crush energy from the above tests was analyzed in two parts by using the traditional "linear-stiffness" parameters obtained from "moving-rigid-barrier" rear impact tests to estimate crush energy for the "bumper engaged" portion of the crush, and then the offset "sheet-metal" body crush "energy" was calculated and adjusted as per the quasi-static test results. Both energy contributions were next added together and then used to calculate "fixed barrier" equivalent velocities for the stuck vehicles of the crash experiments. The average of the "fixed barrier" velocity was then divided into the maximum measured total crush to get an estimate of crash pulse duration. Finally, a trapezoidal crash pulse shape was assumed with equal 1/3-time increments for "rise," "dwell," and "decline" portions of the pulse. The area under the assumed pulse was then equated to the "fixed barrier" velocity to obtain an estimate of the "average-peak-G" force levels. This value was then compared to the measured maximum slope gradient of the experimental crash "speed-change" curve. The values of calculated "average-peak-G" force levels compared within about 10 percent of the measured maximum slope gradient for the tests examined. The method has application to cases with large amounts of offset "sheet-metal" body crush.

Rear-Impact, Bumper Override, Average-Peak-G

C33 Landfill Operations and Vehicle Rearward Visibility Hazards: A Case Study

Harold Josephs, PhD, Kehilla Associates Incorporated, Box 1012, Berkley, MI 48072*

After attending this presentation, attendees will learn some of the hazards involved in landfill operations to include those involved with vehicle visibility issues and other hazards created by the lack of adequate procedures and training.

This presentation will impact the forensic science community by presenting a case study of a largely unreported or under reported industrial hazard situation.

An active "landfill face" is perhaps one of the more hazardous work environments in industry wherein workers and industrial vehicles share the same work space. The active landfill face is a work environment whose topography is continually and continuously changing. Mounds of debris and garbage are delivered and dumped by waste hauler trucks on the landfill face or tipping area as directed by the "waste spotter" or just "spotter." Additionally numerous large noisy earth moving vehicles also under the direction of the spotter are active on the landfill face to both move the debris and to pack it down. The subject track loader which weighs more than 29 tons is a large machine and because of its size will present visibility limitations to the operator especially when travelling in reverse. This is significant given that it is known and foreseeable that these vehicles will travel in reverse approximately 50% of the time during normal operational conditions.

The case study reviewed herein, involves a track loader commonly referred to as a bulldozer working on an active landfill face and travelling in reverse wherein the bulldozer driver was inadequately trained. Additionally, the bulldozer back-up alarm while installed and operating was mounted behind portions of the grill support structure. There was closed circuit TV system provided with the bulldozer to guide the operator while travelling in reverse. The accident occurred while the bulldozer was travelling in reverse over a hillock of debris striking the spotter and amputating both his legs. Although having a back-up alarm its effectiveness was considerably diminished given the loud ambient noise generated by the vehicle's large diesel engine and the blocked mounting location of the back-up alarm.

Given that the spotter works in an especially hazardous environment it is imperative that any landfill operation provide the spotter with a detailed work description and thorough training. In this case study there were no written procedures in place and no training provided for the spotter. Therefore, there were no procedures or any training in place for the spotter and the bulldozer operator to communicate as to their location and intended movement. Even though the landfill operation had a person identified as the landfill's safety director, the person so identified admitted that he had no training in safety, that he was not really responsible for safety and that indeed there was no knowledgeable individual in the company responsible for safety at the landfill operation at the time of the accident. This situation is especially egregious when noting that the subject bulldozer was with an optional "waste handler" package, a configuration that was specifically designed for use in sanitary landfills and other waste handling situations. Therefore at the time of sale, the track loader manufacturer knew of the intended use of the bulldozer and that it would be travelling backwards approximately 50% of the time and when travelling in reverse the vehicle operator would have limited visibility of the vehicle's immediate surroundings. Assessments of the vehicle visibility was made by the manufacturer on the basis of purely humanistic subjective and static driver

evaluations without taking into account the dynamic visibility issues arising with the vehicle travelling in reverse on the crowded and busy active landfill face. The subject bulldozer was not equipped with any of the commercially available in-cab camera systems nor even any outside mirrors to mitigate against the vehicles rearward visibility limitations.

Landfill, Visibility, Procedures

C34 Experimental Model for the Determination of Coefficients Penetrating through the Skin of Bullets from Different Gauges of Short Weapons: A Preliminary Study Partially

Giulio Di Mizio, PhD, MD, Policlinico Universitario Camp, Germaneto, Edificio Clinico, Sec. Forensic Medicine, Viale Europa, Catanzaro, 88100, ITALY; Federica Colosimo, MD, Magna Graecia University of Catanzaro, Forensic Medicine, Campus Universitario S. Venuta, Viale Europa Loc. Germaneto, Catanzaro, 88100, ITALY; Pietrantonio Ricci, MD, Università degli Studi Magna Grecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, ITALY; and Claudio Gentile, PhD, University of Messina, Dipartimento di Fisica, Facoltà Scienze MMFFNN, Salita Sperone, 31, Messina, 98166, ITALY*

After attending this presentation, attendees will: (1) understand some principles of forensic ballistics; (2) the necessary elements for the application on treminal ballistics; and, (3) its experimental paths.

This presentation will impact the forensic science community by describing the key aspect of scientific research in terminal ballistics on a biological target. These experimental applications will be useful for a better and more reliable reconstruction of violent crimes made with firearms in the future.

Before a bullet can cause significant injury, it must be able to pierce the skin. The penetration of a projectile into the skin is different from other tissues because the drilling process requires a relatively high impact velocity. The knowledge of the minimum speed of penetration of the skin is important data for forensic medicine and forensic ballistics to evaluate the penetration ability of offensive missiles or to determine the operating range of the use of a firearm.

It is important to consider that the diversity of materials and the different behavior of individual bullets, depending on their structure and the speed at impact, do not allow the use of a mathematical model generally, but only empirical formulas. On the one hand, some high-speed projectiles deform easily on impact and, on the other hand, some bullets do not rapidly transfer their energy to the target. The starting point for calculating the penetration of the projectile in most materials is its kinetic energy. The penetration of bullets into iron (armor, etc.) has been the subject of extensive studies in the military. From this research, a formula has been developed by Krupp. The penetration of spruce wood is commonly taken as an indicator of the penetration effectiveness of a bullet. It can be calculated with the formula Weigel.

For the study of bone penetration, the formula used is:

$$P = 0.44 \frac{G (V-60)^2}{C \quad 100}$$

V = Velocity at impact

G = weight in grams of the projectile

C = mm caliber bullet

The speed limit at which a projectile is able to pierce human skin has been studied for pistol bullets or spherical balls, using the formula of Sellier:

$$V \lim = 125 \frac{1}{Ds} + 22$$

DS: sectional density of the projectile (G / S)

G: the bullet weight in grams

S: section of the projectile sq. cm

EXPERIMENTAL STUDY: A study was performed to check the validity of the Sellier formula and search for a coefficient of penetration for projectiles involving "no Round Nose". The usefulness of the formula Sellier in terminal ballistics, is its ability to determine - with a close approximation - the speed that a bullet loses in crossing a biological target/human. The study was performed to determine exactly how fast a bullet lost speed as it passed through a biological target, to define the effects of terminal ballistics on the target material (interior ballistics), and clarify many aspects of exterior ballistics of the bullet that caused the gunshot wound (distance firing, identification of such ...). The purpose of the study was to identify a factor of one or two pure numbers which, when inserted in the formula of Sellier, which respectively include a factor (125) or addendum (22), may be representative of the particular morphology of the projectile. In fact, the Sellier is only applicable for round nose bullets, ie round toe, and many times there is a case study on the use of bullets of different morphology [Hollow Point (hollow point), wad cutters (flat tip) truncated cone (conical), metal piercings]. This change, which will be performed on that of the two pure numbers that experimentally vary more depending on the specific type used, would be the attempted penetration coefficient, which in fact is closely connected to the shape of the bullet.

With the testing done, the equation can be rewritten in the form of Sellier and solve the two equations X verifying which of the two numbers that we have replaced the X with several more. The number varies more to become the "C pen"

Experimental limit $V = x \frac{1}{Ds} + 22$

or

Experimental Limit $= 125 V \frac{1}{Ds} + x$

Verification of the Applicability of the Theoretical Sellier Formula

MATERIALS AND METHODS: To make the velocity measurements two ballistic CED M2 chronographs were used which were managed by a microprocessor at 48 MHz with a measuring range from 50 fps to 7000 fps, which can store over 1000 speed measurements.

The two chronographs were placed in tandem with each other by interposing the target on first obtaining the impact speed of the projectile and the second speed output from the target.

The target was made on a young pig slaughtered the same morning of the tests with a skin thickness of 0.2 cm, comparable to the human model.

CONCLUSIONS: Although it is believed that the measurements taken in this first trial are not yet sufficient for the determination of the requested drag coefficient, the trend appears to confirm the validity of the results of the first scenario. The balls from the .32 caliber S & W and the .38 caliber Special lost speed in crossing the simulator at much higher levels than theoretical prediction, and that seems congruent with the obvious lower penetration of these projectiles by the morphology of flat and cylindrical tip section similar to the gauge.

However, there were some inconsistencies in the data, especially in the results obtained for the two series of shots in caliber Br 7.65 mm, which could indicate excessive accuracy of this first experimental model used.

The weapons used in this study were from TSN training center of Messina. These weapons had been fired several thousand times and consequently had very worn barrels. Some variability in speeds measured at the mouth of the weapons appear to contradict the noted condition. Hollow point bullets were not tested using the skin simulant.

To continue this work, which looks promising, it will be necessary to refine the experimental model especially in relation to the medium simulating the biological target. Future experiments should include a tissue of known thickness, which is able to simulate the response of human muscle to a ballistic penetration agent.

Terminal Ballistics, Biologic Paths, Forensic Pathology

C35 Comparison of DOT Certified Motorcycle Helmets and Novelty Helmets in Head Drop Tests

Matthew A. Ivory, BS, and Michelle R. Hoffman, MS, Biodynamics Engineering, Inc., 3720 East LaSalle Street, Phoenix, AZ 85040; Parris Ward, JD, Biodynamics Engineering, Inc., 17383 West Sunset Boulevard, Suite 300, Pacific Palisades, CA 90272; and Carley C. Ward, PhD, Biodynamics Engineering, Inc., 3720 East La Salle Street, Phoenix, AZ 85040*

After attending this presentation, attendees will understand the differences in injury reduction performance of motorcycle helmets that are certified to meet Department of Transportation (DOT) requirements and novelty helmets that do not meet these requirements.

This presentation will impact the forensic science community by demonstrating the differences in the injury reducing performance of two types of similarly looking and similarly priced helmets that do not provide similar head impact protection.

Currently in the United States, laws requiring all motorcyclists to wear a helmet are in place in 20 states and the District of Columbia, while 27 states require only some motorcyclists to wear a helmet. Only three states have no motorcycle helmet use law. Most helmet laws require motorcycle riders to use a helmet that meets the DOT Federal Motor Vehicle Safety Standard (FMVSS) 218. FMVSS 218 requires that in a 138.4cm drop test (5.2m/s) onto a hemispherical anvil, and on a 182.9cm drop test (6.0 m/s impact speed) onto a flat anvil, the peak head acceleration shall not exceed 400g. If the peak head acceleration exceeds 200g, the duration at 200g's must be less than 2ms, and if the peak head acceleration exceeds 150g, the duration must be less than 4ms.

Helmets that are similar in form to a motorcycle helmet designed for on-road use, but that are not certified by their manufacturer to meet the requirements of FMVSS 218 are often referred to as "novelty" helmets. According to the National Highway Traffic Safety Administration (NHTSA), the 2006 NOPUS survey, a probability-based observational survey of motorcycle helmet use in the United States, found that 14 percent of motorcycle riders use helmets that do not comply with FMVSS 218. To combat this problem, NHTSA issued a final rule on May 13, 2011 that changes the labeling requirements on helmets, making it more difficult to sell helmets with markings that resemble current DOT labeling; however, novelty helmets remain a safety hazard.

In the current study, the performance of a DOT certified half helmet and a similar looking novelty helmet were evaluated using a drop tower system. Six drop tests were conducted using a novelty helmet and a DOT certified half helmet. The helmets were placed on a Hybrid III dummy head that was instrumented with a tri-axial accelerometer at its approximate static center of gravity. The head was suspended from a drop tower and dropped onto an asphalt test bed. It was suspended such that the head was free to rotate on impact. The drop height was 152.4 cm, to simulate the height of an average-sized rider on a cruiser-type motorcycle. All data was recorded at 10 kHz. Axis orientation and data filters were used in accordance with SAE J211 Recommended Practice. For the novelty drop tests, the peak resultant head accelerations were 451g, 358g, and 473g for the left, right, and top impacts, respectively. The corresponding HIC_{36} values for the novelty drop tests were 3677, 2260, and 4201. For the DOT drop tests, the peak resultant head accelerations were 143g, 142g, and 243g, for the left, right and top impacts, respectively. The corresponding HIC_{36} values for the DOT drop tests were 739, 595, and 1681.

For this test series, the DOT certified helmet met the DOT criteria described above in all three impacts; however, the novelty did not meet the criteria for any impact. The peak resultant g's from the novelty helmets were 1.9 to 3.2 times higher than those of the DOT certified helmets, depending on head impact orientation. The HIC_{36} for the novelty helmets ranged from 2.5 to five times that for the DOT certified tests, again depending on head impact orientation. These results show that the DOT helmet was at least twice as effective at reducing the potential for head injury when compared to the novelty helmet.

A study by Scher et al., (SAE#2009-01-0248) was similar to the present study with the exception that the head orientation was fixed during impact, so that all head motion was constrained to one direction, similar to FMVSS 218 testing. On average, for the Scher study, the peak resultant g's from novelty helmets were 2.6 times those of DOT certified half helmets, and on average the HIC_{15} for novelty helmets was 2.9 times those of DOT certified half helmets. Thus, based on the average data presented by Scher, both studies showed similar reductions in head accelerations and HICs when using a DOT certified helmet rather than a novelty helmet.

The present study appeared to have higher magnitudes for peak acceleration and HIC for all drop tests when compared to the Scher study. However, because only average data was presented in the Scher study, and because the present study was limited to six tests, direct correlation cannot be accomplished. Possible explanations for the discrepancy between the studies include a constrained head versus a freely rotating head and head impact orientation. Further testing and more information regarding the Scher testing are needed to determine the basis for this discrepancy.

DOT Certified Motorcycle Helmet, Novelty Helmet, Head Drop Test

C36 Frontal Crash Buckle Pretensioner Activation Causing Seat Belt Retractor Skip-Lock Failure

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Avenue, Suite D, Santa Barbara, CA 93111-2326; and Robert D. Anderson, MS*, Biomechanics Analysis, PO Box 7669, Tempe, AZ 85281-0023*

After attending this presentation, attendees will be more informed about a parameter called webbing jerk that can have a detrimental affect on a seat belt retractor's ability to lock as intended in a frontal crash.

This presentation will impact the forensic science community by detailing how the activation of a seat belt buckle pretentioner can cause a retractor skip-lock condition. Case studies will be presented. The presentation will heighten the sense of awareness with regard to undertstanding seemingly conflicting evidence. On one hand, the seat belt assembly reveals artifacts indicating use in a crash. But, on the other hand, the injuries sustained are not those consistent with a properly seat belted occupant.

Introduction: Many modern seat belt assemblies utilize pretensioners to enhance the ability of seat belts to mitigate or prevent injury by removing excess webbing slack and cinching the seat belts on the occupants. By tightening the seat belts, the occupants are more tightly coupled to their vehicle and are able to enjoy the safety benefit of better ride down.

Seat belt pretensioners can be found in the retractor or buckle. When activated, the retractor pretensioner tightens the seat belt by rotating the retractor reel. When the buckle pretensioner is activated, the seat belt is tightened by pulling the buckle and latch plate closer to the inboard anchor.

It has been suspected that certain levels of webbing jerk (rate change of acceleration), upon activation of a buckle pretensioner, can cause retractor to skip-lock. That is, the retractor does not lock before an unintended amount of webbing payout, or does not lock at all. Thus, under certain crash conditions rather than enhancing occupant safety, the buckle pretensioner can induce a skip-lock, thereby negating the safety benefit of seat belt use.

In the past, laboratory tests have demonstrated buckle pretensioner characteristics that produce higher levels of webbing jerk can induce the skip-lock phenomenon. To augment the laboratory results, two examples of skip-lock retractor failure in the field resulting in unrestrained occupant injury patterns to seat belted occupants are presented.

FMVSS: Federal Motor Vehicle Safety Standard 209 is the compliance standard for occupant restraint systems. Section S4.3(j)(1)

states an emergency-locking retractor of a type 1 or type 2 seat belt assembly, when tested in accordance with specified procedures, shall lock before the webbing extends 25 mm when the retractor is subjected to an acceleration of 7 m/s^2 (0.7g). However, it has been shown that certain seat belt assemblies, those with buckle pretensioners, fail to perform within the intent of this section, and at worse, will fail to perform as specified in the standard in real world collisions.

Case 1 Overview: A southbound Nissan Sentra, while crossing a highway, was broadsided by a westbound Plymouth Neon. After impact, the Plymouth came to rest facing westbound in the eastbound lane with no lights. Minutes later, a 2000 Ford Focus, traveling at about 59 mph, struck the Plymouth head-on. The Ford sustained an average of approximately 16 inches of crush, corresponding to a velocity change of about 30mph with a Principle Direction of Force (PDOF) of 12 o'clock. The driver's seat belt was a type 2 assembly featuring a continuous loop webbing, single emergency locking retractor, and a seat-fixed, end-release pretensioning buckle.

Upon impact the Ford's airbag did not deploy and the driver sustained facial lacerations when his head struck and broke the windshield. Inspection of the Ford's interior showed outward bowing of the windshield with bits of hair and tissue embedded in the fracture lines. The steering wheel assembly was loose due to complete separation of the shear capsules. The instrument panel on either side of the steering column was deformed forward. These artifacts, or witness marks, are generally consistent with the forward translation of an unrestrained driver in a frontal crash of this magnitude.

However, inspection of the driver's seat belt revealed that the driver's buckle pretensioner had activated indicating that it had been buckled. In addition, the plastic coating of the D-ring, the plastic opening in the B-pillar trim plastic, and the latch plate showed physical evidence consistent with the webbing rapidly moving through these components. This physical evidence indicates the driver's seat belt was worn, but the emergency locking retractor did not lock, effectively rendering the driver unrestrained.

Review of NHTSA's ODI database did not reveal any defect investigations or recalls for the front seat belts of the 2000 Ford Focus; however, 80 percent of consumer complaints that were related to seat belt or retractor performance in frontal collisions indicated that the seat belt retractor failed to lock.

Case 2 Overview: A three-vehicle collision was initiated when a pickup truck lost control on a rain-soaked highway with a posted speed limit of 70 mph. The pickup truck crossed into the oncoming traffic lane, clipped the left side of a vehicle and then collided broadside with the front of 2000 Cadillac DeVille. The resulting velocity change to the Cadillac was approximately 20 mph with a PDOF of 12 o'clock.

During the second impact, the pickup truck subsequently rode up onto the hood of the Cadillac, pushing the hood rearward toward the windshield. Because the impact was offset to the right front of the Cadillac, the collision resulted in a higher degree of deformation to the front passenger area. The pickup truck may have also engaged the windshield header of the Cadillac, as there was localized intrusion to this region. The Cadillac was equipped with front seat type 2 assemblies that are completely seat integrated, with dual emergency-locking retractors and a pretensioning buckle for the driver and front passenger.

Upon impact the Cadillac's airbags did not deploy and the front passenger sustained serious injuries including multiple facial fractures, a basilar skull fracture, and a comminuted left femur fracture. This injury pattern is consistent with an unrestrained occupant in a frontal impact of this magnitude. Inspection of the Cadillac revealed that the driver and front passenger were in fact seat belted and both their buckle pretenioners activated in response to the crash, but the passenger's emergency locking retractor did not lock, effectively rendering her unrestrained.

Cadillac Product Safety Recall: In November 2000, the passenger lap belt retractor did not remain locked during an in-house 30 mph frontal barrier test. A visual inspection of the retractor revealed a fracture of the lock pawl and shaft tooth, artifacts indicating a partial engagement of the lock pawl to the shaft, or retractor skip-lock.

From December 2000 until March 2001, the seat belt supplier statically tested thirty samples. The conclusion of these tests showed that the damage to the retractor noted in November was an effect—not a cause.

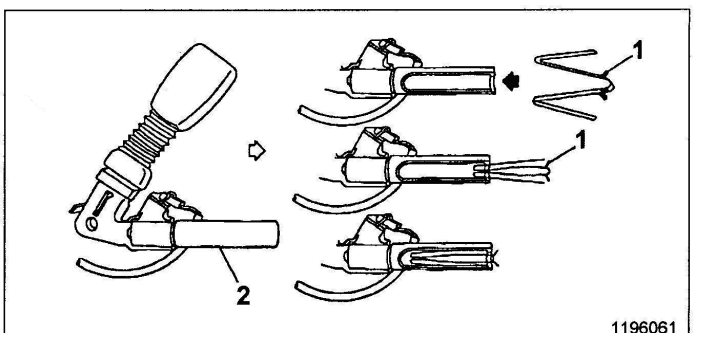
In April 2001, a driver shoulder belt retractor did not remain locked during an in-house 35 mph sled test. Visual inspection revealed a partial engagement of the lock pawl to the shaft.

From April to September 2001, the supplier modified the lock pawl processing to reduce die roll on its tip and improve the area of the lock surface. Static tests were performed to evaluate processing modifications and no significant differences in performance were noted.

In January through April 2002, a sled test series was conducted using seat mounted high-speed cameras to observe the retractor performance and loading profiles, but no suspect retractor behavior was observable. The test protocol was then modified to increase its capability to apply a controlled input to the retractor. It was determined that the velocity of the webbing alone did not duplicate the incident retractor performance. Through data analysis, focus was directed to webbing acceleration onset, i.e., jerk.

A final test series characterized the retractor lock performance over a range of locking pawl pre-positions and buckle pretensioner output (jerk) levels. A trend in retractor lock behavior was determined to be directly related to jerk. As the jerk level increases, the lock behavior transitions from lock on to the design intended tooth to a later lock which may result in a partial engagement of the intended tooth or a lock on a subsequent tooth.

The fix: A revised buckle pretensioner with a reduced micro-gas generator was introduced into the production of the 2002 Cadillac DeVille on May 15, 2002. However, over 269,000 vehicles, produced between May 1999 and May 2002, were subject to recall. Service Bulletins were sent to dealers describing a method to repair the defective buckle pretensioners. The procedure calls for a retainer to be inserted into the pretensioner cylinder (as depicted in the illustration). Once the retainer is seated, when the pyrotechnic micro-gas generator activates, the retainer slows the piston's travel within the cylinder, thereby reducing the level of jerk previously measured.



Conclusion: This study identified two cases where the physical evidence observed on the lap and shoulder belt indicated the system was worn at the time of collision. However, the resulting occupant kinematics and increased forward excursion lead to unexpected upper torso, head and facial injuries. These field examples of retractor failure augment the laboratory results that demonstrated that a jerk condition induced by buckle pretensioner activation could cause a retractor skip-lock condition that resulted in unwanted webbing payout. A vehicle product safety recall was issued for one of the vehicles.

Seat Belt Failure, Skip-Lock, Buckle Pretentioner

C37 Rear Impact Vehicle Occupant Ejection and Seat Belt Slack: Comparison of Upright, Reclined, and Collapsed Seats in Field Investigations and Laboratory Tests

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Suite A, Edgewood, NM 87015; Kenneth J. Saczalski, PhD*, Environmental Research and Safety Technologists, 1440 West Bay Avenue, Newport Beach, CA 92661; Joseph L. Burton, MD, Joseph Burton MD, 13784 Highway 9, Alpharetta, GA 30004; and Todd K. Saczalski, BS, TKS Consulting, 141 Calle Irena, Sedona, AZ 86336*

The goal of this presentation is to inform the engineering, medical and legal community of the phenomenon of seat deflection in foreseeable rear impacts causing vehicle anchored seat belts to predictably fail. This phenomenon has been published in the technical literature since the 1960's but all efforts to enact safety regulations to prevent these failures have been resisted. Alternative designs exist which can prevent these failures.

This presentation will impact the forensic science community by showing how implications of this safety hazard affect all forms of seated transportation, not just ground vehicles.

This study analyzed field and laboratory investigations of rear impacts of passenger cars, utility vehicles, and pickup trucks where belt restrained occupants were partially or completely ejected from their designated upright seating position, and in some instances completely ejected from the vehicle. Hazardous slackening of locked-up vehicle-anchored seat belts was created by collapsing seats, even if seat belt pretensioner systems had been activated by another impact prior to the rear crash. Rear impact crashes analyzed in this study showed severe to fatal injury to front and/or rear seat occupants as a result of seat failure and resultant seat belt failure caused by slackened belts. Changes in velocity ranging from approximately 15 to 30 mph with impact vectors between 160 and 200 degrees. In several crashes there were two belted front seat occupants, with one remaining in a reasonably upright seat and one in a collapsed seat. In all instances the occupant of the collapsed seat was either seriously injured or killed, and the occupant of the upright seat incurred only minor to no injuries. The vehicle anchored seat belt combined with a collapsed seat, was not effective in preventing rearward occupant displacement and/or partial or complete ejection. The slackened belt and poor occupant geometry increased the hazards of submarining under the lap and torso belt. This is consistent with vehicle crash test research published since the 1960's, as well as prior research by Pozzi et. al. conducted and published since the 1970's.

Current research involved further quantifying this belt slackening phenomenon and establishing minimum threshold values for seat movement induced belt slack allowing occupant ejection. Adult male and female human surrogate static testing evaluated vehicle anchored seat belts combined with upright and reclined seats in various vehicles. Approximate seat belt slack was measured for various levels of seat displacement. Approximately 10-12 degrees of static rearward seat movement slackens vehicle anchored seat belts enough to allow rearward ejection of a belted occupant. Slack is exacerbated with dynamic rearward movement of seat belt buckles, seat foam compression, etc. These belt slackening effects were minimized or eliminated on Belt Integrated Seats (BIS). Rearward static load test comparisons using a rigid human upper torso were made between OEM and Modified OEM seats as well as production BIS to establish occupant crash load capacities to the point of allowing occupant ramping out of the seat. Sled and/or crash tests were also conducted to evaluate side-by-side comparisons of various OEM and alternative seat and seat belt designs.

In all rear impact tests in the foregoing velocity range where a weak collapsing seat (600-1,600 lb load capacity) was combined with a vehicle anchored seat belt, the occupant was not effectively restrained or protected. The weakest seats allowed the greatest remaining occupant load contributing to ejection and injury potential. Lap belt loads as the dummy was moving rearward were negligible, and peak vehicle anchored belt loads always occurred on rebound, long after the occupant struck vehicle rear interior structures or a rear seat occupant. The poorest belt performance and greatest slack occurred with vehicle-anchored lap/torso belts that utilized pass-through latch plates. In all tests where a seat remained reasonably upright, the belt remained in significantly more effective contact with the occupant pelvis and upper torso to provide restraint as intended. BIS are significantly stronger, so they resist rearward deformation. BIS upper torso restraints move with the seat so there is no belt slack generated, and proper occupant-to-belt geometry is maintained far better under the same collision conditions than in collapsing seats and vehicle anchored belts.

Crashworthiness, Seatbelt, Seat

C38 Using Surface Volta Potential Measurements to Visualize Fingerprints on Metals

Hefin Dafydd, MPhil, Swansea University, College of Engineering, Student 143422, SA2 8PP, WALES; Geraint Williams, PhD, and Neil McMurray, PhD, Swansea University, College of Engineering, Singleton Park, Swansea, WALES; and Stephen Bleay, PhD, Home Office, Centre for Applied Science and Technology, Sandridge, St Albans, AL4 9HQ, UNITED KINGDOM*

After attending this presentation, attendees will understand how Volta potential measurements are made, leading to the visualization of latent fingerprints on metals. The advantages of this new method will be discussed together with the strategies to further improve the clarity of the fingerprints using Vacuum Metal Deposition (VMD).

This presentation will impact the forensic science community by revealing how a non-contact vibrating capacitor technique can visualize fingerprints on metals without the use of any chemicals, without damaging DNA evidence and with no surface contact.

The fingerprint pattern left on a metal surface often causes corrosion of the underlying metal due to the salt (sodium chloride) content of sweat. The presence of salt on the surface causes the Volta potential to be lowered at fingerprint ridge marks in comparison to the background metal potential. The scanning probe machine is used to measure Volta potential of the metal surface to a comfortable resolution of 500 dots per inch to reveal the latent fingerprint.

The clarity of the fingerprint depends mainly on the corrosive interaction of the fingerprint with the metal. Metals such as iron or brass often give clear images of continuous ridge detail whereas stainless steels or pure zinc are more challenging surfaces due to their higher resistance to corrosion. The image clarity is also affected by the quality of the machine and settings used e.g. resolution, probe dimensions, and scanning height.

The potential contrast between the fingerprint and the background metal can be increased by using the Vacuum Metal Deposition (VMD) technique to apply either silver or gold/zinc coatings that preferentially deposit on the metal. If the fingerprinted metal is noble e.g., copper then the gold/zinc coating is used but if the fingerprinted metal is reactive e.g. zinc then a silver coating is applied.

The typical exhibit that is analyzed is relatively small and flat e.g. a 5cm x 5cm plate or is a piece cut out from a larger exhibit. The machine is equipped with a stage moved by x, y, z and rotational motors allowing moderately non-planar surfaces to be scanned. Cartridge cases of various calibers can conveniently be accommodated and imaged for fingerprint patterns by first establishing a topographic profile for the exhibit followed by volta-potential mapping where a constant probe-to sample spacing is maintained. Examples will be presented of partial print recovery on spent cartridge casings both from laboratory studies and ongoing criminal investigations by United Kingdom police forces.

In summary, this presentation shows how the Scanning Kelvin Probe works and gives examples of fingerprint images obtained on various metal surfaces. The presentation goes on to discuss the use of Vacuum Metal Deposition to further enhance the images.

Fingerprints, Metals, Corrosion

C39 Visualization of Latent Fingerprints Using Columnar Thin Films

Sarah Muhlberger, BS, Pennsylvania State University, Forensic Science Department, 107 Whitmore Laboratory, University Park, PA 16802; Robert Shaler, PhD, 30 Spring Street, Flemington, NJ 08822; Akhlesh Lakhtakia, PhD, Drew Pulsifer, MS, Raul Martin-Palma, PhD, Pennsylvania State University, 212 ESM Building, University Park, PA 16802; and Sarah Muhlberger, BS*, 632A Oakwood Avenue, State College, PA 16803*

After attending this presentation, attendees will have gained knowledge and insight into a new latent fingerprint development technique that does not rely on mechanical or chemical interactions, but instead on surface topology of latent fingerprint ridge detail. Information on optimization of conformal-evaporated-film-by-rotation (CEFR) development for latent fingerprint visualization on multiple substrates as well as comparisons to traditional techniques using split fingerprints and depletion studies will be presented.

This presentation will impact the forensic science community by allowing for an additional option for latent fingerprint development where traditional methods are not ideal or inapplicable. Forensically relevant surfaces for which either typical development methods are ill-suited or multiple techniques are necessary will now have an additional one-step technique available for forensic investigators to utilize.

Similar to vacuum metal deposition, columnar thin film (CTF) technology is a form of physical vapor deposition under vacuum conditions: thermal evaporation of a source material and subsequent condensation of the vapor create a thin film on a substrate that rotates above the vapor flux. Nano-scale CTFs have been employed in optical applications and in materials engineering for more than a century. Typically, surface defects, such as dust or debris, are highly problematic as once a thin film begins to develop on a substrate, the defect results in a non-uniformity, with the underlying defect propagating through the growing film. This phenomenon is, however, ideal for replicating latent fingerprint ridge detail as the topography or surface texture is essentially copied as the film grows. This results in observable contrast between the fingerprint ridge detail and the underlying substrate.

A systematic study was carried out in order to determine the optimal deposition parameters necessary to visualize the best contrast and clarity of developed fingerprint ridge detail. The clarity of development was such that level three details could be resolved. CTF formation was found to rely on: base vacuum pressure during deposition, the average angle of the vapor flux relative to the substrate plane, substrate rotation rate, evaporant material deposition rate, and final film thickness.

Subsequent to the determination of optimal development parameters, the new technique was applied to forensically relevant substrates for which current development techniques are either undesirable or inapplicable. Surfaces such as brass, stainless steel, and various plastics, woods, and adhesive tapes underwent CEFR development using multiple evaporant materials. The evaporant materials utilized included: chalcogenide glass, gold, germanium oxide, nickel, and magnesium fluoride. Each evaporant material was employed on each substrate to determine optimal development conditions for differing surfaces. Split fingerprints were also placed on each substrate, with one half of each print being developed using the optimized CEFR technique, and the other half being developed with traditional techniques such as regular, magnetic, and fluorescent powder dusting, cyanoacrylate fuming, or other techniques recommended for that surface.

The optimal vacuum conditions were determined to be: base pressure of 0.1 mTorr, vapor flux angle of 10 deg, rotation rate of 3 rps, deposition rate of 1 nm/s, and a variable final film thickness of 50-1000 nm depending on the combination of the evaporant material and the substrate under investigation. Multiple evaporant materials were found to be optimal, depending on the underlying substrate. Chalcogenide glass, gold, and nickel all produced development with high contrast and clarity on the substrates investigated, while germanium oxide and magnesium fluoride did not produce optimal results.

Current research is still investigating and assessing the advantages of CEFR technique over traditional fingerprint development techniques on various surfaces, as well as the sensitivity of the technique compared to traditional techniques. The optimal base vacuum pressure found greatly reduces the requirements of a vacuum evaporation chamber necessary for this technology, which allows for increased use of this technique for on-scene development of latent fingerprints in the field. This also greatly reduces equipment cost and increases availability of the new development technique to crime laboratories and law enforcement agencies.

Latent Fingerprints, Conformal-Evaporated-Film-by-Rotation Technique, Columnar Thin Film

C40 Use of Automated Image Analysis Techniques to Determine Impact Velocities in Bloodstain Pattern Analysis

Daniel Attinger, PhD, Iowa State University, Mechanical Engineering, 2025 Black Engineering, Ames, IA 50011-2161; and Zhenguo Li, PhD, Pei-Lun Hsieh, MS, and Shih-Fu Chang, PhD, Columbia University, Department of Electrical Engineering, New York, NY 10027*

After attending this presentation, attendees will understand some principles of automated image analysis and its application to the determination of impact velocity in bloodstain pattern analysis.

This presentation will impact the forensic science community by providing automated methods to determine normal impact velocities of bloodstain patterns. This will enhance the capabilities of bloodstain pattern analysis and crime scene reconstruction.

Bloodstain patterns are deterministic signs of the blood drop volume, impact velocity, and impact angle. Bloodstain pattern analysis is however not straightforward, because the physical relation between the drop impact and the resulting bloodstain is complex and non-linear. For instance, the formation of bloodstains involves a complex interplay of fluid mechanics, heat and mass transfer, the presence of a complex fluid with a deforming free surface, and a solid substrate with specific roughness and wettability. In 2005, Hulse-Smith, Mehdizadeh, and Chandra showed in the Journal of Forensic Sciences that the number of spines (or fingers or rays) at the periphery of a bloodstain could be used together with the stain size to determine both the impact velocity and the initial drop size for the case of mm-size droplets impacting perpendicularly to a target surface. The determination of the impact velocity and the drop size is relevant to the determination of the region of origin of the blood spatter, if parabolic trajectories are to be reconstructed. The hypothesis behind the work presented here is that automated image analysis techniques can be reliably used to count the number of spines and correlate it to the impact velocities.

To this end, automated image analysis algorithms are designed and implemented in the Matlab® programming language, with the ability to accurately detect the edge and centroid of a drop, from where the fingering or ring shape of the drop is described. Given a photograph of a bloodstain, the boundary of the drop is first extracted. This is done by segmenting the

image and detecting the boundary between the drop and the background. Then the boundary in the 2D image is converted into a 1D curve using a distance transform, where the coordinates of a point in the boundary are mapped to its distance to the center of the boundary points. The bumps on the boundary are well preserved in this 1D curve. The number of spines is then obtained by detecting and counting the peaks in the 1D curve, using standard calculus methods.

For mm-size drops impacting at measured velocities between two and five m/s, the number of spines determined by automated image analysis techniques was found to be as reliable as the number of spines counted manually. The method of Hulse-Smith and coworkers was then applied to determine from the number of spines and from the stain size the impact velocity, which was found to be within 20% of the measured experimental velocities. High-density particleboard wood and wallpaper substrates were used, and 100 drops of human blood were tested on each substrate. Other applications of the automated image analysis and pattern recognition methods are discussed, such as the ability to measure the ellipticity of a stain, or the ability to interpret three-dimensional profilometry measurements of bloodstains. The role of the knowledge of drop size and impact velocity on the reconstruction of parabolic trajectories is also discussed.

This project was supported by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. Bloodstain, Image Analysis, Parabolic Trajectories

C41 A Comparison of Tool Marks From Knives, Saws, Axes, and Loppers Used for Dismemberment and Some Comments on Forces

Sarah V. Hainsworth, PhD, University of Leicester, Department of Engineering, Leicester, LE1 7RH, UNITED KINGDOM; Gary Nolan, BSc, University of Leicester, University Road, Leicester, LE1 7RH, UNITED KINGDOM; and Guy N. Rutty, MD, Forensic Pathology Unit, University of Leicester, Robert Kilpatrick Building, Leicester, LE2 7LX, UNITED KINGDOM*

The goal of this presentation is to discuss the types of tool marks left on bone surfaces from knives, saws, axes, and loppers used in dismemberment and to show the characteristic features of the different types of tool marks. Some comments about the levels of force required to achieve dismemberment with the different types of weapons will be made so that a forensic pathologist might have a clear idea of the level of force required with particular implements.

This presentation will impact the forensic science community by showing how implements used in dismemberment leave tool marks. This is particularly important for forensic pathologists but also for forensic scientists and engineers who are asked to provide expert opinions on the force required for dismemberment with the various weapons.

Tool marks are the marks left in a softer material when a harder material is used to cut or strike them. Several types of tool mark are possible: imprints left by the indentation of the tool into the softer surface such as when a knife point embeds in bone; or striations that are left by the edge of the tool by either a sawing or cutting action. Tool marks that leave an imprint or indentation leave a "negative" imprint of the tool itself in the material and as such the imprints can be used to help determine the size and shape of the tool's tip. If the hardness of the bone is known, the size of the impression can be used to calculate the force required (Figure 1). Striations are parallel lines that are caused by a tool's blade either cutting or sawing the material. For sawing, the marks are parallel to the blade's length, for cutting the orientation of the marks depends on the direction of cutting.

Figure 2 shows the typical marks that are left on a bone surface from sawing for example. One goal of the work in this paper is to better understand how tool marks arise in bone or cartilage from the various tools that are typically used for dismembering bodies.

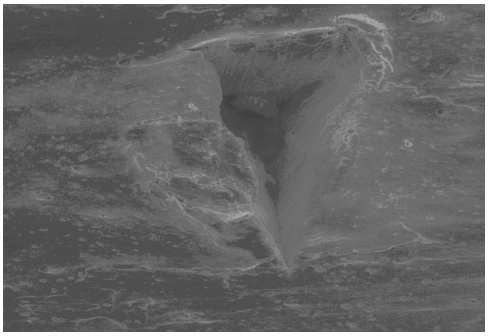

Figure 1: Imprint left in a deer bone from a knife, the size of the impression can be used to estimate the force required.

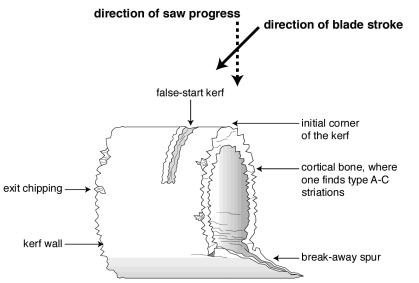

Figure 2: Schematic showing tool marks left on bone from sawing that can be used to identify the tool that made them.

The goal of tool mark analysis in forensic medicine is to compare the marks left on bone or cartilage with the suspected tool or instrument under conditions as close as possible to the conditions under which the original tool marks were made.

Tool mark experts try to match the mark found on the bone or cartilage to weapons that are thought to have made the mark. This can be done by making new marks from the suspect weapon and comparing the dimensions and markings with the ones that were characterized from the bone or cartilage. Traditionally, the impressions or striations are compared with a 3D stereo comparison microscope which allows both samples to be examined at the same time and regions where the marks correspond can be determined from carefully matching the positions of the samples. If a good match is found, over a sufficient area then the marks are deemed to have been made by the same instrument. This technique is used for matching marks from saws, screwdrivers, chisels, knives, hammers etc.

For marks on wood, metal, and polymers, tool marks are often clear and well retained. Bone is also a relatively hard, stiff material and this will also retain good marks. Cartilage is relatively soft and low in stiffness and the marks retained can be less clear. Both cartilage and bone have to be defleshed and dried before tool mark analysis can be performed. Tool mark analysis on bone and cartilage is more challenging because of these factors.

Currently, for marks left with knives, for example, an expert can usually say with confidence in court that a knife *may* have produced the wound, *could* be the murder weapon, or that it is possible to eliminate a particular knife from the enquiry. It is often more difficult to say that a mark *was definitely* made by a particular knife.

The presentation will show a range of examples of the marks left by different tools and show how the forces involved can be determined in some instances and how "uniqueness" can sometimes be determined from the striations left on the surfaces.

Tool Marks, Dismemberment, Force

C42 Soft Computing Application to Anthropological Automatic Characterization in Forensics

Alberto L. Geraci, Dipartimento di Ingegneria Industriale e Meccanica, Università di Catania, Viale Andrea Doria 6, Catania, Catania 95125, ITALY*

The goal of this presentation is to discuss technical methodologies to support forensic anthropology for the identification of the perpetrators of robberies in stores, using video surveillance cameras shots.

This presentation will impact the forensic science community by showing how a modern approach, using a soft computing methodology, can be utilized. In particular, the anthropological correlation is made using fuzzy logic. This allows combining the power typical of non-linear computing methods with the possibility to represent reality using a language similar to the human one.

Forensic anthropology can be used, today, for the identification of the perpetrators of robberies in stores, using video surveillance cameras shots. Literature reports that the most relevant anthropometrical methodsare mainly based on: (1) proportional ratio between height of human figure and of internal furniture items and those displayed on recorded imagery; and (2) observation of subjects characteristics, such as postural poses caused by skeletal pathologies and/or facial details, so that they can be highlighted even though individuals have the face distorted by sunglasses, balaclava, etc.

In many cases, anthropometrical investigation used a fundamental ability to identify people, using video surveillance equipment. Some considerations have to be made: (1) the horizon line (image upper margin) and the ground line (image lower margin) of the perspective representation are drawn on the image shots; (2) The distance between the two lines confirms that the camera vision is from top to bottom; and, (3) The observer position (camera lens) is highlighted when the lines, arranged on the furniture items, reach the horizon line in a point, where the vertexes of the optical cones are.

The human eye perceives things through an imaginary optical cone or visual pyramid, making objects appear greater in the foreground than those in the background. The dimensions of the internal reference structures (furniture) of the crime scene are shown as colored segments. Those drawn on the human figure in the same picture are equivalent to the measurement of the height of the accused subject. It is the anthropological and anatomical correlation that, when defined by the somatic type of the examined subject, makes him absolutely different from others that superficially examined might be considered similar.

A soft computing methodology was proposed to help with the described procedures. In particular, the final anthropological correlation is made using fuzzy logic. The related principle is known as the incompatibility principle. It states that, as the complexity of system increases, the possibility to obtain a precise description of it in quantitative terms decreases. The use of fuzzy logic allows combining the power, typical of non-linear computing methods, with the possibility to represent reality using a language similar to the human one. It appears as a simulating theory to represent phenomena, more or less complex, through a definition of a certain number of fuzzy sets, elaborated with appropriate connectives. The cause-effect connections, regulating the process, are described through fuzzy implications (rules).

Anthropological Characterization, Fuzzy Logic, Soft Computing

C43 Design and Development of a Dynamometer for Quantifying Force Related to Stabbings

Gary Nolan, BSc, University of Leicester, East Midlands Forensic Pathology, Level 3, Robert Kilpatrick Building, Leicester Royal Infirmary, Leicester, LE1 7LX, UNITED KINGDOM; Sarah V. Hainsworth, BEng, PhD, University of Leicester, Department of Engineering, Leicester, LE1 7RH, UNITED KINGDOM; and Guy N. Rutty, MD, Forensic Pathology Unit, University of Leicester, Robert Kilpatrick Building, Leicester, LE2 7LX, UNITED KINGDOM*

The goal of this presentation is to show how dynamometers have a role to play in relating force levels in stabbings to injuries.

This presentation will impact the forensic science community by presenting the design and novel use of a dynamometer that can be used to relate the forces used in stabbings to common actions such as a punch or push. The ultimate goal is to help those in the legal system (judges/barristers/jurors) understand how a force required for stabbing relates to a real life situation, i.e., does the force equate to a hard punch or a slap? The paper discusses whether a scale can be developed that can allow a better appreciation of how engineering data relates to common perceptions about level of force.

In the United Kingdom, murder by stabbing is the most common form of murder. Previously, the forces required for stabbing with knives were considered and shown that the tip radius is important for defining the sharpness of the stabbing implement. Recent work has showed that for blunter instruments such as screwdrivers, the cross-sectional area is important for determining the forces required for penetrating a silicone rubber/foam skin analogue. More recent work has considered how much force is required to penetrate a skin simulant with broken glass bottles and also how much the victim's clothing influences the force required for penetration with knives. Work so far has focused on the force required for penetration of a skin simulant in an effort to identify the most important factors in relation to penetration. The mechanism of knife penetration is controlled initially by the tip sharpness as a knife penetrates the skin, once penetration has occurred, the edge sharpness becomes important for further penetration. Figure 1 shows the sequence of events as a knife penetrates a foam block. In A, the knife is just at the point of contact with the foam; in B, the foam is deflecting elastically but the foam is not penetrated; and, C shows a knife where the tip has penetrated the foam block. This current work furthers the understanding of knife wounding by focusing on the quantification of forces involved in 'real life' stab events.

A series of experiments were conducted using a skin simulant and a dynamometer. A series of everyday actions (such as a push) were carried out and also a series of stabbing actions (such as a thrust or overhand) using a purpose built dynamometer, by a group of volunteers of varying body types, ages, etc. As contact is made with the skin simulant the dynamometer records the load. For the everyday actions the maximum force is recorded during the impact. We will take similar data for the knife penetrating the skin simulant. Previously, stabbing simulations have been conducted using instrumented knives, these have the disadvantage that the knife has been modified to include the instrumentation which makes it more difficult for the person stabbing to use a natural action. In this work, the instrumentation is in the dynamometer and the knife was as manufactured without the additional encumbrance of the instrumentation. This should provide more realistic data to be recorded.

The results should provide quantified force data for both everyday actions and stabbing by volunteers that are representative of the population. These results allow a comparison of forces and are the first stage in an effort to compose a scale that could be used by forensic practitioners in court to explain the forces involved in stabbings to jurors more clearly.

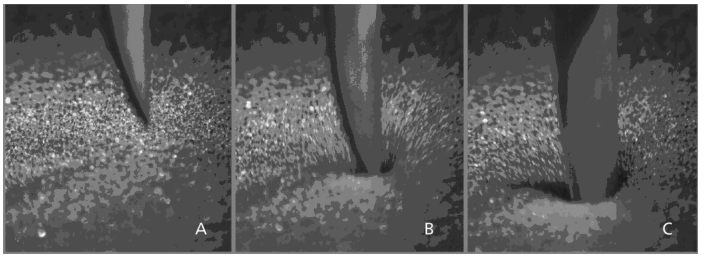

Figure 1: The sequence of events in a knife penetrating a foam block. A shows the tip as it first contacts the foam. B shows elastic deformation of the foam block. C shows both elastic deformation of the block but also the knife penetrating the foam.

Stabbing, Force, Knife

C44 Effect of Surface Tension on the Ability of a Selection of Tribometers to Rank and Differentiate Standard Reference Surfaces

Michael A. Sapienza, BA, Fleisher Forensics, 323 Norristown Road, Suite 130, Ambler, PA 19002; Mark I. Marpet, PhD, PE, 14 Cowie Road, Chester, NJ 07930-9715; and David H. Fleisher, MSCE, Fleisher Forensics, 323 Norristown Road, Suite 130, Ambler, PA 19002*

After attending this presentation, attendees will understand: (1) the significance of surface tension on the slip measuring process; (2) the importance of quantifying and standardizing measurement variables under wet conditions; and, (3) the effect of surface tension on machine bias.

This presentation will impact the forensic science community by demonstrating the effect of surface tension on wet slip resistance measurements and machine bias.

Method: ASTM F2508 was used to measure the effect of variations stemming from the use of surfactants on test results using the same reference materials with a Slip-Test Mark II portable inclinable articulated strut tribometer (PIAST).

Slip resistance and coefficient of friction measurements have been made since the time of Leonardo Da Vinci. In more recent history, efforts to make such measurements meaningful in the context of human ambulation have resulted in a series of test surfaces being subjected to human ambulation studies. The results of those ambulation studies using a select population of young adults produced a suite of walkway surfaces that when wet, ranged in slip resistance from very low (granite) to high (unglazed tile). ASTM F2508 correlated the human-ambulation-study results to tribometer measurements. Slip resistance measurements under water-wet conditions sometimes produce readings that are higher than when that same surface is tested under dry conditions. These results were often considered to be as anomalous, but recently, both normative analysis and carefully controlled tests demonstrated this to be the case. Certain European slip resistance test methods, e.g., DIN-Ramp studies, routinely use surfactants to minimize the effects of surface tension, a factor in the wet-test/dry-test anomaly.

To determine the effect of slip resistance on ranking and discriminating the reference surfaces (Surface), the ASTM F2508-11 specified adjunct tiles from ASTM International: ADJF2508-T4 (Granite), ADJF2508-T2 (Glazed tile), ADJF2508-T1 (Vinyl Composition Tile (VCT)), and ADJF2508-T3 (Unglazed tile) were obtained for this study. These four SURFACEs were tested.

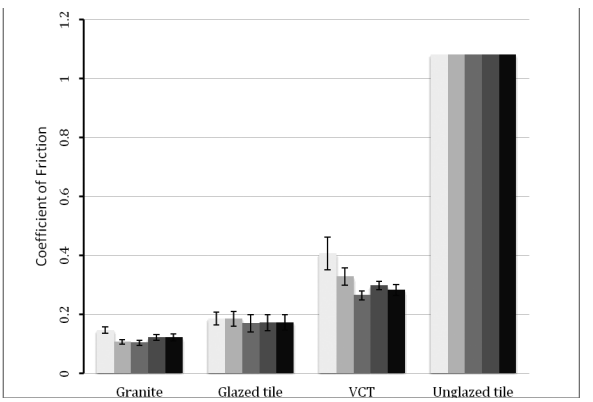
Two Surfactants, sodium lauryl sulfate (SLS) and nonionic surfactant were used to reduce the surface tension of water. Tests were conducted using distilled water and the two surfactants were each tested at two concentrations: 0.05% SLS ((SLS-Low) this is the concentration mandated in ASTM F2508 for cleaning the reference surfaces), 0.10% SLS ((SLS-High) this is the concentration mandated in the DIN Ramp protocol), 0.05% Triton X-100 ((Triton-Low) this is the concentration mandated in ASTM F2508 for testing the granite reference surface), and 0.10% Triton X-100 (Triton-High). Distilled water (Water) was also used, for a total of five Surfactant conditions.

Forty tests for each Surface/Surfactant Condition set were conducted: five replications in each of eight directions 45° apart (Direction). A total of 800 tests were conducted (5 replications x 8 Directions x 4 Surfaces x 5 Surfactants). The tests results were analyzed using a screening ANOVA, with Surface, Surfactant, and Direction as the factors. Direction was found to be not-at-all significant (p-value >40%); Surface and Surfactant were both highly significant (p-values of 0.00% and 0.02% respectively).

The results were aggregated over the not-significant factors, giving the following results, where the first number is the mean value and the second is the standard deviation:

	Granite	Glazed tile	VCT	Glazed tile
Water	0.146/0.01	0.185/0.021	0.406/0.055	≥ 1.08/0
SLS-low	0.106/0.008	0.185/0.025	0.327/0.029	≥ 1.08/0
SLS-High	0.103/0.009	0.169/0.029	0.264/0.015	≥ 1.08/0
Triton Low	0.121/0.009	0.171/0.028	0.297/0.014	≥ 1.08/0
Triton-High	0.122/0.012	0.172/0.026	0.282/0.019	≥ 1.08/0

The bar graph below is clustered by SURFACE, from the most slippery on the left to the most tractive on the right:



The individual bars in each cluster, from left to right (light to dark) are Water, SLS-Low, SLS-High, Triton-Low, and Triton-High. The error bars at the top of the bars are ±one standard deviation. The zero-length error bars for the unglazed tile are a result of the PIAST having reached its maximum reading (1.08); thus there was zero variation. (The results on Unglazed Tile are not to be used.)

The conclusion from the testing is that it matters less what surfactant one uses, but one should use a surfactant, especially in Granite and VCT. Worth noting is that the subset of the results for a given Surfactant: 160 tests, defines the F2508-11 validation sequence.

Surface Tension, Slip Resistance, Reference Surfaces

C45 Progress in the Characterization of Barefoot Pedestrian Friction

Howard P. Medoff, PhD, Pennsylvania State University, 1600 Woodland Road, Abington, PA 19001; Marcus P. Besser, PhD, Thomas Jefferson University, 130 South Ninth Street, Philadelphia, PA 19107-5233; and Mark I. Marpet, PhD, PE, 14 Cowie Road, Chester, NJ 07930-9715*

After attending this session, attendees will appreciate the difficulties inherent in using current methods for measuring barefoot slip resistance. The current state of the art in barefoot tribometry will be discussed, and this paper will focus on improvements in the development of biofidelic test feet.

This presentation will impact the forensic science community by giving current knowledge in barefoot-pedestrian friction metrology. This is significant because it can help determine whether or not a given walkway surface is or is not hazardous to barefoot pedestrians.

Barefoot slip resistance has not received the attention – either through standards, research, or on-site testing – as has the slip resistance of footwear. However, slips and falls in bathrooms, tubs, and showers occur frequently and result in significant injury. The materials in a typical bathroom/shower enclosure are non-resilient which can increase the severity of injury upon contact. Characterization of the friction between the plantar aspect of the heel and a contaminated floor surface would assist architects and interior designers in choosing appropriate materials for those environments where pedestrians can be expected to be barefoot.

The ASTM F462 Standard Consumer Safety Specifications for Slip-Resistant Bathing Facilities, first approved in 1979, used a smooth Silicone Rubber (Silastic 382) test foot in a soapy-water-filled bathtub to determine the slip-safety of a bathtub.[1] More recently, barefoot pedestrian slip resistance has been evaluated using an inclinable ramp to measure the slip resistance of a barefoot pedestrian on a water contaminated walkway surface (DIN 51097 (1992)).[2] Medoff, et al. developed an inclinable Step Meter using an *in vivo* test subject to measure the slip resistance of footwear/walkway combinations, dry and wet.[3] This Step Meter was used with barefoot test subjects, "stepping" onto a varying angle, water-contaminated walkway surface.[4] When the motion of the lower leg was both constrained and passive, it was found that the results were consistent and repeatable. Recently a number of researchers have published studies on the coefficient of friction of a bare foot sliding against marble floor (Sariisik, Ali).[5,6] The Sariisik study used the DIN 51097 Ramp test, with different roughness values of wet marble, while the Ali study was focused on level walking with bare feet on marble with different concentrations of detergent in the water-covered marble flooring.

Medoff, et al.[7] measured the available friction, as determined by a barefoot pedestrian walking on a smooth, water-contaminated, instrumented walking surface, and compared these results with walkway-safety tribometry (WST) measured values on this same water contaminated surface using a smooth silastic 382 test foot. It was found that the tribometer with this silastic test foot was unable to characterize the slip resistance under these conditions, giving essentially zero values for the slip resistance. Siegmund, et al. measured utilized friction when entering and exiting a dry and wet bathtub, barefoot.[8] The bathtub base (porcelain on steel) was modified by adding "slip resistant medallions." They found a wide variation in utilized friction (0.102 to 0.442).

A problem with barefoot WST is that the test feet currently in use lack biofidelity. Our long-term goal is to develop a biofidelic WST test foot. In this paper, we use non-contact optical techniques to characterize the surface morphology of the plantar aspect of the heel.

Methods: Skin morphology was characterized as follows. Plaster casts were prepared of the plantar aspect of the heels of six adults (3M, 3F, ages 21-54). Plaster1 was prepared and placed in a shallow container. The seated subjects' heels were pressed down into the plaster, with the subjects remaining seated until the plaster set (approximately 30 minutes). Subjects' heels were then removed from the plaster, and the plaster was permitted to fully harden for 24 hours.

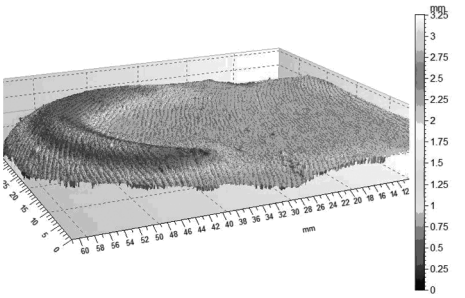
Positive models of the heel were then prepared as follows: Room Temperature Vulcanizing Rubber2 (similar to Silastic 382 medical grade silicone rubber) was mixed according to manufacturer's instructions, poured into the plaster molds, and permitted to harden. This created heel-surface replicates with the associated skin friction-ridge patterns.

The surface morphology of two sample heels was measured using interferometry. These systems use a white light source, where light is focused through an objective lens onto the specimen, and the reflected light is captured. By focusing the lens, the distance from the objective to the sample is captured. Two companies were sent samples for analysis.

The first sample, sent to Zygo,[3] was scanned with a NewView™ 7300 system. This system uses an interferometric objective mounted in a closed loop piezo-scanning device that moves vertically (in the Z direction) over the sample. Data is collected from a CCD camera and processed. The phase relationships of individual components of the white light spectrum in the interferogram are analyzed by Zygo's frequency-domain analysis, resulting in a surface map with ultra-high Z resolution, independent of the objective magnification, with up to one angstrom resolution.

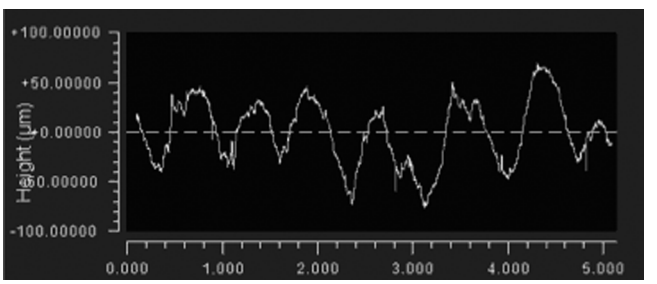
A second sample, sent to Nanovea,4 was scanned with their ST400 Optical Profiler. This system uses "axial chromatism," where white light passes through an objective lens having a high degree of chromatic aberration. (The refractive index of the objective lens varies in relation to the wavelength of the light. In effect, each separate wavelength of the incident white light re-focuses at a different distance from the lens). Due to the confocal configuration of the system, only the focused wavelength will pass through the spatial filter with high efficiency, thus causing all other wavelengths to be out of focus. The spectral analysis is done using a diffraction grating. This technique separates each wavelength and allows direct correspondence to the Z height position. With a measurement range of 10mm, this system has a Z resolution of 280nm and an accuracy of 900nm, with lateral resolution of 2.6 µm.

Results: Overall picture of the 3-D friction-ridge pattern. The three-dimensional graph just below gives an overall view of a typical plantar heel friction-ridge pattern. It has not yet been filtered through a high-pass filter, which would eliminate the low-frequency, i.e., gross height variations.

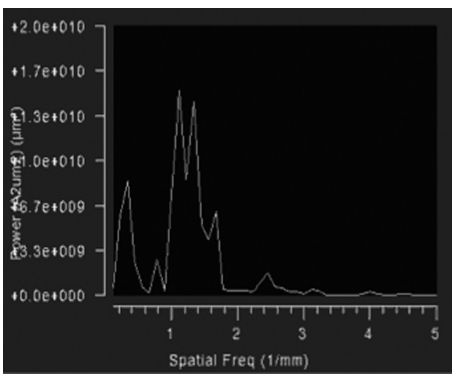


The friction-ridge pattern impressed upon the gross height variations can be seen. A typical cross-sectional result.

Figure 2, below, shows one cross-section of the heel, showing the actual dimensions of a friction-ridge pattern. The ridge-pattern period is roughly 0.8mm with a peak-to-trough extent of roughly 0.1mm. The pattern is very roughly sinusoidal.



In figure 3, below, translation to the frequency domain shows the spacing of the friction ridges (the period) to be between 0.75–0.9mm.



Future Research Directions

The Big Picture: The goal is to produce test feet that, when used with

conventional WST instruments, mimic the Available friction of a pedestrian ambulating with bare feet. The friction-ridge pattern in the plantar surface of the foot has been optimized over evolutionary millennia, forming an essential component of the friction picture. Presently, test feet used to characterize barefoot friction have been smooth. To compensate for the lack of biofidelity inherent is smooth-surfaced test feet, artificially low threshold values for acceptable available friction have been utilized. If the friction-ridge pattern were able to be characterized and implemented in test feet, this would go a long way to making test feet biofidelic, and hopefully eliminate the need for artificially low threshold values.

Mathematical Modeling of the Friction Ridge Patterns: It would be better to develop a generic friction-ridge pattern, versus having someone's friction ridge pattern serve as the standard pattern (in much the same way as the inch was formerly defined as the size of some king's thumb). One approach would be to mill a pattern of grooves in a mold that corresponded to an idealized groove pattern as generated by, say, the averaged-over-multiple subjects' first (or first and second) terms of the Fourier transform of the friction-ridge pattern.

Multi-Phase "Hardness" Characterization: Another important area for friction research is the development of a biofidelic model for the hardness of the friction-ridge pattern. The plantar surface of the heel is comprised of various biologic structures, viz., the epidermis, which contains the friction-ridge pattern, the endodermis, fat pad, the fascia, and the calcaneus (the heel bone). It is rather unlikely, to say the least, that this layered structure could be reasonably characterized by a homogenous material. It is speculated that, at the very minimum, a three-layer test foot is necessary: an outer layer representing the friction-ridge pattern, an inner layer representing the fat pad, and a backing plate representing the calcaneus.

Forensic Science, Walkway-Safety Tribometry, Barefoot Pedestrian

C46 Estimation of TASER® ECD Discharge Duration Based on Surface Morphology Changes

Darko Babic, MS, Exponent Inc., 23445 North 19th Avenue, Phoenix, AZ 85027; Andrew Hinz, BS, Taser International, 17800 North 85th Street, Scottsdale, AZ 85255; Ashish Arora, MS, Exponent Inc., 23445 North 19th Avenue, Phoenix, AZ 85027; and Pedro Peralta, PhD, Arizona State University, Ira A. Fulton Schools of Engineering, PO Box 9309, Tempe, AZ 85287-9309*

After attending this presentation, the attendees will become familiar with analysis techniques that could be used in forensics investigation to correlate the physical evidence to the electrical activity of the Taser ECD. It will become apparent that the changes in surface morphology (physical evidence) indicate the duration of discharge of a Taser ECD.

This presentation will impact the forensic science community by providing a means to analyze and interpret physical evidence that investigators in the past may have neglected to analyze and correlate it to actions taken during an event where a Taser ECD was used. Electrical arcing creates changes in surface morphology that could be used in forensics analysis. This novel approach uses changes in surface appearance and its morphology to estimate the duration of ECD. i.e., it uses physical evidence that was formed by discharging Taser ECD to relate it to discharge duration.

TASER Electronic Control Devices (ECD) are used commonly for self defense and for law enforcement. An ECD is designed to deliver electric current to a subject's body with the purpose of temporarily incapacitating an individual. Activation of the ECD's trigger delivers a burst of energy at the output and to the subject. For example, a TASER X26® ECD is rated to deliver a 1,200 V pulse at the rate of approximately 19 pulses a second (each pulse lasting approximately less than 150 microseconds). The energy flows into the subject's body through the insulated wires and metal probes that penetrate the skin or adhere to the clothing of the subject. The attachment method between the wires and the metal probes creates an air gap between the wire tip and the metal probe's body that must be bridged on both probes to complete and then maintain the electrical circuit. Due to the high voltage pulse, the air gap is bridged by an electrical arc which develops between the wire tip and the metal probe's body. This arcing activity results in visible changes to the wire tip and the metal probe's surface exposed to the arcing. Such surface morphology changes can be useful as physical evidence that may indicate the ECD discharge duration.

ECD discharge tests were performed for a number of time durations. A minimum of three tests were conducted for each discharge duration using two probes connected to a 600 Ohm (Ω) resistor. The metal probe surfaces exposed to electrical arcing during the tests were then analyzed using scanning electron microscopy (SEM) and surface profilometry to determine the correlation between the surface morphology changes and the ECD discharge duration.

SEM analysis indicated that the exposed probe surface appeared visibly more damaged with an increase in the ECD discharge duration. In addition, surface profilometry analysis indicated that the volume of expunged material from the exposed probe area became greater with an increase in ECD discharge time. The preliminary investigation suggests that the changes in surface morphology are a function of the ECD discharge duration. This correlation of the physical evidence with the ECD discharge time can be established by using a combination of SEM and surface profilometry analyses and may become a valuable tool in forensic investigations where the time of ECD discharge is an unknown and a potentially disputed fact.

Duration of Taser ECD Exposure, Probe Surface Morphology, Surface Profilometry

D1 New Suicide Modalities: The Use of a Plastic Bag and Helium - First Case Report in Puerto Rico

Jorge G. Billoch-Lima, MD, University of Puerto Rico School of Medicine, Department of Pathology and Laboratory Medicine, PO Box 365067, San Juan, PR 00936-5067; Dario Sanabria, MD, Puerto Rico Institute of Forensic Sciences, Department of Pathology, Caparra Heights Station, PO Box 11878, San Juan, Puerto Rico 00922-1878; and Irma Rivera, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921*

After this presentation, attendees will better understand the pathophysiology of oxygen displacement by helium and learn information needed in order to process a case like this, should you encounter one.

This presentation will impact the forensic science community by giving the attendees the information needed in order to understand the pathophysiology and process autopsy evidence in a case of this nature. It also adds to the growing list of case reports of this type of suicide.

In statistical terms, suicide (defined as the act of voluntarily taking his/her own life) in Puerto Rico has shown a relatively stable trend during the last decade, shadowing the trend in the United States. Although the methods by which the act is performed have not varied much, new worrisome tendencies have been described in literature. Suicide by hanging is the most common method used in Puerto Rico (for both men and women) and the second most common in the United States. While the use of a plastic bag around the head as a suicide tool had been described for some time, its practice was boosted in 1991 after the publication of the book, *"Final Exit: The Practicalities of Self-Deliverance and Assisted Suicide for the Dying."* Directed towards terminally ill patients, the book presented multiple mechanisms for a dignified death, including, in full detail, the "exit bag" mechanism. In 2002, the third edition of the book included a chapter on the utilization of inert gases as a faster way to reach their objective. Inert gases (e.g., argon, radon, helium) accelerate the death by effectively displacing or substituting the oxygen being aspirated, and depriving the body (especially the brain) of it. Only twenty suicide cases using this methodology have been reported in international scientific literature. Since helium is seldom searched for in the toxicological analysis of a forensic autopsy, it has been hypothesized that the real incidence may be exponentially higher, possibly reaching into in the thousands. A case is presented of a 30-year-old male who five years previously had been diagnosed with bipolar disorder, who was found dead on the floor of a hotel room with an inflated plastic bag around his head, and closed around the neck by an elastic strap. Underneath the bag, a rubber tube entered the bag, connected by a T-fitting connecting to two helium canisters, which were empty by the time the body was found. A piece of elastic strap circled his waist through the belt loops and restrained his wrists without the use of a knot. No suicide note was found on the scene. The scene investigation revealed no sign of forced entry. The deceased had possession of the book, *"Final Exit,"* which was found at his residence. Autopsy revealed mild pulmonary congestion, eyelid petechial hemorrhages, and pressure marks around the neck, wrists, and waist. Toxicology was positive for Buspirone. Airway headspace gas sampling was not performed due to lack of equipment. After ruling out secondary involvement and taking into consideration the scene, family interview and the circumstances around the death, the cause of death was determined to be asphyxia secondary to helium inhalation and the manner of death was determined to be suicide. This is the first suicide case seen in Puerto Rico's Forensic Science Institute utilizing this method.

Helium, Suicide, Puerto Rico

D2 Species Composition of the Maggot Mass

Ashleigh M. Faris, BS, 131 Freddie Drive, Georgetown, TX 78626; Sibyl Bucheli, PhD, Sam Houston State University Department of Biological Sciences, Box 2116, Huntsville, TX 77341; and David A. Gangitano, PhD, 14723 TC Jester Boulevard, Apartment 1118, Houston, TX 77068*

After attending this presentation, attendees will learn how molecular identification techniques were used to validate the hypothesis that the species composition of the maggot mass is comprised of multiple species.

This presentation will impact the forensic science community by determining the species composition of the maggot mass to be a single or multiple species complex. A maggot mass that is composed of multiple species will bear significant impact on insect development studies since the presence of one species can slow or accelerate the developmental rate of another species. These developmental rates will have a direct effect on the postmortem interval estimation.

During initial human decomposition, it has been observed that several adult female fly species visit the body. Even closely related carrion species can differ in their growth rates, diapause response, and/or ecological habits. Therefore, accurate identification of an insect specimen is crucial. Immature stages of many forensically significant species are notoriously difficult to identify in early developmental stages (instars) and lack defining anatomical characteristics. Identifying each maggot according to distinguishing morphological characteristics can be a time-consuming task. In addition, the process can suffer from human error if performed by an untrained forensic entomologist. For these reasons, DNA-based methods of identification should be used.

Currently, the maggot mass is assumed to be of multiple species composition, but this idea has not been validated. Therefore, it is unknown if adult female flies of different species will lay their eggs in the same location on a corpse as other adult female flies. This study will test the hypothesis that a maggot mass is composed of several different species of larval flies. This project will employ the use of automated DNA sequence analysis standards and phylogenetic methods to compare "unknown" maggots to "known" adult flies. Co-Oxydase enzyme I (COI) and Co-Oxydase enzyme II (COII) gene sequences will be amplified and sequenced. COI and COII are unique markers that are highly conserved because they code for respiratory processes (electron transport); and are species-specific genes. The combination of slowly evolving regions coupled with wobble regions makes these genes a perfect marker to use in molecular species identification techniques.

Adult flies and maggots will be collected from three different cadavers during June, July, and August of 2011. Flies will be actively collected with nets for five consecutive days once the human body has been placed. The adult flies will be stored in vials of 95% alcohol until they are identified by species via use of published dichotomous keys, a reference collection, and an Olympus SZX16 stereomicroscope equipped with a DP72 color digital camera. Adults will be stored and saved to serve as positive controls for the maggot DNA sequencing. After one week, first and second instar maggots from the initial maggot mass will be collected and stored in 95% ethanol at

80°C. Fifty maggots from each body will be randomly selected and identified by molecular techniques that have been proposed and validated by forensic entomologist Jeffrey D. Wells[1] and the Bucheli Lab (in prep).

Gut content from frozen maggots will be cut and removed. The remaining maggot muscle tissue will be blended in a tissue homogenizer and DNA will be extracted according to a Chelex extraction protocol. Purification of the extraction will be performed with phenol chloroform protocol. DNA will be quantified by ultraviolet (UV) spectrometry. Polymerase Chain Reaction (PCR) will amplify samples on the GeneAmp PCR System 9700 thermal cycler. Promega Hot Start polymerase master mix will be used in conjunction with primers published by Wells[1] to generate the PCR products. The resulting amplicons will be cleaned using a QIAquick PCR purification kit from QIAGEN. An agarose gel check will be performed to ensure DNA has been amplified prior to sequencing. The sequence will be detected on the Applied Biosystems 3500 Genetic Analyzer with BigDye Terminator version 3.1. The Geneious Pro cross-platform bioinformatics software suite will be used to analyze the resulting sequences. Phylogenetic analysis will be used to perform identification of the maggots sampled from the initial maggot mass. Parsimony analysis will be used to construct a phylogeny where the unknown maggot species and known maggot species will be used. The sister relationship of unknowns to knowns will be used for identification criterion. Bootstrap and jackknife statistics will be calculated to assess clade support and the confidence of the sisters relationship.

Forensic Entomology, DNA, Postmortem Interval

D3 One Murder Case: Advantages of a Holistic Approach in Forensic Science

João De Sousa, Judicial Police of Portugal - Criminal Investigation Department of Setúbal, Praça General Luis Domingues, nº 27, 27A e 28, Setúbal, 2910-585, PORTUGAL*

After attending this presentation, attendees will understand the extreme importance of a multidisciplinary approach to ensure the resolution of a crime of this nature. In this case, a murder crime in which, several areas of research were required, even some that are not commonly applied in this type of investigation, and we will demonstrate clearly that this multidisciplinary approach was crucial to solve the crime.

This presentation will impact the forensic science community by highlighting the importance of a holistic approach that should be used in crime investigations, which is reflected in a multidisciplinary method. With this presentation, the forensic science community will be able to understand the extreme importance of each area of expertise that relates to criminal investigation and leads to the excellence of police work.

Usually, thanatology, biology, and dactiloscopy are forensics areas most commonly requested during a murder investigation. In this case, the reported murder is an example of several disciplines, even those that usually have not been requested for this type of investigation, were crucial for the murder resolution.

On July 10, 2005, in Setúbal District, Portugal (approximately 20 kilometers from the country capital, Lisbon), after a fire extinction in a tree zone used for garbage disposal, the presence of a corpse was detected. This corpse was of a burned and unidentified-male, with no signs of tattoos or any articles that would allow a positive identification. The corpse was gagged with the hands tied behind his back, and after preliminary examination, presented signs of beating. Due to the lack of sufficient identification and interpretation elements, it was necessary to expand the forensic science investigation into areas not commonly used. The use of thanatology, forensic anthropology, lofoscopy, and forensic chemistry for corpse identification was necessary.

About two months later, the corpse remained unidentified. In this period, a vehicle with blood stains was delivered to Judicial Police (Lisbon headquarters), and after collection of blood samples from the corpse (stored in National Institute of Legal Medicine – Lisbon headquarters) and investigation by the Department of Forensics Biology from the Laboratory of Scientific Police, a DNA profile match was obtained.

The corpse was identified as Mr. X, a 71-year-old male individual. The vehicle was purchased during an illicit sale including fake signature (sale contract). Evaluation of the contract was requested and performed at the Department of Handwriting from the Laboratory of Scientific Police.

At this time, the investigators had the victim's identity and, after studying the murderer(s)' profile(s), it was necessary to identify the perpetrators.

After collaboration with the crime scene team of Judicial Police, a home search in the residence of the main suspect, established it was the place where the murder had been committed with help of another individual. Information regarding the exact places where the victim was tortured and murdered as well as the place where the body was placed during two days, the artifacts used during beating, and relocation (covering, transportation, and destruction by fire) of the corpse was obtained. The murderers were sentenced to 18 and 25 years respectively.

Holistic Approach, Murder, Forensic Science

D4 Fatal Wounds Sustained From Falling Bullets: Maintaining a High Index of Suspicion in a Forensic Setting

Amy Rapkiewicz, MD, Miami Dade Medical Examiner's Office, 1851 Northwest 10th Avenue, Miami, FL; and Mark J. Shuman, MD, and Kenneth D. Hutchins, MD, Miami-Dade County, Medical Examiner's Office, One Bob Hope Road, Miami, FL 33136*

After attending this presentation, attendees will recognize the risk factors and fatal wounding potential of falling bullets.

This presentation will impact the forensic science community by showing how celebratory gunfire poses a unique challenge as the investigative and medical community must be made aware of the wounding potential of the falling bullets. We will present two cases of fatal celebratory gunfire injury on New Year's Eve in Miami-Dade, FL.

Case 1: A 69-year-old man collapsed at an outdoor party and was brought into the hospital in cardiac arrest. He had a history of hypertension and was prescribed lisinopril. The emergency room physician certified the death as consistent with hypertensive cardiovascular disease. During an autopsy following postmortem tissue procurement, massive left hemothorax was identified and a fully jacketed projectile was retrieved from the left ventricle. A previously missed entrance gunshot wound was identified in the posterior triangle region of the neck. The bullet lacerated the aorta and heart.

Case 2: A witness saw a 35-year-old man fall down and have seizure-like activity while outside on New Year's Eve. Emergency medical services were called and noted a wound to the top of the head resembling a gunshot wound. At autopsy, an entrance gunshot wound was found at the top of the head with penetrating injury to the parietal region of the brain with a depth of one inch. A copper-jacketed bullet was recovered from the brain.

Fatal celebratory gunfire injury is an uncommon reported event in the continental United States. Cases are predominately documented from the Middle East, Southeast Asia and a rare case series from Puerto Rico regions. Celebratory gunfire injury can be defined as unintentional injury from gunfire into the air. In the American literature, holidays such as New Year's Eve and Independence Day pose as a risk factor for this type of occurrence and a high index of suspicion to recognize such injury is

required during such events. Celebratory gunfire fired from both handguns and rifles can reach a minimum velocity required to penetrate skin and bone producing fatal injury. In terms of inflicting fatal wounds, the head and shoulder are most likely to be associated with deaths from celebratory gunfire; non-fatal injuries are mostly seen in the extremities. In the series from Puerto Rico, as compared to non-celebratory gunshot wounds occurring during the same time period, women and children were more likely to be injured by falling bullets. This case report illustrates that fatal gunfire injuries sustained from falling bullets may pose as a mimic to sudden natural deaths especially in patients with prior medical history.

Falling Bullet, Homicide, Gunfire

D5 UPLC-MS/MS for the Screening, Confirmation, and Quantification of Illegal Drugs Added to Herbal/Dietary Supplements for the Enhancement of Male Sexual Performance

Salman Azimi, MSc, Drug Quality Control Lab, Supreme Council of Health, PO Box 1919, Doha, Qatar 1919, STATE OF QATAR; and Michelle Wood, MSc, Waters Corporation, Atlas Park, Simonsway, Manchester, M22 5PP, UNITED KINGDOM*

The goals of this presentation are: (1) to provide insight into the global problem of the adulteration of herbal and dietary supplements with erectile dysfunction (ED) drugs; (2) detail their synthetic analogues; and, (3) to present a validated method for these compounds.

This presentation will impact the forensic science community by providing a new method for the simultaneous analysis of >30 ED drugs and their analogues.

The adulteration of herbal/dietary supplements with erectile dysfunction (ED) drugs and their analogues is reported worldwide and is an increasing problem.[1,2] The sale of so-called 100%, "all-natural" products has become a highly profitable business for online pharmacies; however, these products can pose a serious threat to consumers due to the undisclosed presence of approved/prescription drugs or the unknown safety and toxicity profile of unapproved ED drugs. Government authorities play a crucial role in the control of these products for the safety of human health. The Drug QC Laboratory in Qatar, has been involved in the testing of adulterated and counterfeit products for a number of years.[3] The goal of this study was to develop an analytical procedure for herbal and dietary products that are marketed to improve male sexual performance and imported to Qatar.

A simple and rapid Ultra Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS) procedure for the analysis of >30 synthetic chemicals in herbals without sample cleanup is presented. A spectral library for synthetic compounds (including 28 ED drugs and their analogues) was generated from reference standards for automated routine sample screening. Full scan MS analysis was performed simultaneously in both positive and in high energy negative Electrospray Ionization modes (ESI); the latter function permitted the detection of new, unknown ED analogues by generation of common, high intensity fragment ions at m/z 282, 298, and 232. In addition, a highly sensitive and selective MS/MS method was developed for confirmation and quantification using two multiple reaction monitoring (MRM) transitions for each compound. This method was validated for three different matrices (capsules/tablets/pills, honey, and herbal drink). Calibration curves (0.2ng/mL – 1000ng/mL) were prepared both in the absence and presence of matrix. The limit of quantification was 0.5ng/mL for most compounds based on a signal-to-noise ratio of ≥10:1 for both quantifier and qualifier ions and with %CV reported less than 11% for 29 compounds spiked in herbal matrices at 2ng/mL. The developed method was applied to 43 suspected dietary products that had been imported into Qatar during 2010 and 2011. The samples were received from customs, herbal registration section and clearance section of health authorities, and analyzed by the developed procedure. A total of 18 products were found to be adulterated: 11 with sildenafil, two with thiodimethyl-sildenafil and five found to contain a combination of yohimbine, tadalafil, aminotadalafil, dimethylsildenafil, and thiosildenafil.

D6 Time Since Death Estimation From Gut Flora

Kathleen Hauther, 250 South Stadium Hall, Knoxville, TN 37916; Tim Sparer, PhD, University of Tennessee, M409 Walters Life Sciences, Knoxville, TN 37996-0845; and Lee Meadows Jantz, PhD, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996-0720*

After attending this presentation, attendees will understand: (1) the principles of current time since death (TSD) investigation including the strengths and limitations; (2) how specific species of gut flora change over time; (3) the relationship between postmortem gut flora change and TSD; and, (4) how to practically utilize the method of estimation.

This presentation will impact the forensic science community by facilitating criminal investigation with a universal method of estimating TSD allowing for the removal of the body from original decomposition context as well as a sampling window encompassing various stages of decomposition

The method limits to stages of decomposition where intestines are present and not mummified. Because the gut flora of an individual impact the earlier stages of decomposition, monitoring the gut flora change over time can yield a formula to estimate TSD. This preliminary study uses 10 human individuals for the basis of the relationship between the change in postmortem gut flora and TSD. None of the individuals were buried, clothed, or covered in any artificial wrap. All individuals were placed in the supine position on the ground at the Anthropological Research Facility in Knoxville, TN, which consists of sparse forest. Individuals are sampled every three days in the first two weeks of May 2011, and due to temperature increase, are sampled once a day from the last two weeks of May 2011 to present. At each time point for each individual, three different samples are taken from the same location in the cecum and stored at -20^{o} C until processing. After the gut flora from the cecum of the large intestine of deceased individuals is sampled, the DNA is isolated using the PowerSoil® DNA Isolation Kit, and specific, common species are amplified in real time with the use of quantitative, real time polymerase chain reaction (PCR) using primers for conserved, ribosomal genes (16S). The real time PCR bases the amplification of the selected bacterial species off a standard curve, which is developed by isolating an organism of the specific species and transforming it into a plasmid so the species chain can be sequenced or decoded, to confirm the correct organism is chosen. The confirmed organism is then run through real time PCR by serial dilutions, which creates the standard curve. The environmental samples compare to the standard curve to confirm the amplification of the correct organism based on size as well as compares to the standard curve to delineate the number of copies. The change in these species over time can be formulated with the known TSD to produce a standard relationship reproducible for popular

use. The study also includes samples taken at known time points from previously un-sampled individuals to cross-verify the determined relationship between the specific species of gut flora and the TSD. A total of six human individuals are sampled for this blind study. The results of this stuffy show observed gut flora change over time as decomposition conditions change resulting in an increase of some species and the decline of others. Shortly after death, the number of observed microbes increases exponentially and decreases in the later stages of decomposition as the intestines no longer remain and other, soil microbes continue with decomposition, or the body and organs mummify to provide an inhospitable environment for the specific flora. The study includes two organisms specifically to observe the phenomenon of microbial competition in the process of decomposition. After publishing, the method of TSD estimation also permits acceptance as expert witness testimony in legal contexts, because the method is based from empirical tests, the error rates are known, and the method uses previously published sampling and processing practices so is generally accepted within the relevant, scientific community. The purpose of the study is to formulate a legally legitimate method for the estimation of TSD so individuals of varying technical backgrounds can understand and easily interpret results. The results obtained from this study of 16 human individuals additionally serve to provide a foundation for future work relating microbial patterns to the practice of Forensic Anthropology; this provides empirical methods off which the field can build.

Time Since Death, Gut Flora, PCR

D7 Singular Skull Fractures Pattern in a Pedestrian

Antonio De Donno, PhD, Section of Legal Medicine - DiMIMP, Piazza Giulio Cesare n.11, Bari, Italy 70124, ITALY; Maricla Marrone, MD, and Pasquale Beltempo, MS, Section of Legal Medicine, Piazza Giulio Cesare,n. 11, Bari, 70124, ITALY; and Francesco Vinci, MD, Section of Legal Medicina - University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will understand the importance and the necessity of a close collaboration between investigators and forensic pathologists in order to reach a comprehensive resolution of the case by integrating their skills.

This presentation will impact the forensic science community by detailing the importance of an accurate external examination of the corpse in order to understand events and cause of death.

The forensic pathologist along with his or her clinical trauma service colleagues, play a similar role in identifying injuries and mechanisms of death. Interpreting injury patterns can provide useful information for accident reconstruction. The injuries to the body can be the equivalent of a report from a reliable witness of the accident. Information that the pathologist provides helps law enforcement and survivors to understand what happened, provide details on how quickly they died, and give potential causes of the accident. Seldomly, forensic pathologists go to the scene of a motor vehicle fatality: however, viewing the scene can often provide vital clues about the dynamics of the accident and the source of the injuries, for example, looking for blood, tissue, or hair can reveal impact sites.

There are many factors to consider: the speed and type of the vehicle, adult versus child pedestrian (stature), position of pedestrian, etc. The causes of death in pedestrians are commonly head and neck injuries: skull fractures, epidural and subdural hemorrhages, cortical contusions, atlanto-occipital dislocation, and cervical fractures. Head injuries can be caused by the impact of the vehicle or the fall to the ground. Many autopsies are performed without information about the circumstances of death. The medical examiner must then attempt to determine the time, cause, and manner of death relying only on autopsy results.

In November 2006, a young woman was found dead on a country road. The postmortem interval was estimated to be about two to three hours prior to the recovery of the body. No witness to the murder was found. The crime scene investigation did not find traces of blood or signs of dragging on the ground near the location of where the body was found. A full autopsy was performed which identified a stab wound by a single edged knife localized in the abdomen and multiple abrasions and cuts on the upper limbs and thorax. However, these were very superficial to represent the cause of death. Also noted were a skull fracture and lacerations of the brain. The depressed circular skull fracture with fragmentation of the bone perfectly matched to each other. In the thickness of the front edge of fracture revealed a series of multiple and minute fractures. These multiple injuries were probably produced by a tool with multiple cutting edges. It was possible to assume that a screw plug located below the engine oil sump could have caused the head injury. Toxicology results were negative.

Investigators examined all the cars that had been identified near the area of crime scene. The morphological and metrical characteristics of the lesion of the head of the victim was then compared with those different engine oil sump screw plugs of those different cars, allowing investigators to identify the car model that could have possibly hit the victim.

In conclusion, it was hypothesized that the young woman was first stabbed with a single edged knife in the abdomen and then run over by a car. The car was finally identified thanks to information supplemented by the autopsy; moreover, blood traces were found on the bottom of the car, which were consistent with the blood type of the victim.

Pedestrian, Identification, Run Over by Car

D8 Deaths Related to Epilepsy in Brazil From 2005 to 2009

Carmen Silvia M. Miziara, MD, PhD, São Paulo University School of Medicine, Rua Capote Valente, 127/111, São Paulo, 05409000, BRAZIL; Ivan D. Miziara, MD, PhD*, ABC School of Medicine, Rua Teodoro Sampaio, 352-22, São Paulo, 05406000, BRAZIL; and Daniel R. Muñoz, MD, PhD, São Paulo University School of Medicine, Rua Teodoro Sampaio, 155, São Paulo, 05406000, BRAZIL*

After attending this presentation, attendees will gain basic knowledge about epilepsy deaths and the profile of victims who die of epilepsy in developing countries, as well as forensic and legal problems posed by this type of death

This presentation will impact the forensic science community because the study of deaths due to epilepsy calls attention to this kind of death, to the profile of the victims in developing countries and also in how to direct the postmortem examination to make the correct diagnosis of the problem.

The occurrence of death due to epilepsy is an issue of great importance, due to its legal and forensic aspects, and should be analyzed on all relevant matters. The identification of the main factors involved in the deaths of people with epilepsy may provide information for public adoption of public remedial action and also for solving problems related to the forensic cause of death. Sudden death in epilepsy (SUDEP) is well known and attracts scientists in the search for the identification of control mechanisms for these types of deaths in Brazil; however, there are few studies dedicated to this purpose. Hence the importance of this presentation is to alert doctors and authorities about the profile of this population in Brazil and help in prevention of this type of death. This problem occurs in various parts of the world. As stated by Leestma, "in most locales in the United States, and likely in other developed countries, such deaths are usually not attended by a physician and are without detailed historical or medical information. They will usually be brought to the attention of a medical examiner or coroner, who is responsible for determining the cause and manner of death and generate a death certificate before the remains may be interred or otherwise disposed of." The goal of this retrospective and descriptive study is to make a statistical analysis of deaths due epilepsy

in Brazil from 2005 to 2009, and to correlate age, sex, race, region of the country, and place of death. This will construct the profile of this population to assess possible factors that may impact public health policy and alert the medical examiners to at least suspect this type of cause of death. The data analyzed in this study were obtained by the Brazil Ministry of Health Department of Informatics (DATASUS), which provides information about the key health indicators, including information on vital statistic, at the national level. Deaths in Brazil for the last five years available in the DATASUS database were evaluated. All variables contained in it were incorporated into the study, including age (from zero to over 80-years-old), gender (female, male), race (Caucasian, black, brown, yellow, indigenous), region of Brazil (north, northeast, southeast, south, and Midwest) and place of death (hospital, other local health, home, street, other, or unknown). Nine thousand, three hundred, eighteen deaths due to epilepsy in Brazil between 2005 and 2009 were analyzed and represented a risk of death around 0.177 when compared with the total number of deaths in the country in the same period. The study consisted of 6,058 men, 3,219 women, and 41 whose data were not available. Approximately half of the deaths involved young adults between 20 and 49 (51.83%) of which the predominant age was between 40 and 49 (40.34%), followed by 30 and 39 years (34.8%). The Caucasian and African subjects predominated over other races at 46.51% and 36.62% respectively. The southeast region, the most populous in the country, as well as the northeast region accounted for the largest number of occurrences. There was a slightly higher prevalence of deaths in hospitals (46.6%) when compared to those which occurred at home (41.34%). The results of this study are consistent with others, especially regarding the subjects' age at the time of death and the predominance of males. Neither the exact description of the death or the characteristics of epilepsy in these subjects were available; however, the large number of events at home, age (young adults), and male predominance show that most of these deaths were due to SUDEP. Therefore, detailed analysis of deaths involving people with epilepsy is a necessity, given the large number of people affected by this disease.

Epilepsy, Death, Epidemiology

D9 Investigation Techniques of a Child Death Involving a Dental Procedure

Sarah R. Weil, BA, and Martha J. Burt, MD, District 8 Medical Examiner's Office, 606 Southwest 3rd Avenue, Gainesville, FL 32601*

After attending this presentation, attendees will recognize the importance of thorough scene investigations and continued utilization of medicolegal death investigation techniques in unusual or complicated medicolegal death investigations.

This presentation will impact the forensic science community by demonstrating the value of continued medicolegal investigation in supporting cause and manner of death.

Cases of child deaths as a result of routine dental procedures are extremely rare and require special investigative considerations. This is an unusual case of a previously healthy 5-year-old boy who went to the dentist for a routine dental procedure. The child was administered a dose of the sedative chloral hydrate. The child experienced respiratory distress during the procedure and was transported to a local hospital where the child died in the emergency room. The subsequent investigation revealed toxic levels of trichloroethanol, the metabolized drug chloral hydrate.

At the time the death report was received, the child had been pronounced deceased in the emergency department and initial information received was from an emergency room physician. Very little information was initially received, other than the child had been at a local dentist office for a routine procedure and had experienced respiratory distress and subsequent cardiac arrest. No known cause for these mechanisms of death existed as the child was reported to be healthy prior to this dental visit.

A scene investigation was initiated with local law enforcement and the local medicolegal death investigator. The dental office was thoroughly documented with photography and copies of medical records obtained from the medical file on-site. Dental equipment was thoroughly inspected for proper working order and initial interviews were conducted with office staff.

Interviews conducted with office staff provided a sequence of events that was later corroborated with testimony from the deceased child's mother. Additionally, the timetable provided by office staff was later corroborated with emergency medical service dispatch times and information from first responders.

An interview conducted with the child's mother revealed her son was previously healthy and had no known medical conditions. The child's most recent medical records were obtained as well as an accounting of the child's most recent physical activity.

Following the initial scene investigation, an autopsy was performed on the child. No apparent cause of death could be established from the gross examination. Further toxicology studies showed significantly high levels of trichloroethanol (the metabolite of chloral hydrate) indicating an overdose of chloral hydrate.

A follow up interview by the medicolegal death investigator was conducted jointly with the dentist and a law enforcement detective. During this interview, several questions were answered about the procedure for administering the chloral hydrate and the measuring device used.

Information was obtained about the chloral hydrate manufacturer and distributer to ensure there was no error in the concentration of chloral hydrate obtained, and therefore administered, by the dental office. Finally, as a result of a thorough scene investigation, the bottle of chloral hydrate collected as evidence was sent to the FBI Toxicology Laboratory for analysis and quantification of chloral hydrate concentration.

This investigation spanned over a year and required continuous involvement from the forensic pathologist, medicolegal death investigator, and law enforcement. Through the information gathered with a thorough initial scene investigation and continued extensive follow up and evaluation of the evidence in the case, many subtle and important questions were answered. The ability to take into consideration the special circumstances of a child death, especially one that occurs as a result of a routine dental procedure, allowed a thorough investigation to be conducted. This thorough investigation will hopefully provide insight into future incidences in which a seemingly benign procedure turns deadly.

Child Death, Chloral Hydrate, Dental Procedure

D10 Unusual Suicides Using Common Mechanical Devices — Case Series and Literature Review

Willis A. Ennis, MD, Medical University of South Carolina, Pathology and Laboratory Medicine, 171 Ashley Avenue, Charleston, SC 29425-9080; Baiyang Xu, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Cynthia A. Schandl, MD, PhD, Medical University of South Carolina, 171 Ashley Avenue, Suite 309, MSC-908, Charleston, SC 29425*

After attending this presentation, attendees will understand the scene investigation autopsy performance, and, reporting of unusual methods of suicide using common mechanical devices. Additionally, attendees will be better prepared to identify clues in these cases that have led to a ruling of suicide as the manner of death.

This presentation will impact the forensic science community by providing key information to help identify the manner of death in rare cases.

Suicide is the 11th leading manner of death in the United States of America. Suicides are classified by the Centers for Disease Control and Prevention in one of three ways: firearm suicides, suffocation suicides, and

poisoning suicides. The forensic community is very familiar with scene investigation and autopsy procedures for these types of suicides. More unusual methods of suicide may pose a challenge for scene investigators and forensic pathologists. By becoming familiar with some of the interesting and creative ways with which persons have committed suicide, scene investigators, coroners, and forensic pathologists will be better equipped to process and evaluate such scenarios. Additionally, this information can serve as a knowledge base which can be applied to unique but similar cases that are scarce within the academic literature.

The use of a circular saw and a power drill which yielded unfamiliar findings upon scene investigation as well as injuries rarely encountered on the autopsy table are reviewed. Interpretation of this information can yield more specific and accurate results if investigators are familiar with the type and severity of wounds that these devices inflict. It is of particular concern that these unusual methods might lead an investigator to consider homicide or accident as a manner of death when a case is actually a suicide.

Cases of suicide using common household mechanized devices are presented. These previously unpublished cases include death by circular saw, chain saw, and elastic-cord-saw apparatus.

Additionally, the existing literature to further supplement the information gleaned from the cases presented are reviewed. Although rare, reports in the literature have described suicides using electric drills, circular saws, band saws, pneumatic hammers, nail guns, and chain saws. Each scenario may have unique scene and autopsy findings important to consider when determining the manner of death.

The violent, unusual, and seemingly painful nature of these injuries may raise doubt as to whether they were truly self-inflicted, considering the numerous, well-known, and often minimally painful methods readily available. It is important to evaluate each individual case empirically, based on the history, the evidence documented at the scene, and the autopsy findings. This information must then be interpreted in the context of the relevant literature and the investigator's experience. The goal of this presentation is to assist investigators, coroners, and forensic pathologists in determining the manner of death in these rare cases.

Suicide, Forensic Pathology, Mechanical Devices

D11 Firing Pin Aperture: Uncertainty of Measurement and Usefulness for Class Characteristics

Heather J. Seubert, BS, Erich D. Smith, MS, Theodore Chavez, BS, and Preston C. Lowe, MS, Federal Bureau of Investigation Laboratory, Firearms/Tool Marks Unit, Room 4340, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will gain a better understanding of: (1) the accuracy and reliability of firing pin aperture marks; (2) the use of discernible class characteristics during the examination process; (3) differences in the appearance of sequential test fires; and, (4) measurements obtained from test fires and casts of the actual firing pin apertures.

This presentation will impact the forensic science community by showing how discernible class characteristics for elimination can affect the outcome of the examination process.

In 1985, the Association of Firearm and Tool Mark Examiners (AFTE) Committee formalized the Criteria for Identification. Their goal was to reach consensus on articulating the three principles for the theory of identification as it related to tool marks – identification, inconclusive, and elimination. One of the examinations integral to the firearms/tool mark examination process is the evaluation of class characteristics, particularly when it comes to the measurements. Class characteristics are those features that are predetermined prior to manufacture (design features) and are restrictive to a particular group (i.e., caliber). For elimination, the AFTE criteria requires there to be a significant disagreement of discernible class characteristics and/or individual characteristics. This study examines the threshold for what is a significant disagreement in class characteristics, through the evaluation of firing pin apertures using the same firearm with different brands of ammunition. When a cartridge or shotshell is fired, the base of the cartridge and primer is forced against the breech face under high pressures. These high pressures sometimes cause the primer to flow into the firing pin aperture creating an outline of the firing pin aperture. When a firearm is manufactured, the size and shape of a firing pin aperture is designed to an acceptable tolerance to allow for the proper passage of the firing pin. A difference in firing pin aperture dimensions between two cartridge cases would indicate a difference in class characteristics, thus allowing for elimination. This study evaluates this effect, the measurement, and the impact of uncertainty of measurement when making an elimination.

In a cartridge case comparison, where firing pin aperture marks are present, the measurement of this feature may be considered a discernible class characteristic. In this particular study, each examiner and trainee made a series of firing pin aperture measurements of test fired shotshells and cartridge cases. These measurements were recorded and the uncertainty of measurement was determined to evaluate the threshold of elimination based on measurable differences. Two types of 9mm Luger ammunition, CCI Blazer, and American Eagle (Federal), were test fired in a Cobray M-11/Nine pistol. The CCI Blazer ammunition included an aluminum cartridge case with a nickel primer, while the American Eagle ammunition consisted of a brass cartridge case with a brass primer. Additionally, two types of 12 gauge ammunition, Winchester #8 Shot and Winchester 00 Buckshot, were test fired in a Mossberg 500-A shotgun. The Winchester 12 gauge, 2 ¾, #8 shot shotshell contains a low brass, gray hull, and copper primer. The Winchester 12 gauge, 2 ¾, 00 buckshot shotshell contains a low brass, red hull, and copper primer. Casts made of the breechfaces, to include the firing pin aperture on the pistol and shotgun, were collected prior to test firing. Both the apertures present on these test fires and those present on casts of the actual firing pin apertures were measured for this study. Prior to performing any measurements, a performance check was conducted on the stage micrometer using a National Institute of Standards and Technology (NIST) traceable calibrated caliper. The measuring platform was also checked to determine if it was level. One comparison microscope was used for all measurements. There were a total of eighty samples – forty shotshells and forty cartridge cases. Each sample was marked with a permanent marker to indicate the position of the extractor mark. There were two measurements recorded for each shotshell and cartridge case – one with the extractor in the three o'clock position and one in the six o'clock position. The approximate line of symmetry for each firing pin aperture was determined using the crosshair reticule. Once the line of symmetry was found, the micrometer was zeroed and the diameter on the aperture was measured. Each participant then recorded their results of the measurements on a data sheet. It should be noted that differences were observed in the general appearance of firing pin aperture marks on the two types of cartridges that were test fired. This presentation will provide the firearms examiner with some useful data regarding the accuracy and reliability of firing pin aperture measurements and their use as a discernible class characteristic.

Firing Pin, Uncertainty, Elimination

D12 Elder Abuse: A Simple Likert Assessment Tool for Investigators

Laura La Cagnina, RN, MSN, 1980 Kramer Way, Marietta, GA 30062*

After attending this presentation, attendees will be able to: (1) identify the top five criteria that place elders at risk for abuse; (2) identify the top five criteria that place caregiver at risk for being abusers; and, (3) demonstrate the correct use of a Likert Scale assessment tool.

This presentation will impact the forensic science community by giving investigators a simple tool to assist in determining credible risk

factors for victims to be abused as well as risk factors for caregivers to be abusers.

Primary care medical professionals, as well as emergency department medical staff, continue to have limited face-to-face time with clients. The fact is, more elders are not being assessed for abuse until the abuse is blatantly evident. Part of this problem is that as our aging population numbers grow, there is no standardized assessment tool to determine risk factors for elders.

While there is physical abuse, there are types of elder abuse that are not as easily visible. Elder abuse can take place in the elder's home, assisted living, nursing home, or living with other family members. Financial exploitation, sexual abuse or harassment, emotional intimidation or humiliation, and healthcare fraud are not as easily witnessed or assessed. Non-accidental injuries that cause pain, misuse of drugs, restraints, and confinement may only be circumstantially evident. Intimidating, isolating, and ignoring behaviors or verbal threats that may not be witnessed. The use of an assessment tool can aid the investigator by establishing baseline criteria to assess risk.

There are spouses, adult children, other relatives and friends who find care giving of an elder to be satisfying and enriching; however, the responsibilities and demands of elder care giving, which can escalate as the elder's condition deteriorates, can take on abusive coping mechanisms. Caregivers are not immune to the stressors that everyday life, work, family, and financial responsibilities include while providing care to a loved one. Assessing caregivers, professional and non-professional, at risk to abuse is equally as elusive as assessing the risk of the elders they abuse.

Vulnerable populations include the economically disadvantaged, racial and ethnic minorities, those with severe mental illness, children, homeless, women and the elderly to name a few. The vulnerability of these individuals is enhanced by race, ethnicity, age, sex, and factors such as income, insurance coverage (or lack thereof), and/or an absence of a usual source of care. Their health and healthcare problems intersect with social factors, including housing, poverty, and inadequate education. We already understand that familial caregivers have an increased risk to abuse. When an elder entrusts caregivers who themselves may be part of a vulnerable population for assistance with regular, everyday activities of living, risk factors for both will increase and can go undetected.

While the medical community has standardized many assessment tools such as pain, wound, and coma scale, it has not agreed on any to assess risk for abuse. Dr. Miri Cohen developed an assessment tool that included both the elder and the abuser. This Expanded Indicator of Abuse (E-IOA) tool is a lengthy comprehensive assessment tool. Using the Likert scale, Dr. Cohen's tool is eight pages long and is numbered as to which questions should be asked of each. Most primary care providers (PCP) spend less than 20 minutes with patients and emergency care providers usually spend less than 25 minutes. Neither has enough time to include any additional assessment tools. Technology may have assisted in expediting certain information but any time saved was immediately replaced by another patient.

Elder Abuse, Assessment Tool, Risk Factors

D13 The Role of the Forensic Nurse Examiner and Persons With Disabilities

Janean M. Fossum, RN, BSN, PO Box 11053, Eugene, OR 97440*

After attending this presentation, attendees will be able to: (1) identify the severity of violence in the community of individuals with disabilities; (3) identify the importance of the history and interview, recognize the signs of abuse as it relates to individuals with disabilities; and, (4) recognize the special needs of the individual with disabilities and the role of the forensic nurse or forensic nurse examiner.

This presentation will impact the forensic science community by increasing awareness that persons with disabilities represent a population who experiences a greater incidence of abuse.

Historically, persons with disabilities represent a population who experience a greater incidence of abuse or neglect According to experts, over ninety percent of all persons with disabilities will experience one or more abusive episodes during their lifetime. The reason for this phenomenon is multifaceted and complex. Contributing factors have been identified within the body of research, which includes decreased understanding of their rights, group home or institutional living conditions, lack of boundaries, diminished knowledge, or education level; and stereotyping portrayed by the public. Therefore, raising awareness and educating the public regarding this issue should be a public health priority. Unfortunately, abuse against persons with disabilities is significantly underreported to law enforcement and human service agencies, and even ignored by their family and/or care providers. All too often, the responsibility for identification and reporting of abuse are placed upon on the medical community thus leaving the medical provider in this pivotal role.

Forensic nurses are specifically educated to provide professional nursing care; this includes holistically assessing individuals through the nursing process for abuse and neglect. This information provides investigators with valuable details that otherwise would be overlooked. One of the major roles identified within the field of forensic nursing is bridging the gap between the legal and medical arenas; therefore, forensic nurses by nature of their role are uniquely positioned to assist the disabled individual who may be experiencing abuse or neglect. Furthermore, it is this reason that the forensic nurse is such a significant element of any medical examination or in any situation where another medical person suspects abuse or neglect. The forensic nurse is educated as a registered nurse and trained in forensics. Through the application of forensic principles related to evidence collection, the forensic nurse documents injury through multiple means; thereby, assisting the investigator and exploring the possibility of abuse and neglect with the patient. Additionally, the forensic nurse provides community resources that are customized for the disabled individual based on the nurse's assessment. Moreover, safety issues, mandatory reporting, and protection for this vulnerable population is one of the primary function that a forensic nurse provides in their plan of care.

This presentation will examine the many indicators of abuse and neglect that medical providers and investigators should be aware of regarding abuse with specific focus on the disabled population. Through case presentation, the attendee will identify through comparative analysis, accidental versus non-accidental injuries. Additionally, a statistical review will reveal disabled individuals as the prevalent vulnerable population. Moreover, it will provide the audience with a greater knowledge base and a greater understanding of the victimization within this population. The forensic nurse's role will be investigated and clear delineations will be given regarding the significant responsibility the forensic nurse holds and contributes in abuse investigations with disabled individuals. Specific information will be provided regarding the offender profile and the process of reporting and documenting information. However, the greatest focus will be the significant impact the forensic nurse can make regarding investigations concerning individuals with disabilities.

Abuse, Disabilities, Forensic Nurse

D14 Do Forensic Nurses Have a Role in Child Maltreatment Investigations?

Melodie Brooks, MSN, 3091 Widdock Street, Erie, MI 48133*

The goal of this presentation is to identify the role of the forensic nurse within the multidisciplinary team (MDT) as well as describe the solutions to MDT challenges in rural communities regarding the medical component.

This presentation will impact the forensic science community by case study exploration leading the attendee to realize the significant and unique role the forensic nurse assumes within the multidisciplinary team (MDT) during a child maltreatment investigation.

Child maltreatment investigations traditionally have excluded medical professionals who are specialized and trained in this emerging field, which is contradictory to experts' recommendations.[1] Moreover, a lack of qualified medical experts has compounded this problem, leaving investigators no alternative but exclusion of the medical component during their investigations. On the other hand, many MDT's are utilizing the expertise of a forensic nurse examiner, propelling this nurse specialty into the forefront of the interdisciplinary team based on the responsibility of linking the legal arena with healthcare, and placing the nurse within the coordinator of care role.[2] According to the American Association of Colleges of Nursing (AACN), one of the essential roles of a registered nurse is to be a coordinator of care, specifically engaged with an inter-professional team.[3] Further exploration within this role can reveal a unique set of skills, which is invaluable during child maltreatment investigations. These activities include medical records review, interpretation of chronic/acute physical findings, and education to the investigative team regarding medical issues and sexual development.[2] Consequently, forensic nurses who work within child maltreatment teams serve a very diversified but significant purpose.

As logical and practical as the forensic nurse role may appear, conflicts and growing pains still persist in some organizations attempting to bridge the gaps that may exist in the MDT regarding medical exams. With the current economic crisis looming in the United States and abroad, communities are faced with limited resources and personnel; however, these entities are held to the same standards and judicial outcomes by the public and the legal system's burden of proof.[4] Moreover, many juries have an expectation of physical evidentiary findings during trials, thus leaving the investigators and prosecutors disadvantaged if the child's testimony is the sole piece of evidence. Budgetary reductions within law enforcement and prosecutor departments have compounded the problem and many communities are forced to reexamine services to victims. With challenging economic times and limited resources, new innovative ideas must emerge to meet these deficits.[4] Through education, determination, and evidenced based practice principles, MDT's have the ability to flourish and provide quality outcomes for children and their families through inclusion of forensic nurses on the MDT.[1] As the coordinator of care, nurses provide education to patients and families; however, forensic nurses have an added educational responsibility of instructing juries on medical findings with patients entrusted to their care.[5, 6]

This presentation will describe through case studies the challenges and solutions faced by a rural community MDT providing investigative and support services to children experiencing child maltreatment. The participant will view the significant role the forensic nurse examiner assumes within the MDT and the importance of the coordinator of care role. Evidenced based practice principles will be emphasized and the participants will leave with ideas for MDT development in rural community settings when attempting to fulfill the medical role.

D15 Win in Court - Analysis of a Home Environment to Make It Wheelchair Accessible

Robert D. Lynch, BArch, Lynch & Associates, Architects, 5408 Zoysia Court, Haymarket, VA 20169-6203*

After attending this presentation, attendees will understand how to: (1) make the case in court for or against the extent and construction costs of wheelchair-accessible home renovations; (2) determine what is needed to base the case; (3) evaluate the home, determine what is required to make it accessible and usable, and design renovations; (4) Write an effective report; and, (5) know what exhibits are needed.

This presentation will impact the forensic science community by providing a technically correct and legally solid path to make a successful claim for plaintiff or defense for defendant in court for compensation to make necessary accessibility changes to the home of a claimant injured or diseased.

Making the case: Determine the nature of the client's needs as determined by the data of medical reports, life-care plans of both plaintiff and defendant, existing home conditions (floor, site plans, and photographs), and local costs of construction. Life care plans are typically divergent in their evaluations of the disabled client, and thus possibly quite different in evaluating the disabled client's needs, both currently and especially in the long term or end of life evaluation. This could have significant effect on what modifications are determined to be needed in order to make the client's home accessible and usable.

What is needed to base the case legally: Review the data for consistency, engage expert opinion by an architect experienced in both the disability needs of the client and residential design, and write a report supporting the case in narrative and graphic (drawings & photographs) form and include defensible construction estimates consistent with local building conditions. Where significant divergence is found between plaintiff and defendant, it is important to try at that point to obtain agreement between the life care planners as to what is actually required for the disabled person. If agreement cannot be reached by the life care planners, then design and cost estimates for construction must proceed on the basis of either the plaintiff or the defendant, whoever the expert is working for. This situation will put the onus of decision on the court and will necessitate a trial by judge or jury to determine the outcome.

Design: It is important to engage an experienced architect whose practice demonstrates expertise in design for persons who have disabilities, and who can reliably prepare designs and construction cost estimates for the locale in which the claimant's home is situated. If engaged at an early stage, the architect may contribute valuable guidance as to what data must be acquired and may advise the attorney as to the best path of strategy to win. The architect should be able to technically defend or oppose a case made by his or her testimony in deposition or at trial. The architect should be conversant, experienced, composed, and articulate in the sometimes adversarial atmosphere of legal testimony.

Writing the report: The expert report in support of or to defend against the claim must consist of accurate, comprehensive, and persuasive narrative, supported by clear, descriptive graphic floor plan drawings and credible construction cost estimates predicated upon local conditions.

Exhibits: Exhibits need to be brief and cogent in their narrative and clear in their presentation. The narrative should be tied, issue by issue to a set of graphic documents (drawings) and to an itemized list of construction items. An example case will be presented as representative and will be included in the handout.

Wheelchair, Injury, Plaintiff or Defendant

D16 Post-Coital DNA Recovery Phase 2: Early Results From Participating Couples

Patricia M. Speck, DNSc, University of Tennessee Health Science Center College of Nursing, 877 Madison Avenue, Suite 653, Memphis, TN 38163; Jack Ballantyne, PhD, University Central Florida, Department of Chemistry, 4000 Central Florida Boulevard, Orlando, FL 32816-2366; Pamela D. Connor, PhD, University of Tennessee Health Science Center, Department Preventive Medicine, 600 Jefferson, Memphis, TN 38105; Marion L. Donohoe, DNP, University of Tennessee Health Science Center, College of Nursing, 877 Madison Avenue, Memphis, TN 38163; Erin K. Hanson, PhD, PO Box 162367, Orlando, FL 32816; Wendy Likes, DNSc, DNP, University of Tennessee Health Science Center, College of Nursing, 920 Madison Avenue, Memphis, TN 38163; and Ann Cashion, PhD, College of Nursing, 920 Madison Avenue, Memphis, TN 38163*

After attending this presentation, the attendees will be able to review factors that may impact DNA detection after coitus as found in Phase 1 of the Post-Coital DNA Recovery Study[1] and will receive the results of Phase 2. This is a feasibility study on the methods and tools used in the Post-Coital DNA Recovery research in an early sample of participants.

This presentation will impact the forensic science community by providing attendees to plausible biological environmental explanations that impact DNA recovery (Phase 1) and present the research findings from the early group of couple participants (Phase 2) enrolled in the post-coital recovery of DNA.

The current published forensic science evidence implies that recovery of DNA occurs from the posterior fornix within a 36 hour time frame and from the cervix up to 72 hours. Medical infertility literature and one forensic study found that the cervix might yield DNA up to 72 hours. One forensic science publication found DNA at five days using routine analysis. When additional Y-STR methods were applied, DNA has been found up to seven days. Phase 1 of the Post-coital DNA Recovery research project brought together subject matter experts (SMEs) in 2010 to identify the biological and environmental factors that impact the recovery of DNA.[1] This presentation will briefly review Phase 1, including history of the 72 hour time limit for evaluation of victims and the methods for identifying factors that influence recovery of post-coital DNA. Attendees will be introduced to the IRB approved protocols and the feasibility study (Phase 2) of the first few couples that evaluated the procedures, methods, tools, and analysis of the blinded methodologies and evidence-based tools used by the data collectors. In the feasibility study (Phase 2) and the full-scale study (Phase 3), the data collectors and the evaluator will be blinded to the activities in the forensic laboratory. Demographic data will also be blinded to the data collectors, the forensic laboratory and the evaluator in Phases 2 and 3; however, the focus of the presentation will be on Phase 2, the barriers in the protocol for collection of sample data, the strengths in the implemented methods, reliability of the tools used to evaluate the environment of the vagina and cervix, and the reliability of the results of the data analysis from the first group of monogamous couples submitting samples according to the Post-coital DNA Recovery protocol. In summary, this presentation will briefly review Phase 1 identification of the biological and environmental barriers to locating DNA post coitus and present. Phase 2 that evaluates the feasibility of the methods, tools and protocols, as well as provide an explanation about the appropriateness and difficulty of using the new tools designed to capture specific characteristics of the female at the time of collection of the post-coital sample. These results are expected to provide specific insight for the researchers about the process and outcomes from the chosen methods so they may proceed to the full-scale study (Phase 3) with up to 150 couples entitled Post-Coital DNA Recovery. The feasibility results from Phase 2 will be presented and discussed.

Post-Coital DNA Recovery, DNA, Rape and Sexual Assault

D17 Sexual Assaults in Geneva, Switzerland: 2006-2010

Romano La Harpe, MD, Institut de Médecine Légale, 9 Av de Champel (CMU), Geneva, 1206, SWITZERLAND; and Anne-Thérèse Vlastos, MP, Département de Gynécologie et Obstétrique, 30 bd de la Cluse, Geneva, 1206, SWITZERLAND*

After attending this presentation, attendees will understand the incidence and the prevalence of the sexual assaults of female victims in Geneva in the last years, including the reasons which encourage formal complaint. Results of toxicological analyses performed on victims of sexual assaults are also presented.

This presentation will impact the forensic science community by explaining the necessity of collaboration between the gynecologist and the forensic pathologist with the utilization of a kit. Finally, this study looked at socio-demographic characteristics of the victims of sexual assaults such as age, site of offense, marital status, numbers of offenders, time of offense, and time from the offense until the examination.

The number of women who visit the Maternity of Geneva, the hospital which is a part of the department of Gynecology and Obstetrics at the Faculty of medicine of Geneva, for sexual assault cases has been increasing in recent years from about 20 cases per year in the late 1990s to about 100 cases per year in the years leading up to 2010. For this reason, a protocol was established so that all victims of sexual assault are supported in the same way, no matter when they may arrive.

In Switzerland, since April 1, 2004, rape or forceful sexual relations among spouses is considered in the same way as with strangers, and it is prosecuted automatically and not just treated as a complaint. The incurred penalty is a maximum of 10 years, if no other aggravating factors are involved, such as the use of weapons or the jeopardizing of the life of the victim. The women who consult medical professionals after a sexual assault do so primarily for therapeutic purposes, that is to say, to rapidly receive care (disinfections of wounds, etc.), to detect and treat sexually transmitted diseases, including hepatitis and the HIV virus, and to detect a possible pregnancy (emergency contraception). Victims also seek relief for psychological trauma, where they are heard and understood. If the psychic trauma is sufficiently affected, a psychiatrist sees the patient in the emergency department or room and decides whether she should be hospitalized or not. In other cases, the victim is sent for a consultation at the Interdisciplinary Medicine and Prevention of Violence unit the next day, where doctors and psychologists coordinate and take the necessary steps to care for the victim.

In Geneva (450,000 inhabitants), all female victims of sexual assaults who undergo a medical examination are examined by both a gynecologist and a forensic pathologist, even if the victim has not formally made a complaint. Indeed, different situations are imaginable. A victim can arrive with the police after they file a complaint. The victim can also depose a complaint after the medical examination. The third possibility is that the victim waives a complaint. In this instance, respect for medical confidentiality is maintained and prosecutorial action is not taken.

The role of the forensic pathologist is to perform a complete examination of all lesions observed on the body and to ensure that all necessary specimens are taken in case of a complaint, or in the case the victim changes her mind and makes a complaint in the future. A certificate, with all the findings, is systematically given to the victim ten days afterwards.

Finally, this study looked at socio-demographic characteristics of the victims of sexual assaults such as age, site of offense, marital status,

number of offenders, time of offense, and time from the offense unti the examination.

Sexual Assaults, Geneva, Socio-Demographic Characteristics

D18 Forensic Experiential Trauma Interviews – A Conversation With the Brainstem

Russell Strand, BS, United States Army Military Police School, 401 Mancen Loop, Suite 1721, Fort Leonard Wood, MO 65473; and Donald Hayden, MFS*, 21150 Ridgetop Lane, Waynesville, MO 65583*

The goal of this presentation is to familiarize the attendees with the impact of physical and emotional trauma on a victim's ability to accurately recall key data points needed in criminal investigations.

This presentation will impact the forensic science community by providing an understanding of how trauma victims undergo physiological changes in the brain stem during trauma which causes memory and recall to be reduced.

Trauma victims undergo a process many professionals and victims do not commonly understand. Most criminal justice professionals have been trained to believe when an individual experiences a troubling event, particularly, emotional of physical trauma, the cognitive brain records the vast majority of the event including: who, what, where, why, when, and how, as well as peripheral information. Therefore, when the criminal justice system responds to the report of a crime, most professionals are trained to obtain this type information. Sadly, collecting information about the event in this manner actually inhibits memory and the accuracy of the details provided. Trauma victims do not record the experience in the same way most non-trauma victims do. Research shows that the body and brain react to and record trauma in an entirely different way than we have been led to believe. When trauma occurs, the cognitive brain frequently shuts down leaving the brainstem to experience and record the event. The brainstem does a great job recording experiential and sensory information but does not record traditional investigative information very well. Most of our interview techniques have been developed to interview the cognitive brain and obtain cognitive information such as the color of shirt, description of the suspect, time frame, and other important information. Some victims are capable of providing this information in a limited fashion. However, most trauma victims are not only unable to accurately provide this type of information, but when asked to do so often inadvertently provide inaccurate information and details which causes the fact finder to become suspicious of the information provided. The vast majority of our training and experience has caused us to focus on the cognitive brain. Research clearly shows the cognitive brain is not generally involved in recording the experience when a victim is experiencing trauma, whether physical (i.e., a sexual assault) or emotional (i.e., witnessing a horrific death). We must develop and implement proven methods to properly interview the brain stem. This innovative and revolutionary interview technique is a way to interview the brain stem in a manner that not only reduces the inaccuracy of the information provided but greatly enhances understanding of the experience, increasing the likelihood of a better understanding of the event and ultimately, the collection of better investigative information. This interview technique revolutionizes the manner in which forensic physiological evidence is identified and collected. The Forensic Experiential Trauma Interview has already been proven to be a game changer in the investigation and prosecution of many forms of violence including child abuse, adult sexual abuse, and domestic violence. This technique enhances crime scene investigation by enabling trauma victims to recall critical information in a more thorough manner than traditional interview techniques.

This interview technique draws on the best practices of child forensic interviews, critical incident stress management, and motivational interview techniques combining them into a simple three pronged approach to unlock the trauma experience in a way we can better understand.

Trauma, Memory, Physiological Evidence

D19 Profiling as a Utility to Criminal Interrogations

Alan A. Price, MA, University of Northern Colorado, PO Box 336433, Greeley, CO 80633*

After attending this presentation, attendees will understand the significance of incorporating seven basic functions of profiling when conducting interrogations.

This presentation will impact the forensic science community by informing investigators of seven profiling components that should be integrated into a criminal interrogation.

Criminal profiling consists of seven integrated components: (1) the investigator's knowledge and experience; (2) the crime scene; (3) victimology; (4) offender behavior before and after the crime; (5) analysis of direct evidence; (6) crime analysis of the *modus operandi*; and, (7) knowledge of the "case controls" used to validate information being provided by the suspect. This presentation will show how and why all seven of these profiling components should be thoroughly assessed prior to initiating an interrogation.

As a prelude to this discussion, it must be noted that interrogating a suspect is not the same as interviewing one. These two investigatory functions are distinctly different and defined by law as having two separate legal standards. As such, the terms cannot be used interchangeably. For this presentation, the focus is on interrogation and specifically, how criminal profiling is used during the interrogation process to manipulate a suspect into confessing and providing details of their participation in a crime.

A skilled interrogator must be experienced and have a good knowledge of human behavior. Additionally, the interrogator must be knowledgeable in a suspect's neurolinguistics and kinetics. Being able to recognize and interpret a suspect's body language during interrogation is crucial.

The interrogator must have a comprehensive knowledge of the four different types of crime scenes (organized, disorganized, confined and extended) and what each one contributes to revealing the personality of the offender. Frequently, the crime scene may exemplify the mental culpability of the suspect during the commission of a crime. Was there premeditation or did the offender supply his own instrumentalities for the commission of the crime? This alone might provide the offender with an alibi of self-defense versus premeditation.

A strong understanding of victimology is imperative for constructing questions to present to the suspect at the time of interrogation. Interpreting what happened to the victim is essential. Whether the victim is alive or deceased, the investigator must be able to decipher the interaction that transpired between the victim and the suspect. Examining and understanding whether the victim is associated with a high, medium, or low lifestyle risk category is very important.

It is vital for the interrogator to have a working knowledge of psychology and basic principles of psychiatry in order to determine the possible motivation for the crime. For example, understanding the motivation of the arsonist compared with that of the pedophile are entirely different and the interrogator must understand and deploy these distinctions against a suspect during the interrogation. These issues may lead to questions of insanity or mental incompetence by the defense.

The interrogator must have a strong knowledge of the direct or physical evidence in the case being investigated. Sometimes this is the most challenging of all seven components. Evidence collected from the victim, the crime scene, or the suspect requires time to have it analyzed in a forensic laboratory. Most frequently the more violent a crime, the more

physical evidence is available. Being able to confront a suspect with forensic findings can frequently weaken an individual's alibi or denial.

Crime analysis of the *modus operandi* is a crucial analytical process that contributes significantly to assessing possible patterns of serial crimes. Patterned behaviors of the suspect before, during, and post-crime activities become very beneficial in assessing serial patterns. Knowing these patterns prior to the interrogation, an investigator can prepare questions that only the suspect is going to be able to validate. Any suspect's signature left at a series of crimes scenes can eliminate "copy cat crimes" or crimes with a similar *modus operandi*.

The interrogator should have knowledge of existing "case controls," since those "case controls" are a means of validating information being disclosed by a suspect, and they can contribute to the various interrogation strategies. Only case investigators should have knowledge of this information. A skilled interrogator must have the ability to elicit specific information from a specific crime without disclosing the "case controls."

By incorporating these seven components of profiling into an interrogation, the investigator can deploy the appropriate strategies and props for guiding the suspect into providing valid confession.

Criminal Profiling, Interrogation, Case Controls

D20 Forensic Polygraphy in a Global Environment: Comments on the Worldwide Growth of an "American Obsession"

Frank Horvath, PhD, National Academy for Credibility Assessment, 7540 Pickens Avenue, Fort Jackson, SC 29207-6804; and Thomas P. Mauriello, MFS, 8775 Teresa Lane, Laurel, MD 20723*

After attending this presentation, attendees will be educated on the early history of "lie detection" in the United States and how it influenced the public perception of the role of forensic sciences in the resolution of criminal investigations. More to the point of the theme of this AAFS meeting, the audience will also learn about the global growth of "lie detection," a component of forensic Credibility Assessment, as it has been adopted in countries outside of the United States.

This presentation will impact the forensic science community by revealing a rationale for global growth in the field of forensic polygraphy and demonstrating how U.S. based developmental features in that field specifically and the forensic sciences generally, good and bad, have been influential elsewhere.

In his recent book, "*The Lie Detectors,*" historian Ken Alder, focused on the personalities credited with the early development of the "lie detector." Leonarde Keeler, Dr. William Moulton Marston, and Fred E. Inbau are prominently featured. However, Alder's perspective, generally, is antagonistic. "The "lie detector," he says, is a peculiarly American device. Americans, and Americans alone have been obsessed with the "lie detector."" "Why, despite the avalanche of scientific denunciations, does the United States—and only the United States—continue to make significant use of the lie detector?"

Alder answers his own question by stating that: "The lie detector has thrived in America because the instrument played into one of the great projects of the twentieth century: the effort to transform the central moral question of our collective life—how to fashion a just society—into a legal problem." "In the end, though, we believe in the lie detector because—no matter what respectable science says—we are tempted." The "lie detector," more appropriately, the polygraph instrument, was indeed fashioned in the United States. The use of that instrument, in its early history, was given extraordinary media attention. And, of course, the device captured the public imagination as it played a key role in many of the most heinous and media-driven criminal investigations of the time, such as the Lindbergh kidnapping. The "lie detector" focused attention on the forensic sciences in the way that DNA has today. Much of the attention was driven by the expectation that the "lie detector" would forever alter social relations; criminal activity, because it could no longer be hidden from the authorities, would be dramatically reduced. Some of this thinking was the result of promotion by early practitioners. Dr. William Moulton Marston, for example, was especially prominent. He promoted in many ways, one still popular today: his comic book character Wonder Woman, who with her magic lasso could ensnare the most pathological liar and learn the truth.

Aside from the media attention and the sensationalized publicity "lie detection" received, there was also a more serious side. The "lie detector" became one of the mainstays in the nation's first Crime Laboratory in Chicago, eventually to be headed by one of the early Presidents of the American Academy of Forensic Sciences, Fred E. Inbau. He deserves credit for taking "lie detection" with a polygraph seriously. He brought to forensic polygraphy a sense of professionalism and a belief that it deserved a proper place among the various forensic techniques.

History shows that the polygraph was used in Europe since at least the 1950's, possibly earlier. An astute observer of polygraphy today, though, would surely see that the field has been and is continuing to expand dramatically, more so outside of the United States than within. This is not because American gimmickry is easy to pass on to naïve audiences. Nor is because other countries wish to be foolhardy, to defy the ostensible wisdom of American criminal courts and scientific opinion as Alder argues. The record shows that there is clearly something more going on here. It is undeniable that in spite of its many flaws and limitations, the field of forensic polygraphy is growing dramatically around the world. Why is this so?

In this presentation the growth in forensic polygraphy will be assessed using a number of primary sources of evidence: membership rosters in professional associations, the development of training schools catering to those with an interest in polygraphy, the interest shown in U. S. government-sponsored attendance at international conferences on polygraphy, published descriptions of the development of polygraphy in a number of countries, and internet-based searches of popular media focused on polygraphy-related articles of interest.

In addition to discussing the growth of polygraphy on a global basis, in this presentation there also will be commentary devoted to polygraph testing as it can be seen in contrast to other forensic techniques. Some of this will be revealing of a rationale for global growth. In reinforcement of that rationale, the presentation will conclude with a discussion of empirical data collected to uncover reasons for the growth in polygraphy as seen by those outside of the U.S. who have experienced it firsthand.

Forensic Polygraphy, Worldwide Lie Detection, Forensic Credibility Assessment

D21 Privileged Access: Trained Listening to Serial Killers Yields Insights

Katherine Ramsland, PhD, DeSales University, 2755 Station Avenue, Center Valley, PA 18034*

After attending this presentation, attendees will learn about historical efforts in psychology and psychiatry to identify factors in the development of extreme offenders (serial and mass murderers), and how these efforts became the foundation for today's neuroscience of violence.

This presentation will impact the forensic science community by illustrating how intensive professional interviews may have drawbacks and benefits of clinical associations with extreme offenders.

Serial killer Ted Bundy once said that keeping him alive to study would provide valuable insights about the type of extreme violence he committed. Others have echoed him. Over the past century, some mental health experts took this idea seriously. They ventured beyond the typical evaluation period and devices to thoroughly explore a specific criminal's mind. These singular in-depth studies, starting with nineteenth-century "criminal autobiographies," offer tools and techniques for spending productive clinical time with violent offenders. Although some theories have been discarded as psychiatric fashions evolved, interviewers continue

to seek clarity about motives, criminal behavior, and viable therapeutic interventions. We have more than a dozen case examples of extended professional interviews with serial and mass murderers from the past century from which to learn.

Thanks to clinical training, coupled with privileged access, these professionals have provided ideas about what makes the most perverse serial or mass murderers tick. No one is better positioned to offer intimate details than experienced professionals who know how to examine an abnormal mind.

Ever since the earliest days of psychiatry, "alienists" have tried to understand the violent acts of the criminally insane. At first, they believed that anyone who acted contrary to rational sense must be psychotic, but then a certain type of rational criminal stood out. In 1809, Philippe Pinel became the first to acknowledge the disturbing behavior of psychopathy. Following him, other wardens of insane asylums studied "moral insanity" to learn how the faculty for socially appropriate behavior could become corrupted.

French pathologist and jack-of-all trades Andre Lacassagne first urged offenders to tell their stories in full, instigating what he called criminal autobiographies. He encouraged a number of prisoners to write about themselves, and each week he checked their notebooks, correcting and guiding them toward insight. He learned that their family histories were full of violence, tension, and disease, so he developed a theory about social criminality.

During the 1930s and 40s, Dr. Fredric Wertham examined a demented deviant named Albert Fish, who cannibalized a child, and Karl Berg interviewed sexual sadist Peter Kürten. Two decades later, Marvin Ziporyn befriended mass murderer Richard Speck, who'd killed eight nurses in Chicago in a single night. While Ziporyn thought Speck's upbringing was overly protective, he also considered the unique new idea of a brain disorder. As serial murder became more prevalent, more professionals have taken time with these offenders to gain greater comprehension. Today, neuroscientists are putting criminal psychopaths through MRI machines.

Collectively, psychologists and psychiatrists who have used their training and skills to probe the minds of these extreme criminals have retrieved important information about motives, pre- and post-crime behavior, fatal fantasies, mental rehearsal, compartmentalized personalities, and the role of mental disorders. Thus, it has become possible to isolate recurring conditions and factors. From the first person who believed that criminals had self-insight to today's advanced technological approach, much has been learned from extended, engaged professional listening about how and why some people commit shocking acts of violence.

Criminal Autobiography, Violence, Serial Killer

D22 The Evolution of Polygraph in the People's Republic of China

John J. Palmatier, PhD, Dawn Associates, LLC, 8600 Northwest 53 Terrace, Suite 121, Miami, FL 33166*

After attending this presentation, attendees will understand the legal system that has facilitated the growth and application of the polygraph process in the People's Republic of China (PRC), as well as significant contributors and the probable future for polygraph in China.

This presentation will impact the forensic science community by providing a glimpse of how an applied forensic science began in, and is used by, a country comprising approximately one fourth of the world's population.

In 1947, United States Army asked the Michigan Department of State Police to assist in the training of military officers from the forces of the Kuomintang, the Nationalist Chinese party who were at war with the communist following World War II. In 1990, Dr. Palmatier, then a PhD candidate at Michigan State University and a Detective Sergeant with the Michigan State Police, was the first foreigner to be asked by the PRC to present information regarding the assessment of credibility using the polygraph process.

In 1991, Dr. Palmatier traveled to China where he gave several seminars and demonstrated the use of an analog polygraph instrument to members of the Ministry of Public Security, the armed police and members of the military. The relationships formed continue today and provide a unique insight into the entire history of China's quest to procure, develop, and apply the polygraph process for the purposes of assessing credibility.

This presentation begins with a short discussion of the Chinese legal system, which is substantive in nature, and why it is conducive to the use of polygraph as compared to Western legal systems, which are procedural in nature and questionably focused on the truth. This is followed by a discussion of the actual history, which began in 1947, but was used by the Kuomintang to root out communists during the 1947 – 1949 Civil War, which created a great deal of skepticism regarding the validity of the polygraph by the communist (i.e., new China or the PRC).

Following the Civil War, the People's Republic of China first explored the possibility of polygraph testing in the 1960s by purchasing an instrument from the West, but their efforts were cut short by the Cultural Revolution and the idea of polygraph died until 1980. In 1989, China began a program focused on the development of a viable computer-based polygraph instrument and the following year invited Dr. Palmatier to speak in China.

Although it started out slow, over the next 21 years use of the polygraph process and its related methodologies have continued to grow. Some police universities in China offer graduate programs focused on the polygraph process and its use in many contexts. All levels of government, law enforcement, procurator's offices, courts, military, and the Ministry of State Security have varying levels of polygraph ability. Estimates suggest that today, the People's Republic of China administers somewhere between a low of 30,000 and a high of 60,000 examinations each year; and the use continues to grow exponentially.

Surprisingly, even though the United States government does not prohibit the teaching of any subject related to the assessment of credibility using the polygraph process, the United States Department of Commerce still prohibits the exportation of any American polygraph instrument to that country. This has only spurred China's development of its own instruments and purchase of instruments from countries other than the United States.

China, Polygraph, Credibility

D23 Objective Determination of Eyewitness Identification Accuracy Employing Ocular Measures

Frank M. Marchak, PhD, Veridical Research and Design Corporation, 211 West Main Lower Level, PO Box 6503, Bozeman, MT 59771*

After attending this presentation, attendees will understand the potential application of a novel methodology to objectively determine the accuracy of eyewitness identification using cognitive and physiological measures that do not solely rely on traditional verbal decision making processes.

This presentation will impact the forensic science community by providing an additional tool that can be combined with current techniques used in eyewitness identification to add an objective measure to perpetrator recognition and supplement current computer-based lineup approaches.

Mistaken identifications are a leading factor in wrongful convictions in the United States and have contributed to over 75% of wrongful convictions overturned by post-conviction DNA evidence. In addition, witness subjective confidence is a poor indicator of memory accuracy.

Compilation of mug shots by federal and local law enforcement has provided a corpus of data that can be drawn upon to construct lineups.

Recent efforts have focused on developing computer systems that facilitate administration of eyewitness identification tasks. These systems have been shown to be effective in both laboratory situations (MacLin, Zimmerman, and Malpass, 2005) as well as with local law enforcement (MacLin and Phelin, 2007).

Such advances in the ability to create computer-based lineups have been complemented by advances in non-contact, easy to use eye tracking technology. Current systems can be incorporated straightforwardly into video monitors and permit simultaneous collection of gaze, pupil diameter, and blink rate data unobtrusively while individuals view presentations of text and images.

Previous work has shown that individuals examine images of previously seen faces differently from novel faces, exhibiting fewer eye fixations, less overall viewing, and less statistical constraint in their viewing patterns (Althoff and Cohen, 1999). Further studies have shown that other ocular parameters, including changes in pupil diameter and blink rate, also reliably differentiate between novel and familiar faces (Marchak, et al., 2007; 2010). The goal of this effort was to determine if these measures could be used to objectively measure the performance of an eyewitness determining the presence of a perpetrator in a lineup.

Participants watched a video that involved a secretary entering an office, putting down a purse, and leaving the room to get coffee. A perpetrator passed by the open door, rifled through the purse and took objects, fleeing when the secretary returned. At the end of the video, the participants engaged in a word search distracter task for five minutes to prevent rehearsal and then completed a questionnaire describing the suspect and the crime. Lastly, half of the participants viewed a simultaneous lineup and half a sequential lineup of six faces while eye movements, pupil diameter, blink rate, electrodermal activity, and judgment confidence ratings were measured. In addition, for each lineup type, half did not contain the perpetrator.

The findings showed that eye movement measures can differentiate between the perpetrator and foils, in particular the first return fixation to a previously viewed region, the greatest fixation duration, the proportion of fixations, and the proportion of gaze time. Further, differences in maximum pupil diameter between the perpetrator and foils were also highly diagnostic. Blink rate data were mixed and a less reliable predictor. Of special note, these ocular measures were indicative of the perpetrator even in some instances when the participant made an incorrect response and selected a foil as the perpetrator.

A detailed overview of the paradigm and an analysis of the contribution of the multiple ocular measures will be presented, as well as the differences in effectiveness of the approach when applied to simultaneous and sequential lineups. The implication of the findings and recommendations for field application and evaluation will be discussed, along with plans for future research.

Eyewitness Identification, Memory, Methodology

D24 Computer Tomography (CT) Superimposition of Unidentified Skull to Postmortem Photograph of James–Younger Gang Member

James A. Bailey, PhD, University of North Carolina Wilmington, 601 South College Road, Wilmington, NC 28403; and B.G. Brogdon, MD*, and Brandon Nichols, MD*, University of South Alabama Medical Center, 2451 Fillingim Street, Mobile, AL 36617*

After attending this presentation, the participant will understand: (1) serendipitous discovery of a possible James-Younger gang member's skeleton, (2) evaluation of gunshot wound locations on postmortem photographs of gang members; and, (3) the process of craniofacial superimposition using computer tomography (CT) images of unidentified skull with postmortem photographs of Clelland D. "Clell" Miller for personal identification.

This presentation will impact the forensic science community by familiarizing forensic scientists with a new superimposition technique using CT images in an historic case. Moreover, forensic scientists will be able to adapt this technique in contemporary cases.

On September 7, 1876, the James-Younger gang robbed the First National Bank of Northfield in Minnesota. Joseph Heywood, bank clerk, was mortally wounded and a citizen, Nicolas Gustavson, was shot on the street and died three days later. Henry Mason Wheeler, a Northfield resident and University of Michigan medical student, shot and killed Clell Miller with a .50 caliber Smith Carbine. Anselm R. Manning, a Northfield merchant, shot and killed William "Bill" Chadwell also known as William "Bill" Stiles. The robbers fled Northfield with a posse in pursuit. However, before departing with the posse, Wheeler directed two classmates to disinter Miller and Chadwell's bodies from the Northfield Cemetery. Since the medical school was closed, to temporarily preserve the bodies, they stored them in barrels and submersed them in Chub Creek north of Northfield. In due course, Miller and Chadwell's bodies were shipped in barrels to the medical school to be used by students in anatomy classes.

The posse killed Charlie Pitts, also known as Samuel Wells, near Madelia, Minnesota, on September 21, 1876. Dr. John H. Murphy, Surgeon General of Minnesota, took possession of Pitts' body and purportedly gave it to an unidentified medical student to be used as an anatomical model. The Younger Brothers were captured and the James Brothers escaped eliminating their remains for analysis.

Controversy exists regarding disposition of Miller's remains. When Miller's family learned Miller's body was at the medical school, they sent Edward, Miller's brother, and Samuel Hardwicke, a lawyer, to retrieve Miller's body. They received a corpse and shipped it in a barrel filled with preservatives to Missouri. The corpse's head was damaged in transit and the alleged remains were buried in Muddy Fork Cemetery, Kearney, Missouri.

In 1880, after graduation from medical school, Wheeler practiced medicine in Northfield. He relocated in 1881 to Grand Forks, North Dakota where he remained until he retired in 1923. Although Miller's alleged remains were buried in Muddy Fork Cemetery, Wheeler claimed a skeleton he displayed in his office belonged to Miller. The Grand Forks Herald reported the skeleton was destroyed when Wheeler's office burned November 22, 1884; however, in 1985 Wheeler's son, Henry M. Wheeler, Jr., and Peter Nickle, who assisted with disposal of Wheeler's estate, refuted that claim.

When Wheeler retired, he donated a skeleton purported to belong to the man he killed in Northfield to the Odd Fellows in Grand Forks. In the mid 1980s, an auction was conducted liquidating Odd Fellows property. During the auction, a citizen searched the building, discovered a skeleton and arranged to acquire the skeleton. In 2010 while searching for the current owner of the Smith Carbine that Wheeler used to kill Miller, a skeleton allegedly belonging to Wheeler was accidentally discovered. It was the same skeleton acquired from the Odd Fellows in the mid 1980s.

Visual examination disclosed no bullet injury evidence to the skeleton in Grand Forks. However, postmortem photographs of gang members show bullet wounds to the chest. In his memoir, Coleman "Cole" Younger, a James-Younger gang member, described both Chadwell and later, Pitts as being "shot through the heart." Miller, he described as shot by Wheeler "lay dying in the street." Using anatomical surface markings to overlay proportional drawings of the bony thorax and pectoral girdle on the postmortem photographs, it became obvious only in Miller's case that there was likelihood the bullet could have left no postcranial skeletal stigmata.

The skull and associated mandible from the skeleton were scanned by Altru Hospital Imaging Center, Grand Forks, North Dakota, using thin sectional (2mm) CT slices permitting high resolution 3D reconstruction of the skull capable of 360° spatial manipulation. This allowed superimposition of the skull upon Miller's photograph, with remarkable concordance of craniometric and cephalometric landmarks between the

skull and photograph. A demonstration of the new superimposition technique is presented elsewhere in the program.

In conclusion, the identity of the alleged James-Younger gang member's skull could not be excluded from Miller's postmortem photograph based on a craniofacial superimposition. However, numerous factors must be evaluated in cases to establish personal identification. Although the craniofacial superimposition of Miller's postmortem photograph could have eliminated the skull as a possible match to Miller, the craniofacial superimposition suggests the skull could be that of Miller.

Craniofacial Superimposition, Computer Tomography, James–Younger Gang

D25 Ashamed Orgasm: A Rogerian Approach

João De Sousa, Judicial Police of Portugal - Criminal Investigation Department of Setúbal, Praça General Luis Domingues, nº 27, 27A e 28, Setúbal, 2910-585, PORTUGAL*

After attending this presentation, attendees will understand the importance of a Rogerian approach as an alternative solution for sexual abuse cases. After this presentation, the importance of this method of approach in the collection of testimonies in children's sexual abuse cases will be shown, either as a witness or the onlooker's first step of the therapeutic intervention.

This presentation will impact the forensic science community by detailing the application of a new approach method, the Rogerian approach, to collect testimonies in cases of the sexual abuse of minors where another method based in a cognitive interview is commonly used.

In 2010, the Criminal Investigation Department of the Judicial Police of Setúbal (Portugal) was asked to investigate another case of the sexual abuse of the two minors. The police were presented with the parents of two minor girls, one 13-years-old, and the other 8-years-old. A male subject, 45-years-old, reported it as sexual abuse that had the confidence of the family. Once the investigation began, one of the capital moments came in investigations of this nature: the questioning of minors.

The Judicial Police officers who work in this area have training that allows them to work through the complexity of a sexual abuse victim's complaint. The training is based on the Cognitive Interview (C.I.).

Although the exposed above, in this case, the C.I. was not used, the reason is presented in this "case study." In this research, the choice relapsed on the Rogerian method - an approach based on the individual.

It was flagged the fact that the 13-year-old girl presented a testimony that was not truthful in its entirety, showing gaps in the information she could provide, being evident a notable incongruence between the "self" and the traumatic experiences, as well as a defensive distortion and denial of the facts. During the interaction, the minor had a defensive maintenance of the "self", a condition that was overtaken only when the interaction was supported by an unconditional positive regard and empathetic understanding by the interviewer about what had happened to the victim.

The blockage in the testimony had its genesis in the fact the minor may have experienced pleasure during the various abuses that she was subjected to by the individual, creating a latent incongruence between what she thought should be the experience and what she felt on this occasion. The use of the Rogerian method, emphasizing the importance of self-consciousness and congruence between the "self" and the experience allowed the young abused to realize that what she felt at the time was not reprehensible, but the result of mechanical stimulation of her genitals, that can promote pleasure and feelings, without being an acceptance of rape and active participation in the act.

We believe we also showed that the Rogerian method could be used in the collection of the children's testimonies in sexual abuse cases, either as a witness' onlooker or as a first therapeutic step of the intervention.

Rogerian Method, Cognitive Interview, Sexual Abuse

D26 Identifying Potential Molecular Chronometers in Fingerprints Using C60+ Secondary Ion Mass Spectrometry

Edward Sisco, BS, University of Maryland, Department of Chemistry & Biochemistry, College Park, MD 20742; Leonard Demoranville, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; and Greg Gillen, PhD, and Jessica L. Staymates, MFS, National Institute of Standards and Technology, 100 Bureau Drive, Mailstop 8371, Gaithersburg, MD 20899*

After attending this presentation, attendees will be familiar with some of the possible uses of Dynamic C60+ Secondary Ion Mass Spectrometry (SIMS) for the chemical analysis of fingerprints. The potential abilities of this technique to image a fingerprint and monitor the changes in composition with time will be emphasized.

This presentation will impact the forensic science community by providing an evaluation of a new technique to analyze fingerprints.

C60+ SIMS involves the bombardment of a focused ion beam on a sample to generate secondary ions characteristic of the chemical composition of the sample. The benefit of C60+ SIMS over the traditional techniques is that C60+ SIMS could provide spatially resolved analysis and also has the potential to probe the composition of a fingerprint as a function of depth. With respect to mass spectrometry techniques, the C60+ is a soft ionization technique, which allows for a less fragmented molecular profile of the sample. In addition, using this technique also does not completely destroy the fingerprint, making it possible for comparisons to be made after being analyzed by C60+ SIMS.

Fingerprint development and imaging is a well-established and well-researched area in forensic science; however, the ability to both image and chemically analyze a fingerprint has been less commonly studied. The research focuses on the changes in the composition of fingerprints with time when exposed to a variety of environmental conditions (i.e., heat, humidity, and ultraviolet radiation). By doing so, potential molecular chronometers can be identified in an attempt to determine a timeframe of deposition. This could be useful evidentiary information as it may allow investigators to place a suspect at a scene within a certain timeframe or, similarly, rule out the presence of a suspect during the time of a crime based on the timeframe. To better understand changes which occur due to environmental factors, a chemically relevant artificial fingerprint material was developed to mimic both the eccrine and sebaceous secretions found in a normal fingerprint. The artificial fingerprint material provides more consistent and repeatable results than using actual fingerprints.

In this study, synthetic fingerprint material was either drop coated or printed, using a high viscosity polymer printer, onto silicon disks which were analyzed using the SIMS technique. A control disk was studied simultaneously with all environmentally exposed disks to note any changes in sample due to the vacuum. Experimentally exposed disks were subjected to a variety of conditions and mass spectra of the disks were collected at various time points throughout the study. The spectra were then compared to determine what, if any, chemical changes occurred which could be used as molecular chronometers for measuring time since deposition. Once completed using the artificial fingerprint material, the studies were replicated with actual fingerprints to see if the same chronometers were found to produce similar results. The imaging capabilities of actual fingerprints using C60+ SIMS were also studied.

Fingerprints, C60+ SIMS, Chemical Analysis

D27 Conducting Laboratory Analysis of Gunshot Residue (GSR) on Clothing to Identify a Shooting Suspect

Alan A. Price, MA, University of Northern Colorado, PO Box 336433, Greeley, CO 80633*

After attending this presentation, attendees will understand the significance of why laboratory analysis is not routinely conducted on clothing.

This presentation will impact the forensic science community by showing how television dramas misrepresent the forensic laboratory analysis capabilities when analyzing gunshot residue (GSR) on clothing.

Fictitious annals of television crime dramas depict criminalists in crime laboratories being able to determine which individual discharged a firearm by examining their clothing. From this misrepresentation of laboratory capabilities, attorneys and law enforcement personnel frequently have incorrect perceptions of the analysis process for gunshot residue. Actually, most crime laboratories do not routinely examine clothing for GSR. Considerable research has been conducted to determine muzzle to target distance using GSR and stippling; however, studies are absent in assessing whether a specific item of clothing worn by a shooting suspect contains GSR. This research focused upon the utility of examining fabric for GSR in an attempt to identify a specific individual's clothing subsequent to a shooting incident, using a scanning electron microscope (SEM). Three common pieces of fabric were used as samples for collecting GSR and were then examined. Researchers used cotton, polyester, and denim sleeves for collection of residue samples. The revolver used in this project was a .357 magnum, with a 2.5 inch barrel. The three basic elements of gunshot residue are barium (Ba), antimony (Sb), and lead (Pb). Carbon-coated aluminum stubs were used to collect GSR particles from each individual fabric sample.

Each of the three fabric samples were washed with liquid detergent to remove any potential contaminates. The samples were collected on an outdoor firing range to avoid cross-contamination from any extraneous indoor particulates. Six bullets were fired for each collection sample. To prevent contamination researchers wore latex gloves while handling each sample. Immediately after the fabric was exposed to the weapon's discharge, they were placed and stored in individual clean paper "sleeves." All three-fabric samples had a 10 mm square marked onto the top of each sleeve. This is the area directly behind the "web" of the thumb and index finger and mostly exposed when holding and discharging a handgun. The primer control was discharged without gun powder or a bullet being present in the shell casing. Particulates from the primer were collected from stubs mounted on paper.

In the laboratory, the sample sleeves were pressed with the prepared stubs ten times. The samples were collected from within each 10 mm square previously marked on each sleeve. The two detectors used were backscatter and energy-dispersive spectrometry (EDS). After a GSR particle was located, it was then analyzed for five minutes at one location for EDS confirmation. Each fabric sample was manually scanned for one hour to search for GSR particles. In order to limit selection of possible particles on the samples, auto-brightness and contrast were performed on the primer sample. With this setting the sample stubs were examined, which prevented extraneous particles from showing up. The findings are as follows: GSR was readily detected from the primer standard; GSR was detected on the cotton fabric; GSR was detected on the polyester sample; and no GSR was detected on the denim fabric sample. Although not all elements of GSR were detected on the cotton and polyester samples, sufficient elements were present to conclude that GSR existed.

The analysis of clothing for GSR can be very inconclusive. Multiple extraneous variables will influence GSR analysis results. Movement or shaking of the fabric sample may dislodge particulates from the fabric. Rubbing or contact with another object may also result in dislodging GSR particulates. Air currents around the weapon and the fabric may have a significant influence of GSR adhering to a fabric. Without having the scanning software capabilities for an SEM/EDS, searching for and identifying GSR is very difficult and time consuming. This study illustrated that GSR on fabric cannot by itself be initially identified merely by shape, size and brightness under the SEM/EDS. Even though no GSR particles were found on the denim fabric, it cannot be concluded that a specific type of fabric has any more or less propensity of retaining GSR particles. As previously stated, mythical television entertainment is incorrect in representing forensic laboratory capabilities.

GSR Particle Identification, Misperception of GSR Analysis Capabilities, Television Drama Misrepresentation

D28 Forensic Art: Another Piece of the Identification Puzzle — A Case of Homicide in Mammoth Lakes, California

Sandra R. Enslow, BA, Los Angeles County Sheriff's Department, 4700 Ramona Boulevard, Room LL40, Monterey Park, CA 91754*

After attending this presentation, attendees will understand two different aspects of forensic art, the forensic composite and three dimensional skull reconstruction as well as their role in the identification process of an actual criminal investigation. The presentation will show how forensic art, along with mDNA and isotope analysis, was used to gain information about the victim.

This presentation will impact the forensic science community by raising awareness about forensic art and the role it plays in the identification process.

Popular culture often refers to composite drawings as images of criminals, which is another aspect of forensic art; however, this aspect of forensic art delivers the image of the victim. This presentation includes a timeline for this case and shows the detective's integration of other forensic science disciplines in order to get this victim identified – the first step to solving this crime. By reaching out and tapping into all of these forensic resources, the detective's due diligence paid off.

Composite sketches are done when a forensic artist sits with a witness to the event and creates a drawing of the witness' memory. In this case, the witnesses were employees at the Mammoth Lakes Visitor's Center and had contact with the victim before her death, the previous autumn. Once discovery of the skeleton was made, in the early spring and the case distributed to the local media, these witnesses came forward with the incident they remembered. The Los Angeles County Sheriff's Department forensic artist was contacted to do the composite drawing. She drove up to Mammoth Lakes from Southern California. These witnesses met with her and described the woman they recalled. While each witness met separately with the artist through the process, one final drawing of the victim was completed.

Betty Pat Gatliff, of the Skullpture Lab, was contacted and asked to do the three-dimensional skull reconstruction for this case. The victim's skull was sent to her office in Norman, Oklahoma.

The practice of restoring facial features from a human skull was first used over a hundred years ago. At that time, its purpose was to identify remains of famous historical figures. Betty Pat Gatliff, a medical illustrator, developed forensic facial reconstruction in the United States of America in the 1960s.

Three dimensional reconstruction is done by marking tissue depths, according to a tissue thickness measurement chart, onto a skull or a cast of the skull and then fleshing the face out with clay. There are also formulas for the size and shape of the lips and length of the nose. The European method of facial reconstruction is by creating the musculature of the face before fleshing it out, while still matching to tissue depth markers.

This case example shows the consistency of the image of the unidentified woman from the two forensic art techniques. These techniques, created by the two different artists at two different times, in

different parts of the country, demonstrate the strength of forensic art as a discipline. Through the forensic composite, the witnesses speak and give their description. With the three dimensional skull reconstruction, the skull speaks and corroborates that description.

Forensic art, isotope analysis, and mDNA made it possible to get this victim's physical features, country and town of origin, and finally a name, Barbara. While this case is still an open investigation, the detective, through forensic science, developed more information about his victim than other traditional and earlier methods of investigation could have given him.

Forensic Art, Skull Reconstruction, Criminal Investigation

D29 Analysis of the Organic Composition of Gunshot Residue

Amanda Roth, BA, 188 Sheridan Avenue, Apartment 1, Pittsburgh, PA 15202; and Stephanie J. Wetzel, PhD, Duquesne University, Department of Chemistry and Biochemistry, 600 Forbes Avenue, Pittsburgh, PA 15282*

The goal of this presentation is to demonstrate the analysis of the organic composition of gunshot residues by LC-MS/MS and to determine if the residue produced by particular ammunition is unique to its manufacturer.

This presentation will impact the forensic science community by providing an analysis method for the organic composition of gunshot residues and by exhibiting a comparison of the organic compositions to be used as a tool by forensic investigators to discriminate between manufacturers of ammunitions.

Gunshot residue can be defined as the particles expelled from a firearm upon its use and can be deposited on the skin or clothing of both the shooter and the victim. The residues are generally composed of inorganic particulates from the primers and organic particulates from the propellant powders used in the firearm's ammunition. Traditional gunshot residue analysis entails the determination of the presence of particles containing lead, barium, and antimony using SEM/EDX. Due to safety concerns, however, many manufacturers are no longer using lead in the production of their ammunitions. Previous methods analyzing the inorganic composition of gunshot residues are therefore no longer as valuable in forensic investigations.

Analysis of gunshot residues by liquid chromatography tandem mass spectrometry provided both qualitative and quantitative data on the organic compositions of the residues. This research is presented as an alternative to the traditional inorganic methods previously used and as a means of comparing residue compositions. Certain organic components of propellant powders, such as nitrocellulose and nitroglycerine, are commonly used in the manufacturing of other products, and as such were not analyzed. The seven organic compounds primarily studied in this research are explicitly indicative of gunshot residue: ethyl centralite, methyl centralite, akardite II, diphenylamine, N-nitrosodiphenylamine, 4-nitrodiphenylamine, and 2-nitrodiphenylamine.

Initially, standards of each of these compounds were analyzed, both separately and as a mixture, to optimize the liquid chromatography and mass spectrometer parameters. Gunshot residues produced from several different ammunitions were then collected on fabrics and extracted before being analyzed under these optimal conditions. A solid-phase extraction technique was utilized with C-18 cartridges to concentrate the residue samples. A multiple reaction monitoring (MRM) method was used to discriminate between the parent and daughter ions of each compound for increased sensitivity. All samples and standards were prepared and processed with a combination of acetonitrile, methanol, and water, and were ionized by the mass spectrometer via positive electrospray ionization. Gunshot residue samples were also subjected to Quadrupole Time-of-Flight mass spectrometry to qualitatively identify any additional significant organic compounds.

Various gunshot residues were analyzed to determine if this method is reliable for use in forensic investigations to positively identify a substance as gunshot residue. The organic composition of each residue was evaluated to establish variations between manufacturers of ammunitions. Any significant deviations in composition would allow investigators to identify the manufacturer of an ammunition that produced a particular sample of gunshot residue. Following Locard's principle, the ability to identify the manufacturer of ammunition from gunshot residues can further assist investigators by linking possible suspects to the scene or by eliminating potential suspects.

Gunshot Residue, Organic, Mass Spectrometry

D30 Analysis of Footprints and its Parts for Stature Estimation in Indian Population

Tanuj Kanchan, MD, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; Kewal Krishan, PhD, Panjab University, Department of Anthropology, SECTOR-14, CHANDIGARH, 160 014, INDIA; and S. Shyam Sundar, K.R. Aparna, and Sankalpa Jaiswal, Kasturba Medical College, LHH Road, Mangalore, Karnataka 575001, INDIA*

After attending this presentation, the attendees will be able to recognize that stature can be estimated from footprints and its parts with a reasonable accuracy in Indian population.

This presentation will impact the forensic science community by recognizing that stature can be estimated from footprints with a reasonable accuracy in males and females. The findings may prove to be useful in identification of unknown prints. It can give vital evidence in identification of the perpetrator of the crime in cases where the footprints are left behind at a crime scene.

Footprints are often encountered at crime scenes especially in cases of murders and sexual assaults. Estimation of stature from the footprints found at the crime scene can be crucial in the identification of the perpetrator in forensic examinations. A positive correlation exists between stature and foot size and hence, analysis of footprints can be useful in estimation of stature. Although a few researchers have attempted to estimate stature from footprints, the recent studies on the subject are confined to males only. The present research is aimed to estimate stature based on detailed analysis of length measurements of footprints in Indian population using statistical considerations.

The present research was conducted on 100 young adults (50 males and 50 females) at the Department of Forensic Medicine, Kasturba Medical College, Mangalore, India. Healthy individuals aged between 20 – 25 years were included in this study after giving informed consent. The subjects with any disease/deformity of the foot/spine were excluded from the study. The stature of each subject was measured in centimeters using standard techniques. Each subject included in the study was asked to wash their feet with soap and water. A clean plain glass plate was uniformly smeared with black duplicating ink with the help of a roller. The subjects were asked to step onto the smeared plate and then transfer them onto a white paper. Regular pressure was applied on the foot area to obtain the footprints. Five measurements were taken in centimeters on right and left footprints obtained from each subject. The measurements were taken from the mid-rear heel point to the most anterior point of each toe on right and left sides and designated as T1, T2, T3, T4, and T5 for the measurements of heel to toe 1, 2, 3, 4, and 5 respectively. Male-female differences in stature and foot measurements were analyzed using Student's t-test. Asymmetry between sides in the foot measurements was calculated and tested using paired t-test. Pearson's correlation coefficients were calculated between stature and various measurements of the foot. The stature was estimated from foot and its various measurements by using linear and multiple regression analysis. Statistical significance was defined at the standard 0.05 level.

Mean stature was significantly higher in males than females. Statistically significant sex differences were observed in the various measurements on the footprints between males and females in right and left feet. Right-left differences were observed in footprint measurements among males and females. Statistically significant correlation coefficients were observed for correlation between stature and various footprint measurements. Thus, the stature is found to be positively and strongly related to various foot measurements in males and females. In males, various foot measurements show relatively higher values of correlation coefficients than in females. The linear regression models were derived for stature estimation from each measurement as "S (stature) = a + b x" + SEE, where, "a" is constant and "b" is the regression coefficient of independent variable (i.e., individual foot measurement) and "x" is an individual variable/foot measurement. Multiple regression models were derived as S (stature) = a (constant) + b1 (1: regression coefficient of the variable) x X1 (1: variable) + b2 (2: regression coefficient of the variable) x X2 (2: variable) + . . . bn (n: regression coefficient of the variable) x Xn (n: variable) + SEE. Multiple regression models show a higher accuracy than linear regression models in stature estimation.

Forensic Science, Stature Estimation, Footprints

D31 Forensic Devices for Maximizing Crime Scene Sample Procurement

Luciano Garofano, PhD, General of Carabinieri, Via G. D'Annunzio N.9, Parma, ITALY; and Pasquale Linariello, BSc, and Luca Salvaderi, BSc, NGB Genetics, Via Ruggero Grieco 5, Bologna, ITALY*

After attending this presentation, attendees will understand the importance of innovative collection devices for recovering and preserving DNA traces for crime scenes investigation.

This presentation will impact the forensic community by introducing innovative and more reliable devices for collecting and preserving small amounts of DNA for profiling. It will show how cotton, polyester, rayon, or paper swabs are widely used for evidence collection from crime scenes; however, swabs can affect the evidence obtained and subsequently analyzed. FLOQSwabs™ (FFS) are specifically designed to facilitate and maximize crime scene sample collection, and neutralize microbial contaminants while preserving nucleic acids (NA) integrity without the need for drying the swab prior to transport or storage. Each forensic collection kit consists of specially designed regular, flat, round/rims, or nails flocked swabs associated to a Nucleic Acid Optimizer (NAO), a semi-permeable basket that allows efficient release of all sample collected from small traces during a crime scene investigation.

The objectives of this study were to: (1) compare the 4N6 FLOQSwabs™ collection kits (FFS+NAO) to traditional forensic collection devices for procurement and preservation of nucleic acids for forensic investigation; (2) to validate the FFS ability to preserve nucleic acids in samples with a heavy load of bacterial flora; (3) to validate the quality of nucleic acid for profiling; and, (4) to validate the ease of use of the special designed FFS for sample collection.

In this study crime scene traces (n=13) were simulated in the laboratory and included: Seven dry blood traces spotted on different types of surfaces including two with strong bacterial contamination; four sweat traces on different types of surface; one saliva trace on bottlenecks; and one human skin trace under fingernails. Six replicates were prepared for each trace and duplicate samples were collected with FFSs, and traditional rayon forensic (RFS) (Sarstedt), and absorbent filter paper forensic swabs (PFS) (Whatman). Each swab was pre-wetted with 50ul of sterile distilled water. All samples collected were stored 10 days at room temperature and then tested for DNA quantity and quality for profiling. The FFSs were used in association with the NAOs during the purification procedure in order to completely drain the swabs after the lysing step. Nucleic acid was extracted with DNA blood mini elute, quantified by Real Time PCR, and profiled with a amplification kit.

In all the samples tested, the Copan FFS recovered from blood, saliva, sweat, and skin under nail traces 0.20ng/ul, 0.83ng/ul, 0.15ng/ul, and of 0.3ng/ul of human DNA, respectively, compared to 0.15ng/ul, 0.07ng/ul, 0.05ng/ul, and 0.06ng/ul of human DNA for the RFS and 0.0097ng/ul, 0.01ng/ul, 0.0033ng/ul, and 0.0044ng/ul of human DNA for the PFS, respectively. When comparing the total qPCR results, Copan FFSs recovered an average of 0.24ng/ul of human DNA compared to an average of 0.106ng/ul for the RFS and of 0.0072ng/ul for the PFS. From two heavily contaminated blood traces, FFS detected 0.61ng/ul versus 0.014ng/ul for RFS and 0.0ng/ul for PFS. Copan FFS collected 2.26 times more DNA than RFS and 33.3 times more DNA than the PFS.

When analyzing the STR profiles, Copan FFSs recovered from blood, saliva, sweat and skin under nail traces respectively 85.90%, 100%, 57.40% and 93.80% of the total alleles amplified, compared to 72.10%, 93.80%, 21.10% and 26.60% recovered by RFS and 24.30%, 31.30%, 0.40% and 4.90% recovered by PFS.

The 4N6 FLOQSwabs™ easily collected all samples from all collection sites due to the specially designed geometries. The traditional swabs performed fine but were limited due to a single geometry, shredded during collection, and did not have a transport tube.

Copan forensic collection kits are increasing and preserving DNA collection from 2.2 to 33 times and increasing the percentage of recovered alleles in STR analysis. The FFS can be used for sample collection in a heavily contaminated environment even after 10 days storage at room temperature without the need of drying. The FFS were easy to handle especially for the hard surfaces, bottleneck, and under nail collection.

FLOQSwabs, Forensic, Collection

D32 A Comparison of Cyanoacrylate, Ninhydrin, and Gel Lifters for the Development of Latent Prints on Latex Gloves

Stephanie A. Johnson, BA, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; Jay M. Peterson, BS, Michigan State Police Marquette Forensic Laboratory, 1924 Industrial Parkway, Marquette, MI 49855; Catherine G. Rushton, MS, Marshall University Forensic Science Graduate Program, 1401 Forensic Science Drive, Huntington, WV 25701; and Pamela J. Staton, PhD, Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will gain a better understanding of the effectiveness of ninhydrin, cyanoacrylate, and gel lifters when developing latent prints on latex gloves.

This presentation will impact the forensic science community by providing latent print examiners with added insight into the most effective technique for developing latent prints on latex gloves as well as whether or not time is a factor in the efficacy of these techniques.

Latex gloves are notorious for being difficult substrates for the development of latent fingerprints. Varying degrees of texture and fit, along with a multitude of other, uncontrollable variables make developing prints a very difficult task. Some of the most commonly used techniques in latent print development are cyanoacrylate fuming, ninhydrin, and gel lifters. These three techniques are relatively inexpensive and have been used in the past to develop prints on a variety of substrates, including latex gloves. Time is also important when processing evidence and can affect how well a print is developed or how well a technique will work. Fingerprints can potentially last for years depending on the substrate and conditions; however, it is still important to understand the effects of time on evidence and the quality of the results.

The experiment compared cyanoacrylate fuming with magnetic powder, ninhydrin, and black gel lifters to determine which produced the highest quality results when developing latent prints on latex gloves and whether or not time affected the quality of these results. Multiple pairs of size large, powder-free latex gloves were worn by eight different

participants for 15 minutes at a time and were then divided into batches which were processed after being stored for varying amounts of time, from one day to six weeks. Latent prints were developed both on the inside of the fingers of the gloves as well as in the palm area, where a print was placed by the participant after removing the glove. Gloves from each batch where further divided into three different sub-groups which were processed by the different techniques. After processing, any results were given a rating of 0-3, with 0 being no results or only a fingermark present, 1 being small amounts of ridge detail present with or without the overall pattern visible, 2 being sufficient ridge detail to make an identification but without either or both 1st and 2nd level detail, and 3 being an identifiable print which has all three levels of detail. Results with a score of one or higher were photographed and reviewed a second time. The percentage of identifiable results produced was calculated for each technique along with the average rating over the course of the experiment.

The results of the experiment indicate that the cyanoacrylate with magnetic powder and the black gel lifter techniques produce comparable results, with the black gel lifter producing a slightly higher percentage of identifiable prints. The ninhydrin technique produced no identifiable prints in either of the finger and palm areas and consistently yielded much lower amounts of ridge detail than the other methods. Additionally, the amount of time the gloves were allowed to sit did not appear to affect the quality of the results, as prints with a score of three were developed in the six week group. The most important factors when it came to the quality of prints developed seemed to be the fit of the glove, with tighter fitting gloves producing better results.

Latent Prints, Latex Gloves, Fingerprint Analysis

D33 Development of Rapid Semi-Quantitative Colorimetric Test for Trinitrotoluene (TNT)

Aree Choodum, PhD, Prince of Songkla University, Department of Applied Science, Khohong, Hat Yai, Songkhla 90112, THAILAND; Niamh Nic Daeid, PhD, University of Strathclyde, Centre for Forensic Science, 204 George Street, Glasgow, G1 1XW, UNITED KINGDOM; Proespichaya Kanatharana, PhD, Prince of Songkla University, Department of Chemistry, Hat Yai, 90112, THAILAND; and Worawit Wongniramaikul, PhD, Prince of Songkla University, Faculty of Technology and Environment, Phuket Campus, Kathu, 83120, THAILAND*

After attending this presentation, attendees will understand the adaptation of a simple colorimetric chemical technique for the identification of TNT in power and extracted from soil samples to provide semi-quantitative information.

This presentation will impact the forensic science community by providing useful insight into the modification and development of an existing colorimetric test to facilitate the semi quantitative analysis in the field.

Explosive compounds are increasingly used around the world by terrorist groups and individuals; as a result, the rapid identification, detection, and quantification of explosives has become an important topic in forensic science and antiterrorist activities. Often explosives have also been used for military proposes, mining, and other industries. They can contaminate soil and water due to military activities (e.g., manufacturing, testing and training, demilitarization, open burning/open detonation, buried land mines, and industrial activities). This can cause significant environmental pollution and there is a need for a rapid, low-cost method for semi-quantitative or quantitative trace explosives detection for hazardous waste site characterization and land mine detection.

One important method for explosive detection involves the use of colorimetric techniques. This method could be used both off-site as the field test and as an on-site laboratory screen. Such techniques have the advantages of speed and low facilitating efficient sample analysis per unit time. This method has been used to analyze a large number of samples in mobile laboratory units as well as a number of commercial chemical kits have been developed; however, these can only produce qualitative analysis. Spectrophotometric detection has been reported for quantification of the product from colorimetric techniques; however, these require access to appropriate instruments. Therefore, there is a gap in current provision for field operators for a rapid, reliable, and low cost quantitative or semi-quantitative detection system for explosive trace and residue samples, both pre- and post-blast.

In this work, a rapid semi-quantitative colorimetric test for trinitrotoluene (TNT) was developed using digital image analysis. TNT was reacted with Nessler's reagent providing a purple colored product, which was recorded using digital images. The colored images were analyzed using a graphics editing software program to obtain analytical data in the form of Red Green Blue (RGB) values. The relationship between the individual RGB intensity and absorbance and the concentration of the target species were presented as calibration curves. A wide linear range and low detection limit was obtained in each case (1-50 mgL-1 for the color intensity and absorbance for red and blue as well as absorbance for green, and 1-25 mg L-1 for the color intensity of green, limit of detection of 0.73±0.01 mg L-1 to 1.75±0.07 mg L-1). The known concentration of TNT solution and TNT spiked in soil were tested for the accuracy of the method and satisfactory results were obtained. The results show great potential to continue the development for use as a semi-quantitative field test for TNT.

Colorimetric Test for TNT, Semi Quantitative, Digital Images

D34 A Case Study of DNA Typing From Human Feces

Sung-Woo Park, PhD, Chungnam National University, 305-764, Daejeon, KOREA; and Choi Yong-Bok, PhD*, Korea, Chungnam Provincial Police Agency, 301-708, Korea, Daejeon, KOREA*

After attending this presentation, attendees will have a better understanding on the subject of STR as genetic analysis.

This presentation will impact the forensic science community by highlighting STR as genetic analysis.

It is possible to have an individual identification through DNA analysis from body secretions such as hair, saliva, sperm, and an epithelial cell which are found in a crime scene. Short Tandem Repeat (STR) markers which are effective genetic markers that use a common forensic DNA typing. STR is studied in many fields such as a genetic map, a disease diagnosis, evolutionary biology, and forensic medicine, and it uses DNA profiling with amplified STR points by PCR using many kinds of STR kits.

Feces are composed of complex compounds such as a digested microorganism, food scrap, mucus, and a cell from the intestine's wall. It is also used the in the field of disease diagnosis. mtDNA is extracted successfully and analyzed from bear feces in a study by Hoss, et. al., in 1992. DNA analysis from human feces is also studied by the field of medical diagnosis.

Feces, which is one of the body's excretions, provides useful information on the physical condition of the colon through a microorganism in the colon and a desquamated epithelial cell. It is also provides the source of mtDNA for sequencing and nDNA for genotyping. From the same individual, sequences of samples of feces and blood are equal, but it is observed 4.88 average sequences per 400bp, between the ranges of 1-10 nucleotide.

In March 2009, victim A (a 50-year-old female) and victim B (A's daughter, a 23-year-old female) were murdered by stabbing in CheonAn-si, ChungNam, South Korea. Victim A was found in her master bedroom and the victim B was found in a garden next to her home. During the investigation, feces believed to be the suspect's and a glove with blood were found, and upon the analysis of evidence, DNA was found and the suspect C was arrested.

In this case, extracted DNA from human's feces, the glove with blood, and the part of wrist in glove were used to STR point's analysis after STR DNA profiling. There were three conclusions leading to the arrest of the suspect: (1) the man's DNA was found from feces, and it was the same as DNA from the suspect's oral swab received from the CheonAn SeoBuk police station; (2) the blood on the glove was identified the victims' blood, when analyzing to wipe the wrist part of glove's inside, complex DNA linking victims and the suspect were found; and, (3) when analyzing Y-STR which is the male DNA marker, it matched the DNA of suspect. Therefore, the suspect was found to be male and the DNA of the suspect was analyzed in more detail from the wrist part of glove.

In many crime scenes, criminals leave feces because of psychological pressure, and as a result it is evidence equally important as blood and saliva.

This case shows the DNA collected from the feces was the same as the suspect's DNA, shown through DNA typing. The compound of feces is very complex and the occurrence of microorganism ever changing; however, it can be analyzed perfectly with DNA. Therefore, it can be one of the most important evidence retrieved in crime scenes and it needs various studies.

DNA, Human Feces, STR

D35 Analysis of Triacylglycerols in Fingermark Samples as a Dating Technique by Laser Desorption/Ionization Time-of-Flight Mass Spectrometry

Elizabeth L. Emerson, MS, University of Arkansas, Department of Chemistry, 345 North Campus Drive, Fayetteville, AR 72701; Jennifer Gidden, PhD, and Jackson O. Lay, Jr., PhD, Arkansas Statewide Mass Spectrometry Facility, 345 North Campus Drive, Fayetteville, AR 72701; and Bill Durham, PhD, University of Arkansas, Department of Chemistry, 345 North Campus Drive, Fayetteville, AR 72701*

After attending this presentation, attendees will understand: (1) how TAGs in fingermark samples can be detected; (2) the mechanism and duration of their degradation; (3) and examples of decomposition over different experimental conditions.

This presentation will impact the forensic science community by providing a reliable way to detect the degradation products of TAGs in fingermark samples. This detection could serve as a potential dating method for fingermarks. At the present time, no established method is accepted for dating fingerprints or fingermarks.

The chemical composition of fingermarks could potentially be important in the investigation of criminal activity. This includes application of a possible dating method to place an individual identified through a fingerprint at the time of a crime. Determination of the age of a fingermark, in particular, would be useful to confirm or dispute a suspect's alibi. For example, an individual could assert that a fingerprint recovered from a crime scene was present for weeks before the crime was committed. Determining that the print was left hours before the offense could be critical in establishing a time-line of events and a subsequent conviction

Fingermarks are the recovered traces of material transferred to other surfaces upon contact. The material transferred is a complex mixture of chemicals, mostly lipids including triacylglycerols (TAGs). In this study, fingermark samples containing TAGs were analyzed using laser desorption/ionization (LDI) time-of-flight mass spectrometry (TOF MS). Only LDI appeared to be useful for this application while conventional matrix-assisted laser desorption/ionization (MALDI) TOF MS was not. Analysis of fingermark samples exposed to light conditions on a stainless steel target indicated the formation of TAG degradation products. As the sample degraded, additional peaks were observed in the mass spectrum particularly in the m/z range of 650-750. The decrease in relative intensities for some TAGs occurred after exposure to light for less than 12 hours with almost complete degradation taking place after 72 hours. These products were not detected in samples exposed to dark conditions. TAGs that decreased in intensity corresponded to those previously identified as having at least one unsaturated fatty acid. Other TAGs that were still present after 72 hours were identified as containing all saturated fatty acids. Monitoring these changes in the TAGs over time and under different conditions could establish a consistent pattern for dating applications.

Analysis of an unsaturated TAG standard (triolein, C57:3) was used for comparison. After exposure of this sample to the same conditions as fingermarks, decomposition was observed under light conditions. Tandem mass spectrometry was used to identify/confirm selected TAG degradation products. Formation of bound C8:0 and C9:0 aldehydes and carboxylic acids were observed. These products are consistent with those found in fingermark degradation products.

Fingermark samples were also allowed to undergo degradation on alternative sample surfaces to determine if the process is rate dependent upon the sample medium. Comparison of different surfaces, as would be the case for fingermarks collected at crime scenes, is thus important for determining degradation rates. Samples were allowed to degrade on surfaces of glass, plastic, and wood under light and dark conditions. These samples were then analyzed in 12 hour increments for 60 hours by LDI-TOF MS for comparison to the stainless steel target samples.

Fingermarks, Triacylglycerols, LDI-TOF MS

D36 Electronic News Media Reports of Potential Bioterrorism-Related Incidents Involving Unknown White Powder

Geroncio C. Fajardo, MD, 1600 Clifton Road NE, MS C-18, Atlanta, GA 30333; and Joseph Posid, MPH, United States Centers for Disease Control and Prevention, National Center for Emerging & Zoonotic Infections, 1600 Clifton Road, Northeast, MS C-18, Atlanta, GA 30333*

After attending this presentation, attendees will understand how bioterrorism (after the 2001 anthrax attacks in the United States) is a potential threat in the United States and around the world. Incidents related to potential anthrax-related unknown white powder/suspicious packages occur in practically every state in the United States, and responses to these incidents could entail significant amount of human and financial resources.

This presentation will impact the forensic science community by analyzing the submitted specimens. Furthermore, this presentation will help the attendees to understand that potential bioterrorism-related incidents continue to exist and pose a threat to national or local security, and to help to allocate limited resources efficiently.

Potential anthrax-related incidents involving unknown white powders that were reported online by news media from June 2009 through May 2011 were reviewed and compared them with incidents reported to the U.S. Centers for Disease Control and Prevention, Division of Preparedness and Emerging Infections, Emergency Preparedness and Surveillance Branch (CDC DPEI/EPRB). Geographic distribution and location of these powder-related incidents, the identity of the unknown white powders, and responders involved in these incidents will be presented.

Internet searches for "unknown white powder" using various search engines were performed. Incidents reported to and responded by the CDC DPEI/EPRB were also reviewed. The following types of information were collected: report date, state of incidence, specific location of incidence, identification of the unknown white powders, emergency responders involved, and FBI involvement. Using Microsoft Excel® 2003, an electronic spreadsheet was constructed, and a descriptive statistical analysis was done using SPSS 17.0.

There were 267 news media reports from 43 states and the District of Columbia included in this study. One incident might be reported in two or more electronic news media; however, this event was counted only as one incident for purposes of this study. In addition, there were reported

incidents from eight U.S. Embassies in Senegal, Turkey, Israel, Canada, Norway, England, Malta, and Cyprus which were not included in this analysis. In comparison, there were only ten white powder incidents from various states and 14 white powder incidents from U.S. Embassies around the world that were reported to and responded by CDC DPEI/EPRB.

Most of the media-reported U.S. incidents came from California (n=29, 10.9%), Florida (n=26, 9.7%), Texas (n=21, 7.9%), New York (=19, 7.1%), and Alabama (n=11, 4.1%). More than half of these reported incidents (n=158, 59.2%) occurred in government facilities (including law enforcement offices and courthouses (n=96, 36.0%)). The remainder occurred in private business establishments (n=32, 12.0%); schools at all levels (n=19, 7.1%); private homes (n=11, 4.1%) and other sites (n=109, 40.8%) including banks, hospitals, churches, airplanes, airports, TV stations, newspaper mail rooms, a school bus, and theaters. Although the majority of news reports (n=207, 77.5%) did not mention the final identity of the suspicious powder, many of the white powders were identified as flour, baking powder, talcum powder, baby powder, cornstarch, or sugar. None of the articles were identified as a harmful substance.

Even though the suspicious white powder was harmless in all of these reported incidents, public health emergency responders, and forensic investigators responded to the incidents. Responders included fire department, police department, bomb squad, FBI, U.S. Postal Inspection Service, public health laboratories, State Department of Environmental Protection, National Guard, U.S. Marshal Service, and/or regional transit authorities. In some cases, the media reported the incidents led to evacuations and precautionary hospitalizations. Joint public health emergency responder and FBI investigations were mentioned in only a few reported incidents (n=35, 13.1%).

Because of the highly sensitive forensic nature of some cases; however, some white powder incidents were investigated by the FBI and were not covered by news media. Thus, it is likely that powder incidents in this study were underreported. Furthermore, emergency responses to unknown white powder incidents are generally managed at the local level and therefore, they may or may not be reported to CDC DPEI/EPRB for emergency response assistance.

Results of this study showed that unknown white powder incidents continue to occur. In addition, these incidents require integrated medical, public health, preparedness, and response activities from various emergency responders and cause substantial concern (as evidenced by media reports).

Bioterrorism, Unknown White Powder, Anthrax

D37 Shooting Euthanized Pig Heads to Determine Penetration Capabilities of Frangible Bullets and the Impact on a Forensic Investigation

Steven L. Downs, MFS, 816 Tumbleweed Trail, Temple, TX 76502; Michael V. Graziano, MFS*, Forensic Science Consultant, 2447 River Road, Fayetteville, NC 28312-8443; and David G. Pauly, MFS*, Methodist University and TruForensics, Limited Liability Company, 3512 Gables Drive, Fayetteville, NC 28311*

After attending this presentation, attendees will better understand weights, velocities, and kinetic energies of bullets frequently encountered at criminal shooting incidents. The attendee will learn the differences between common lead-based bullets and frangible bullets, their intended uses, the potential loss of bullet evidence at shootings involving these bullets, and the destructive effects of shooting frangible bullets into euthanized pig heads.

This presentation will impact the forensic science community by providing a definition of frangible bullets, their uses in tactical and close quarter combat/shooting events, and their ability to penetrate tissue and bone. The presentation will also explain the complexities for the investigator and forensic firearms examiner in evaluating the frangible bullet or remnants involved in the shooting incident.

Frangible Bullet Penetration Study: What is a frangible bullet, what are they utilized for, what are their wounding capabilities on tissue and bone, and how does the use of frangible bullets affect a forensic investigation?

Many students of forensic science, forensic science practitioners, law enforcement officers, and other justice related personnel are not familiar with frangible bullets, their availability on the U.S. market, and the potentially negative evidentiary effects of a frangible bullet when involved in a criminal forensic investigation. In the United States, the majority of homicides are committed by use of a firearm. During systematic crime scene searches and postmortem examinations of victims, it is common to recover bullets or fragments of bullets. Most bullets are made of lead and normally contain a metal jacket to provide strength. These bullets and/or fragments can be examined in the forensic laboratory for class and possibly individual characteristics. These bullet characteristics may make it possible to further the investigation by linking the physical bullet evidence to a suspected shooter, a firearm in his control, a box/lot of cartridges, or a previously known firearm common to the suspect. This presentation will include the basics of bullet composition, a variety of common firearm calibers, weights of bullets, velocity of these common bullets, and the differences in kinetic energy frequently found in firearm bullets observed in shooting incidents in the United States. Frangible bullets typically do not contain lead and therefore are considered to be more environmentally friendly. From an environmental standpoint, these bullets are preferred to lead-based bullets which may pose a more significant negative impact on the environment. This presentation is the result of a graduate school study set forth to answer the question of what the impact would be of a frangible bullet on tissue and bone, and their ability to be examined after striking a target or victim. Frangible bullets are commonly used with the intent of not over-penetrating solids, such as wooden and metal doorways. This study set out to answer whether or not frangible bullets were capable of penetrating tissue and bone and whether or not they could do so without breaking apart. The study also sought to answer the question of whether or not the frangible bullet would remain intact sufficiently to establish class or individual characteristics. This presentation will help answer these questions, as well as, provide insight to the attendee on the impact on homicide or death investigations involving the frangible bullet.

Frangible Bullet, Firearms, Shooting

D38 Pilot Comparison of Conducted Electrical Weapon Effectiveness: Old vs. New Technology

Jeffrey Ho, MD, Hennepin County Medical Center, Department of Emergency Medicine, 701 Park Avenue South, Minneapolis, MN 55415; Donald M. Dawes, MD, Lompoc Valley Medical Center, 518 East Hickory Avenue, Lompoc, CA 93436; Sebastian N. Kunz, MD, Institute of Forensic Medicine, Ludwig - Maximilians University, Nussbaumstr. 26, Munich, 80336, GERMANY; James R. Miner, MD, Hennepin County Medical Center, Department of Emergency Medicine, 701 Park Avenue South, Minneapolis, MN 55415; Andrew Hinz, BS, Taser International, 17800 North 85th Street, Scottsdale, AZ 85255; and James Sweeney, PhD, Florida Gulf Coast University, 10501 FGCU Boulevard South, Ft. Myers, FL 33965*

The goal of this presentation is to discuss and view new generation Conducted Electrical Weapons (CEW) and their effectiveness in the field by comparing them to older generation technology. The audience will understand how effective each of these technologies is when compared to each other.

This presentation will impact the forensic science community by aiding in event reconstruction and in understanding the capabilities of these devices. Event understanding and reconstruction of events involving

newer technology will remain accurate by comparing effectiveness to familiar and known (older) technology effectiveness.

The CEW is a popular law enforcement tool used in the control and restraint of potentially violent persons. The TASER X26 CEW, in service since 2003, is the most widely used CEW in society, and is considered older generation technology. The TASER X2 CEW has been recently released for service, is expected to replace the X26 over the next several years, and is considered new generation CEW technology. In general, the X2 is less familiar to most forensic personnel.

The X2 is different than the X26. In addition to a multi-shot capability, it has redesigned electrical waveform and output characteristics when compared to the X26. This pilot study describes an initial head-to-head comparison of the effectiveness of these devices in stopping a motivated person when compared to each other. This information may be important forensically when evaluating or reconstructing a situation where new generation CEW technology has been used.

This study presentation should provide attendees with an understanding of how effective each of these CEWs is in controlling/restraining a motivated person. It will also help attendees to understand how effective the CEWs are when compared to each other. This information should prove to be helpful to the forensic, legal, and investigative community when reconstruction of events must be made.

Four human volunteers were recruited and had metal TASER XP probe pairs manually placed to a depth of 13 mm. Each volunteer had two pairs of probes emplaced (one pair on the right and one pair on the left of the abdominal/inguinal region). Superior probe placement was at the costal margin, five inches lateral of midline (as guided by the umbilicus). The Inferior probe was placed vertically inferior at predetermined spread distances. These distances were 6, 9, 12, and 16 inches apart (15.2-40.6 cm). Each volunteer was given the goal of holding a rubber knife and slashing a suspended dummy 10 feet (3.05 meters) away during the CEW exposure. As a means of motivation, they were told that the CEW exposure would continue until they reached their goal (in reality, the CEW exposure was terminated when the operator determined that no further forward progress was being made). Each volunteer received two CEW exposures, one each from an X26 and an X2 factory standard CEW. The order of the exposures was randomized. There was an approximate two-minute rest period between the two exposures. All exposures were recorded by a high-speed, high-resolution video camera. The videos were later reviewed and scored for effectiveness by a panel of physician and law enforcement experts.

No subjects were excluded and all completed the testing protocol for a total of eight exposures (four pairs) for evaluation. The review experts evaluated each exposure for degree of upper extremity effect, lower extremity effect, total body incapacitation, and whether or not they were able to reach their goal. The exposure reviews were then descriptively compared independently for probe spread distances and then compared between devices.

In this pilot study, results show that there was no discernible, descriptive difference in effectiveness between the TASER X26 and the X2 CEWs when compared in head-to-head fashion. Based on this, end-users and forensic investigators should expect similar performance characteristics during use and in event reconstruction. As new generation CEW technology becomes more popular, it may be important to increase the scope of this research for validation.

Conducted Electrical Weapon, Electronic Control Device, TASER

D39 Shooting Incident Analysis: Critical Case Studies

Alexander Jason, BA, ANITE Group, PO Box 375, Pinole, CA 94564*

After attending this presentation, attendees will better understand the elements within an analysis and reconstruction of shooting incidents.

This presentation will impact the forensic science community by providing new data from original research on shooting incident analysis and reconstruction.

A central element in any analysis of a shooting incident is the realization that all shootings involve time and motion: from visual perceptions, decision process, neural transmission, to muscle movement during the "squeeze" of the trigger, bullet travel, and gross defensive or offensive movements of the shooter and person being shot. Along with this understanding, the analysis and reconstruction of shooting incidents often requires consideration of several forensic and human performance components including wound ballistics, psycho-neurological factors, bullet flight dynamics, terminal ballistics, gunshot residue characteristics, firearms operation, and other associated areas of knowledge such as bloodstain interpretation. The integration of the data from these areas can be extremely useful in any forensic examination of a shooting incident – particularly when multiple shots are involved.

Of these dynamic elements pertaining to shooting incidents, the movement of persons involved in the shooting incident is often of extreme significance in the analysis of the incident and the legal determination (homicide, self-defense, etc) that is always produced after a shooting incident. The location of entry wounds and the associated wound paths within the body are often utilized as indicators of a victim's body orientation and stance when the bullet(s) struck. While this data is highly useful, its value can only be validated when the data from these elements are integrated into the dynamics of the shooting incident.

Over several years, this study covers numerous research projects to address these issues. The results of the research and the significance of the results when applied to the analysis of shooting incidents are presented within this presentation. The research presented in this presentation is the result of forensic analyses and reconstruction of shooting incidents performed for criminal and civil litigation. Many of the findings presented have been used during court testimony and found to be relevant to the understanding of significant issues relating to the position, orientation, and location of persons involved in shooting incidents.

Case reviews of actual shooting incidents have established that in many shooting incident analyses, the movements of shooters – and particularly – the person(s) being shot are inappropriately ignored. Research on the actual movements of participants in shooting incidents was performed and the results demonstrate that a consideration of body movements during the incident can provide significant data directly useful in the analysis, reconstruction of shooting incidents, and in the legal determination (adjudication) of the incident.

Shooting cases reviewed and presented in this presentation include one in which a (police officer) shooter's description of the incident was described as "inconsistent with the physical evidence" by an expert witness biomechanical engineer. This opinion was based on the expert's attempt to analyze the incident without consideration for the movement of the shooter and person being shot. In another shooting case, a key element was the integration of dynamic movement of a suspect and the repositioning that occurred with the suspect's clothing during movement.

Additional examples of shooting victims are presented on video with detailed analyses of the various movements that occur and their potential significance in shooting incident analysis.

Shooting Analysis, Shooting Reconstruction, Shooting Incidents

D40 Term and Definitional Analysis of Sex-Related Homicide

Tanisha V. Henson, MFS, Richmond Office of the Chief Medical Examiner, Central District, 400 East Jackson Street, Richmond, VA 23219*

After attending this presentation, attendees will: (1) understand the difficulty in conducting proper research when no single term or definition exists; (2) understand the difficulty in maintaining statistics when no single

term or definition exists; and, (3) understand the importance of having a single term and definition both for law enforcement and clinicians.

This presentation will impact the forensic science community by better informing attendees of the importance and need of a single term and definition in the recognition, investigation, and classification of sex-related homicide.

Sex-related homicide is a heinous crime. It is also a crime that grips the community in which the crime occurs. What is not well known about this particular crime is what the appropriate, correct, or even most descriptive term or definition is. What is also not known about sex-related homicide is what the true statistics are. Researchers vary in their opinion as to whether or not sex-related homicide is rare or rampant. With 18 terms and 48 definitions, it is easy to see how it would be difficult to decide if it is rare or rampant. These terms range from erotophonophilia to lust psychotic killing to sexual murder. Several of the terms have multiple definitions and some terms have no definition. Given the broad spectrum of terms and definitions, it is easy to see how it would be difficult to determine the statistics. The Federal Bureau of Investigation (FBI) uses information voluntarily submitted by law enforcement agencies all over the United States to prepare the Uniformed Crime Report (UCR) and the Supplemental Homicide Report (SHR). From the information submitted, they use motive to classify the homicide. A cursory glance of UCR and the SHR would lead one to believe that sex-related homicide is rare if they were to only consider rape, other-sex offenses and possibly prostitution & criminalized vice. Sex-related homicide is much more than rape, other-sex offenses and prostitution & criminalized vice and should be recognized as such.

This research explored a wide range of terms and definitions, as well as unpublished data from the FBI. The resources utilized were from peer reviewed articles, educational textbooks, and the National Clearinghouse for Science, Technology, and the Law (NCSTL). The unpublished data revealed the statistics prepared by the FBI for the UCR and SHR for homicides with known or obvious sexual relations range from 0%-2%. These particular homicide statistics only include rape, other-sex offenses, and prostitution & criminalized vice. There is also a large homicide category which is labeled as unknown. The unknown category averages 29% of the annual homicides. A brief overview of the total number of homicides in comparison to the unknown motive category shows: the total number of homicides from 1980 through 1989 was: 190,020. Of these homicides, 42,363 or 22.29% were placed into the unknown motives category. The total number of homicides from 1990 through 1999 was: 190,906. Of these homicides, 56,409 or 29.55% of these were placed into the unknown motives category. The total number of homicides from 2000 through 2008 was: 129,559. Of these homicides, 48,732 or 37.61% were placed into the unknown motives category. From the 1980's to the 1990's there was an increase of 7.25% in homicides placed into the unknown motives category. From the 1990's to the 2000's there was an increase of 8.07% in homicides placed into the unknown motives category. Overall, from the 1980's to the 2000's there was a 15.32% increase in homicides placed into the unknown motives category. With the number of unknown motive homicides increasing, the need for better categorization becomes more apparent. Several researchers acknowledge the unknown category as a veritable dumping ground for homicides with no known motive and this category has a high likelihood of being the category where the majority of sex-related homicides are placed.

There are a wide variety of terms and definitions to choose from when researching sex-related homicide. These can contribute to research weakness, inaccurate statistics, and subpar investigations. To remedy this problem, there should be one universal term and definition which both law enforcement and clinicians can use. In addition to the use of one term and definition, the statistics for sex-related homicide would be better maintained with the use of the four categories as ascribed by Vernon J. Geberth rather than on the basis of motive as is currently used by the FBI. At the conclusion of this study, the following facts remain: researchers and law enforcement cannot agree on a universal term or definition, they cannot agree on whether sex-related homicide is rare or rampant, and the available statistics are not entirely accurate.

Sex-Related Homicide, Lust Murder, Sexual Killing

D41 Detection of Gasoline From Lung Tissue and Heart Blood for Use in Determining Victim Status at the Time of a Fire

Kevin Pahor, BSc, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, ON L1H 7K4, CANADA; Gregory O. Olson, MSc, Office of the Fire Marshal, 2284 Nursery Road, Midhurst, Ontario L0L 1X0, CANADA; and Shari Forbes, PhD, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, ON L1H7K4, CANADA*

The goal of this presentation is to understand how gasoline can be detected from the lungs and heart blood of a deceased victim post fire for use in determining the victim's status at the time of the fire.

This presentation will impact the forensic science community by demonstrating the importance of analyzing a victim's tissues for ignitable liquid residues post fire as it can allow for the determination of a the victim's status.

In Ontario, fire investigators from the Office of the Fire Marshal (OFM) are responsible for determining the origin and cause of fires and explosions within the province and in particular those of suspicious nature. As part of the fire investigation, debris samples are collected from the scene and analyzed by the Center of Forensic Sciences. The standard practice is to collect items that are porous, highly absorbent, or adsorbent with high surface areas as they allow for better retention of the ignitable liquids. The items collected most often are carpets, cardboards, soils, cloths, and other items that have not been impinged by flame such as material under baseboards. These samples are analyzed for the presence of any ignitable liquid residues which may be evidence of an accelerant used in the fire. This information will aid in determining if the fire was intentionally set.

The purpose of this study was to determine the feasibility of identifying whether a victim was alive or deceased at the time of a fire started with accelerants by detecting gasoline residues within their lungs and heart blood post-fire. It was hypothesized that only when a victim was alive and performing respiration would sufficient gasoline for detection be present in the lungs and heart blood post-fire. This experiment involved anesthetizing a live pig, exposing the pig to gasoline vapors for 10 minutes, and then euthanizing it. The carcass was clothed with a cotton t-shirt and placed in a house where additional gasoline was poured onto it and the house set ablaze. The house also contained two pig carcasses, one with gasoline poured directly onto it (positive control) and the other with no gasoline exposure (negative control). Thermocouples were placed under each carcass and in the center of each room at ceiling and floor levels to measure the temperature. After the fire had reached flashover and was suppressed, the carcasses were collected and their lungs and heart blood excised at a necropsy. The lungs and heart blood were then placed into glass jars as per OFM protocol. The headspace from the samples was analyzed by thermal desorption-gas chromatography-mass spectroscopy for the presence of a gasoline signature.

Preliminary results showed that only the lungs and heart blood from the live pig that inhaled gasoline contained gasoline residues. This indicates that it is possible to determine a victim's status at the time of the fire based on the detection of gasoline in the lungs and/or heart blood. The thermal data showed that the bodies act as an insulator and protects the underside, as the temperatures under the carcasses did not exceed 30□C while the room was over 900□C. This protective feature of the body was also demonstrated when portions of the t-shirt were found intact underneath

the carcasses after the fire. To validate these findings an additional three house fires and four vehicle fires will be conducted.

Fire, Accelerants, Chemistry

D42 Hyperspectral Remote Sensing of Individual Gravesites

Eva Snirer, BA, McGill University, Department of Geography, 805 Sherbrooke West, Montreal, QC V5A 1S6, CANADA; Margaret Kalacska, PhD, McGill University, Department of Geography, Montreal, QC H3A-2K6, CANADA; George Leblanc, PhD, National Research Council Canada, Flight Research Laboratory, Building U-61, Ottawa, ON K1A-0R6, CANADA; and Raymond Soffer, MSc, National Research Council Canada Institute for Aerospace Research, Flight Research Laboratory, Building U-61, Ottawa, ON , CANADA*

After attending this presentation, attendees will better understand airborne hyperspectral remote sensing as it relates to locating clandestine gravesites including known limitations and areas that need future exploration.

This presentation will impact the forensic science community by outlining a potential new tool for detection of individual gravesites using airborne platforms, enabling coverage of a wider area than is possible using ground based detection methods such as Ground Penetrating Radar and Cadaver dogs.

The use of hyperspectral remote sensing for the detection of clandestine graves is emerging as a potential alternative tool in forensic investigations. Previous studies have demonstrated it is possible to use hyperspectral remote sensing techniques in detection of mass graves. With this study, however, the goal is to demonstrate the feasibility to utilize this same technology for the detection of individual burial sites under specific conditions.

Detection of clandestine burials is of interest to police and first responders, with cases arising from victims of crime as well as situations where no foul play is suspected, such as missing hunters and hikers. Airborne hyperspectral remote sensing enables coverage of a wider area than is possible using ground based detection methods, such as ground penetrating radar and cadaver dogs. However, as with all detection technologies, it has its limitations and a fundamental aspect of using this technology for single grave detection is to understand what these limitations are.

Detection is based on of the alteration of the environment by the body through decomposition; it essentially being a form of environmental contamination which can affect both the soil and vegetation. It is known that a decomposing body alters the surrounding environment and that the changes in the soil matrix can alter plant chemistry. The degree to which this alteration takes place is highly dependent on season, geographical location, vegetation type and the state of the body when it is buried, as well as characteristics of the body such as its weight. Due to the chemical changes in the soil, plants undergo a stress response, changing the levels of plant pigments. These changes in plant pigments have been shown to be detectable by hyperspectral sensors with mass graves. However, the case of a single grave poses a far more difficult detection problem, primarily because the body mass is much smaller than with mass graves. Furthermore, the simple question of how burial depth affects detectability and persistence of the spectral changes is unknown.

For this study, 20 pig (*Sus scrofa*) carcasses were utilized as proxies for human cadavers. The effects of three burial scenarios – surface were examined, and 30cm and 90cm soil cover (all with and without the bodies being wrapped in garbage bags) - on the detectability of single bodies (150-200 lbs each) from an airborne sensor, as well as from laboratory analyses of the spectral signatures of the soil and subsurface methane concentration and surface methane flux.

A Twin Otter with hyperspectral sensors covering the visible to shortwave infrared range sensors flew over the site and collected imagery as time and weather permitted from July - October. The two airborne hyperspectral sensors were used coincidentally to cover the 450 to 2450 nm range of the electromagnetic spectrum. In addition to the airborne sensor, a portable spectroradiometer was used to collect plant spectra in field and soil spectra in the lab.

This study compares and contrast the signatures of graves at different burial depths with and without garbage bags and discuss the influence of these two factors on the detectability of single graves using this technology. Situations in which these tools may be feasible for the location of single bodies as well as a description of the detailed calibration procedures that are required in order to adequately use such data will be discussed.

Hyperspectral Remote Sensing, Clandestine Graves, Cadaver Detection

D43 County Burial: A Look at the Final Resting Place of Unclaimed and Unidentified Remains

Sharon M. Derrick, PhD, and Patricia C. Smith, BA, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to identify the process for referring unclaimed and unidentified remains to county burial. The steps will include how the remains are handled, the period prior to the county burial referral and how county burials are handled after family has been located and notified. This presentation will also examine other county and state programs and compare those processes with Harris County. Statistics regarding the number of remains that have been unclaimed and the number of remains that remain unidentified will be included. Statistics on the number of remains where family was located after the referral for county burial was completed will also be provided. Lastly, case studies for a 2007 homeless veteran, two 1973-murder cases that have been identified, and a 1980's death of a Marine will be provided.

This presentation will impact the forensic science community by serving as an educational tool for family members of those deceased and can help other jurisdictions augment or implement new procedures for handling unclaimed or unidentified remains. A county burial program will continue the respect and support for those remains that are unclaimed and unidentified. A county burial program will allow time for family members or friends to come forward to pay their respects and claim or acknowledge the deceased and their life.

The state of the economy has created difficulty with locating family members of deceased persons. The unemployment rate is on the rise and job prospects are fewer and farther between. Society has to travel farther and in some instances, move out-of-the-state in order to obtain employment. This makes it more challenging for families to keep up with loved ones and maintain close relationships. This also creates difficulty for HCIFS when trying to locate next-of-kin (NOK).

This presentation will provide information to the attendees regarding the timeline, process, and requirements needed for county burial referrals. The Investigation Division utilizes a checklist of contacts to look for the legal next of kin. After the checklist is exhausted, then the case is referred to the ID Unit for county burial referral. Part of the checklist is various internet searches, like public records, ancestry, and county clerk databases. Information from criminal and civil histories, bankruptcy court records, child support payments, life insurance, property ownership, and licenses can help in locating family. A news router or consulate letter is sent when NOK cannot be located, in the hope of someone reading the article and recognizing the description or picture provided. An abandonment letter is sent to the NOK 15 days after the NOK was notified. Fifteen days after that mailing, county burial will be referred, unless the NOK responds with their

choice of a funeral home. Families may apply for county burial assistance through the Harris County Community Services Department Bereavement Services program. The status of the families and the decedent's estate will need to meet financial criteria before assistance will be approved. Upon approval, the referral is usually immediate.

Fetuses and infants have a separate criteria regarding burial. Fetuses and infants must meet live birth or gestation/weight requirements of >500g/22 weeks and have been abandoned. The HC Burial Services will not provide burial assistance for an unclaimed fetus of <20 weeks and/or 500 grams; a surgical specimen disposal form is completed and processed by the morgue as a surgical specimen. HCBS will provide burial assistance for an unclaimed neonate, regardless of age or weight, if neonate took a breath or showed signs of life at birth.

County Burial, Unidentified/Unclaimed Remains, County Burial Program

D44 Animal Attack-Related Deaths in Florida

Brett E. Harding, MBA, District 21 Medical Examiner's Office, 70 Danley Drive, Fort Myers, FL 33907; and Barbara C. Wolf, MD, District 5 Medical Examiner's Office, 809 Pine Street, Leesburg, FL 34748*

After attending this presentation, attendees will have an appreciation of the nature of the varied types of deaths resulting from the interactions between humans and indigenous and exotic animals and reptiles in Florida, and the species involved.

This presentation will impact the forensic science community by providing a unique insight into Florida's varied fatal human/animal encounters and by illustrating the importance of the multidisciplinary medicolegal death investigation in these cases.

Florida has been the setting of several high profile deaths caused by captive animals in its amusement parks; the most recent being the death of a trainer killed by an orca whale, as well as two previously reported deaths caused by elephants. Nationally Florida also has the third highest rate of deaths due to attacks by canines, the most common offending species being the pit bull. Additionally, the state has also been the location of a number of deaths caused by indigenous species, as well non-native mammals and reptiles, which are frequently kept as pets in the state. Florida's unique climate provides an environment suitable for many potentially hazardous native and exotic species, including reptiles. This has resulted in a multitude of unforeseen fatal encounters between these animals and the ever expanding human population.

Files from the District 21 Medical Examiner's Office, which serves three counties in southwest Florida, and the District 5 MEO, encompassing five counties located in the central part of the state, in addition to previously tabulated records of deaths resulting from animal attacks/encounters, to elucidate the types of deaths and the species involved were reviewed. The most frequently reported deaths have resulted from shark attacks (25) on swimmers visiting Florida's many beaches and alligator attacks (18), most commonly attributed to alligators that have lost their innate fear of humans because they have been fed by individuals who have ignored the widespread warnings against such feeding. In addition to deaths caused by horses and dogs, Florida jurisdictions have seen five alligator-related deaths and one death caused by the mauling by a Siberian tiger kept in a private sanctuary. In addition, two deaths caused by snakes, including the first death due to the envenomization of a coral snake reported since anti-venom was developed 40 years ago, and in spite of the fact that non-lethal coral snake bites are frequent in Florida. The other snake-related death was that of a 2-year-old child who was the victim of mechanical asphyxiation by an improperly housed albino Burmese python that was kept as a pet. In spite of Florida's large bear population, there has never been a reported death in the state caused a bear. The immediate causes of death in these cases varied nearly as much as the species involved, and included exsanguination, drowning, sepsis, asphyxia, and blunt force trauma. The determination of the cause and manner of deaths in these cases requires a multidisciplinary investigation and necessitates the cooperation of the investigating law enforcement and wildlife conservation agencies, the medicolegal death investigator and the forensic pathologist. Whether foreseen or unforeseen, the underlying cause of death is always a result of the human/animal interaction.

While the literature and knowledge pool for more routine deaths (motor vehicle collisions, gunshot wounds and overdoses) is abundant, that of animal-related deaths is far less widespread. The deaths reported in this presentation provide a unique insight into Florida's varied fatal animal encounters.

Animal Attack, Death, Florida

D45 Animal Nutrition Investigative Techniques Essential to Obtaining Investigative Forensic Information From Multiple Sites

Gary M. Pusillo, PhD*, INTI Service Corporation, 2017 230th Street, Marshalltown, IA 50158

After attending this presentation, attendees will understand how careful interpretation of alleged animal nutrition related deaths and abnormalities in the presence of concomitant examination of all husbandry and environmental factors, is critical to scientifically valid conclusions.

This presentation will impact the forensic science community by showing how to use valid scientific principles to help differentiate the consequences of feed and nutritional inadequacies from husbandry practices, improper veterinary care, idiosyncratic drug induced complications, intentional abuse, accidents, and genetic disorders

Contaminated, distressed, or adulterated animal nutrition inputs can result in feed associated dysfunctions (FAD) within an animal population or in a specific individual. Nutrient deficiencies, excesses, and imbalances can result in nutrition associated dysfunction (NAD). NAD is associated with nutritional profile and ingredient mistakes and oversights in the manufacture, preparation, formulation, or the presentation of daily dietary components.

An essential component in the evaluation of animal feed and nutrition related claims is a scientifically valid set of investigative techniques required to accurately evaluate FAD and NAD in animals. As an example of the practical application of these techniques, a case study will be presented involving multiple Alpaca's at multiple sites, and a commercial Alpaca feed alleged to be contaminated with an alleged toxic substance, salinomycin.

Alleged toxic substance exposure from a commercial Alpaca feed requires the professional investigator to consider all other factors, management, environment, infectious agents, additional feeds, nutrition, and accidents; that may influence the appearance of abnormalities in a typical alpaca operation. Checklists and techniques will be provided to attendees, which along with firm scientific reasoning can be applied in the examination of an animal or population, the feed related components, and the facilities that existed at the time prior to, during and after exposure to an alleged toxic substance in commercially prepared feed.

Forensic nutrition requires a specific application of highly specialized and exacting disciplines that require the application of a unique set of interdisciplinary scientific skills and practical experience in animal husbandry and feeds and feeding. Defining the exact nature of the problems reported by alpaca caretakers, owners, trainers, and veterinarians requires the forensic professional to identify those dysfunctions within either the animal's environment or the daily ration, which may have attributed to the problems and financial losses relating to its performance, quality of life, and health.

Standards of what is acceptable evidence for causation in FAD- and or NAD-related illnesses in domestic animals do not currently exist. As a

result, cases of commercial animal feed alleged to be contaminated, distressed or adulterated may result in the perpetuation of a misdiagnosed abnormality and the proliferation of erroneous methods of domestic animal FAD and NAD evaluation.

Modern animal forensic investigations cannot separate valid scientific observations from the complexity of the environmental realities that act singly, together, and in a holocoenotic manner. At the same time, it is recognized that the animal or targeted population, in turn, reacts upon their environment, often producing marked modifications. Cases of NAD and FAD are often improperly investigated, documented, and analyzed. This presentation will provide actual details on how to successfully perform feed and nutrition investigations with proven techniques.

Feed Contaminants, Nutrition, Animals

D46 Using Thermal Imaging to Detect Trauma and Disease Processes in Animal Cruelty Cases

Amanda Fitch, MS, University of Florida, ASPCA, Maples Center for Forensic Medicine, 4800 Southwest 35th Drive, Gainesville, FL 32608*

The goal of this presentation is to understand how thermal imaging works and how it can be used to help diagnose injuries in animal victims.

This presentation will impact the forensic science community by exploring a method of identifying recent and healed traumas, as well as infections, in victims of animal cruelty. Due to limitations set by animal fur, and the sometimes-fractious nature of injured animals, a method of examination that requires minimal handling is beneficial.

Based on the electromagnetic spectrum, infrared light is a wavelength of light that is not visible to the human eye. Within the spectrum, visible light consists of seven colors with a range of wavelengths. Violet has the shortest wavelengths and red has the longest. The prefix "infra-" is derived from the Latin word infrā, meaning "below or further on". Therefore, the word "infrared" means "below red" indicating its position in the electromagnetic spectrum, with wavelengths longer than the color red.

According to the International Commission on Illumination, infrared light can be broken down into three bands:

- IR-A: 700 nm – 1400 nm (0.7 μm – 1.4 μm)
- IR-B: 1400 nm – 3000 nm (1.4 μm – 3 μm)
- IR-C: 3000 nm – 1mm (3 μm – 1000 μm)

This division structure is commonly broken down into five sub-divisions:

- Near-infrared: 750 nm – 1400 nm (0.75 μm – 1.4 μm)
- Short-wavelength infrared: 1400 nm – 3000 nm (1.4 μm – 3 μm)
- Mid-wavelength infrared: 3000 nm – 8000 nm (3 μm – 8 μm)
- Long-wavelength infrared: 8000 nm – 15000 nm (8 μm – 15 μm)
- Far infrared: 15000 nm – 1,000,000 nm (15 μm – 1000 μm)

Near infrared and short-wavelength infrared are considered "reflective" infrared. It is within these two ranges that forensic science applications typically fall. Both ranges are effective based on the amount of water absorbed by the surface being examined and its contrast to the evidence on it (i.e. fingerprints, bitemarks, bloodstains, etc.). The near and short-wave infrared ranges are also used to identify chemicals based on the substance's ability to absorb the wavelengths.

The term "thermal infrared" includes the mid- and long-wavelengths of infrared light. Unlike the near and short-wavelengths of infrared light which are reflected off of surfaces, thermal infrared is emitted by an object in the form of heat (radiation). These ranges are used only minimally in forensic sciences. The long-wavelength range is considered the "thermal imaging" range and is typically used for the investigation of mechanical and structural systems.

In the practice of human medicine, thermal imaging is being researched as a possible detection tool. It is currently used as an alternative, non-invasive diagnostic procedure for detecting breast cancer, as well as for monitoring conditions such as back injuries, vascular disease, and stroke screening. The principle behind using infrared imaging for the detection of cancerous growths is that tumors have an increased amount of blood vessels, which are necessary to sustain the high metabolic rate of cellular growth and replication. This increase in blood flow results in an increase in temperature. Similarly, nerve compression and soft tissue inflammation that may be a cause of pain can be visualized through thermal imaging when it may not be apparent on x-ray or MRI.

Thermal imaging has been researched and used within veterinary medicine for over 40 years. While the technology has been used on a variety of animals (including livestock and zoo animals), the majority of research has centered on injury detection and diagnosis in racing horses. Thermal infrared has been used to diagnose joint inflammation, tissue injury, muscle atrophy, and general diagnostics. The same principles will apply, to the detection of contusions as to that of cancerous growths. If there is an area of increased blood, this should show as an area of increased heat. Areas of infection should also show up as hot spots. In contrast, scars should show up as cold spots due to minimized blood flow.

Case studies will be conducted using a Forward Looking Infrared (FLIR) camera, model i60. This camera has a spectral range of 7,500 to 13,000nm (7.5 to 13μm) and a temperature range of -4 to 662°F. Information will be gathered from canine and feline patients of the University of Florida College of Veterinary Medicine. Case studies will include patients with confirmed traumatic injuries, suspected trauma, no traumatic and surgical procedures performed. When possible, animals will be scanned multiple times in an attempt to record the thermal image differences between recent and healing injuries. Trauma data, as well as thermal images will be documented and analyzed.

The use of thermal imaging in veterinary medicine has primarily focused on large animals. In dealing with animal cruelty cases, the question has arisen as to how thermal imaging can be used as a non-invasive way of diagnosing trauma and infection in animal victims. Because animals are typically covered by fur, the identification of contusions and scars can be difficult and sometimes impossible. It is hypothesized that these injuries will be detectable with the thermal infrared camera, and possibly a general stage of healing/time since injury can be established. Because close contact is not required to use this device, veterinarians and technicians will be safer in dealing with fractious animals. The data acquired is also in real time, allowing for quick diagnoses.

Animal Cruelty, Thermal Imaging, Infrared Photography

D47 The Scientific Working Group on Disaster Victim Identification

Elias J. Kontanis, PhD, National Transportation Safety Board, Trans Disaster Assistant, 490 L'Enfant Plaza East, Southwest, Washington, DC 20594; Victor W. Weedn, MD, JD*, Maryland State, Office of the Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223; Aaron Uhle, MS, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; Lynn Aspinall, BS, INTERPOL DVI Steering Group, Wiesbaden, GERMANY; Robert E. Barsley, DDS, JD, Louisiana State University School of Dentistry, Oral Health Resources, Room 2115, New Orleans, LA 70119; Thomas F. Callaghan, PhD, Federal Bureau of Investigation, 935 Pennsylvania Avenue Northwest, Washington, DC 20535; Joyce L. DeJong, DO, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; Frank DePaolo, PA-C, New York City, Office of Chief Medical Examiner, 520 First Avenue, New York, NY 10016; Dennis C. Dirkmaat, PhD, Mercyhurst College, Applied Forensic Sciences Department, Glenwood Hills, Erie, PA 16546; Shuala M. Drawdy, MA, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND; Lyle W. Konigsberg, PhD, University of Illinois, Department of Anthropology, 109 Davenport Hall, 607 South Mathews Avenue, Urbana, IL 61801; Peter J. Knudsen, MD, University of Southern Denmark, Winslowparken 17, DK-5000, Odense C, DENMARK; Demris A. Lee, MSFS, Armed Forces DNA Identification Laboratory, 1413 Research Boulevard, Rockville, MD 20850; Craig T. Mallak, JD, MD, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850; Richard B. Marx, BS, Federal Bureau of Investigation Laboratory, Evidence Response Team Unit, 2501 Investigation Parkway, Quantico, VA 22135; Dennis E. McGowan, BA, 1700 South Crestview Drive, Snellville, GA 30078; Yvonne I. Milewski, MD, Forensic Sciences Building 487, North County Complex, 725 Veterans Memorial Highway, Hauppauge, NY 11787-4311; Thomas Parsons, PhD, Forensic Sciences International Commission on Mission Persons, 45A Alipasina, Sarajevo, 71000, BOSNIA-HERZEGOVINA; Michael S. Pollanen, MD, Office of the Chief Coroner, 26 Grenville Street, Toronto, ON M7A 2G9, CANADA; Helena J. Ras, BSc, South African Police Service, Private Bag x 22, Hatfield, Pretoria, 0028, SOUTH AFRICA; Laura A. Regan, PhD, Armed Forces Medical Examiner System, 1413 Research Boulevard, Building 102, Rockville, MD 20850; Gary W. Reinecke, BS, MA, Boston University School of Medicine, Medical Campus, 72 East Concord Street, L-1004, Boston, MA 02118; Kyle Scherrer, MS, Federal Bureau of Investigation, Office for Victim Assistance, 935 Pennsylvania Avenue, Northwest, Washington, DC 20535; David R. Senn, DDS, University Health Science Center at San Antonio, 7703 Floyd Curl Drive, Mail Code 7919, San Antonio, TX 78229-3900; Paul S. Sledzik, MS, National Transportation Safety Board, Transportation Disaster Assist, 490 L'Enfant Plaza East, SW, Washington, DC 20594; Morris V. Tidball-Binz, MD, 4 Chemin des Fleurs, Ferney Voltaire, L'Ain 01210, FRANCE; and Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, participants will understand the operating structure, purpose, and objectives of the Scientific Working Group on Disaster Victim Identification (SWGDVI).

This presentation will impact the forensic science community by raising awareness of SWGDVI efforts to assemble organizations and individuals to exchange ideas, develop, disseminate, and advance consensus guidelines, best practices, and other recommendations and/or findings relevant to disaster victim identification.

Disaster victim identification (DVI) refers to the component of mass fatality management that involves the scientific identification of human remains. Based on DVI experiences both here and abroad, forensic practitioners in the U.S. voiced the need to assemble professionals from the medicolegal and forensic communities in a collaborative effort to identify and promulgate DVI guidelines and best practices. In response, the National Institute of Justice provided funding to the Federal Bureau of Investigation (FBI) to develop the SWGDVI.

The twenty-five member SWGDVI Board is composed of permanent member agencies/organizations and individual members. Permanent member agencies/organizations are entitled to appoint representatives with subject matter expertise in the broad DVI discipline. Individual members are selected based on individual qualification, not by agency affiliation. The SWGDVI Board consists of fifteen individual members and nine permanent member organizations, including: FBI, National Transportation Safety Board, Department of Health and Human Services/Assistant Secretary of Preparedness and Response, Department of Defense/Armed Forces Medical Examiner System, National Association of Medical Examiners, International Association of Coroners and Medical Examiners, INTERPOL DVI Steering Group, International Commission on Missing Persons, and the International Committee of the Red Cross.

The purpose of SWGDVI is to advance the scientific basis for disaster victim identification by assembling professionals from the DVI community, including international participants, in a collaborative effort to exchange ideas regarding scientific analysis methods, protocols, training, and research related to DVI. The SWGDVI will develop, disseminate, and advance consensus guidelines and best practices, studies, and other recommendations and/or findings for DVI, with an emphasis on scientific evidence-based methods with appropriate quality assurance and quality control processes. The SWGDVI shall also encourage and evaluate research and/or innovative technology related to DVI.

To achieve these objectives, the SWGDVI has created committees, which are populated by U.S. and international professionals from the DVI community to examine targeted issues for the purpose of identifying and codifying existing guidelines, or, where clear guidelines do not exist, to formulate guidelines and best practices and disseminate them to the broader forensic community. Currently, the SWGDVI has created the following committees, chaired by Board members and populated by advisory members: Search and Recovery, Pathology, Anthropology, Odontology, Friction Ridge Analysis, Molecular Biology/DNA, Data Management, Identification Data Synthesis and Quality Control, Victim Information Center/Family Assistance Center, and DVI Management.

The SWGDVI is not, by its chartering instrument, a regulatory body with any formal enforcement authority. The SWGDVI bylaws specifically state that the SWGDVI promulgates best practices and guidelines, but not standards, because of the real or perceived notion that standards are enforceable. Essential to the successful promulgation of guidelines and best practices is general acceptance (i.e., consensus, by the international DVI community). To foster community input, committees are comprised of advisory members selected for specific knowledge and experience in the relevant subject matter areas. Advisory members are encouraged to participate in drafting proposals/products for review by the SWGDVI Board. Committees are also encouraged to solicit input and receive commentary from members of the DVI community that are not directly involved with SWGDVI. All SWGDVI draft products are posted on the SWGDVI website (www.swgdvi.org) for public comment before formal adoption. The public is encouraged to submit comments and propose changes to SWGDVI products at any time, either through direct contact with the SWGDVI Board, relevant committees, or through the feedback forum on the SWGDVI website. Additionally, the SWGDVI will forward proposed documents to relevant professional organizations for input.

This session will provide a general overview of SWGDVI and will present summaries of draft guidelines to the forensic community for review and discussion.

Disaster Victim Identification, Mass Fatality, Scientific Working Group

D48 The Crossroads of Forensic Science and Cultural Traditions at the Base of Mount Everest: The Crash of Agni Air Flight 101

Denise To, PhD, JPAC-Central Identification Laboratory, 310 Worchester Avenue, Building 45, Hickam AFB, HI 96853; and Cullen J. Black, MSc, JPAC-Central Identification Laboratory, 310 Worchester Avenue, Building 45, Joint Base Pearl Harbor Hickam, HI 96853*

The goal of this presentation is to provide an outline for the attendees on the sequence of events that occurred after the crash of Agni Air Flight 101 near Kathmandu, Nepal. After this presentation, attendees will: (1) gain a better understanding of the complex role of the forensic anthropologist in mass disasters and victim identification; and, (2) gain a greater awareness of the religious and cultural pressures often involved in multi-national aircraft crashes.

This presentation will impact the forensic science community by providing an example of how international cooperation, sensitivity, and understanding of specific cultural and religious practices led to successful identifications of victims of a multi-national aviation disaster. By addressing these potential issues, this presentation will provide the forensic community with additional approaches and insights that can be applied to a variety of mass disasters in a multi-national and multi-religious setting. With a global trend of increasing interaction between disparate societies, this disaster provides the forensic community with the opportunity to be better prepared when catastrophes strike again in the future.

On August 24, 2010, Agni Air Flight 101, a Dornier 228 turboprop aircraft with fourteen individuals onboard, was traveling from Kathmandu to Lukla, Nepal. The Tenzing-Hillary Airport in Lukla is the usual starting point for the Everest Base Camp trekking route. Shortly after take-off, the aircrew requested immediate return to Tribhuvan International Airport in Kathmandu due to increasingly poor weather at Lukla. Several minutes later, the captain reported technical difficulties. Approximately 20 minutes after takeoff, the crew made their last radio contact, reporting they were inbound to Kathmandu. The aircraft never arrived.

Law enforcement was notified of an aircraft crash in Shikharpur, a village approximately 50 miles south of Kathmandu. Due to the remote location and heavy rains, first responders arrived by foot two hours after the incident. Nepalese police and army personnel located a crash crater approximately three meters deep with a surrounding debris field over 100 meters in diameter. All fourteen on board the aircraft where killed including eight Nepalese citizens, four Americans, one British citizen, and one Japanese citizen. Recovery efforts were severely hampered by continued heavy rainfall, flooding, and landslides. The Nepalese army conducted extensive searches of the surrounding area collecting various portions of human remains in plastic bags. Due to the high-speed impact of the crash, fragmentation and disruption of the human remains were extensive. Numerous portions of human remains were commingled in bags by the recovery personnel to facilitate helicopter transportation to the Tribhuvan Teaching Hospital in Kathmandu.

Forensic pathologists of the Tribhuvan Teaching Hospital preformed an initial inventory of seventeen bags of human remains detailing over 800 fragments. Due to extreme pressure from the local community to perform immediate religious mortuary rites, the team presumptively identified portions of five Nepalese individuals and released them to their next-of-kin for cremation. The condition of the human remains from this crash differed significantly from previous small (15-20 passenger-sized) aircraft and helicopter crashes in Nepal in that the remains from the Agni Air Flight 101 were severely fragmented. The Tribhuvan pathologists were accustomed to aircraft fatalities that were intact and did not present with such severe disruption. As a result, the Nepalese team contacted the U.S. Embassy in Kathmandu for assistance in the identification process.

Forensic anthropologists from the U.S. Department of Defense's Joint POW/MIA Accounting Command's Central Identification Laboratory (JPAC-CIL) traveled to Kathmandu, Nepal and arrived on August 27, 2010. While the CIL anthropologists were enroute, the Tribhuvan pathologists presumptively identified a partial torso as that of the Japanese victim and intended to release the remains to the next-of-kin the following day. To prevent delay of this release, the CIL anthropologists, upon immediate arrival to Nepal, examined the presumptively identified portion and retained a bone sample for DNA analysis to aid in the identification process of additional remains.

The CIL anthropologists took operational control of the remains processing and with the assistance of the Tribhuvan pathologists, conducted a complete inventory of the remains and documented primary and secondary identifiers including, dentition, tattoos, piercings, and other bodymarks. Due to severe disruption and fragmentation, as well as moderate decomposition, much of the separated soft tissues was unrecognizable and could only be assigned to body region when identifiable skeletal elements were adhered. A total of 130 DNA samples were taken (mostly from bony elements) and immediately delivered to the U.S. Department of Defense's Armed Forces DNA Identification Laboratory (AFDIL) for sequencing and comparison with reference samples obtained from the next-of-kin.

Once DNA results were obtained, each sample sequence and subsequent sample identification was matched to the parent material retained at the Tribhuvan Teaching Hospital in Kathmandu. All six foreign nationals (four American females, one British male, and one Japanese male) were positively identified through nuclear DNA analysis. The remaining samples sequenced at AFDIL were individualized into seven distinct sequences (four males and three females). All next of kin of the Nepalese victims declined to submit a family reference sample and declined individual identification of any remaining body parts through DNA analysis. To this end, the parent material of these sequences was combined with the human remains that could not be sampled and designated as group remains by the Tribhuvan pathology team. It should be noted that the successful cooperation of all forensic teams, as well as the support of multiple agencies and international offices, demonstrated how efficiency and exceptional professionalism can facilitate a family's mourning and subsequent healing in their time of extreme personal loss.

Mass Disasters, Aircraft Crash, Forensic Anthropology

D49 Mass Fatality Incident Planning and Preparation in Montgomery County, Ohio

Kenneth M. Betz, MS, Robert L. Hunkeler III, MFS*, and Kent E. Harshbarger, MD, JD, Montgomery County Coroner's Office, 361 West 3rd Street, Dayton, OH 45402*

After attending this presentation, attendees will understand how to prepare for a mass fatality incident by conducting exercises, procuring equipment and supplies, and preparing a written plan.

This presentation will impact the forensic science community by providing the necessary tools for a coroner/medical examiner office to process remains and property in a mass fatality incident.

In the past decade, mass fatality incidents came to the forefront through a series of terrorist-related incidents and natural disasters, where deaths ranged from the dozens to the thousands. The definition of a mass fatality incident is an incident where the number of fatalities overwhelms local resources. Some jurisdictions would be overwhelmed with five bodies; whereas others may be able to handle 50 or more with current resources. It is absolutely imperative for coroner/medical examiner offices to be as prepared as possible to handle a mass fatality incident.

Montgomery County Coroner's Office in Dayton, OH investigates over 4,500 deaths per year and conducts approximately 1,300 autopsies per year. In addition to investigating deaths in Montgomery County proper, Montgomery County Coroner's Office provides contract autopsy support for 28 additional counties, making up approximately one-third of the state of Ohio. Many of the counties supported are rural in nature and have relatively few resources should a mass fatality incident occur in their

jurisdiction. Supported counties have clearly stated that should a mass fatality incident occur in their county, the Montgomery County Coroner's Office would be called to assist. Ohio has a Disaster Mortuary Operational Response Team (DMORT) which has a significant response capability; however, if there is a multi-focal event as was seen with the 9/11 Terrorist Attack, resources to assist lesser-affected areas may be harder to obtain. In light of this, the Montgomery County Coroner's Office designed a incidence response team which would be able to stand alone for a short period of time, or be attached to a larger DMORT response should the need for additional resources arise.

The most important component to handling a mass fatality incident is a well-written plan. The Montgomery County Coroner's Office Mass Fatality Incident Plan took over two years to complete. The plan is 48 pages in length and has 31 references, 23 of which are hot-linked directly to the plan for easy access. The references include county, state, and federal documents. The plan was coordinated locally with organizations to include the Montgomery County Office of Emergency Management, the American Red Cross, and the Greater Dayton Area Hospital Association. The plan was also coordinated at state-level. The plan includes sections on roles and responsibilities, processing capacities, incident management, scene investigation, temporary morgue/examination centers, identification of remains, personal property, mass burial, communications, media interaction, Family Assistance Centers, Weapons of Mass Destruction, pandemic events, transportation, storage of remains, and local hospital and university body storage capacities. This plan was provided to all counties supported as well as other counties upon request. The plan currently serves as a baseline for much of Ohio, with each jurisdiction changing location-specific guidance. This allows all entities to be working off of the same general concept.

In addition, Montgomery County Coroner's Office has participated in and helped design multiple exercises within Montgomery County as well as with two neighboring counties. Equipment is essential in processing a mass fatality incident. Montgomery County Coroner's Office has two 18-foot refrigerated morgue trailers, each capable of refrigerating 18 sets of remains. A third trailer is a 26-foot command trailer consisting of supplies, global positioning systems, and radio communications equipment. In addition, a 22-foot mass fatality trailer has been procured, containing a 20-kilowatt generator, two 3.5 ton HVAC systems, one 13' x 21' Small Fatality Management Center, one 13' x 33' Medium Fatality Management Center, lighting, and flooring. Other equipment includes portable digital x-ray technology, automated fingerprint identification system, portable dental x-ray equipment, and portable lighting capable of lighting up areas as large as two football fields.

This equipment is available for use upon request in Ohio or in neighboring states. It is vital to ensure this type of equipment and supplies are made available to those jurisdictions needing additional resources which may be required to handle a large mass fatality incident.

Mass Fatality, MFI, Disaster

D50 Two Portable Infrared Detectors: A New Method for Crime Scene Examinations

John Z. Wang, PhD, Californian State University-Long Beach, Department of Criminal Justice, 1250 Bellflower Boulevard, Long Beach, CA 90840; and Shiquan Liu, MS*, Suzhuo Police Department, China, P.R., Apart 502, Guyuan Road, Xiangcheng, Building No. 6, Suzhou, Jiangsu Province, PEOPLES REPUBLIC OF CHINA*

After attending this presentation, the attendees will: (1) learn the results of experiments; (2) view a live demonstration with the two devices used; (3) be provided a detailed introduction of the digital viewer in terms of the four light sources, micro digital measurements, and nine geometrical formats; (4) understand the portable feature with a laptop via a USB and with a projector via a VGA cable; and, (5) see magnification choices.

This presentation will impact the forensic science community by showing how the digital viewer may promote current optical technology to be more reliable and valid instruments for both qualitative evaluations and quantitative measurements.

The majority of current forensic examinations rely heavily on chemical, biological or physical methods to detect, develop, and visualize latent evidence. One of the disadvantages of the three methods is their destructive effects during the examination process. In recently years, optical methods have gradually gained attention as the first or recommended selection, especially with a limited amount of evidence. Among the common optical sources, portable UV, polarization, laser, X-ray, or multi-light sources devices (technology) have been developed and employed for forensic examinations. From years in the field and research experiences, four observations on optical equipment can be summarized. First, due to certain technical obstacles, portable infrared devices have been missing from the market. Second, except for IR cameras, most IR devices are not capable of taking digital images for storage or transmission. Third, available optical devices rarely provide any quantified measurements during an examination. Finally, certain cameras with limited IR functions are very expensive, making it unrealistic equipment to purchase and difficult to operate. The four observations clearly suggest our technical challenges for optical equipment: portability, digitability, and quantitability. These three premises are also part of criticisms or challenges from the 2009 National Academy of Sciences Report, "*Strengthening Forensic Science in the United States: A Path Forward.*"

To address the challenges, a joint research project was initiated between the U.S. and China in early 2011: Examinations with Portable Infrared Detection: A Comparative Approach. Two types of IR devices are utilized: An IR flashlight (850 nm) and a digital viewer (near IR). Three test designs (before-and-after) are employed: (1) detection of bloodstains on four types of fabric surfaces (red cotton sweater, red polyester socks, red polyester carpet, and black cotton socks) by different time intervals; (2) detection of bloodstains on a kitchen knife at different time intervals; and, (3) detection of ink writings (five different pens) for potential handwriting traces in four situations (added writing without crossing, added writing with crossing, indented writing, and charred writing).

It is argued that the digital viewer has met three unique challenges for optical equipment: being portable, digital, and measurable. The device has four portable light sources of infrared, black/white, UV, and polarized lights. It also can provide nine different geometrical measurements simultaneously: (1) line; (2) continuous line; (3) polygon; (4) radius circle; (5) diameter circle; (6) three points circle; (7) three points arch; (8) three points angle; and, (9) four points angle.

Testing its further applications in a police debriefing room, in the lab for a supplemental/verification examination, or in the DA's office is strongly encouraged to colleagues. In particular, this study suggests a possible utilization during an expert testimony in court. This palm-size device can provide an effective live demonstration in court to the jury with straightforward digital images and geometric measurements of known and unknown samples. Finally, this new device should be considered to be a great tool in teaching forensic science in classrooms.

Digital Viewer, Infrared Flashlight, Micro Digital Measurements

D51 Testing the Ability of Birds to Detect Forensic Odorants: Comparison With Canine Abilities and Instruments

Paola A. Prada, PhD, Florida International University, 3301 Arena Boulevard, Apartment 94, Sacramento, CA 95834; Gabrielle Nevitt, PhD, University of California Davis, One Shields Avenue, 196 Briggs Hall, Davis, CA 95616; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will learn some basic objectives in the area of avian olfaction and the potential uses in forensic applications. As this is a new area of study, this presentation will provide

initial insights into the uses of an alternative biological detector for target chemical odorants of importance to the forensic community.

This presentation will impact the forensic science community by presenting novel techniques in biological detection for target forensic odorants using birds as a potential tool in this context.

Historically, birds have been thought to be functionally anosmic (smell-blind). However, recent work has shown that some species use olfaction in behaviors ranging from foraging, navigation to kin, and nest recognition and that their sense of smell rivals that of dogs. Because this work is relatively recent, little is known in avian species on the evaluation of olfactory sensitivity to specific odorants and direct comparisons to the olfactory tracking power of canines have not been made. To date, most work in this area has been focused on Procellariform seabirds, which have among the largest olfactory bulbs of any bird. This study builds on recent advances in bird olfaction, and combines these approaches with studies of explosive volatile organic compounds (VOCs) and canine odorants for the evaluation of explosive analog odors in a forensic application evaluating birds as a possible biological detector.

In this study, the primary model being used is Leachs' storm petrel (Oceanodroma leucorhoa). This species has one of the largest olfactory bulbs of any bird, and Nevitt's group has developed methods for testing olfactory abilities with respect to burrow recognition. Leach's storm petrels nest on offshore islands and are able to relocate their burrow among hundreds by olfaction. Our study co-opts this nest-recognition behavior to investigate sensitivity to explosive analogue compounds. For example, 2,4-dinitrotoluene and 2-ethyl-1-hexanol are important volatile compounds used by canines to identify cast and polymer based explosives. We are adapting similar odor delivery methods currently employed for canine explosive detection and training to scent artificial burrows. This allows us to screen biological detection ability at different concentrations with known permeation rates under field conditions. Controlled odor mimic permeation systems (COMPS) were chosen as an optimized method of delivering known concentrations of an odor mimic. COMPS devices are polymeric devices providing differing quantities of volatile compounds in a field setting. Previous studies have shown the efficient use of COMPS devices in determining olfaction thresholds using canines as experimental models as well as for determining instrumental detection limits. COMPS devices have never been used on birds even though recent studies show that olfaction plays a much more important behavioral role in some avian species than previously thought. Because these studies are relatively recent, not much is known of the olfactory sensitivity of these birds to a wide range of odors.

Initial experiments entailed an instrumental evaluation of various nest materials to identify naturally occurring VOCs as a foundation to understand the types of VOCs that are innate to their environment prior to introducing target odorants for detection. Using a forensic analytical approach, preliminary data corroborate behavioral results suggesting that most burrows have an individual chemical profile. Behavioral experimental assays were also conducted using established Y-maze and choice test approaches using target explosive odorants such as 2-ethyl-1-hexanol with both adult and chick Leach's storm petrels. These odorants were presented at varying concentrations to monitor behavioral thresholds. Data from behavioral field assays suggest that the olfactory threshold for 2-ethyl-1-hexanol is comparable (and even lower) than that of canines. These results indicate that birds are capable of detecting forensic odorants, such as the explosive odorants tested here, at levels of forensic importance.

Birds, Forensic Odorants, Olfaction

D52 An Interdisciplinary Study About the Role of the First Responder at the Crime Scene in Colombia

Claudia Delgado Aguacia, MSc, AFFIC Foundation, Avenida Calle 26 No. 68C-61, Oficina 321, Edificio Torre Central, Bogota, DC 110931, COLOMBIA; and Carolina Restrepo, MSc*, Karen B. Rodriguez, MA, Fernanda Pazmiño Moncayo, MSc, and Carolina B. Gutierrez de Piñeres, PhD, AFFIC Foundation, Avenida Calle 26 No. 68C-61 Oficina 321, Centro Comercial y de Negocios Torre Central, Bogotá, D.C., 110931, COLOMBIA; Carlos A. Villalobos, BA, National Institute of Legal Medicine and Forensic Sciences, Cra. 7A Nº 12-61, Bogota, COLOMBIA; and Santiago Reina Camacho, AFFIC Foundation, Avenida Calle 26 No. 68C-61 Oficina 321, Centro Comercial y de Negocios Torre Central, Bogotá, D.C., 110931, COLOMBIA*

After attending this presentation, attendees will know the procedure of the first responder at the crime scene within the Colombian Criminal System context from an interdisciplinary (psychological, forensic, and legal) point-of-view including the relationship between mass media and crime scene protection.

This presentation will impact the forensic science community by presenting an interdisciplinary approach about the first responder work in Colombia and how the Colombian Police face several factors (mass media, stress, criminals, and victims among others) when they arrive at a crime scene and apply every preliminary procedure.

Crime is an issue in every nation of the world and especially in large and congested cities like Bogotá. With the city expansion and the population increase, the crime scenes handled by the police become more complex and the development of new technology and procedures is necessary. The nature of every crime as well as the social context in which it occurs makes the first responder's work increasingly methodological, scientific, and complex.

Bogotá, D.C. is the Colombia capital with a population of 7,500,000 inhabitants divided in 20 localities. During 2010, the Bogotá Metropolitan Police were first responders in more than 1,700 homicides, 44,000 interpersonal violence cases, and 20,000 cases of robbery, and other crimes. Although the Colombian police have the appropriate training for the procedures as first responder at the scene of crime, the high numbers of cases as well as the presence of mass media covering crimes in Bogotá have had legal, psychological, forensic, social and criminal investigation consequences directly affecting the Justice administration and the Adversarial Criminal System.

This presentation is the result of the project named "Support to management in the security and coexistence for citizens within the framework of the twenty integral plans for local security," with financial support from the Bogotá Mayor's Office, through the Surveillance and Security Fund Secretary. The goal of the project was to support and strengthen the Metropolitan Police of Bogotá in its arduous surveillance work, giving the appropriate procedures as first responders in different scenes of crime in a practical and readable way, and empowering its capabilities to write and present reports as well as to give effective testimonies in the courtroom.

This project emphasized to the relationship between the police officers and many types of people at the crime scene, showing an appropriate approach to witnesses, relatives, suspects, and mass media from psychological and criminalistics points-of-view. It also gave a special consideration to the proper management of evidence in uncommon and complex situations that requires basic forensic knowledge (trace evidence, human remains, etc).

Through the presentation of videos and three specific cases, the AFFIC foundation team will show how the Bogotá Police has been improving its procedures as first responders and how they are approaching people at the crime scene and assuring evidence is handled in a proper way. At the same time, the project also helped Bogotá Police members to avoid psychological

diseases by teaching self control techniques to prevent and manage anxiety disorders.

Crime Scene, First Responder, Colombia

D53 Pre- and Post-Maturation Growth of External Ear: It's Application in Personal Identification

Ruma Purkait, PhD, Gour Central University, Department of Anthropology, Sagar, Madhya Pradesh 470003, INDIA*

After attending this presentation, attendees will be aware of the fact that the external ear, which is emerging as one of the leading biometric traits, does not have a permanent form throughout life. The ear can be used as a biometric trait after it attains maturity of form and ceases to be useful when it loses its elasticity and starts elongating.

This presentation will impact the forensic science community by cautioning against indiscriminate use of the external ear for establishing identity throughout life. The study has for the first time furnished data for age of maturation for a central Indian population and also sets the ceiling age of 60 years (from previous study) for the external ear's use as biometric trait.

Establishing identity from the dead or living is a routine job for a forensic scientist and law enforcement agencies. When a person is alive, identification is established by comparing him with his image or identification symbol. In the present electronic age with increased networking in communication, mobility, and advances in technology the conventional methods of identification (i.e.: identification card, magnetic card, password, etc.) are replaced by a faster and more sophisticated method of identification, that is biometrics. Biometrics is the method of identification from physiological & behavioral traits of an individual. The traits can be facial features, fingerprint, hand dimensions, voice, signatures, etc. It is a machine-based vision system in which a database of the traits are stored. During authentication the image/data of the individual taken on the spot is automatically compared with the image/data already stored in the machine. In this context the external ear is emerging as a convenient and dependable biometric trait. One of the essential properties of a biometric trait is constancy of shape and size over time. If the ear undergoes rapid change in its form, there are chances of rejection of an authentic person at the time of verification, in other words the false rejection rate will be too high. Hence, it is of utmost importance for forensic scientists to identify the period during which the proportion of external ear remains unchanged.

An extensive study was undertaken with the goal of determining the age of maturation of the external ear. An earlier study has already determined the age after which the external ear starts elongating. The data was collected from hospitals, schools, day care centers, and residence of the subjects of central India. The subjects were normal and did not suffer from any craniofacial abnormality, malnutrition, or endocrine dysfunction. The sample size of 1,960 consisted of boys (1053) and girls (907) ranging in age from birth to 18 years. To determine the age of maturation of the ear, the age groups were categorized on a yearly basis up to 18 years. In the present study, dimensions have been determined by physically measuring the ear with a sliding caliper (Dial Caliper; Mitutoyo Corporation, Kawasaki, Japan, accuracy 0.01 mm). Consent was sought from the subjects or their parents before taking necessary measurements. The measured dimensions included maximum length, width of external ear, and length and width of lobule. All the measurements except lobular width were taken following the Knußmann method. Lobular width was defined by the author for the current study. The age of maturation was determined by the method suggested by Farkas & Posnick (1992).

The maturation of different dimensions of the external ear in females is found to range from 8 to 12 years, and 11 to 14 years in males. After attaining maturity the proportion of the external ear has been found to remain relatively unchanged until the age of 60 years, after which it starts elongating rapidly. Most of the elongation was attributed to the lobule being made of elastic fiber which is more susceptible to the pull of gravity. Hence, it was inferred that the external ear can be used as a biometric tool for establishing identity from 14 to 60 years among males and from the age of 12 years among females.

The information of age of maturity of the external ear will be of great use to law enforcement agencies for using the ear as a biometric tool.

Personal Identification, Biometrics, External Ear

D54 Safeguarding Prisoner Patients and Forensic Staff Orientation at Hospitals

Anthony N. Potter, MS, Forsyth Medical Center, 3333 Silas Creek Parkway, Winston-Salem, NC 27103*

After attending this presentation, attendees will be familiar with the medical and legal issues surrounding the treatment of prisoner patients and the training of forensic staff (defined by The Joint Commission as law enforcement and corrections officers, and contract guards). Specific attention will be given to the prevention of escapes, and compliance with The Joint Commission standards and Centers for Medicare and Medicaid Services (CMS) Conditions of Participation.

This presentation will impact the forensic science community by focusing attention on the risks of treating prisoner patients in a general hospital environment, the need for adequate training of both forensic staff and hospital clinical and security personnel, and the consequences of failure to do so.

In recent years, the number of attempted and successful prisoner escapes from general hospitals has increased significantly. This is due to the closure of many correctional medical facilities due to budgetary reductions, and the increasing number of prisoners receiving external medical care. The presence of prisoners in a general hospital environment presents significant risks to the hospital's patients, visitors, physicians, and employees. These risks can be minimized, and the opportunity for escape limited, by the effective training of both forensic staff and hospital clinical and security personnel.

Hospitals, other than correctional medical facilities, are not configured or staffed to provide medical care for persons in custody. While the responsibility for ensuring their custody resides with the criminal justice agency having jurisdiction, a prisoner's presence and treatment present many standards-compliance issues that must be addressed. Both The Joint Commission and the Centers for Medicare and Medicaid Services (CMS) require that hospitals provide the same standards of care for the treatment of prisoners that are required for all other patients. The use of law enforcement or correctional restraints (handcuffs, shackles, etc.), patient privacy issues (including the presence of law enforcement or corrections officers during treatment), the configuration of patients' rooms used by prisoners, and compliance with hospital policies (visitation, telephone usage, etc.) are all potential conflicts that must be addressed. Failure to do so may result in sanctions when a prisoner's hospital stay is evaluated using tracer methodology by The Joint Commission, CMS, or state regulatory agency.

Because of the wide diversity of local, state, and federal agencies bringing prisoners to hospitals for treatment, each hospital must develop a detailed policy for the training of forensic staff (defined by The Joint Commission as external law enforcement and corrections officers, or contract security personnel) that includes subjects mandated by The Joint Commission. This policy should be reviewed and approved in advance by the heads of all local, state, and federal agencies involved. In addition, the hospital should prepare a handout for forensic staff detailing this policy, and obtain each officer's signature as documentary evidence that they have read and will comply with its provisions. Such evidence is frequently required during a Joint Commission survey, or CMS or state audit. One of the most effective ways to train law enforcement and corrections officers in a

hospital's prisoner patient policy is to have it included in the curriculum of the local training academy, or incorporated into local agencies' in-service training programs.

While responsibility for the prisoner rests with the agency having custody, hospital clinical staff and especially security officers must be thoroughly familiar with prisoner patient procedures so that they do not inadvertently compromise the prisoner's security. In addition to briefing law enforcement or corrections officers on hospital policies and procedures, security officers should monitor the prisoner and forensic staff while in the hospital, and immediately report any policy violations or other problems so they can be immediately addressed.

This presentation will include distribution of a template for a hospital policy on prisoner patients and the orientation of forensic staff, as well as a manual for distribution to law enforcement and corrections officers and a shorter handout for use when an officer brings a person in custody to the emergency department for treatment.

Prisoner Patient, Forensic Staff, Hospital

D55 The Case for a Professional Doctorate in Forensic Science

Michael D. Cole, PhD, Anglia Ruskin University, East Road, Cambridge, CB6 2UD, UNITED KINGDOM*

After attending this presentation, attendees will understand the process of obtaining a Professional Doctorate (Prof. Doc.) in Forensic Science. They will understand the similarities and differences between the Prof. Doc. route and traditional doctoral studies. The value of the Prof. Doc. to forensic science employers will be understood. The commitment required from candidates and employers will be detailed.

This presentation will impact the forensic science community by allowing candidates and forensic science employers to make informed decisions about the route to take for staff development at the doctoral level.

Over the last decade, forensic science has seen an unprecedented growth in the number of undergraduate programs in the United Kingdom. This growth has been mirrored, in part, by similar growth in Europe and other parts of the world. Destinations for graduates from such programs for further education and development in the subject area include traditional MSc, MPhil, and PhD programs. These can be studied as full-time degrees, part-time degrees, or as distance learning programs. Additionally, there is the opportunity to achieve PhD by publication although within the context of forensic science such doctoral candidates are rare.

Within the United Kingdom the validity of the traditional PhD as a degree training program for anything other than an academic career has come under scrutiny. There is now a movement towards doctoral programs which have a wider applicability, where doctoral candidates engage to a greater extent with their communities, the end users of the outcomes of their programs, and have developed a wider skills base including the transferable skills than has previously been the case.

One doctoral degree pathway which may be considered better suited to the needs of industry, commerce, and in our case the forensic science community is the professional doctorate. The award achieved is of exactly the same academic rigor and standard as a traditional PhD, but the award is achieved by the candidate via a different route.

The professional doctorate is undertaken by experienced colleagues who have a number of years in experience and who have, traditionally, honors level or masters level qualifications but little or no research experience. It has the advantage that it does not take them away from the organization in which they are working in the same way that a lab based doctoral program might. It has the advantage that it can be offered equally in management and administrative functions as well as laboratory based functions that are found in forensic science labs. The starting point is that an identifiable problem/challenge needs to be found in the workplace. This means that at the end of the study period – typically three to six years – a solution has been found to the problem that can be applied in the workplace with beneficial impact demonstrable from the outset.

Professional doctorate candidates achieve their award in two stages. Stage one involves the production of three- seven thousand word documents in which the candidate develops research skills at the doctoral level. In the first of these papers, there is reflection on the practice in the workplace as it currently stands. In paper two, the candidate reflects on the material already published in the area around practice. In paper three the research design aimed at addressing the challenge identified in the workplace, is described. The three papers themselves form a substantive body of work of 21,000 words. In stage two of the program, the candidate undertakes the research itself which addresses the issues identified. The candidate produces a thesis and in time undertakes a viva voce examination in the same way that a traditional PhD is examined. Identical outcomes can be achieved.

This presentation makes the case for development of the Professional Doctorate in Forensic Science given the very great number of forensic science systems that are encountered and the large number of challenges that this can present. The similarities, differences, advantages and disadvantages between this and traditional programs are highlighted. At the end of the presentation attendees will be better placed to determine whether they would best undertake doctoral level study in forensic science via a traditional route or via a professional doctorate.

Doctoral Study, CPD, Professional Practice

D56 Forensic Awareness for the First Responder: A Sample Training Curriculum

Jennifer R. Schindell, BSN, Linn/Benton County, 1115 Jackson Street Southeast, Albany, OR 97322*

After attending this presentation, attendees will understand some of the key concepts used to successfully teach first responders the significance of their actions and observations during an injury or death investigation.

This presentation will impact the forensic science community by offering a sample curriculum for use in future trainings of emergency medical service providers and other first responders.

Fire personnel, emergency medical providers (EMS), and/or law enforcement personnel are routinely the first to arrive at the scene of an injury, illness, or death; and therefore, have the potential to dramatically alter the course of an investigation for better or worse. Information gathered during initial interactions can be of great value, not only to any subsequent investigation, but also to any subsequent medical care. The same information used to determine cause and manner of death can be used to determine the most appropriate medical response. Situations involving environmental hazards, evidence of drug use, and evidence of traumatic events are among the scenarios in which first responder observations can be pivotal. First responder actions and observations are particularly important in incidents involving death, injury, or Apparent Life-Threatening Events (ALTEs) in children.

First responders may be the only professional to speak with a victim before they become unconscious, intubated, or otherwise unable to communicate. They may also be the only professionals to view a scene as is, before it is altered by resuscitation attempts, suspects, or well-meaning helpers. First responders may overhear statements or may be given an account of an event that is not later repeated for investigators. Also, in their attempts to render aid, it is expected that first responders will alter scene and body to some extent.

The first step to improving forensic awareness is to provide training about the importance of initial scene findings, statements, and the potential ramifications of alteration to the scene. Patient care must never be compromised in an effort to protect evidence, but first responders can be trained to maintain forensic awareness while providing life-saving care. If the patient is declared deceased, the goal must change from "life-saving" to "information-saving." Like nurses and other medical providers, EMS and fire professionals commonly participate in forensic situations whether they are aware of it or not. Although their primary obligation is to the health and

safety of their patients, the patient and the community as a whole is better served when forensic awareness is maintained. The goal of this training is to elevate participants from a level of unconscious participation/obstruction to at least a level of basic awareness.

For this training to be effective, professional first responders must receive training that they interpret as relevant and realistic. Instructors who have knowledge regarding care and treatment of the sick and injured as well as experience in death investigation and basic crime scene procedures are best suited to provide this training. Case reviews are essential to this curriculum as they allow first responders to fully appreciate and personalize the rationale for minimizing their impact on a scene while documenting or reporting any observations or actions which may have altered the scene.

In summary, improving forensic awareness in first responders can enhance patient care as well as the efficiency and accuracy in investigation of injury or death. Cases in which paramedics and other first responders recognized, documented, and volunteered key information in a death investigation following attendance at a training based on these principals will be reviewed.

Evidence, EMS, Training

D57 Advancing Forensics Through Training: Police Transition Teams

Ashraf Mozayani, PhD, PharmD, and Jason L. Schroeder, MS, MBA, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to explore the advancement of forensic applications within Iraq and specifically the Iraqi Police.

This presentation will impact the forensic science community by highlighting the advancement of forensics in challenging and often austere environments.

Military operations increasingly occur outside traditional warfare, including counter insurgency (COIN) environments. These types of conflicts often include several types of transition teams. One type of transition team is the Police Transition Team (PTT). The mission of a PTT is to coach, train, and mentor host nation (HN) policemen in all aspects of basic and advanced law enforcement. Host nation military forces are often the primary contact agencies with a civilian populace in a COIN environment. However, police transition teams and host nation leadership seek to create and support a professional, educated police force in an effort to provide legitimacy to an effective police force. The objective of the transition team is to create an Iraqi Police Force capable of safeguarding and gaining the trust of the local populace, ultimately serving as the primary contact agency with Iraqi citizens.

A well-constructed and effective transition team is ideally an interagency and multinational operation. Police transition teams generally include military, military police units, International Police Advisors (IPA's), Law Enforcement Professional's (LEP's), and other individuals or agencies with skill sets suited to training common police skills. Additional individuals with specific skill sets may assist the PTT by conducting specialized training. This training may include detentions, interrogation, communications, traffic or riot control, or police administration. These skill sets also include knowledge of crime scene forensics involving the identification, collection, and preservation of items of evidentiary value. The challenge is establishing these skills and gaining acceptance within the Iraqi Police Department. These challenges include establishing and enhancing the capability of forensic applications as well as developing an understanding of how to effectively incorporate forensics into the judicial process, often not conducive to dramatic changes in existing processes.

Several independent but supporting divisions exist within the Iraqi National Police. One such agency is the Criminal Investigation Division (CID). This agency acts as the lead investigative agency and maintains interdependence between a code of law and a judicial system (further supported by judicial transition teams). Accordingly, the CID served as the optimal division to introduce crime scene forensics into the Iraqi judicial process.

The application of forensics by Iraqi Police (IP's) is similar to traditional law enforcement operations with the added responsibility of a significant tempo of counterterrorism and intelligence gathering operations necessary in a COIN environment. This wide ranging relevance and broad application provide ample opportunities to introduce forensic training into PTT operations. These include both classroom and practical scenarios. Finally, the training given can be applied immediately in real world situations.

In conclusion, this presentation will provide a brief history of forensics in Iraq as well as the current efforts and state of forensics within the Iraqi National Police Agency. Additionally, the potential for future forensic applications as well as pitfalls and challenges will be presented. This information impacts the forensic community by highlighting the advancement of forensics in challenging and often austere environments.

Police Transition Team (PTT), Training, Iraq

D58 Reinforcing the Value of Continuing Education in Forensic Science

Samantha H. Neal, BS, 1600 University Avenue, 208 Oglebay Hall Box 6217, Morgantown, WV 26506-6217*

The goal of this presentation is to provide the forensic science community with information regarding the value of continuing education in forensic science for practitioners.

This presentation will impact the forensic science community by providing information regarding the value of continuing education in the field of forensic science.

With a variety of disciplines, forensic scientists require a complex combination of skills, knowledge, and experience in order to carry out their role effectively. It is widely recognized that maintenance of skills and knowledge over time plays an important part in ensuring that standards of practice are current and that competence in the position is promoted. Continuing education for the forensic scientist is structured educational activities designed or intended to support their continuing development and to maintain and enhance their competence. This training can be either internal or external to the forensic science laboratory. Some commonly used approaches to continuing education are instructor led, professional conferences/seminars, distributed learning, apprenticeship, residency, internship, teaching, and presentations by trainee/employee, workshops, short courses, web-based instruction, and independent classes.

Forensic science is a continuously developing field, yet continuing education is not a requirement to the field as a whole. Certifying bodies within the forensic science community may require continuing education for certification and recertification. The quality of continuing education for the forensic scientist should follow specified minimum requirements and be consistent with recognized, peer-defined standards that are set by specific accrediting bodies or forensic disciplines (e.g., ASCLD/Laboratory Accreditation Board, Scientific Working Groups, IAI, and ABC).

Training and continuing education was identified as a significant area of need within the forensic science community in several studies including National Institute of Justice's (NIJ) *Forensic Sciences: Review of Status and Needs (1999), TWGED's Education and Training in Forensic Science: A Guide for Forensic Science Laboratories, Educational Institutions, and Students* (2004), and the 180-day Study Report: *Status and Needs of United States Crime Laboratories* (2004). The release of the 2009 National Academy of Sciences Report (NAS), *Strengthening Forensic Science in the United States: A Path Forward,* also addressed the issue of continuing education for all working forensic scientists. The NAS report states that continuing education is "critical for all personnel working in crime laboratories as well as those in other forensic science disciplines…" The

report also addresses that the quality of continuing education is an issue and regardless of the discipline, there are core elements that need to be followed. These elements include the following: standards of conduct (ethics training); safety (biological, chemical, physical hazards); policy (SOP's, quality assurance, accreditation); legal (expert testimony, rules of evidence, court procedures); evidence handling (recognition, collection, and preservation of evidence); and communication (written, verbal, and nonverbal communication skills). The discipline-specific elements should include history of discipline, relevant literature, methodologies, instrumentation, statistics, and testimony; plus an assessment of knowledge is needed to measure the performance of the practitioner.

Many opportunities for quality continuing education are available but the lack of financial support from the agency or crime laboratory can hinder the forensic scientist from taking advantage of this training. Funding for training is an issue with most agencies' diminishing budgets. The recommended budget for training is 1-3% of the total laboratory budget, which on average is $1.3 million for publicly funded crime labs. Some labs have allotted $1,000-$1,500 per year for each person for training or continuing education. According to the Bureau of Justice Statistics (BJS), *Census of Publicly Funded Forensic Crime Laboratories* (2002), the budget for training is less than 1% of the overall laboratory budgets. Even when laboratories have the funding for training, they lack the personnel to cover the person who is away for training. A few agencies see training as a reward to the scientist and not a need to continue his or her professional development. Worse, some view training as an opportunity for the employee to travel and have fun, not to improve their skills. However, continuing education for practitioners strengthens the agency and the field as a whole.

Continuing Education, Training, NAS Report

D59 A National View of Forensic Art: Current Forensic Art Units and the Services They Provide

Catyana Sawyer, MFS, Broward Sheriff's Office, 201 Southeast Sixth Street, North Wing, Room 1799, Fort Lauderdale, FL 33301; and Sandra R. Enslow, BA*, Los Angeles County Sheriff's Dept, 4700 Ramona Boulevard, Room LL40, Monterey Park, CA 91754*

After attending this presentation, attendees will understand the scope of forensic art and the extensive use of this discipline across the United States.

This presentation will impact the forensic science community by introducing the law enforcement departments and locations of the forensic art units and practitioners across the nation. It will also educate the forensic community about the different aspects of forensic art.

Forensic art is any art that is used in the court of law. This includes composite sketches, facial reconstruction, post-mortem images, age progressions, and image clarifications. Forensic art has evolved through the decades and now has updated tools and research to draw from. Not only are forensic artists using the traditional skills of drawing, many have also incorporated graphic software skills to enhance images for criminal investigations. Forensic art is a valuable investigative tool in multiple situations for detectives and forensic scientists alike.

The United States has approximately 28 full-time forensic art units identified around the country, with about 45 full-time artists. There are also at least 80 part-time forensic artists who work for law enforcement agencies or universities. The presentation will inform forensic scientists of the available resources in their area and around the country.

Forensic art is not, and does not claim to be, a positive identification technique. Forensic art is an information-generating tool, primarily used to create leads in a case by stimulating the memory of the public. It is used to assist with the identification of unknown decedents as well as unknown criminal suspects. The National Institute of Justice (NIJ) funded program called NamUS is an online database where details about unidentified decedents and information of missing individuals can be matched up. This site estimates that there are approximately 40,000 unidentified human remains in the medical examiner's offices around the country. Also in a typical year, medical examiners and coroners handle approximately 4,400 unidentified human decedent cases, 1,000 of which remain unidentified after one year (www.namus.gov). In 2003, there was also a DNA Initiative launched by the Office of Justice Programs (OJP) and the NIJ that provides DNA analysis for all unidentified and missing persons across the nation for free, provided by the University of North Texas. Currently there are approximately 7,923 unidentified persons in NamUS and 7,432 missing persons in NamUS. Professional, quality forensic art is a key tool in this initiative, providing postmortem images and facial reconstructions that give the investigators examining the cases a clear image of the unidentified decedent that might foster a lead to the identification of a missing person. The presentation informs the viewers of the resources available around the country to utilize forensic art skills and to make them aware of the possible cases that forensic art may be used for.

Forensic Art, Unidentified, Identification

D60 Detection and Identification of Volatile Organic Compounds in Dried Human Blood Samples by Instrumental Analysis and Canines

Lauryn DeGreeff, PhD, 4437 Duke Street, 403, Alexandria, VA 22304; Patricia T. Caldwell, PhD, 1757 River Bend Way, Apartment 2012, Woodbridge, VA 22192; Christopher Tipple, PhD, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Martin Grime, BS, GSS International, Botley Road Romsey, Hampshire, UNITED KINGDOM; Rex Stockham, MS, Federal Bureau of Investigation Laboratory Federal Bureau of Investigation, Evidence Response Team Unit, 2501 Investigation Parkway, Quantico, VA 22135; Blake Rushing, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; and Brian A. Eckenrode, PhD, Federal Bureau of Investigation, Counterterrorism and Forensic Science Research Unit, Building 12, Quantico, VA 22135*

After attending this presentation, attendees will have a better understanding of the volatile organic components in blood collected using different extraction methods.

This presentation will impact the forensic science community by being among the first to identify such volatile organic compounds (VOCs) in dried blood samples and show that a properly trained detector canine is capable of locating extremely small quantities of human blood.

Detector canines are commonly used by law enforcement, military, and private organizations to locate a diverse collection of targets, including explosives and drugs, as well as bedbugs and agricultural products. Canines are often trained to locate living and deceased humans and human blood. It is generally accepted by the canine community that detector canines locate the targets of interest using one or a combination of volatile organic compounds (VOCs) unique to that target odor. Several studies have been performed on the VOC odor profiles of specific targets of interest to the law enforcement community, including explosives, drugs, and humans (living and deceased); however, such a study has never been conducted to determine the components of blood odor. Furthermore, in all instances involving the detection of trace human blood via canines, dried human blood is used for training, which makes it difficult to establish detection thresholds using actual blood samples, and to eliminate other non-human sources of blood from consideration while on an investigation. For this reason, the use of human blood VOC mimics to assist handlers or canine

specialists for training purposes to effectively locate dried blood associated with a crime is new and desirable.

In this research, VOCs from the dried human blood samples, similar to what may be found associated with a crime were analyzed. The VOCs were collected from the headspace of the blood samples using two different sampling methods: air sampling with traditional thermal desorption techniques and solid phase microextraction (SPME). All samples were analyzed by gas chromatography/mass spectrometry (GC/MS). The protocols used for the determination of VOCs for blood were developed for both sampling methods, using blood from a single human donor. Following method optimization, blood was collected from a small sample population in which the blood was dried under controlled conditions, and then the headspace was sampled and analyzed. The VOC content of each sample was compared and similar compounds were considered to be possible key compounds for canine detection. The VOCs produced by human blood during aging of the dried blood under oxygen-deprived and oxygen-rich environments were also compared. Further research included canine trials using dried blood from the sample population, as well as mixtures of such key compounds.

Based on the VOCs identified using both extraction methods it was observed that the two techniques do not necessarily yield similar results, yet instead can be considered complimentary extraction methods. Using both sampling methods a number of VOCs were identified and were shown to be consistent across the sample population. These compounds will likely be crucial to identifying the unique combination of VOCs utilized by blood-specific canines. Additionally, the trained blood canine was able to successfully locate small amounts of blood from different subjects. This study will be among the first to identify such VOCs in dried blood samples, and will be the first to scientifically show that a properly trained detector canine is capable of locating extremely small quantities of human blood as well as the VOCs responsible for the odor profile.

Canine Detection, Blood, Volatile Organic Compounds

D61 The Hiring Preferences of Crime Scene Evidence Technician Applicants: A Survey

Nina B. Rodriguez, BS, National University, Forensic Sciences Program, 11255 North Torrey Pines Road, La Jolla, CA; Ismail M. Sebetan, MD, PhD, 12752 Via Nieve, San Diego, CA 92130; and Paul Stein, PhD, 25757 Bellemore Drive, Ramona, CA 92065*

After attending this presentation, attendees will understand the importance of determining whether crime scene investigation degree programs meet the needs of law enforcement agencies by evaluating their views of forensic science degree programs, and relevant research on the subject. Data from a survey of law enforcement agencies will also be presented.

The presentation will impact the forensic science community by serving as a reference for future research in determining the value of crime scene investigation degree programs for law enforcement agencies and crime scene evidence technician applicants. This research study will also benefit crime scene evidence technician applicants who decide to pursue a degree, and apply for positions within law enforcement agencies.

There appears to be a lack of research about law enforcement agencies' views of crime scene evidence technician applicants with degrees in crime scene investigation. Is education an asset for a future career as a crime scene technician in a law enforcement agency? Previous research has focused on the current issues and status of forensic science education and degrees, the qualifications of educators teaching forensic science courses, and the development of college-level degree programs that prepare students for careers as crime scene evidence technicians. Recent research has also focused on how law enforcement agencies view forensic science and the forensic science knowledge they expect their new recruits to posses. While previous studies can provide an understanding of crime scene investigation degree programs offered in colleges and universities, research has not addressed law enforcement agencies' views of these degree programs.

To measure law enforcement agencies' views of crime scene evidence technician applicants, a survey was designed and administered to 102 various law enforcement agencies in the state of Maryland. The survey was adapted from a similar survey utilized by Lambert in a study titled, *The Forensic Science Needs of Law Enforcement Applicants and Recruits: A Survey of Michigan Law Enforcement Agencies.*[1] The new survey consisted of 17 questions, divided into three parts (general background, work experience and education). The questions were a combination of fill-in-the-blank, short answer, rankings, and multiple choice. After collecting all returned surveys from the respondents, answers for each question and sections were converted to numerical data for entry into a spreadsheet. Afterwards, percentages and means were calculated based on the response rates. The following statistical tests were used:

- A two-proportion z-test was used to determine if law enforcement agencies prefer crime scene investigator applicants with work experience over applicants with education in crime scene investigation.
- To determine whether crime scene investigator applicants' education is weighted less than work experience, a two sample t-test that does not assume equal variances was used.
- A two-sample t-test was used to determine whether forensic science education areas are viewed the same as the qualifications for a crime scene investigator position.

A total of 40 surveys were returned, resulting in a 39.3% response rate. Characteristics of the responding law enforcement agencies are as follows: 17 (44.7%) rural, 15 (39.4%) suburban, and 6 (15.7%) urban. Twenty-four (60%) agencies are either local or municipal, and 13 (32.5 %) are county. The mean number of sworn officers was 151.9 (SD 394.2), and the mean number of civilian employees per agency was 37.9 (SD 84.7). Additionally, 75.7% reported that they did not have an officer or a unit specifically dedicated to crime scene evidence collection; 26.3% indicated that they had their own crime/forensic lab; 24.3% hire civilians to assist in the collection of forensic evidence. When comparing work experience to education, 84.6% of the respondents indicated that they prefer work experience, and 80.7% of the respondents indicated that they prefer education. There was not enough statistical evidence to suggest that law enforcement agencies prefer crime scene evidence technician applicants with work experience over those with a degree in forensic science or crime scene investigation ($p > .05$), and there was not sufficient evidence to suggest that the agencies give less weight to education than work experience ($p > .05$).

Although, the number of crime scene investigation degree programs has grown tremendously in the past ten years, there is no research suggesting that law enforcement agencies prefer crime scene evidence technician applicants with these degrees. On the surface, it appears that forensic science degrees fulfill the requirements of crime scene evidence technician positions within law enforcement agencies.

Crime Scene Evidence Technician Applicant, Hiring Preference, Crime Scene Investigation Degree Programs

D62 Differentiation of Human Subjects Based on Scent Profile

Sarah J. Milam, MS, Oak Ridge Institute for Science and Education-Visiting Scientist Program, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Douglas Beussman, PhD, St. Olaf College, 1520 St. Olaf Avenue, Northfield, MN 55057; Blake Rushing, Oak Ridge Institute for Science and Education-Visiting Scientist Program, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Rex Stockham, MS, Federal Bureau of Investigation Laboratory, Evidence Response Team Unit, Quantico, VA 22135; and Brian Eckenrode, PhD, and Christopher Tipple, PhD, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will gain knowledge of the research being performed to provide scientific support to the use of canines in scent discrimination, suspect trailing, and missing person searches. The areas specifically addressed by this research include method development, headspace analysis of human scent samples, and differentiation between individuals based on those scent profiles.

This presentation will impact the forensic science community by educating the public about the current status and challenges of forensic canine use in investigations. This research will provide a scientific foundation for canine validity and unbiased analysis of scent profiles that will bolster the acceptance and legitimacy of canines in both the field and in court.

Canines have been used for decades to identify individuals based upon their unique scent profile. Most commonly this involves either trailing a suspect in a crime or searching for a missing person. Although the exact mechanism by which a canine is able to identify an individual from among a group is not clearly understood, it is clear that canines are able to perform that task. However, such feats are still heavily scrutinized because there is an apparent lack of scientific evidence that supports them. In recent years, there have been several studies published aimed at identifying the essence of human scent in order to provide some of the necessary scientific evidence to support canine responses. These studies have used relatively small subject pools, strict washing procedures, and inherently selective sampling methods such as solid phase micro-extraction (SPME).

In criminal cases where canines may be used, suspects and victims will not undergo procedures to "standardize" their scent profile for the dogs, so the dogs must use these complex scent profiles to identify their target. To mimic these real-life situations, human subjects for this study were not required to perform any specific washing or cleansing procedures, but instead were asked to maintain their normal routines. The lotions, soaps, and other products that each person uses contribute to his or her volatile profile and can be used to help analytically differentiate between individuals.

A large subject group, at least several hundred, will be asked to sample their own forearms by using gauze pads in a procedure similar to those used by law enforcement canine handlers. In this study, a headspace sampling protocol will be used in an effort to eliminate the selectivity of previous methods and provide a more complete picture of human volatile emissions. These gauze pads will be sampled with a cryogenic pre-concentrator and analyzed via gas chromatography with mass spectrometry detection (GC/MS). The resulting scent profiles will be analyzed and compared to one another to determine if they can be used to differentiate between individuals or groups of individuals. Ethnicity, gender, and age will be considered in comparisons, and significant differences between groups will be explored. Ultimately, if analytical differentiation is possible, this research will provide a means for canine handlers to sample scented items given to dogs as well as sample individuals or items located or identified as the result of a canine search. These samples could be sent to a laboratory for analysis and comparison and the data could be used to support canine responses. If "markers" for groups of individuals can be identified, this information could also be used to provide investigative leads by narrowing down a field of suspects or helping to tie an item to a specific victim.

Human Scent, Individualization, Canine

D63 The Associated Evidence Analysis and it Impact in Human Rights Violations Cases in Chile

Dina A. Jimenez, DDS, and Isabel A. Martínez, BA, Servicio Médico Legal, Av. La Paz 1012, Independencia, Santiago, CHILE*

After attending this presentation, attendees will understand the value of the associated evidence analysis as support to establish the cause and circumstances of death, which is of inestimable emotional significance for the family in human rights violations cases.

This presentation will impact the forensic science community by showing how the analysis applied produced relevant results after 38 years of the events. On the other hand, the recovery and reconstruction of the clothing and personal belongings of the victims is of inestimable emotional significance for the family.

The analysis of associated evidence is a process that was standardized after a 2007 finding in Litueche, Chile. More than 500 associated pieces of evidence were recovered, amongst which were small fragments of textile of different types, footwear, and personal items, among others. The judge of the investigation requested expert analyses that could provide the greatest possible detail about each piece of evidence in order to support the process of victim identification and the determination of the cause and circumstances of death.

The process consists of keeping the chain-of-custody, and documenting all of the expert analysis process through written, photographic, and sometimes video record. A qualitative (descriptive) and quantitative (measurement) analysis is carried out after recovering trace evidence (earth residues, study of stains, firing residues) and manual cleaning, taking care that the evidence is not damaged.

At the same time, the condition of the clothing and the recovered fragments is established; the color is determined through the use of a textile pantone; the type of fiber (natural or synthetic) and the type of fabric is also determined. The process continues with the reconstruction of textile fragments until rebuilding the clothing as much as possible has been completed, then continues with the determination of trauma, not related to taphonomic damage, such as the passage of a projectile.

Along with this, a judicial procedure for the recognition of associated evidence is usually performed with the participation of families linked to the case and the appearance of the judge.

Finally, the conclusions of the expert process are compared with ante-mortem information provided by the family and the judicial investigation.

This type of analysis can mean an important contribution to the inquest, given the peculiarity of some objects and articles of clothing and findings related to trauma in them, are useful information in determining the cause of death and the circumstances surrounding it.

In this sense, it is important to note that the consideration of the contribution of the associated evidence analysis depends on all of the elements of the investigation, its correlation with each other, the interpretation of the findings of each discipline and the integration of all information gathered.

On the other hand, the recovery and reconstruction of the clothing and personal belongings of the victims is of inestimable emotional significance for the family. Many times, the family can even restore a link with their beloved ones, when after a long time they see the woolens or garment that they may have made for, lent to, or helped choose for the victim while they were still alive.

Associated Evidence Analysis, Human Rights Violations, Recognition Process

D64 The Role of the State and the Clarification of Human Rights Violations in Chile

Patricio Bustos, MD, Servicio Medico Legal, Av. La Paz 1012 Independencia, Santiago de Chile, CHILE; and Dina A. Jimenez, DDS, Medical Legal Service, Recoleta, Av. la paz 1012, Santiago de Chile, CHILE*

After attending this presentation, attendees will understand the value of the forensic sciences in the investigation and prosecution of human rights violations.

This presentation will impact the forensic science community by showing how forensic science, at the service of justice within the framework of a State policy to investigate gross violations of human rights, opens a real possibility for justice, truth, and reparation. Above all, it can be seen that the constraints imposed by the circumstances of the atrocities are overcome by an adequate scientific work of humanitarian outreach. It is the obligation of states to investigate crimes against humanity, which are by nature imperscriptable.

The judicial investigation, detection, recovery and analysis of thousands of tiny and fragmented skeletal remains hidden in the desert, military compounds, illegal mass graves, cemetery for unidentified bodies, corresponding to victims of gross human rights violations that occurred during the dictatorship have been analyzed from the forensic point of view, to determine its identification, cause, manner and circumstances of death.

After 35 years, only now is it possible to respond to injunctions and families by using all currently available methods of the various forensic science disciplines, to analyze small fragments of bone remains that resulted a strategy implemented by General Augusto Pinochet, to make the bodies of victims disappear.

The political will of the Chilean state and the provision of the necessary resources gave origin to set up the Human Rights Program in the Servicio Médico Legal, devoted to perform expert analyses of the recovered remains, with the participation of the international scientific community, the creation of a family members genetic bank, the implementation of all forensic disciplines, continuous education, and ongoing communication with family members. The team has worked closely with investigators and judges.

Physical evidence recovered is extremely scarce and fragmented, with taphonomic changes left by the passage of more than 17 years before recovering. This has imposed the need to use everything that is within reach of science and to interpret and integrate all the information in understandable language single report with the judge and other parts of the judicial process.

At present, Chile has incorporated the international protocols to the analysis processes such as Istanbul, Minnesota, Missing ICRC, and genetic analysis in accredited laboratories using the three markers. The techniques of forensic archeology, anthropology, medicine, dentistry, ballistics, associated evidence analysis, chemistry and other areas of forensic interest are also used in the resolution of cases. From the humanitarian point of view, close ties with the families involved in this painful process have been developed.

In addition and pursuant to the complexity of the cases, an international committee of experts including leading forensic medicine, anthropology, and genetics, scientists made recommendations for each case to ensure transparency and credibility to the actions undertaken by the program.

Human Rights, Forensic Science, Commingled Remains

D65 Setting up and Running a New Forensic Student Organization Within a University Setting

Erin L. Berdanier, BA, 3909 Creekway Trail, Dayton, OH 45440*

After attending this presentation, attendees will learn about the challenges and strengths of organizing a local university group for current and potential forensic students. Attendees will understand the importance of creating these groups in locations that have student interest but do not have a forensic science program, and how the program helps the students personally.

This presentation will impact the forensic science community by enhancing the quality of students lives in order that they are better prepared for the work force when they have completed their bachelors degree.

To encourage students who are interested in the field but for whatever the reason could not attend formal programs, this presentation will include details on how to: set up a student organization, get students motivated to do independent learning, deal with legal problems such as students with felony charges, and get students to support and learn from one another.

This presentation focuses on organizing a university based student-group's members. This will include the officer positions and their interactions, and how every member earns titles (levels) within the group as a symbol of their academic achievement. Attendees will also hear about getting students motivated to present at meetings and to do more than just the minimum requirements for their university. This will help when attending conferences like the American Academy of Forensic Science (AAFS) and the International Association of Forensic Science (IAFS). Ultimately this will produce members who are willing to do individual projects and present the findings to further our knowledge in forensics sciences.

At the conference, attendees will see a sample of portfolios made by students within the university organization. These binders will allow the attendees of the conference to see how the program is helping the students on a personal level, and take suggestions back to their own student groups or staff. Some of the feedback from the students to the university group will also be available at the conference; therefore, listeners may learn some "do's and don'ts" within forensic student organizations.

Attendees will discover how to host small conferences that are specifically targeted to students. By learning this skill, attendees can train students, interns, or new employees faster and cheaper than traditional methods. Skills and motivational techniques to get students to help run the conferences will also be taught to attendees making planning and follow-through significantly easier.

Having a member who ultimately cannot work in the field because of a felony conviction is problematic. Attendees will learn how to remove member from a student group in a considerate and ethical manner. Other legal implications and concerns will also be addressed in the presentation.

The ultimate goal of this project is to support students at the university level who do not have a forensic science program yet by fostering learning, sharing, and the development of new techniques in the forensic sciences. By teaching attendees at the American Academy of Forensic Sciences meeting how to set up and run a student group, the worth of the students within the group will may rival the quality of the students in the established forensic science programs. Since our future as investigators will be eventually resting in the hands of these students, attendees will learn how to set up or improve their programs so that the overall quality of investigators will advance.

University, Education, Organizations

D66 Distinguishing Peri-mortem and Postmortem Fracture Patterns in a Mass Grave Scenario

Kenda K. Honeycutt, BA, North Carolina State University, Raleigh, NC 27695; and Ann H. Ross, PhD, North Carolina State University, Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107*

The goal of this presentation is to perform experimental research to simulate a mass grave with the intention of identifying the effects of taphonomy on fracture characteristics with relation to time-since-death.

This presentation will impact the forensic science community by showing how the research in this experimental study is novel in its goal to establish fracture characteristics and taphonomic changes within the context of a mass grave. This is significant in that the findings can be used to help establish time-since-death and cause-of-death for investigations involving human rights abuses.

Forensic anthropologists are often asked to assist in the investigation of international human rights violations. A review of the literature indicates that little research has been conducted on the occurrence of features as it pertains to distinguishing the peri-mortem interval from the postmortem interval. The purpose of this study is to perform experimental research to simulate a mass grave with the intention of identifying the effects of taphonomy on fracture characteristics with relation to time-since-death.

The research in this experimental study is novel in its goal to establish fracture characteristics and taphonomic changes within the context of a mass grave. This is significant in that the findings can be used to help establish time-since-death and cause-of-death for investigations involving human rights abuses. Despite the fact that such a study will only record a fraction of lethal injuries, it provides a better understanding of the manner in which taphonomic variables (in a mass grave setting) have the potential to mask evidence of a crime.

To replicate the conditions of a mass grave, a sample of ten intact pig carcasses were used. The sample of ten were euthanized in the same manner (by captive bolt pistol) and were transported to the NCSU field facility to observe taphonomic processes and the effect they have on fracture patterns. In addition to the original injury from the captive bolt pistol, each of the ten pigs received both blunt force and sharp force trauma. All ten pigs were then haphazardly interred together in an open grave to allow for observation and accelerated decomposition. In addition, to evaluate bone degradation, all ten pigs underwent a full body bone density scan prior to placement within the mass grave; they will be scanned again following skeletonization.

Documentation of trauma was conducted through gross morphological assessment, photography, diagrams, and charts; allowing for a detailed comparison to their appearance after exposure. However, this research remains within the initial data collection stage. Prior to the meeting, several macroscopic features will be observed: fracture outline, fracture edge, fracture angle, surface weathering, and color of the fracture surface—fractures will be determined as peri-mortem or postmortem based on these indicators. Observations were also made regarding stage of decomposition, insect activity, scavenging, and daily temperatures/precipitation.

In terms of interpretation, both statistical and morphological analyses will be implemented in order to find correlations between fracture characteristics. Categorical data analysis, such as logistic regression, will also be utilized to determine which specific taphonomic variables have more influence in disguising the peri-mortem interval for each type of trauma (gunshot wound, blunt, sharp). Additionally, variation between peri-mortem and postmortem changes will be examined using chi-square and odds ratio.

The null hypothesis tested is that taphonomic processes do not affect the appearance of peri- and postmortem fractures and it is expected that due to moisture retention from bodily fluids, fractures will appear peri-mortem into the postmortem interval. In addition, the pattern of skeletonization will be evaluated using three-dimensional spatial analysis (GIS). It is expected that the pigs on the periphery of the grave will skeletonize more quickly and the bone damage (fractures) will appear to be more characteristically peri-mortem than the pigs located in the center and bottom of the grave. Thus, this research should display how the conditions of a mass grave will simulate bone damage that will appear peri-mortem for an extended period of time and help establish guidelines for forensic scientists working globally in post armed conflict arenas.

Mass Grave, Fractures, Taphonomy

D67 Categorical Analysis of Pennsylvania SPCA Humane Law Enforcement Animal Cruelty Cases: 2008-2011

Susan C. Underkoffler, MFS, 783 Cowpath Road, PO Box 26, Telford, PA 18969; and William Welsh, MS, Drexel University College of Medicine Master of Forensic Science Program, 245 North 15th Street, Philadelphia, PA 19102*

After attending this presentation, attendees will have a better understanding of the trends seen in cases investigated by Pennsylvania humane law enforcement officers over the course of several years. This will highlight animal crime as a subset of the overall crime statistics within Philadelphia and across Pennsylvania. It will show what types of animal crimes have demonstrated increases and decreases, and will therefore allow for future study into the connections of these crimes with additional ones, or reasons or explanations for the trends as they relate to accompanying crimes. Attendees will also be provided insights into the job responsibilities of a humane law enforcement officer within the state of Pennsylvania, some of their investigatory techniques including surveillance, and court appearances, and will also hear an overview of the state's animal-related laws.

This presentation will impact the forensic science community by serving as an example of anti-cruelty investigatory trends and by establishing a starting point for further study into the interdisciplinary aspects of animal cruelty and other crimes.

This study is an attempt to demonstrate trends in suspected animal cruelty cases investigated by the Pennsylvania SPCA's (PSPCA) humane law enforcement division both state-wide and in the city of Philadelphia from the years 2008 to 2011. The types of cases were evaluated categorically and include "unsanitary confinement," "lack of food/water/shelter," "lack of veterinary care," animal fighting," "abandonment," "commercial breeders," "stables," and "pet stores." The categories were then compiled graphically to provide visual illustrations regarding the numbers of cases investigated per year. In this way it was easy to see the prevalence of each category of cases within each year. However, it should be noted that the Pennsylvania areas (counties) served by PSPCA humane officers has changed drastically throughout the course of the study period due to budget constraints, and that the numbers may reflect these changes. PSPCA humane officers are authorized to carry weapons, obtain search or arrest warrants, issue citations, and make arrests for violations of Pennsylvania's anti-cruelty laws. They often work in conjunction with traditional law enforcement officers. There are ten PSPCA humane law enforcement officers working within Philadelphia (some are authorized to work in other counties as well), and two officers for the remainder of the state.

Investigations into cases of animal cruelty are more common nationwide now than in years past, due to increased public awareness and the resulting pressure from communities armed with more knowledge and a changing attitude toward animals. A growing enthusiasm for animal rights, as well as more research and literature related to animal welfare, and even popular reality television shows have helped shed light on what was once an underreported and often unacknowledged occurrence but is now a recognized crime. As awareness of animal abuse and aversion for it has grown, laws have evolved and expanded, resulting in harsher punishments for offenders. This in turn has prompted a greater need for forensic investigatory practices which may aid in successful prosecution.

Animal abuse has long been seen as a connection to other crimes and it is often a precursor to more severe offender behavior. Veterinary and wildlife forensics are new branches of forensic science that incorporate the

applicability of science to animal laws. While the use of forensics in animal-related investigations is still in its infancy, it will continue to increase as the number of reported cases of animal cruelty and the resulting investigations grow. Further research is merited with regards to categories of cases not reported in this study but encountered with increasing frequency by PSPCA's humane officers, including hoarding and ear cropping.

Animal, Cruelty, Investigation

D68 Database of Family Members of Human Rights Violations Victims in Chile

Patricio Bustos, MD, Servicio Medico Legal, Av. La Paz 1012 Independencia, Santiago de Chile, CHILE; and Dina A. Jimenez, DDS, Medical Legal Service, Recoleta, Av. la paz 1012, Santiago de Chile, CHILE*

After attending this presentation attendees will have a raised awareness regarding the need to build a solid normative basis and validated scientific protocols a bank for a Sample of Families, to enable identification if this information is required with relatives who are no longer alive.

This presentation will impact the forensic science community by increasing the understanding of how this bank represents a heritage and a legacy for future Chile generations that tell about what happened and the hope of the families to know the fate of their loved ones and their whereabouts. It also allows having the necessary samples in the face of new findings, to advance in the identification process irrespective of the time of the find.

Knowing the history, context, circumstances, and time when the disappearance and execution of the victims occurred allows modeling a forensic approach strategy and clarifies the needs of the process to succeed in the identification of victims.

In the initial days following the Coup d' État, some of the deaths and arrests followed by disappearance were selective, affecting leaders of political movements, trade unions and neighborhoods, indigenous people, students, and supporters of Salvador Allende. Most of the deaths in the specified time period were people without political connections, paupers, young men who lived on the streets, persons accused of committing misdemeanors or for violation of curfew.

During the 17 years of dictatorship, most of the remains were not found. With the advent of democracy in Chile, the search and recovery of remains began with findings of mostly commingled, fragmented, without medical and dental characteristics, individualizing features, except in few cases.

The first antemortem data bank of the victims was set up by a non-governmental body in 1976, the Vicariate of Solidarity, where families are interviewed by social workers and volunteer lawyers. In 2006, facing the difficulties of making a comparative process of identification considering medical, dental characteristics, clothing, etc. and due to the state of the remains recovered, the international scientific community recommended the establishment of a bank of blood samples from family members with the limitations of time such as the absence of parents of the victims who have already died.

Despite the time elapsed and the distrust on the State, family members, with a vote of confidence and hoping for news of their beloved ones, donated blood samples. The process is carried out according to the international standards (national and international regulations; ethical, technical, and humanitarian aspects). In the sampling process, thousands of families have been received, going to their places of residence in Chile and also abroad through consulates, have launched a communication campaign with informative videos, and to date, all this has resulted in 3,200 samples with genetic profiles.

Each family will be giving at least three samples depending on the availability of relatives, with four FTA cards; all information is encrypted and protected according to the rules of sensitive data, and all have been obtained by genetic profile at least at two markers.

Antemortem Data Bank, Genetic Profiles, Family Members

D69 Humanitarianism and Human Rights in the Context of Post-Conflict Forensic Investigations

Adam R. Rosenblatt, PhD, Champlain College, 163 South Willard Street, Burlington, VT 05401*

After attending this presentation, attendees will understand the distinctions that have been drawn between international forensic investigations serving the cause of human rights and those motivated by humanitarian concern for families of the missing. They will acquire background in the historical circumstances, particularly in Latin America and the former Yugoslavia, that lead to a perceived competition between these two purposes, as well as the roots of the human rights/humanitarian split in a broader, non-forensic context.

This presentation will impact the forensic science community by providing a critical look at how terms borrowed from international law and politics can ill-serve the specific context of scientific investigations of violence, and by fostering dialogue amongst practitioners about the basic terminology they employ in the field.

The current use of a humanitarian/human rights distinction for international forensic investigations tends to confuse practical questions of institutional and political constraint for questions of political philosophy. In Argentina, where the first wholly independent forensic team was created in the mid-1980s to deal with persons missing as a result of repression, impunity laws made it next to impossible to put the perpetrators of dictatorship-era human rights abuses on trial until decades later. The Argentine Forensic Anthropology Team thus focused its efforts on identifying individual victims and accompanying families in their grief—a set of priorities they shared with other organizations conducting forensic investigations throughout Latin America, where impunity laws have been widespread. On the other hand in the former Yugoslavia, initial forensic investigations into genocide in the 1990s were sponsored by the International Criminal Tribunal for the former Yugoslavia, which gave priority to prosecutors' need for evidence of war crimes. The situation was nearly the reverse of the one in Latin America, with many families of the missing and some forensic experts viewing the investigations as too focused on legal outcomes and not enough on the needs of families and other mourners.

A number of experts from the forensic field have proposed that this perceived tension between evidence-collection and identification be described as a difference between human rights and humanitarian priorities. In this view, collecting evidence for trials constitutes "human rights work," while the identification and repatriation of individual bodies is a matter of "humanitarian" concern for the families of the missing. A human rights/humanitarianism distinction that is itself hotly contested in other areas of international activism and intellectual discourse is thus altered and imported into the context of international forensic investigations.

Drawing on years of interdisciplinary research into international forensic investigations, this paper argues that the distinction exacerbates, rather than ameliorates, the perceived power disparity between international institutions and families of the missing. By using a purely legalistic definition of human rights that associates human rights investigations with war crimes trials, it ignores the many human rights claims that families of the missing have traditionally made in other venues—including some rights, such as the right to know the fate of the missing and the right to mourn, that are directly related to identification and repatriation efforts. At the same time, by associating the needs of families of the missing solely with the humanitarian tradition of political neutrality (as embodied by the International Committee of the Red Cross), it also minimizes the stake that

families often feel in trials—which has even motivated some family members, such as members of Argentina's Mothers of the Plaza de Mayo, to forgo efforts at exhumation or identification until they are assured that all perpetrators will be held accountable. The association of human rights with court cases and humanitarian concern with identification thus proves to be too simplistic for the complex reality of post-conflict forensics.

The paper concludes by suggesting that evidence-collection and identification are both bound up with human rights as well as a number of other political projects and moral values, even when they are applied unevenly or at different times. Planning for their implementation in any given post-conflict context can only occur by drawing on experience in previous locations, understanding the specific limitations of the new context, and working directly with families of the missing to understand their priorities.

Human Rights, Post-Conflict, Missing Persons Identification

D70 The Contribution of the Clothing Analysis in Determining Cause and Manner of Death in Two Cases of Political Executions in Chile

Germán E. Tapia, MD, Servicio Médico Legal, Av. La Paz 1012, Santiago, CHILE; and Isabel A. Martínez, BA, Servicio Médico Legal, Av. La Paz 1012, Independencia, Santiago, CHILE*

After attending this presentation, attendees will understand the value of the clothing analysis as support to establish the cause and manner of death in human rights violations cases.

This presentation will impact the forensic science community by showing the analysis applied produced relevant results 38 years after the event.

In September 1973 three people were executed in a northern city of Chile by state agents under conditions of political repression that prevailed in the country. The two males, who are the focus of this presentation, were university students. Once executed, the bodies were taken to a cemetery where there was allegedly performed an external examination, recognized by relatives and friends, and buried in the same cemetery in a perpetual niche.

On August 25, 2010, upon a court order, these three victims were exhumed and subsequently transferred to the Unidad Especial de Identificación Forense of the Servicio Médico Legal in Santiago, to determine the cause and manner of death. In the historical context of that time, these executions were justified as a result of the detainees escaping (Escape Act); although this was not consistent with the circumstances.

The expert analysis performed included the analysis of clothing, which purpose was to help in the determination of the cause and manner of death. The three bodies were dressed, and had to be undressed in the laboratory of the Unit. This presentation discusses only the analysis of the two male victims, as the third one, female, showed no peri-mortem alteration of forensic interest in her clothing.

In the analysis of the clothes, the macro morphological characteristics were taken into account to determine the type of garments and its historical context, as well as the individualization and characterization of the alterations that are directly related to the time of death.

The clothes had tears consistent with bullet holes, which matched-up with bone trauma of the same origin. The support of a chemist and a ballistic expert was requested to determine the trajectory and distance of the shot by applying the inductively coupled plasma-mass spectroscopy method to samples taken from the aforementioned tears, in search of metal particles present as gunshot residue, mainly Barium (Ba), Antimony (Sb), and Lead (Pb).

Despite 38 years having passed since the time-of-death, with the help of the clothing and chemical analyses, the judge had more scientific evidence to aid in the clarification of the facts, since the chemical results obtained show that in some tears the level of metal elements detected (Ba, Sb, and Pb), were consistent with short range shots with contact, typical of an execution.

This presentation shows the forensic impact that the clothing analysis can have as a supporting tool, in the determination of cause and manner of death in a human rights violation context, despite the time elapsed since the event.

Clothing Analysis, Cause of Death, Human Right Violations

D71 Is it Possible to Identify 15 Victims in a Mass Grave With More Than 5,000 Human Skeletal Remains? Lonquén Case, Chile

Macarena Arias, BS, Servicio Médico Legal de Chile, Avenida La Paz 1012, Santiago, CHILE; Isabel A. Martínez, BA, Servicio Médico Legal, Av. La Paz 1012, Independencia, Santiago, CHILE; and Dina A. Jimenez, DDS, Medical Legal Service, Recoleta, Av. la paz 1012, Santiago de Chile, CHILE*

After attending this presentation, attendees will understand the importance of a comprehensive approach in human rights violation cases. The analyses carried out by the various disciplines as well as continuous work with the families of the victims is highlighted, as a part of contributing in a better way to the judicial objectives, it provides emotional reparation to persons affected by political violence.

This presentation will impact the forensic science community showing how interdisciplinary work could help to resolve complex forensic cases associated with grave human right violations.

In the role of the expert in relation to the elucidation of the truth in cases of human rights violations, lies the need of an entire community to build trust and social ties.

This work presents the methodology used to identify 15 victims of the military dictatorship (1973-1990) illegally buried in a mass grave containing more than 5,000 commingled skeletal remains.

In 1978, as a consequence of an anonymous report to the Archbishopric of Santiago, semi-skeletonized human remains of 15 individuals were found in an old lime kiln in the area of Lonquén. This was the first finding of bodies reported through the mass media, as an explicit evidence of something that was already known in the depths of the society but which had steadily been denied by the authorities of the time.

At that time, the court ordered the recovery of remains and their transfer to the Instituto Medico Legal of Santiago, work that was carried out by unskilled staff. This situation resulted in the dismemberment of the bodies and the subsequent loss of individualization of the same.

The technical and political conditions neither allowed the victims to be identified (only one of them was identified) nor elucidating the cause of death; however, the investigation determined that the bodies belonged to 15 individuals arrested in the town of Isla de Maipo, near Santiago, in October 1973, who were mostly farmers that had participated in the Agrarian Reform process promoted by the two previous governments. Finally, following the public uproar, the Military Justice acknowledged the illegal inhumation of the remains in a mass grave of the cemetery of Isla de Maipo.

In March 2006, thanks to the perseverance of the families and according to the request of the Court, all of the content of the mass grave was exhumed, exceeding 5,000 elements corresponding to at least 30 adult individuals. Documentary, anthropological, dental, clothing, and genetic analyses were performed for almost four years, establishing the effective presence of the 15 individuals recovered in 1978 from the Lonquén kilns. Also established was their cause of death as well as the identification of 13 of the victims. On March 28, 2010, a funeral was celebrated for the victims with a massive and emotive act in the cemetery of Isla de Maipo.

At present, genetic analysis that would determine the identification of the two victims who are still missing is still pending.

Commingled Human Remains, Human Right Violations, Multidisciplinary Forensic Analysis

D72 America's National Tragedy: The Missing and Unidentified

Amber D. Riley-Burns, BA, 29649 Masters Drive, Murrieta, CA 92563*

After attending this presentation, attendees will have a greater understanding of the importance of gathering comprehensive dental record data efficiently and compassionately while conducting missing person investigations. Attendees will learn of the significant variance in state-to-state dental record retention guidelines and/or mandates, thus allowing for enhancement of future investigations.

This presentation will impact the forensic science community by increasing the knowledge of the most critical elements of the antemortem dental record required, as well as useful supplemental records.

As of January 2011, the FBI reported 84,352 active Missing Person records (MPR) and 7,539 active Unidentified Person (UIP) records in the National Crime Information Center (NCIC). The problem: only 8,060 (10.47%) of MPR have dental data associated with them. It is reasonable to conclude that hundreds or thousands of registered missing persons are no longer missing but rather recovered and unidentified due to incomplete antemortem data collection.

The specific evidence a dental record provides to the antemortem and postmortem comparison review is critical to positive identification. An ideal dental detail entry into the NCIC facilitates the highest accuracy in possible correlations between unidentified and missing persons. All correlations, a "cross match" strong and weak, are generated as $.M (dollar "M") analysis reports delivered daily from the Criminal Justice Information Services (CJIS) to the investigating agency. Case detectives and consulting experts review the reports for plausibility in meriting further investigation. Thus, the individual translating the dental record from written form into NCIC code for upload is as important to the case management as is the record itself.

This delegation should be given to a specifically trained NCIC dental coding expert; this is normally not the dentist who has supplied the dental record to investigators. A comprehensive antemortem dental record provided to an Odontologist will give the necessary data for postmortem comparison and expedites this reliable, scientifically sound, and cost-effective method of positive human identification. Often this data can be easily obtained by asking the correct questions of immediate family and the primary care dental provider for additional record collection.

Furthermore, during the course of new and cold case missing and unidentified person investigations, it is also important to note that dental record retention laws and/or guidelines vary significantly from state to state, and this can significantly impede the recovery of antemortem dental records even when a valid source for the record is located. This further delays identification, as well as forces more time and revenue consuming methods to be employed if dental identification cannot be utilized.

It will be shown that in several states there is no law or mandate to prohibit a dentist from destroying a patient record at any time he or she is inclined to do so. Data and graphs will be presented that are representative for the United States and Canada. Recommended antemortem dental record data that should be collected for missing person investigations and their transcribed results as entered into NCIC and the National Dental Image Repository (NDIR) will be discussed, as well as The Health Insurance Portability and Accountability Act (HIPAA) and its impact on dental record release for forensic investigations. The organizations NamUS, The Doe Network and the North American Missing Persons Network will be reviewed as adjuncts to the NCIC. These are available to law enforcement and the public for investigative lead development and community contribution to solving missing and unidentified person cases.

Other forensic investigations effected by dental record retention include: state conducted investigations into patient complaints of malpractice and/or diminished standard of care; patient or employee initiated reports of insurance fraud, and illegal record amendment or destruction. Experts of jurisprudence and forensic accounting will be able to apply the knowledge gained regarding dental record retention mandates in their practice states immediately for plaintiff, defendant, and expert witness deposition in civil casework. The knowledge gained may prioritize the process of evidentiary discovery within a state with a low or non-existent requirement for dental record retention, or when a statute of limitation for a claim being investigated approaches the threshold for legal dental record destruction within a state.

Police and law enforcement, medical legal investigators, cold case teams, family assistance facilitators, medical examiners, coroners, and forensic consultants have a significant focus upon unidentified persons, and the investigation of criminal acts against them. A criminal and/or homicide investigation begins with the identity of the decedent, and the process is significantly impaired without it. The NCIC is a powerful investigative tool in the process of identification when the information uploaded into it is accurate, and knowledgeable experts review the reports created to keep investigative resources focused on likely matches.

Missing, Dental, NCIC

D73 Assisted Suicide Teams: A Final Exit Case Study

Bobbi Jo O'Neal, BSN, and Brittney Martin, BS, Charleston County Coroner's Office, 4050 Bridge View Drive, Suite 500, North Charleston, SC 29405; Charles L. Ghent, BS, South Carolina Law Enforcement Division, 104 Simmons Street, Walterboro, SC 29488; and Rae H. Wooten, BSN, Charleston County Coroner's Office, 4050 Bridge View Drive, Suite 500, North Charleston, SC 29405*

After attending this presentation, attendees will understand how assisted suicide teams, also known as "Exit Guides," are being used in order to provide hands-on assistance in executing a suicide as well as removal of all evidence from the death scene in order to elude detection that the death was an intentional act.

This presentation will impact the forensic science community and legal community by providing information regarding the methods used by the Final Exit Network and their "Exit Guides."

Assisted suicide is a controversial topic with many supporters on both sides of the debate. However, what is not debatable is that in most of the United Sates and other countries all over the world, assisted suicide is considered to be illegal; with some areas considering it to be a homicide to assist someone in ending their life. Physician-assisted suicide is legal in certain instances in three states which include Oregon, Washington, and Montana. Many cases have documented family/friends assisting a loved one to commit suicide. This presentation will focus on volunteer Exit Guides from the Final Exit Network and provide information regarding the signs/evidence to look for when investigating a death which may initially appear to be from natural causes.

The Final Exit Network is the only organization in the United States that will help individuals who have non-terminal illnesses to hasten their deaths. The best known "how-to" guide is Derek Humphry's 1991 Final Exit: The Practicalities of Self-Deliverance and Assisted Suicide for the Dying, which was a New York Times best seller.[1] Individuals considering taking their own life are able to obtain assistance from this network after they become a member of the Final Exit Network and undergo an application process. Once approved to receive services they are then assigned two Exit Guides to assist them with the preparation of, completion of, and clean-up after their suicide. Methods for hastening death are varied with the most notable being the use of helium and plastic bag asphyxiation.[2]

A case study of the death of a 64-year-old woman whose death was initially thought to be from natural causes will be presented. Months later, the women's name appeared on a list obtained by the Georgia Bureau of Investigation (GBI) of individuals who contacted the Final Exit Network for assistance with their suicide. The GBI contacted the South Carolina State Law Enforcement Division (SLED) who notified local jurisdictions of

potential cases that may need to be reviewed. The case was re-opened and investigated. This presentation will show participants the forms used by the Final Exit Network, the information they gather before agreeing to provide exit assistance, and the instructions provided to those seeking their assistance which ensure that the suicide is not detected. It is recommended that medicolegal death investigators become familiar with the methods used by the Final Exit Network and volunteer Exit Guides as deaths, which may initially appear to be from natural causes, may be a suicide which was covered up by "Exit Guides" who remove evidence from the death scene. Exit Guides have been criminally charged in multiple states after further investigation into the deaths of individuals whose names appeared on the list obtained by the GBI.

Assisted Suicide Teams, Final Exit, Death Investigation

D74 Death Investigation and the Scientific Method

James M. Adcock, PhD, 1304 Mandalay Parkway, McDonough, GA 30253*

After attending this presentation, attendees will: (1) learn about the frequency of homicides in the United States and the clearance rates associated with them; (2) will learn about some of the reasons why so many cases are still unresolved; and, (3) will learn how to apply a scientific approach to death investigation by utilizing a Death Investigation Protocol specifically designed to incorporate the scientific method.

This presentation will impact the forensic science community by addressing some of the concerns relating to investigative failures and how these concerns may be remedied through the application of the scientific method to each investigation. It will also outline a scientifically based model to be utilized during the conduct of any investigation that will help to reduce the number of unsolved murders.

At the AAFS meeting in Chicago, in February 2011, Dr. Adcock presented a paper entitled "Managerial Responsibilities in the Homicide Investigation Process: Making a Case for Periodic Reviews of All Ongoing Death Investigations" that is also relative to this presentation but with more of an emphasis on the actual investigative process versus the managerial responsibilities. It is believed that coupling supervisory oversight of death investigations that utilize a scientifically based model will enhance the resolution rate and make other cases stronger for court.

The "scientific method" as practiced by science scholars, researchers, and practitioners is quite straight forward and has proven itself time and time again as the approach to use above all other possibilities. While some have variations, the following steps are commonly accepted: (1) state a problem; (2) observe; (3) form a hypothesis; (4) conduct experiments; (5) collect data; and, (6) draw a conclusion.

However, according to Dr. Thomas Young, "The scientific method, a time-honored approach for discovering and testing scientific truth, does not and cannot work for the forensic sciences in its standard form because it does not work for past events. Past events cannot be observed, cannot be predicted or deduced from physical evidence, and cannot be tested experimentally."[1] It was this premise and writings by Young that were the impetus for the design of the Scientific Method for Investigators in hopes that investigators would realize this process of analysis is not just for scientists and that utilization of it would in fact make stronger cases and increase solvability. Therefore, the Scientific Method for Investigators: (1) obtain from witnesses the accounts of what happened; (2) based on these accounts anticipate the questions you will be asked by others so you can properly collect and record the physical evidence; (3) collect and record the physical evidence: (4) formulate hypotheses about the events that occurred and anticipate the questions you will be asked; and, (5) determine whether the witness statements are consistent with the physical evidence; gather more information or evidence as needed.

Through the process of verifying witness statements, admissions/confessions, consider the evidence at hand and disprove as many hypotheses as you can. Formulate an assessment (final hypothesis) to a reasonable degree of certainty, recognizing the existing limitations.

While keeping those seven steps in mind, the scientifically based model called the Death Investigation Protocol was also designed. It includes all of the steps in a simple format that is easily followed. In its simplest form the death act begins with behavior from two people, a suspect and a victim. Then law enforcement is brought into the picture where the investigation begins at the scene with the collection of the physical evidence and the informational pieces of the puzzle. The standard process moves into the autopsy, crime lab analysis of all evidence, and hopefully the design of a victimology. Once those are all collected and created, the preliminary analysis begins where hypotheses (to some theories of the crime) are promulgated.

The next phase of the model is to evaluate these hypotheses through reconstruction of the physical and informational aspects of the investigation to see if a final analysis can be attained. In the interim, a review of all the pre-offense, peri-offense or "crime behavior," and post-offense behavior should be reviewed and evaluated. Once all this is accomplished the investigator needs to identify the hypotheses that are confirmed; if not, then the process returns to the preliminary analysis. If confirmed are all future questions answered? If not then back to the preliminary analysis, etc. If all questions that can be answered are answered and the hypothesis is validated then one can state a more accurate conclusion as to what happened.

Death Investigation, Scientific Method, Protocol

D75 Suicide, Homicide, or Death by Misadventure: Requirement for Collaborative Relationship Between Forensic Investigators and Forensic Pathology

Jeff J. Tanguay, Ontario Coroner's Office, 26 Grenville Street, Toronto, ON M7A 2G9, CANADA; Michael S. Marchen, MA, Toronto Police, Forensic Identification Services, 2050 Jane Street, Toronto, ON M9N 2V3, CANADA*

After attending this presentation, attendees will gain a better understanding of the collaborative relationship that should exist between forensic investigators and forensic pathologists in relation to suspicious death investigations

This presentation will impact the forensic science community by demonstrating the importance of removing bias or "tunnel vision" when conducting homicide investigations.

Currently in the United States, laws requiring all motorcyclists to wear a helmet are in place in 20 states and the District of Columbia, while 27 states require only some motorcyclists to wear a helmet. Only three states have no motorcycle helmet use law. Most helmet laws require motorcycle riders to use a helmet that meets the DOT Federal
Motor Vehicle Safety Standard (FMVSS) 218. FMVSS 218 requires that in a 138.4 cm drop test (5.2 m/s, meters/sec) onto a hemispherical anvil, and on a 182.9 cm drop test (6.0 m/s impact speed) onto a flat anvil, the peak head acceleration shall not exceed 400g. If the peak head acceleration exceeds 200 g, the duration at 200 g's must be less than 2 ms (milliseconds), and if the peak head acceleration exceeds 150 g, the duration must be less than 4 ms. Helmets that are similar in form to a motorcycle helmet designed for on-road use, but that are not certified by their manufacturer to meet the requirements of FMVSS 218 are often referred to as "novelty" helmets.

According to the National Highway Traffic Safety Administration (NHTSA), 2006 NOPUS survey, a probability-based observational survey of motorcycle helmet use in the United States, found that 14 percent of motorcycle riders use helmets that do not comply with FMVSS 218.

To combat this problem, NHTSA issued a final rule on May 13, 2011, that changes the labeling requirements on helmets, making it more difficult to sell helmets with markings that resemble current DOT labeling. However, novelty helmets remain a safety hazard. In the current study, the performance of a DOT certified half helmet and a similar looking novelty helmet were evaluated using a drop tower system. Six drop tests were conducted using a novelty helmet and a DOT certified half helmet. The helmets were placed on a crash test dummy head that was instrumented with a tri-axial accelerometer at its approximate static center of gravity. The head was suspended from a drop tower and dropped onto an asphalt test bed. It was suspended such that the head was free to rotate on impact. The drop height was 152.4 cm, to simulate the height of an average-sized rider on a cruiser-type motorcycle. All data was recorded at 10 kHz. Axis orientation and data filters were used in accordance with SAE J211 Recommended Practice. For the novelty drop tests, the peak resultant head accelerations were 451g, 358g, and 473g for the left, right, and top impacts respectively. The corresponding HIC36 values for the novelty drop tests were 3677, 2260, and 4201. For the DOT drop tests, the peak resultant head accelerations were 143g, 142g, and 243g, for the left, right, and top impacts respectively. The corresponding HIC36 values for the DOT drop tests were 739, 595, and 1681.

For this test series, the DOT certified helmet met the DOT criteria described above in all three impacts; however, the novelty helmet did not meet the criteria for any impact. The peak resultant g's from the novelty helmets were 1.9 to 3.2 times higher than those of the DOT certified helmets, depending on head impact orientation. The HIC36 for the novelty helmets ranged from 2.5 to 5 times that for the DOT certified tests, again depending on head impact orientation. These results show that the DOT helmet was at least twice as effective at reducing the potential for head injury when compared to the novelty helmet. A study by Scher et al., (SAE#2009-01-0248) was similar to the present study with the exception that the head orientation was fixed during impact, so that all head motion was constrained to one direction, similar to FMVSS 218 testing. On average, for the Scher study, the peak resultant g's from novelty helmets were 2.6 times those of DOT certified half helmets, and on average the HIC15 for novelty helmets was 2.9 times those of DOT certified half helmets. Thus, based on the average data presented by Scher, both studies Short Title: D.O.T. and Novelty Helmet Comparison [For Reference Purposes Only] showed similar reductions in head accelerations and HICs when using a DOT certified helmet rather than a novelty helmet.

The present study appeared to have higher magnitudes for peak acceleration and HIC for all drop tests when compared to the Scher study. However, because only average data was presented in the Scher study, and because the present study was limited to six tests, direct correlation cannot be accomplished. Possible explanations for the discrepancy between the studies include a constrained head versus a freely rotating head and head impact orientation. Further testing and more information regarding the Scher testing are needed to determine the basis for this discrepancy.

Drop testing clearly demonstrates that DOT certified motorcycle helmets are much more effective at protecting the head than novelty helmets.

Collaborative, Forensic, Pathology

D76 Assessing the Need for Family Assistance Services within the Medical Examiner System

Bethany Lynn Bless, MS, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be familiar with the current role of the Harris County Institute of Forensic Science as it pertains to family assistance. The challenges of assisting grieving families will be outlined and current limitations of assistance within the Harris County Institute of Forensic Science will be identified. This presentation will assess the need for improved family assistance services.

This presentation will impact the forensic community by contributing to the understanding of challenges in assisting grieving families and identifying the need for a specialized program to assist with family assistance services.

By Texas Law, (CCP Art. 49.25), the medical examiner is mandated to determine the cause and manner of death in all cases of accident, homicide, suicide, and undetermined death. In cases of natural death, when the person is not under a doctor's care, or the person passes away in less than 24 hours after admission to a hospital, the medical examiner must be notified, as an autopsy may be required. The forensic investigators are responsible for conducting death investigations by developing organized, concise, and accurate death reports in accordance with Texas Code of Criminal Procedures 49.25. The investigators are also responsible for handling proper identification of the decedent and notification of family. The medical examiner must use all information available to make a determination about the death. This may include information from his/her own investigation, police reports, staff investigations, and discussion with the family and friends of the decedent.

Medical examiner investigators may be the first official to contact the family of the deceased individual and as such, need to be sensitive and exhibit an understanding of the initial grieving process. The sudden and unexpected death of a family member/friend can bring a range of emotions including guilt, shock, anger, sadness, resentment, and regret, as well as a number of unanswered questions. There is no time frame for grief and no right or wrong way to grieve. It is important to understand that everyone grieves differently. Grief is an individual experience that is unique to each person and to the relationship he or she had with the deceased. The act of informing family members of a death requires a responsible, well-trained, and sensitive individual who can manage to cope with this mutually traumatizing experience. Family members of deceased victims have a wide range of needs and reactions to the sudden and untimely death of their loved ones. Consequently, the individuals who deliver death notifications and the manner in which they carry out this duty factors significantly in the trauma experienced by the family.

The Harris County Institute of Forensic Science currently has limited resources to locate, notify, and support families. There are more than 2,000 violent deaths per year in Harris County. Approximately 85% percent of families are located and notified within 24 hours of death. However, the remaining 15% require in-depth searches to ensure timely identification and notification of death. Families often require ongoing communication to obtain further information and to provide final determination of cause and manner of death. There is no formal means for the Harris County Institute of Forensic Science to assist families in identifying local victim related services and resources.

A specialized family assistance program is necessary in the medical examiner's system. The program would ensure timely notification of death, compassionate assistance in understanding the medicolegal death investigation process, and early access to local relevant victim family related services. The program would assist in the collaboration and coordination of local governmental and not-for-profit victim assistance service providers to meet the emotional, physical, mental, and financial needs of those affected by untimely violent death.

Medical Examiner, Grief, Family Assistance

D77 I Shot Him: A Case for Murder or Self-Defense

Larry D. Marshall, MFS, Meigs County General Health District, 112 East Memorial Drive, Suite A, Pomeroy, OH 45769*

After attending this presentation, attendees will have an understanding of the challenges faced by investigators and prosecutors in a homicide case where the perpetrator is the sole survivor witness and claims self-defense. Attendees will be presented with the facts of the case and an evaluation of these facts with regard to murder or self-defense.

The presentation will impact the forensic science community by articulating the investigative steps necessary in sound crime scene processing and the theory underlying the claim of necessity of self-defense in a criminal case.

On April 3, 2009, the decedent was shot to death by his wife in their rural Meigs County home. The wife told her stepson and responding investigators that her husband was showing her how to shoot a gun and she didn't know that the safety was off, and the gun went off and then kept going off multiple times until empty. The weapon was a 9mm semi-automatic pistol. The wife told the responding investigators that she and her husband had a good marital relationship, had had no argument, and that the gun "just kept going off."

The decedent was found in the home living room reclining in a cloth-covered recliner chair. He suffered gunshot wounds of the upper and mid chest, abdomen, left arm, right leg, and right thumb. The room and home was neat and orderly with no signs of a struggle. The weapon and ejected casings were found nearby the body.

At trial the wife was charged with aggravated murder. Rather than to assert an accidental shooting due to weapon misfire as she had originally stated to investigators, she alleged self-defense and that she had been a victim of "Battered Wife Syndrome." A jury found her not guilty of aggravated murder, but deadlocked regarding the lesser included offense of murder and a mistrial was declared.

The wife was subsequently tried before a second jury for murder. At the second trial she again asserted self-defense stating the decedent became increasing abusive after retiring several years previously. At trial, both the prosecution and defense provided expert testimony both with regard to the movements and positions of the defendant and decedent at time of the shooting and also about Battered Wife Syndrome. The defendant claimed the decedent, a very large man, attacked her with a paddle and was standing over her, after knocking her to the floor, when she was forced to shoot him in self-defense. Prosecution maintained the decedent did not assault his wife, that she had no assaultive injuries at time of the initial investigation, and he was either in his chair or coming out of it when the shooting occurred. The defendant was found guilty of murder and sentenced to life with parole.

In the State of Ohio for a defendant to assert the self-defense claim of necessity the defendant must show by a preponderance of the evidence that she reasonably believed herself to be in imminent danger of death or serious bodily harm and that a reasonable person would feel the same way in the same or a similar situation. In this case the evidence did not support a history of violence or battering, nor did the evidence support the weapon misfiring.

Murder, Self-Defense, Gunshot Wounds

D78 Multiple Gunshot Suicides

Stewart D. Ryckman, MD, 1468 Brookpark Drive, Mansfield, OH 44906; and Jodie A. Flynn, MSN*, 484 Honey Creek Road, Bellville, OH 44813*

After attending this presentation, attendees will have a better understanding of the prevalence, features, and implications of multiple gunshot suicides.

This presentation will impact the forensic science community by showing how reviewing literature and case studies will reveal several key features that are similar in multiple gunshot suicide case outcomes. Understanding these factors has the potential to significantly impact medicolegal death investigations of multiple gunshot suicides.

Multiple gunshot wounds are found in 6-10 % of all gunshot suicides. Most cases involve two gunshots, but as many as nine gunshots have been reported. The alternate possibility of homicide may be suspected when there are multiple gunshot wounds. As a result, case management problems often exist. Problems may be related to the skepticism and disbelief of family, media, and others. As in all death investigations, a thorough scene investigation and team approach is critical in determining the manner of death. The position of the body and gun, wound entrance and exit locations, wound characteristics, blood spatter pattern, past and recent medical and psychiatric history, statements from household members, and the presence or absence of a suicide note are important features in trying to determine evidence of suicidal intent.

Research shows that multiple gunshot wound suicide features are similar to those found in single gunshot wound suicides. Wounds are contact or near contact and involve classic entrance wound sites of the head and neck. Soot or back spatter can be present on the hand(s). Multiple gunshot wounds to the head are relatively rare, but do occur. The most common wound area is the left chest or precordial region. Wound characteristics must be documented to determine instant verses delayed incapacitation. Several types of weapons have been documented in suicide cases, including long rifles and shotguns. Twenty-two caliber handguns are used most frequently according to case findings. Four case reports will be presented and characteristics will be compared to the literature findings:

Case #1 - an 86-year-old male who suffered from Depression and Parkinson's disease. The investigation determined a self-inflicted GSW to the chest with a .22 caliber handgun, followed by a second gunshot wound to the head.

Case #2 - a 42-year-old male with a history of Bipolar Disorder, occasional erratic behavior, and past suicide attempts. History revealed verbal threats of shooting himself first in the chest and then in the head to "do it right." The male went into the bedroom, and was found with gunshot wounds to the head and chest from a 9 mm pistol.

Case #3 - a 41-year-old male who was found in a pickup truck at an isolated, rural location. He apparently died from a self-inflicted shotgun wound to the head. Secondary scene investigation revealed a first, unsuccessful shot in the head with a .22 handgun while at home. He then drove to a rural location, and shot himself in the head with a 12 gauge shotgun. The bullet lodged in the head, but did not perforate the skull bone, and was recovered at autopsy.

Case #4 - a 53-year-old male left a suicide note and apparently shot himself four times in the chest with a low power handgun.

Review of the literature and case studies reveal several key features that are similar in multiple gunshot suicide case outcomes. Understanding these factors has the potential to significantly impact medicolegal death investigations of multiple gunshot suicides.

Suicide, Multiple Gunshot Wounds, Self-Inflicted

D79 A Survey of Forensic Professionals and Law Enforcement on Synthetic Drugs

Lindsey E. Crass, BS, Forensic Science Initiative, West Virginia University, 1600 University Avenue, 208 Oglebay Hall, PO Box 6217, Morgantown, WV 26506-6217*

After attending this presentation, attendees will gain an understanding of the prevalence of synthetic drug samples commonly observed in the law enforcement field and forensic laboratory. In addition, current testing protocols for the samples will be discussed based on information obtained from a given survey.

This presentation will impact the forensic science community by highlighting the distribution demographics of synthetic drug samples in the United States, trends of synthetic drugs, and the laboratory procedures used for testing these samples.

In recent years, synthetic drugs have increasingly grown in popularity in the United States and subsequently, more samples are being seized and tested in the forensic science community. A survey was sent to a group of forensic professionals who participated in online continuing education courses from August 2010 through November 2011, regarding the prevalence of synthetic drug samples in their work environment. The questions in the survey were used to gather information regarding the frequency of synthetic drug samples by demographic region and laboratory testing capabilities.

The survey is comprised of the following questions:

1. In what state do you work?
2. Do you work for a local or state agency?
3. What is your job title?
4. Have you encountered synthetic drug (e.g., synthetic cannabinoids, and bath salts), samples in your position?
5. What synthetic drug compounds are you specifically seeing?
6. How often are you working with synthetic drug samples?
7. Do you perform testing in-house for synthetic drugs?
8. If yes, can you elaborate on your testing protocol?
9. If no, what is the protocol for synthetic samples in your agency?
10. What further information can you provide regarding synthetic drugs?

The survey was distributed to forensic professionals and law enforcement with ranging experience levels and job positions in order to gain a wide range of information. Due to the growing number of synthetic drug compounds and samples, it is important for the forensic community to understand and become familiar with the trends of synthetic drugs. Once trends are recognized, the forensic community can understand what they may be experiencing in the variety of compounds being seen and testing methods being used. Trends are important for law enforcement and analysts to be aware of in order to recognize what the drugs and their packaging look like, where they are sold, what drug compounds are currently controlled, how the samples should be collected, and what testing protocols need to be established. Because synthetic drug manufacturers can change the compounds that are being used or where they are distributed, it is important to have regional contacts in order to share information.

When information is shared amongst the field, progress can be made towards the standardization of protocols and methods. Legislation can build off of the standardization by working towards scheduling the entire class of synthetic drugs and not only single compounds and their analogs. By understanding current trends, the community may be able to determine future synthetic drug trends and be prepared for new drugs in the future. Preparedness is an important aspect in the forensic community, especially with drugs like synthetics, where a slight change in a compound can make an illegal drug, legal again.

Synthetic, Drugs, Trends

D80 Medicolegal Elderly Death Trends Within Harris County, Texas: Are Changes in Practice Warranted?

Matthew W. Doyle, BSN, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; Stacy A. Drake, MSN, The University of Texas Health Science Center at Houston School of Nursing, 6901 Bertner Avenue #667, Houston, TX 77030; Roger A. Mitchell, Jr., MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; Jason L. Burnett, PhD, The Crest Office Quentin Mease Community Hospital HCHD, 3601 North MacGergor Way, Houston, TX 77004; and Carmel B. Dyer, MD, The University of Texas Health Science Center at Houston School of Medicine, 6431 Fannin, 1150, Houston, TX 77030*

After attending this presentation, attendees will learn to identify categories of elderly death trends and barriers that inhibit thorough death investigation of the elderly. Understanding these categories of death as well as recognizing potential barriers will impact death investigators by allowing them to target improvement efforts within the medicolegal death investigation system.

This presentation will impact the forensic science community by providing information on interesting trends in elderly deaths and case study examples to illustrate key points. Initiatives to improve investigation of the elderly will be presented which could be implemented within any medicolegal death investigation system.

The demographics of our population are changing. As our society ages, in part because of advances in healthcare services, people are living longer than at any other time in history. At the same time, the aging population requires additional healthcare resources or family support. The role reversal of children caring for their parents can be overwhelming and unexpectedly stressful. The majority of deaths in the elderly population are due to natural causes; however, often the people reporting these deaths are not aware of nor did they consider prior or ongoing Adult Protective Service (APS) investigations. When investigators are unaware of an APS history during the initial death report, the likelihood of further investigation into the cause and manner of death subsides. The impacts would include those deaths from non-natural manners and especially elder mistreatment.

This retrospective study was initiated in efforts to describe death trends and barriers of the elderly falling within medicolegal jurisdiction in Harris County, Texas. The study is a four-year longitudinal descriptive study looking at deaths of people aged 65 and above (N=38,827) where medicolegal jurisdiction was retained and an examination did occur (n=4,400). The purpose was to describe any differences within the decedent sample with no APS reports (n=4208) and the decedent sample that had an active or closed APS investigation (n=192). There was no distinction made between APS cases in which the decedent was investigated for self-neglect or whether there was a caretaker who was investigated by APS. Of the 38,827 deaths reported to the Medical Examiner's Office, there were 4,400 cases in which jurisdiction was retained and an examination occurred. Of the 4,400 cases surprisingly only 192 had APS history; the initial report only included information about active or past APS investigations in 28 of those cases. Additionally, after cross-tabulating medical examiner cases with APS database it was discovered that of the 34,427 elderly deaths that were reported but which jurisdiction was released, 1,310 cases had a history of an APS investigation. In some of those cases, jurisdiction may have been retained and a physical examination performed if knowledge about APS history was attained during the initial investigation. The consequences of not having this APS history available at the time of the initial report may have led to deaths being released from medicolegal jurisdiction. Efforts were initiated to identify and remove barriers impeding investigators from obtaining APS history. Two of the initiatives included improving communication with APS and providing additional education regarding elder mistreatment to death investigators.

Some interesting trends in elderly deaths and case study examples provided to illustrate key points will be presented. Initiatives to improve investigation of the elderly will be presented that can be implemented within any medicolegal death investigation system.

Medicolegal Death Investigation, Elder Mistreatment, Adult Protective Services

D81 Body Donation and Death Reporting: Three Case Studies

Charlotte A. Wacker, MS, University of California, Davis School of Medicine Body Donation Program, 4800 Broadway, Suite 100, Sacramento, CA 95820; and Brandi Schmitt, BS, MS*, University of California, Office of the President, 1111 Franklin Street, Oakland, CA 94607*

After attending this presentation, attendees will gain an understanding of how body donation programs interact with coroners and medical examiners in the state of California through three specific case reports.

The presentation will impact the forensic science community by raising awareness of body donation programs and role and their interactions during death reporting.

Each year over 1,000 individuals donate their bodies after death to the University of California (UC). These donations are made to one of five campus locations at Davis, Irvine, Los Angeles, San Diego, or San Francisco. Most of these deaths are from natural causes; typical for the aged donor population. They result from long-term illness such as cancers, heart disease, or pneumonia, but occasionally, the circumstances surrounding the death are not typical and require further inquiry or formal investigation.

Standard protocol for receiving a donor at UC includes death notification to the program personnel and confirmation of registration in the donor program. A medical and social history screening is performed during the notification phone call. If the donor meets the criteria for donation, the remains are then transferred to the program. A serology sample is taken and submitted for communicable disease testing. Simultaneously with the preparation of death certificates and burial permits, donor program personnel conduct a thorough external examination and photograph the remains; noting trauma, surgical history, identifying markings, and other significant findings. The following are three cases that required further investigation.

Case number one is a 70-year-old Caucasian female who died in a nursing home. The attending physician provided cause of death information, the local coroner provided a case number and the death certificate was accepted by the local health department. During preparation for scientific use, donor program personnel found a foreign object and reported the case back to the coroner.

Case number two is an 85-year-old female. This case was received after a residential death and was transported by a contracted mortuary service. Program personnel determined that there was no doctor to sign the death certificate, concluding that the decedent had not seen a doctor in a number of years. The case was referred to the coroner's office for follow up at which point, that office determined that the death was not caused naturally. Case number three, a 71-year-old Caucasian male, was received after his death occurred in his residence. The local coroner had responded to the death, but declined to investigate the case. Upon external examination by the donor program personnel, evidence of traumatic injury was identified and the decedent was returned to the coroner's office for investigation.

Of the estimated 4,500 deaths accepted for donation in the UC System since 2008, 1,142 of them have been assigned coroner case numbers. The vast majority of these are assigned case numbers due to required reporting circumstances such as an emergency room death, hospice death or similar circumstances. In some cases, donor program personnel identify atypical circumstances that result in reporting to obtain a referral number or initiate a full investigation. The UC Davis donor program reports approximately 30 cases per year for further investigation.

It is essential that donor program personnel be trained to recognize normal postmortem processes so that abnormal cases can be appropriately referred to local officials for full review or follow up. It is possible that whole body donors for scientific use, who account for less than one percent of the total annual deaths in the state of California, may not always be subject to the same postmortem reporting process as those who choose a more traditional disposition. Theoretically, this may be due to caretakers who want to facilitate the donors' disposition wishes or for other, less obvious, reasons such as incomplete information provided in the initial death report. Further analysis of donation data may reveal reporting patterns, or a lack there of, for decedents who do not follow a typical disposition path.

Body Donation, Death Reporting, Death Investigation

E1 Sanity and Insanity in a Criminal Trial: The European Experience Seeks the American Experience

Vincenzo Lusa, JD, Via Ferdinando, Palasciano #72, Roma, 00151, ITALY; Matteo Borrini, PhD, Via del Mattone 17\a, La Spezia, 19131, ITALY; and Selene Pascasi, JD, Via Cesare Fabrizi 5, L'Aquila, 67100, ITALY*

After attending this presentation, attendees will learn from the data presented in this thorough and comprehensive examination the legal and scientific definition of "sanity" and "mental instability" to be evaluated within the criminal process, both during the investigation phase and in a courtroom.

This presentation will impact the forensic science community by providing an easy examination of the different categories of sanity and mental instability, in order to use them during their studies and professional practice.

A correlation between the existing Italian system between liability and social dangerousness intended to understand the authentic predisposition of the suspect/defendant to commit a crime is observed. The notion of insanity in our legal system is correlated with the legal institution of imputability: an essential condition for an offender to be punishable (Articles 88 (total defect of mind) and 89 (partial defect of mind) of the Italian Criminal Code). The concept of "crime" as a criminal act will be explained, and therefore what typical action is perpetrated with criminal intent and perceived as such by the community that suffers. Following, the guilt of a crime as a key element connected to the psychic sphere of the subject in the form of malice, misconduct, or involuntary act will, be defined on a level very different from liability, where an non-indictable (a minor) has acted with intent.

Otherwise, liability is correlated to the ability to be in full possession of one's faculties given that Article 85 in the Italian Criminal Code stating that no one can be punished for an act seen by law as a crime "if, at the moment of the act, was not liable" and that "is liable those who are in full possession of their faculties."

The ability to be in full possession of one's faculties is linked in the Italian penal system, like those in Europe, to the concept of criminal responsibility, recognizing that the offender is capable of understanding and self-determinating their actions, performing them "with consciousness and will." Thus it is necessary to distinguish the ability to understand (perceive the external reality and understand the worthlessness of their actions/omissions) from will (to control the impulse to act). Italian legislators have introduced two presumptions of capacity: an absolute (relative to an adult capable of understanding) and the other relative (the minor who is over fourteen years of age, whose capacity will be evaluated case by case). The scientific aspect of liability and guilt is then determined, being able to distinguish between consciousness and the will to act on the ability to understand what is accomplished.

The Law, in line with science, has created a concept of insanity associated to the medical criteria of a mental disease. In Italy, magnetic resonance imaging is used in the forensic field to highlight structural changes in the cerebrum of the brain that can lead to crime. From the ethological point of view, it has been observed that primates are able to recognize subjects with mental and physical impairments and therefore are not addressed with the same punitive attitudes in response to behavioral deficiencies. Moreover, "the partial defect of mind" as understood by the Cassazione Penale (Italian Supreme Court) will be examined, a vice compatible with the existence of intent (consciousness, will and prediction of the act). In this context the "reactions to short-circuit" can also be induced by particular emotional or passionate and pathological states (Art. 90 of the Italian Criminal Code) which can predispose the individual to perform acts of brutal violence. The criminal is evaluated as such via the application of three benchmarks: the first related to the biology of the brain (area where the study of genes as potential source of violent behavior is essential); the second associated with the personality of the offender (sector in which psychology and forensic psychiatry are already active); the third is identified with the environment in which the criminal lives or has lived (under jurisdiction of behavioral sciences and judiciary bench).

The data obtained are compared with the American penal system. Finally, it examines the conscious participation of the accused at the trial in an Italian context, also in light of "neuroscience," and then is compared to the American system.

Criminals, Biology, Criminal Law

E2 Explaining DNA and DNA Results to Judges and Juries

Pamela A.W. King, JD, 400 South Broadway, Suite 15, Rochester, MN 55904*

After attending this presentation, attendees will have new ideas about how to present complex, often technical concepts in DNA litigation to judges and juries, using technology in the courtroom.

This presentation will impact the forensic science community by encouraging lawyers to explore new approaches to presenting important yet technical concepts to judges and juries. This will provide the fact finder with the skills necessary to be able to understand and apply scientific evidence in a particular case, thus raising the quality of DNA forensic testimony in the courtroom.

Assuring that judges and juries understand the scientific evidence presented to them, including an assessment of the weight that should be given to any particular piece of forensic evidence, is where lawyers play a crucial role in the forensic science community. In any given case the fact finder is asked to understand DNA evidence involving complex mixture analysis, different statistical analysis designed to assist the trier of fact in assigning weight to a particular DNA match, inclusion or exclusion, and consider different processes such as STR typing, YSTR, and Mitochondrial DNA analysis. They may be confronted with a multitude of issues surrounding sample collection, serology test results, machine malfunctions, etc. Many jurors and judges have little to no scientific background. Typically, their "knowledge" of forensic science is founded on what they see in pop culture and the media. As such jurors and to some degree judges must rely heavily on the ability of scientist and attorneys to explain these concepts in a manner that is simple and approachable.

The research that has been done in a multitude of forensic science disciplines looking at whether jurors understand and properly assign weight to particular types of evidence suggests that jurors in particular do not understand much of what the forensic scientist and the lawyers are trying to relay to them. Examination of exoneration cases also suggests that in some cases where the value of forensic evidence is being overstated or misrepresented by scientist or lawyers, juries haven't recognized these flaws or it may be the evidence was simply misunderstood by the finder of fact. Therefore, lawyers must attempt to find more effective tools to explain scientific concepts and present scientific evidence in the courtroom.

How can this material be presented in a more effective manner? What tools can be provided to the fact finder to allow them to properly assess the weight of this evidence? What role can the attorney play in helping judges and juries understand DNA evidence? This presentation will explore the

particular challenges faced when DNA evidence is presented to the fact finder. It will then look at examples of how DNA evidence has been presented using tools such as visual aids to explain to the jurors how DNA typing is done and the challenges presented by things such as complex mixtures. These tools can be used by the prosecution as well as defense to assist the trier of fact in better understanding how DNA typing works, its limitations and what the forensic scientist is assessing in reaching their conclusions. This presentation will focus on specific cases and how the information was presented. The effectiveness of these tools has not been measured in any formal study. The suggestions are designed only to provide lawyers and forensic scientist with ideas and to encourage creativity on behalf of those presenting this evidence to assure the trier of fact has the tools necessary to effectively make a decision in a particular case.

DNA, Expert Testimony, Juror Comprehension

E3 Evidence Retention/Post-Conviction DNA Testing: Issues and Answers

Rockne P. Harmon, JD, 2846 Lincoln Avenue, Alameda, CA 94501; and Melissa Mourges, JD, District Attorney's Office, New York County, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will understand the challenges facing policymakers, police, defense attorneys, and prosecutors who must determine what evidence retention policies to put in place, in light of the role DNA testing plays in criminal cases.

This presentation will impact the forensic science community by illustrating the problems presented by evidence retention issues. Prosecutors, who employ new forensic techniques to develop cold cases, and defense attorneys, who hope to expand post-conviction testing, need a reliable system to maintain evidence. Police need to know what they need to save, for how long, and must find a way to do it all in an era of shrinking resources.

In light of the attention recent exonerations have brought to post-conviction DNA testing, significant efforts are being made to draft new evidence retention statutes in states that do not already have them. This presentation will discuss these efforts in light of the overall need for the statutes, the nature of previous exonerations, the infrequency of those exonerations, and the complicated legal issues that arise when legislators attempt to fashion remedies for defendants whose evidence is unavailable for testing.

Complicated issues abound. What is the scope of post-conviction testing? Should it be available only to those who are convicted after trial, or should defendants who plead guilty be entitled to post-conviction testing as well? And in what type of cases? Only in serious felonies like rapes and homicides? In all felonies? In misdemeanors? Only in cases where the defendant is still in jail? Should there be a statute of limitations on a defendant's right to request testing? Should he/she be allowed to request testing only where the results would be a "game changer," or should testing be permitted in every case?

Police agencies, which in most jurisdictions are responsible for maintaining evidence, have an enormous task. Policies differ - some agencies keep property through the final appeal, some keep homicide evidence and destroy the rest, and some discard evidence after the statute of limitations has run. Sexual assault evidence kits may be stored indefinitely, stored until tested, destroyed without testing depending on the investigator's opinion of the case, or destroyed if no arrest is made within a specific time.

Besides deciding what to store (guns and knives are an easy call, but what about cars and other vehicles?) must police departments build climate – controlled facilities to maintain biological evidence in case testing is ever requested? Who will pay for those facilities, or for the computerized, bar-coded or RFID systems to track the evidence? What remedies, if any, should be available to defendants whose evidence was destroyed in compliance with former or present-day policies?

Finally, who should make these decisions? Should policymakers rely only on advocates for defendants who hope to be exonerated or to have their sentences reduced, or should prosecutors, lab personnel and police be at the table?

Evidence, Retention, Exonerations

E4 Issues in Eye Witness Identification From Composite Sketches to Photo Array Lineups

Thomas L. Martin, BS, Crime Scene Forensics, LLC, PO Box 515, Red Hook, NY 12571*

After attending this presentation, attendees will understand the issues being raised nationwide regarding the reliability of eyewitness descriptions, identifications and photo array line-ups.

This presentation will impact the forensic science community by defining the purpose behind using composite sketches and witness descriptions as investigative leads, and explaining the variables and limitations that exist when asking a witness or crime victim to describe the physical characteristics of an offender.

It is a common investigative practice to ask a victim or witness of a crime to describe the offender alleged to have committed that crime. Often these descriptions will result in either the generation of a composite sketch or with the victim or witness viewing a series of photographs in the form of what is commonly called a photo array or photo lineup. Eyewitness identifications are commonly used to support probable cause for arrest and as evidence against a defendant in trial; however, *erroneous* eyewitness identifications are commonly cited as reasons for false convictions. The variability by which eyewitness identifications are made increases the importance that investigators understand how to properly qualify the offender descriptions and identifications.

In any criminal case there is a commencement of an investigation, and an eventual trial in which evidence will be presented and an outcome will be determined. There are different stages involved in an investigation, and consequently, evidence and information will be obtained during that investigation that will amount to different levels of proof. In other words, certain investigative tools or techniques employed by investigators may not necessarily rise to the level of evidence required to demonstrate proof beyond a reasonable doubt; however these investigative tools may prove useful in generating information that allows for the investigation to proceed to the next level.

Composite sketches are a good example of an investigative tool. Composite sketches or artist's renderings are generated by a qualified artist and are based upon the descriptions of an offender as detailed by the victim or witness of a crime. The final drawing will be disseminated to the general public, in the hopes that information will be obtained regarding the unknown person responsible for the offense.

While composite sketches may prove to be a valuable investigative tool, they should remain just that; an investigative tool. The accuracy of the composite however, may prove quite useful in the investigation, therefore it is important that the rendering be as accurate as possible. To that end, the investigator taking the information must qualify the descriptions given by the victim or witness.

People perceive things differently, and consequently, descriptions of the same offender may differ as given by different witnesses. Techniques should be employed to ensure that the witness is accurately describing the offender, and can accurately identify that offender at a later time. Even in the case of a "positive identification" follow up investigative steps are necessary to ensure that the correct person is identified.

This presentation will discuss the role that composite sketches and photo arrays play in a criminal investigation as well as their respective limitations. Corroborative steps that can be taken to ensure that accurate

details are obtained in order to verify the accuracy of eye witness identifications will also be detailed.

Eyewitness Identification, Photo Lineup, Investigations

E5 Juror Expectations for Scientific Evidence in Criminal Cases: Empirical Studies of the "CSI Effect" Myth

Donald E. Shelton, JD, PhD, PO Box 8645, 101 East Huron, Ann Arbor, MI 48107; and Gregg Barak, PhD, and Young S. Kim, PhD, Eastern Michigan University, Department of Sociology, Anthropology, and Criminology, Ypsilanti, MI 48197*

After attending this presentation, attendees will learn that the results of two empirical juror studies do show increased juror expectations and demands for scientific evidence but do not support the simplistic accusation that "CSI" and similar television programs are the cause of those heightened expectations. Attendees will be presented with the suggestion of a larger cultural "tech effect" on jurors and to the suggestion that law enforcement and forensic scientists must adapt to the increased juror expectation generated by that phenomenon.

This presentation will impact the forensic science community by revealing the nature and extent of juror expectations for scientific evidence and confronting ways in which the forensic science community must adapt to those heightened expectations and demands.

The so-called "CSI effect" has many meanings but it's most popular connotation, called the "prosecutor version," is that jurors are wrongfully acquitting criminal defendants when the prosecution does not present the sophisticated (and perhaps non-existent) types of forensic science evidence featured on popular crime scene investigation television programs. Prosecutors blamed jurors when they lost cases. The news media picked up on these complaints, accepted them as factual, and quickly labeled it the "CSI effect." The mass-media-created CSI effect was repeated again and again, almost always in the context of blaming the television programs for what prosecutors claimed was a *crisis* of misguided juror demands for scientific evidence. But is it true?

The presentation focuses on two large empirical studies of Michigan jurors in diverse jurisdictions, finding that this "prosecutor version" of the so-called CSI effect cannot be substantiated empirically. In the first study, 1,027 persons called for jury duty in Washtenaw County, Michigan were surveyed as to their television watching habits, their expectations for scientific evidence in certain types of criminal cases, and their likelihood of conviction in several evidentiary scenarios. In the second study 1,219 jurors were surveyed in Wayne County (Detroit), Michigan. The survey was similar but also included questions designed to test the earlier suggestion of a "tech effect" as the cause of juror expectations and demands.

Statistical analyses of the survey results reveal that modern jurors do have high expectations that the prosecutor will produce scientific evidence and that, in some cases, jurors will demand such evidence before voting to convict. However, there is no significant statistical relationship between those factors and the television viewing habits of the jurors. It is suggested that the increased expectations and demands arise from a much greater cultural shift toward the awareness and use of technology, described as the "tech effect." Analysis of the separate, and then the merged, data from the two studies supports the suggestion of this "tech effect" based on cultural changes, rather than any direct impact from viewing certain specific or genre television programs.

It is suggested that while the prosecutor version of the CSI effect is a myth, there are indeed increased juror expectations that arise from the combination of the tech effect, the general media portrayal of forensic evidence, and the misperception of attorneys and judges that the CSI effect really does exist. Possible justice system responses to that combined effect will be explored.

It is suggested that the legal system, and in particular the role of forensic sciences in the criminal justice system, must adapt itself to modern juror expectations rather than blaming jurors for "unreasonable" expectations and demands for forensic science evidence. In our legal system, jurors decide what is proof beyond a reasonable doubt and jurors have decided that what is "reasonable" to expect from the prosecution in a criminal case is very different from what was considered reasonable just a few years ago. To meet those expectations, the government will have to expend a significant amount of resources and energy, both before and during trial, and the cost and methods for meeting those expectations will be discussed.

CSI Effect, Jurors, Evidence

E6 Contextual Considerations for Evidence Collection and Testing Decisions: A Conceptual Framework for Investigators, Analysts, and Attorneys

Ted R. Hunt, JD, Jackson County Prosecutor's Office, Jackson County Courthouse, 415 East 12th Street, Fl 7M, Kansas City, MO 64106*

After attending this presentation, attendees will be familiar with a framework of heuristic factors for analyzing and interpreting the contextual significance of items located at a crime scene.

This presentation will impact the forensic science community by providing a framework with which to help facilitate logical and relevance-based evidence collection and testing decisions by investigators, analysts, and attorneys.

The term "context" may be defined as "that which surrounds, and gives meaning to, something else." In forensic science, an item's evidentiary context consists of the presence or absence of a probative relationship between the item and a criminal act. Depending on the facts of a particular case, this relationship may be direct and explicit, circumstantial and inferential, or a combination of each. For purposes of this discussion, a candidate object, article, or substance under consideration for forensic collection or testing will be referred to as an "item."

Many times, the critical foundational question of a crime scene item's contextual significance is bypassed or ignored. This may stem from investigative efforts that increasingly emphasize testing an ever-larger number of collected samples. The result is a technology-based, high throughput approach primarily focused on the question of source determination. This practice can be characterized as *forensic question begging*–drawing an inference of significance from a *testing conclusion* that includes or excludes a particular individual *absent* preliminarily establishing the *contextual probative value* of the item from which the test result was obtained.

To avoid such fallacious reasoning, an essential foundational question must be asked: Given the sum of the collective situational circumstances surrounding the item and the extrinsic information about the item provided by the victim(s), witness(es), and suspect(s), can a reasonable inference be drawn that will support the conclusion that the item is or is not related to the criminal activity being investigated? In some cases, the answer will be obvious; in others, that will be far from the case. It is for this reason that a conceptual framework for analyzing and interpreting evidentiary context is helpful.

The analysis of evidentiary context is composed of three distinct levels of significance: Level I, the intrinsic attributes of the item and its surrounding contextual circumstances at a crime scene; Level II, extrinsic information about the item provided by the victim(s), witness(es), and suspect(s) that tends to establish, enhance, diminish, or destroy its Level I significance; and, Level III, the presence or absence of an associative relationship between the item and a relevant person, place, or other crime scene item determined by forensic testing. This includes the statistical significance of a match, if any, that gives the item its evidentiary weight.

The ten Level I factors involved in contextual evidentiary analysis are: (1) the item's **Environment**, be it open or closed; (2) whether the item is **Native or Foreign** to the environment; (3) the **Nature** of the item, such as blood, semen, saliva, hair, or tissue; (4) the **Location** of the item, relative to other relevant persons, places, objects, or substances; (5) the **Relation** of the item, either direct or circumstantially inferred, that *connects* it to other relevant persons, places, objects, or substances; (6) **Action**, an inference of movement, force, or velocity associated with the item; (7) the **Quantity** of the item, meaning its relative abundance or scarcity at the scene; (8) the **Rarity** of the item, meaning its commonality or infrequency in general or in the crime scene environment; (9) the **Portability** of the item, meaning its transferability or fixity; and, (10) the **Condition** of the item, meaning the ability to reasonably infer the general period of time it has been present at a crime scene based on an examination of the item's external and/or internal characteristics and properties.

Level II of contextual evidentiary analysis is extrinsic to the item. It concerns assertions, omissions, or denials by the victim(s), witness(es), and suspect(s) regarding items recovered at a crime scene. A witness' assertion about an ostensibly insignificant and prosaic item located at a scene can *transform* it *into evidence*. Likewise, a witness' statement about an item apparently possessing strong Level I significance can relegate it to the status of a meaningless crime scene artifact. Level II assertions, omissions, and denials have the ability to enhance, diminish, or entirely eliminate the prior analytical interpretation and significance of the Level I factors.

Level III of contextual evidentiary analysis concerns the testing conclusion and statistical weight, if any, attached to a match. Any item recovered from a crime scene, depending on the facts of the case and analysis under Levels I and II, has a certain starting quantum of contextual significance prior to forensic testing. Forensic testing may then "individualize," "match," "include," be declared "inconclusive," or "exclude" a particular individual, object, or substance. Additionally, the item may be qualitatively or quantitatively insufficient to answer the question posed. Although a testing conclusion alone will not alter the preexisting contextual significance of the item analyzed, the probative value of that item, as an aspect of contextual relevance, can be exponentially enhanced or diminished.

The usefulness and applicability of the foregoing three levels of contextual analysis by investigators, analysts, and attorneys will be discussed. It is desired that these factors will help promote logical, relevance-based, and targeted evidence collection and testing decisions.

Evidence, Context, Collection and Testing

E7 Michigan MRE 703 a Study in Fairness

Michael J. Nichols, JD, 3452 East Lake Lansing Road, East Lansing, MI 48823*

After attending this presentation, attendees will have a better understanding of the boundaries for an expert witness to present the factual basis of an opinion.

This presentation will impact the forensic science community by discussing the difference between what facts or data must be admitted in evidence when testifying as an expert in a Michigan case. It will also allow forensic examiners to understand the "backdoor hearsay" rationale behind the rule and the difference between underlying facts or data that must be admitted as evidence and learned treatises and studies that do not need to be admitted.

Courts all over the country are presented with the problem of how to assess the reliability of proposed expert testimony and opinions and most importantly, whether the opinion applies reliably to the facts of the case. In Michigan, the facts or data upon which the expert relies in forming the opinion "shall" be in evidence by virtue of the requirement of Michigan Rule of Evidence (MRE) 703. The Federal Rule of Evidence is inconsistent with this requirement. It states: "The facts or data in the particular case upon which an expert bases an opinion or inference may be those perceived by or made known to him at or before the hearing. If of a type reasonably relied upon by experts in the particular field in forming opinions or inferences upon the subject, the facts or data need not be admissible in evidence."

Often, the ability of an expert to provide the baseline facts upon which he or she relied allows the expert to introduce testimony that would be otherwise inadmissible but is introduced to the jury only because the expert was allowed to provide it as a baseline fact. Often, these facts are assumptions or hypothetical and further, do not necessarily apply to the facts of the case for which the expert is providing an opinion.

The sufficiency of the application of the opinion to the facts of the case as a threshold matter is addressed in the voir dire process of the expert; however, the reliability of the expert's facts or data to support the ultimate conclusion of the expert can only be analyzed through requiring sufficient foundation for the admission of the witness who can authenticate those facts or data and be subject to cross examination on the admissibility of those baseline facts or data in the case for which the expert is called to testify.

A case study involving an expert's proposed testimony in an area called "retrograde extrapolation" will be presented. Retrograde extrapolation is a technique in which a person with knowledge in the field (often a toxicologist or pharmacologist) uses a subject's assumed bodily alcohol content at one point in time to opine as to what the bodily alcohol content was at an earlier point in time that has specific relevance to a contested fact in a case. The attendees will learn how the proponent of the opinion failed to meet the threshold of admissibility and why the judge's ruling was fair by preventing the admission of expert testimony that was not supported by facts that were reliable.

Expert, Hearsay, Reliability

E8 Go or No Go: Screening Scientific & Technical Studies and Reports Presented in Court

Joseph J. Maltese, JD, New York Supreme Court, 130 Stuyvesant Place, 3rd Floor, Staten Island, NY 10301*

After attending this presentation, attendees will have an understanding of the factors judges and attorneys consider in screening scientific studies and expert witness report.

This presentation will impact the forensic science community by providing a better understanding of how judges scrutinize studies and reports presented by expert witnesses in court.

When Jason Daubert and Eric Schuller were born, with serious birth defects, their parents sued Merrell Dow Pharmaceuticals, Inc., the manufacturer of a prescription anti-nausea drug known as Bendectin, which was prescribed to their mothers during pregnancy to limit "morning sickness." The plaintiffs claimed that Bendectin caused birth defects in their children. Before the case was able to be tried by a jury, the defendant manufacturer made a motion for summary judgment before the judge, asserting that Bendectin did not cause birth defects in humans. In support of that assertion, the manufacturer presented the affidavit of a physician, who was also an epidemiologist that had reviewed all of the 30 plus published studies involving over 130,000 patients. The doctor concluded from his review of the studies that the use of Bendectin in the first trimester of pregnancy, when nausea is at its worst, had not been capable of causing malformations in fetuses.

While the plaintiffs did not contest the characterization of the published Bendectin studies, they opposed the motion for summary judgment and presented eight well credentialed experts in the fields of pediatrics, veterinary medicine, pathology, toxicology, developmental biology, clinical pharmacology, epidemiology, biostatistics in reproductive epidemiology, biometry, and pharmacology.

But, the trial judge rejected the plaintiffs' proffered opinions of those eight experts in favor of the sole defendant's expert, who had summarized

all of the studies concerning whether Bendectin taken by pregnant mothers could cause birth defects in their children. The judge granted the defendant-manufacturer summary judgment, in essence in dismissing the case and did not allow the case to proceed to trial where a jury could evaluate all of the expert opinions. Clearly, under Federal Rule of Evidence §702, each expert was well qualified in their respective fields by education, training, skill, experience and knowledge. Yet, the trial judge found that their proposed testimony was insufficient to rebut the more than 30 studies that failed to find a causal link between the ingestion of Bendectin and birth defects in children.

Why were the plaintiffs' eight experts muzzled by the judge?

What the plaintiffs' experts presented was a recalculation of the data from some of the previous human epidemiological studies, which demonstrated no causal relationship. After the recalculation it should show a positive correlation between the drug and the cause of the birth defects. But those recalculations were never published or subjected to peer review. They also presented animal studies and pharmacological analysis to demonstrate that there was a statistically significant association between a component of Bendectin and birth defects. Others would testify that the chemical composition and physiological activity of a drug are important in ascertaining whether it is a teratogen, capable of causing birth defects. Because the plaintiffs did not present any contrary epidemiological evidence to counter the published studies in the field, the court rejected the plaintiffs' contention.

The *Daubert* case was ultimately appealed to the U.S. Supreme Court.[1] The Supreme Court outlined that judges as the gatekeepers of evidence should consider some or all of the following flexible factors to determine: (1) whether proposed expert testimony or evidence was tested or capable of being tested or refuted; (2) whether there was a margin of error; (3) whether the evidence was ever published and subjected to peer review; and, (4) whether the evidence or theory was generally accepted in the discipline to which it belongs. While scientists distinguish validity – does the principle support what it purports to show? – from reliability – does application of the principle produce consistent results – in law where a case involves "scientific evidence," the evidentiary reliability will be based upon scientific validity. Moreover, it must be relevant to the case presented. That is, the evidence or theory fits the facts of the case at hand.

The Supreme Court established or reasserted a judge's role as a gatekeeper of evidence, especially evidence concerning science, technology, and other specialized knowledge; it did not give the trial judges a definitive framework or checklist of factors to consider before admitting such evidence into a trial to be scrutinized by a jury.

The trial judge is confronted with a "go" or "no go" determination as to whether the proffered expert testimony or evidence is scientifically valid. That is, that it followed established scientific or technical methods and procedures to arrive at a conclusion that is relevant to issues of the case before the court. There is no middle ground – the evidence is either admissible, that is sufficiently reliable to go before the jury or inadmissible and will not go before the jury. Such decisions are not just another evidentiary ruling. Most decisions concerning the admissibility of scientific evidence are dispositive of the entire case. Therefore, judges need guidance in determining whether to go or not go with scientific evidence before a jury.

This presentation will provide several considerations for judges and attorneys to consider when scrutinizing scientific studies or reports. Since this is a time consuming endeavor for any judge, studies and reports asked to be admitted or adopted as the basis to support an expert opinion ought be presented and scrutinized well in advance of a hearing or trial with time allowed for opposing studies and reports to be submitted by the opposing side.

Screening Studies, Expert Witness Reports, Admissibility

E9 The Exclusion of Forensic Identification Science Evidence Since *Daubert vs. Merrell Dow Pharmaceuticals, Incorporated*

Mark Page, BDSc, DipCl, University of Newcastle, Department of Oral Health, Ourimbah, New South Wales, AUSTRALIA; and Jane Taylor, PhD, and Matt Blenkin, MDSc, University of Newcastle, Ourimbah, AUSTRALIA*

After attending this presentation, attendees will be able to describe incidences and patterns of judicial reasoning in cases where forensic science evidence has been excluded since the decision in *Daubert v. Merrell Dow Pharmaceuticals, Inc.*

This presentation will impact the forensic science community by presenting how analysis of judicial reasoning for exclusion of forensic evidence reveals that pure deference to the *Daubert* factors is not the primary means by which to avoid potential exclusion of forensic science evidence in court. Judicial reasoning in decisions to exclude forensic identification science can be categorized in such a way as to be of relevance to forensic scientists as they conduct their analysis and present their evidence. These criteria for exclusion, derived from case law examples, are explained to participants so that they may take heed from other forensic scientists' experiences and avoid exclusion of their evidence in court.

The 1993 United States Supreme Court decision in *Daubert v. Merrell Dow Pharmaceuticals, Inc.* transformed the way scientific expert evidence was reviewed in courts across the United States. Five hundred fourty eight judicial opinions were analyzed from cases involving a challenge to forensic identification evidence since the *Daubert* decision in order to gauge its impact on the admission of such testimony. Eighty-one (15%) of these cases resulted in exclusion or limitation of evidence. These eighty-one cases were then coded according to the reasons given for exclusion or limitation. Relevancy issues accounted for exclusion of evidence in fifteen of these cases (19%); and, the witness was deemed not qualified as an expert in a further in sixteen (20.3%). A failure to meet the state or federal requirements for reliability was cited in fifty of the eighty-one cases (65.7%), mainly due to lack of an underpinning scientific foundation (twenty-seven cases), and inappropriate or unsupported witness conclusions (seventeen cases). Further analysis revealed that forensic odontology was the discipline most likely to be excluded due to reliability issues (100% of excluded odontology cases), followed by handwriting analysis (72%), fingerprint analysis (58.3%), and firearm and tool mark analysis (52.8%). The greater incidence of exclusion or limitation due to a lack of demonstrable reliability compared to other reasons suggests that there is a continuing need for the forensic sciences to pursue basic research validating their underlying theories and techniques of identification in order to ensure their continued acceptance by the courts.

Following a statistical analysis of these cases, those in which forensic science evidence was excluded were analyzed qualitatively in an attempt to discern patterns in judicial reasoning. The results reveal that exclusion of forensic science evidence is not simply based on superficial application of the *Daubert* indicia to the evidence in question. The use of unfounded statistics, a failure to address the reliability of the evidence as it relates to the case at bar, an inability to clearly explain the methodology behind analysis, and the failure to adhere to recognized standards have all been fatal to the admission of forensic science evidence in the United States since 1993. In addition, the existence of observer bias, unrealistic proficiency testing, a lack of objective standards, custom experiments and implausible error rates have also contributed to decisions to exclude fingerprint, firearm and tool mark, odontology and handwriting evidence. A reliance on general acceptance alone has also been cited by several cases as reasons for rejection. None of these reasons for exclusion can successfully be addressed by the legal community. It falls to the researchers and practitioners in forensic science to discern ways in which to overcome these shortcomings.

Forensic Science, *Daubert*, Law

E10 Bringing the Complex Crime Scene Into the Courtroom: Using Animation and Still Illustrations to Simplify Testimony in Criminal and Civil Litigation

Rod Englert, BS, Englert Forensic Consultants, PO Box 605, West Linn, OR 97068*

After attending this presentation, attendees will understand the use of moving diagrams and still illustrations in the courtroom.

This presentation will impact the forensic science community by showing how a complex crime scene can be explained meaningfully to jurors through the use of demonstrative aids in the form of moving diagrams and still illustrations.

Drawings (illustrations) in cave dwellings date back to historic periods and have demonstrated many sequential events to help the observer understand the occurrence(s). These illustrations have provided us insight into the ancient world, the Renaissance period, and into the Twenty-First Century where illustrations have been animated beyond cartoonish figures into realistic people and places. The use of moving diagrams (animation) and illustrations (art) is not that common, but is becoming more so, and is highly dependent upon the accuracy of the event to be explained.

Demonstrative aides (moving diagrams/illustrative art) in jury trials are, by their very nature, a method to help juries understand what occurred during an event, be it criminal or civil.

Sometimes the event involves multiple parties or actions and necessitates more of an explanation of the facts beyond what photographs, physical evidence, charts or graphs can do. Development of animation and illustrations help the expert witness better explain the case to the triers of fact.

This presentation will show how to go about reconstruction of several officer-involved shootings and a homicide. Because of the complexity of the events, moving diagrams (animation) of each scene are digitally created representing what actually occurred. The re-creation is based upon facts from reports, photos, and detailed documentation from each scene. The accuracy of the animation/illustration is important to withstand the scrutiny of opposition motions to suppress.

The cases used as examples can be used in a variety of expert disciplines to simplify what may sound complex if only verbally presented from the witness stand. Some of the examples are in real time, accomplished by time clocks on the viewer's screen and with voice transmissions built into the diagram, such as radio calls to dispatchers. Examples involving airplane disasters, motor vehicle collisions, industry accidents, and miscellaneous cases will be shown where both illustrations and moving diagrams are used.

Some of the examples have animated figures built into the actual scene photographs of buildings, vehicles, blood patterns, and physical evidence at the scene. Some walk the viewer through a living body.

Often, moving diagrams (animation) are not as valuable a tool as an artist's rendition and illustration of the event. Illustrations also involve the development of stills based upon measurements and facts for the visual re-creation. For example, the wound path of a bullet through the body on its destructive path through vital organs could best be described in one or several artistic poses in still frames.

When to use animation and/or illustrations, along with the cost of producing the rendition will be discussed. Some renditions become very expensive.

Additional areas to be covered will be suppression motions that are often encountered from opposing counsel. Also discussed will be what happens when both sides produce moving diagrams, both quite different from each other. When two moving diagrams are presented, the one likely to survive the court's scrutiny will be the one most accurately portrayed. There can be no guesswork in the final product.

Animated Scenes, Still Illustrations, Demonstrative Aids

E11 Casework Peer Review Evidence: Understanding What It Really Means and When Such Evidence Will Be Precluded

Andrew Sulner, JD, Forensic Document Examinations, LLC, 220 East 57th Street, Suite 200, New York, NY 10022*

After attending this presentation, the attendees will learn about the different types of casework peer reviews that occur within the various forensic disciplines and the standards that define the meaning of each type of case review. Attendees will learn about the legal basis for excluding peer review testimony by the actual reviewer.

This presentation will impact the forensic science community by providing forensic scientists with examples of the problems and challenges they can face when testifying in court about peer reviews of their own casework. All stakeholders in the administration of criminal or civil justice – experts, lawyers, and judges – will benefit from learning about expert testimony, casework, and peer reviews; how it is disingenuous and misleading; and when courts will preclude such testimony.

Expert witnesses from various forensic disciplines often testify that their casework is subjected to peer review, without ever describing the particulars of the so-called "peer review." Such testimony, generally elicited during direct examination, invariably conveys the impression that the testifying expert's casework is regularly scrutinized and verified by another expert, and that some other, non-testifying expert independently examined the same evidence and reached the same conclusion as the testifying expert in the case at hand. Most lawyers seek to challenge such testimony by establishing that the casework peer review was not conducted anonymously and that the reviewer was a "friendly" colleague or co-worker, often working in the very same laboratory unit or office.

However, in most instances, expert testimony about casework peer review is misleading because the so-called "peer review" did not consist of a thorough and complete re-examination of the evidence, and often comprised little more than a "spell check." Lawyers and trial judges frequently assume that the mere mention of the words "peer review" equates to a comprehensive, independent verification of a given opinion or conclusion. This presentation will clearly establish the fallacy of that assumption.

This presentation will examine expert testimony from actual cases to demonstrate instances of self-serving, disingenuous testimony about peer review(s) of casework that arise in criminal and civil cases. Although this presentation focuses on expert testimony concerning peer review of casework of forensic document examiners, the information disclosed in this presentation applies to many other forensic disciplines.

The ASCLD-LAB standard for performing case reviews, as well as a proposed standard for conducting case reviews that was drafted by the Scientific Working Group on Documents (SWGDOC) and submitted for approval to ASTM, will be examined and analyzed. Attendees will become knowledgeable about the different types of "peer review" occurring within the forensic community and the true meaning of each type of case review. Attendees will also learn about the legal basis for excluding peer review testimony by the actual reviewer.

Peer Review, Case Review, Disingenuous Testimony

E12 Selecting and Verifying Experts

Gil Sapir, JD, PO Box 6950, Chicago, IL 60680; and Mark G. Giangrande, JD, DePaul College of Law, Vincent G. Rinn Law Library, 25 East Jackson Boulevard, 5th Floor, Chicago, IL 60604*

After attending this presentation, attendees will understand and recognize the use of available resources and strategies for locating and evaluating experts.

This presentation will impact the forensic science community by enabling interested persons to readily obtain background information and history of the expert witness.

Litigation periodically requires expert testimony to explain technical or scientific issues that are a substantive part of the case. Attorneys handling these types of cases will need to engage an expert or defend against one. The Supreme Court said in its *Daubert*[1] opinion that expert witness testimony is the most persuasive evidence. Experts, in some circumstances, are permitted to state opinions regarding the ultimate issue of case.

Expert testimony is regulated by Federal Rule Evidence 702 and state counterparts. Federal Rule of Civil Procedure 26 requires additional disclosures by attorneys regarding the experts they retain, including records of past contributions to literature, litigation performance, and other documentary evidence. The applications of these rules reveal information about experts to assist federal judges fulfill their gate keeping role as defined by *Daubert*. The same disclosures give attorneys a framework for discovery and litigation strategies.

There are numerous sources for locating expert witnesses. These include traditional print directories that list experts, commercial research services, such as Lexis and Westlaw, and various expert witness directory sites available through the Internet. Each source has different advantages and disadvantages. One factor that is common to all of them; however, is reputation.

Print directories from a reputable source, such as Martindale-Hubble, have a history and some editorial control over the listings. The disadvantage of print; however, is its information cannot be changed or updated until a new edition appears.

Lexis and Westlaw also perform some editorial control over expert listings in their database by licensing content from other commercial providers. The fact that both of these research services would license content from others, rather than create their own, implies that they would attach their high reputations for accuracy to these listings. Lexis, for example, licenses content from the Daubert Tracker, a respected Internet site for expert research.

Lexis and Westlaw have an additional research advantage through their leverage of extensive collections of case law and litigation documents, acting as a comprehensive source for research on individual experts. A researcher can search categorical material on expertise, locate resumes, access prior reports and other documents filed with courts. Additional analytical tools are available to evaluate an expert's performance. The disadvantage is that they require expensive subscriptions to access this content.

The internet has any number of expert directory sites. Many of them are businesses, which sell other legal services, such as continuing legal education materials. These sites often use expert directories as a draw to advertise other services to attorneys. As such, these sites tend to encourage individuals to list their services as a way of increasing the size of their roster, without offering any kind of oversight on qualifications. Too often attorneys only rely upon these listings or the person's resume to assess the expert's qualifications. Expert witness directories, or agencies, generally do not verify credentials and the background of the expert. Therefore, it is necessary for the reviewing attorney to conduct additional research using other information sources to confirm the listed expert's background and suitability. The selection and pretrial examination process must validate the expert witness' credentials, credibility, competency, and charisma.
