This presentation will offer strategies for selecting and evaluating experts. It will cover available sources of experts, including the Internet, commercial research services, and other sources. It will detail ways to explore and corroborate the background of potential experts, taking into consideration additional points such as an expert's personality, communication skills and ethical obligations. It will also take into account how to locate materials that document an expert's record. An expert's viewpoints on a technical subject are often available in his or her scholarship. This type of literature is usually the more difficult type of material to assemble compared to litigation documents. The presentation will offer strategies locating and acquiring copies of scholarship. The selection and verification of experts is integral to litigation and corresponding success or failure – it should not be minimized.

Experts, Credentials, Selection

E13 The Breath Alcohol Test: A Continued Call for the Pretest Observation Period

Jay Zager, HS, Jay Zager Forensic Consultant, 10638 NW 69th Street, Parkland, FL 33076*

After attending this presentation, attendees will understand the importance of pretest observation and deprivation period in forensic breath alcohol testing in driving under the influence (DUI) cases.

This presentation will impact the forensic science community by reinforcing the necessity of conducting a proper pretest observation period in breath alcohol DUI cases.

A pretest observation period is defined as a continual, uninterrupted period of 15 or 20 minutes during which a person suspected of DUI is observed by law enforcement personnel.[1] It is designed and intended to eliminate the possibility of introducing a contaminant into the breath sample before analysis.

Breath alcohol concentration (BrAC) testing is an indirect form of measuring the soluble gas exchange of alcohol between the blood and lungs relying on established partition ratios.[2] Alcohol is absorbed into smooth tissue between 10 to 12 minutes.[3] Therefore, a 15 to 20 minute uninterrupted deprivation and observation period is required to decrease possible contamination of the evidentiary BrAC test result.[4] Common sources of contamination include: chewing tobacco; smoking; vomit; mouth and breath fresheners; dentures; gum; wet belches; gastric reflux; regurgitation and residual alcohol in the throat; nasal cavity; and, mouth. If the pretest observation period is compromised, then the BrAC result is unreliable. "Although all aspects of the testing process are important in a Q.A. sense, the scientific safeguards are the most critical."[5] If the observation period is removed, then the test result's evidential or confirmatory attributes are compromised and reduced to those of a presumptive indication.

Contamination of the oral cavity prior to collection of breath alcohol specimens may cause false high or boosting BrAC results. Therefore, simple analytical safeguards are used to minimize sample collection contamination during the statutorily mandated pretest observation period. Law enforcement uses a portable breath alcohol test device (PBT) as a screening tool for roadside testing in DUI cases. It is commonly used as a screening device to inform law enforcement that alcohol like substances may, or may not, be in the test sample. A PBT test result is not a substitute for the pretest observation period or an evidentiary BrAC result. When the observation period is compromised, for any reason, reasonable doubt is created regarding the BrAC test result.

Law enforcement agencies frequently begin the observation period when the officer first comes into contact with the suspect and lasts until driving to a breath alcohol testing facility. Even though this may be a deprivation period, it is not a proper observation period. It is impossible for the officer to focus his attention during the entire time period on the DUI suspect. Any number of events, or acts, during this period may compromise the observation period and BrAC test result.

An improper pretest observation period creates a conflict between science, law and public policy. When the observation period has been compromised the government often endeavors to still justify the BrAC test result. Too often law enforcement, or the prosecution, attempts to minimize or abridge the pretest observation period by extolling the virtues of approved, technologically sophisticated, evidential breath testing equipment to minimize violations of the required observation period.[6,7]

There is a paradox between case law and forensic science. Legislators have changed *per se* legal intoxication levels downward from .15 to .10 to .08 g/210L, in an attempt to remove DUI violators. However, the basic laws of BrAC science testing, (e.g.) Henry's Law, Charles Law and Lambert-Beer's Law) are inviolate. Ergo, the paradox – public policy versus good science and equal justice.

Although modern evidential breath alcohol testing machines employ detectors to screen for potential interfering substances and mouth alcohol, they are not perfect. Violations of pretest observation period may cause false positive or boosting of BrAC results. The observation period was instituted to ensure these factors do not occur. Law enforcement must comply with all DUI procedures. Without the appropriate pre-test observation period and mouth alcohol detectors being effectively utilized, the reliability of BrAC results are suspect.

E14 Drug Recognition Experts are not Qualified to Testify as Experts and Should Only Testify as Fact Witnesses

David M. Benjamin, PhD, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918*

After attending this presentation, attendees will learn why Drug Recognition Experts (DREs) should testify only as fact witnesses and not as experts.

This presentation will impact the forensic science community by reviewing how the lack of scientific training and bias have allowed DREs to testify incorrectly about the effects of drugs in OUI-Drug cases.

Background: State prosecutors should be prosecuting meritorious cases and not oppressing or burdening citizens with cases that cannot be won in court. There is no way to meet your burden of proof in many cases, and large amounts of money and time are wasted in pursuit of "unwinnable cases."

Case Law: The prevailing case law regarding OUI-Drug cases and the use of so-called Drug Recognition Experts (DREs) has stated that DRE examinations are not scientific and that they are well within the ability of a juror to understand (see *Williams v. State of Florida*, 710 So. 2d.24 (1998)). If they are not scientific, then the testimony DREs offer cannot come in under FRE 702 as "expert testimony" but only under 701 as testimony from a fact witness. Moreover, a Drug Recognition Expert (DRE) who never examined the defendant at the time of the alleged infraction cannot be smuggled into court as an expert witness and, accordingly, should never get to testify in the prosecution's case.

DREs are employed as police officers and work in a para-military organizational structure. Their job descriptions state, "to support prosecution" not "to determine the truth." They are inherently biased. Their testimony is intrinsically unreliable. Unlike the defense witness, the DRE cannot tell the state's attorney that the data do not support the case because that would be insubordinate, and perhaps grounds for dismissal, despite the prospect for a subsequent civil suit for wrongful dismissal

An Example of an Unwinnable OUI-Prescription Drug Case: One such case involved defendant ED who was stopped for crossing a road line. When her toxicology report came back, it was found to have been positive for a small amount of butalbital, a barbiturate found in common anti-migraine medications.

Unfortunately, butalbital has a half-life of 1.5 – 3.5 days. Based on generally accepted pharmacokinetic principles, it takes 6-10 half-lives to rid the body of a drug. This means that she could have taken the drug more than a month before she was stopped and still had a positive urine test on the day she was stopped, even though its pharmacologic effects on migraine relief and impairment last only a few hours.

The commonwealth in that case, enlisted the assistance of a DRE who had not conducted an assessment of the defendant at the time of the police stop. The state planned to have the DRE testify at trial that the defendant had been impaired, an opinion that could not be supported by the urine test results, and one to which the DRE was not percipient, as she had never met or assessed the defendant.

It is important that defense attorneys educate themselves about the pharmacologic properties of butalbital, and to assist with the preparation of a motion to suppress the urine test result and either strike the DRE or significantly limit her proposed testimony.

On the day of the motion hearing, the commonwealth reconsidered its position and agreed to let the defendant off with probation.

To this day, it is not known why the defendant did not drive in an acceptable manner, but it is believed that it had nothing to do with her prior use of the migraine medication.

Drug Recognition Expert, Bias, Insufficient Scientific Training

E15 Understanding Latino Youth Gang Violence: From the Prison Yard to the Streets

Cliff Akiyama, MA, MPH, Philadelphia College of Osteopathy Medicine, Department of Forensic Medicine, 4170 City Avenue, Philadelphia, PA 19131-1694*

After attending this presentation, attendees will be able to explain the organization of Latino prison and street gangs. Understand and interpret common graffiti and tattoos. Discuss some of the recent gang enhancement laws including gang injunctions that several states have in place to help tackle the gang problem.

This presentation will impact the forensic science community by informing and educating attendees about youth gangs. Particularly Latino youth gangs in order to keep safe while investigating the deaths of these youths.

One cannot open the newspaper or watch the local news without hearing of another casualty of gang violence. Throughout the country in urban, suburban, and rural communities gang violence has reached epidemic proportions according to the Department of Justice, Office of Juvenile Justice and Delinquency Prevention. Furthermore, gangs have been identified in every single state, meaning that gangs are no longer a California problem. Nationwide there are 24,500 gangs with a gang membership of over 750,000, while the ethnic composition of these gangs include 47% Latino, 31% African American, 13% Caucasian, 7% Asian, and 2% Mixed. In particular, youth gang violence in the Latino community has had a dramatic increase in the last two years. In Los Angeles County, California alone, there are currently 650 documented Latino gangs with a gang membership of over 83,000. Demographics show a gang member average age of 15 with a range of 8-22 years. Other counties in California

and nationwide have seen increases in Latino gangs, especially in rural communities. The Mara Salvatrucha (MS 13) an El Salvadorian gang originating in the Pico-Union area of Los Angeles, California since 1983, has seen the largest increase in membership nationwide with over 60% in some states. Over 400 gang members out in the streets, jails, and juvenile halls in California and Pennsylvania were interviewed. This study identified eight distinct manifestations of gang violence and nine ethnic differences and similarities among Latino gangs i.e., definite cultural differences between Latino gangs and various other ethnic gangs; drugs; weaponry; killing over turf/territory; extortion; defacing property/graffiti; and, women in gangs).

This study found that Latino gangs are motivated by a state of mind driven by "La Raza" which translated means "for the race." It is important to note that La Raza is more of a cultural ideology than a gang related motto. Latino gangs are extremely territorial and unlike African American gangs where the individual is important, for Latino gangs it is the gang as a whole that is important and not the individual. To illustrate this point, when Latino gang members go to prison, they are run and controlled by one of two prison gangs depending on the geographic location of the prison: La Eme or Nuestra Familia. La Eme otherwise known as the Mexican Mafia is a prison gang originating in California and considered the leadership arm of all Latino gangs in Southern California. The letter "M" in Spanish is pronounced "eme" and is the 13th letter of the alphabet. Consequently, throughout Southern California, Latino gangs will often call themselves by the City or area that they represent, followed by the number "13" to indicate "La Eme" or "Southern" by giving respect to the Mexican Mafia. In Northern California, the Nuestra Familia which is translated to mean "our family" is the prison gang that controls every Latino gang north of Fresno, California and is often indicated by the number "14" representing the letter "N" for Nuestra and Northern. It is important to remember that Latino gangs are not just a California problem, although California is where these gangs originated. Rural, suburban, and urban communities across the nation are now seeing an increase in Latino gangs which mimic the California based Latino gangs, such as the MS 13.

In direct response to the increase in gangs, the state of California, North Carolina, Virginia, and Idaho have passed gang enhancement laws, which increase the penalty if an individual is found to have committed for the benefit, association, or direction of a criminal street gang a felony. Other states including California have also filed a civil injunction or "gang injunction" against specific gangs, whereby removing the leadership of the gang and disbanding its members.

The purpose of this paper is to present timely data on Latino youth gangs; offer strategies on how to recognize and interpret various tattoos and graffiti associated with these gangs, which could assist the medical examiner/coroner and death investigator in the positive identification of the decedent out in the field and/or in the autopsy room. This paper will also discuss some of the recent gang enhancement laws including civil injunctions that California, North Carolina, Virginia, and Idaho have in place to help tackle this deadly problem.

Youth Gangs, Gang Enhancement Laws, Tattoos

E16 Biological Evidence Storage and Disposition: A Discussion of Legal Implications and Trends

Shannan Williams, MPP, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; Rockne P. Harmon, JD*, Alameda, CA; and Rebecca Brown, MA*, Innocence Project, 100 Fifth Avenue, 3rd Floor, New York, NY 10011*

After attending this presentation, attendees will learn about the legal considerations and trends regarding biological evidence storage. Further, this presentation will provide an overview of Technical Working Group on the Preservation of Biological Evidence activities to date and preliminary recommendations.

This presentation will impact the forensic science community by bringing awareness to legal and policy issues in evidence storage and the solutions being proposed by the working group. Recent headlines have highlighted significant problems with the storage of potentially exculpatory biological evidence in property and evidence storage units across the country. Court orders for the location of evidence have demonstrated inadequacies in the packaging, storage, and tracking process of some evidence. Investigations into these inadequacies reveal underlying factors such as: capacity of the storage facility; laboratory backlog; materials available for packaging; geographic distance between the collecting and storage facility; and, the selected tracking system. While preserving and readily retrieving biological evidence from adjudicated and unsolved cases is a goal and has clear benefits for all members of the criminal justice system, the management of retaining and eventually disposing of biological evidence requires that each state and jurisdiction consider the relevant legal and policy issues.

In August of 2011, the National Institute of Justice (NIJ) and the National Institute of Standards and Technology's Law Enforcement Standards Office (OLES) convened the first meeting of the *Technical Working Group on the Preservation of Biological Evidence Preservation.* The primary objective of the working group is to establish best practices, based in science, to reduce the premature destruction and degradation of biological evidence, thus ensuring its availability for future analysis. A key dimension to the work of the group is the legal and legislative landscape of biological evidence retention. The purpose of this presentation is bring awareness to these issues and introduce the preliminary recommendations being proposed by the working group.

Most states have laws that provide guidance for the evidence disposition process but these laws vary widely. This process may include getting a court order, district attorney approval, notification of the law enforcement agency, or notification of the defendant/defense attorney or attorneys of record. Recent Supreme Court decisions including *Melendez-Diaz v. Massachusetts* and more recently *Bullcoming v. New Mexico* set out the importance chain of custody documentation and the importance of evaluating the integrity of evidence and the circumstances of testing. Creating the appropriate sanctions for evidence destroyed in violation of relevant policy and ensuring remedies for the wrongly convicted are also issues under consideration by the working group based on its analyses.

The group's key deliverables will include a report on legislative considerations, a handbook outlining best practices and standardized protocols for property and evidence clerks, a report discussing current technological trends and possible applications, and a web-based clearinghouse for biological evidence handlers in the property rooms, courts, and law enforcement agencies.

DNA, Evidence, Storage

E17 State Crime Laboratories — Open or Closed to Criminal Defense Attorneys?

Justin J. McShane, JD, The McShane Firm, LLC, 4807 Jonestown Road, Suite 148, Harrisburg, PA 17109; Richard O. Middlebrook, JD*, and Jeremy C. Brehmer, JD*, Law Office of Richard O. Middlebrook, APC, 5201 California Avenue, Suite 450, Bakersfield, CA 93309*

After attending this presentation, attendees will begin to appreciate the conflict between science-related decisions and policy-related administrative decisions made by a crime laboratory as to its desire to be transparent in its process and its data reporting.

This presentation will impact the forensic science community at large by providing a starting point for discussing and focusing the debate between those who are in favor of transparency and those who are not. The impact to the forensic science community is to provide data to sharpen and highlight this debate. To date, this is the first formal and systemic experiment that tests this apparent divergence of thoughts.

Interaction at previous AAFS meetings between criminal defense attorneys and forensic scientists employed by various state crime laboratories has led to collegial interactions that have suggested criminal defense attorneys would be welcome to visit such laboratories. Such visits would include interactions with the laboratory administration, bench analysts performing the forensic assays, photographs of instruments, examining procedures, and observing actual forensic specimens being processed.

The present study was designed to test the following hypothesis: State crime laboratories will permit criminal defense attorneys to visit individual laboratories, observe forensic specimen analyses, photograph pertinent laboratory equipment, have interactive sessions with employed forensic scientists, and access to standard operating procedures.

For evaluation of the hypothesis, a standardized letter was sent to heads of crime laboratories in all 50 states plus the District of Columbia. The letter identified requesters as criminal defense attorneys who practice DUI defense. The letter asked the following:

- Will you grant us a tour of your laboratory?
- Will you allow us to take pictures of your laboratory?
- Will you give to us a current uncontrolled copy of your policy, procedures and instructions used for blood ethanol analysis?
- Will you give us evidence of the validation of your assay and method? If not, why not?
- Will you grant us an interview (no more than 30 minutes) with your most proficient analyst who routinely performs blood alcohol analysis?

As in any questionnaire research, less than 100% response was observed. Findings suggest that there exists a gap between what bench forensic scientist perceive as openness to criminal defense attorneys and what the laboratory administrators are willing to permit.

Data collected included:

- Date the letter was sent;
- Date the letter was received (tracked by certified letter, return receipt requested with restricted delivery);
- The date of the response (if any);
- The nature of the response.

The follow through with any commitments the laboratory made as to the requests of one through five above.

The substantive responses to the above five requests and the actual fulfillment of any commitments that were made related to the five requests above were compiled. This data was collected and analyzed for the edification of the forensic science and legal defense communities and to enhance their spirit of cooperation. A fact-based, data-driven presentation that outlines the findings of the above will be presented. The underlying raw data will be available for attendees to review.

Transparency of Crime Laboratories, Administrative Control of Crime Laboratories, NAS Recommendation #4

E18 The Design and Analysis of Calibration Experiments and the Reporting of Prediction Errors

Robert J. Belloto, PhD, 2508 Queen Elizabeth Court, Beavercreek, OH 45431*

After attending this presentation, attendees gain an appreciation of the design and analysis of calibration experiments and how to construct an appropriate prediction interval of the result.

This presentation will impact the forensic science community by serving as an introduction to the importance of expressing not just a number, but an interval to explain the uncertainty in the experimental work and setting appropriately derived quality standards rather than choosing an arbitrary percentage agreement.

The design of calibration experiments is critical in deriving an estimate of the prediction error in reporting a drug analysis result. The reporting of only a single number gives the impression that the result has a negligible error when in fact the error is dependent on the design of the calibration experiment and the number of predictions to be made from the calibration curve. A high R-squared from the regression of the calibration curve is often misinterpreted as showing linearity and a correct model though neither is correct. Neither does a high R-squared imply that the regression model will be an accurate predictor. It is often forgotten that randomization is the basis for many statistical tests and this is also true with the design of a calibration experiment. Failure to randomize will confound instrument drift and other problems that may arise in the analysis of samples limiting the conclusions that can be drawn from the experiment. An analysis of the residuals is important since this can highlight problems such as instrument drift and outlying and influential points. Usually the instrument software will allow the calculation of the calibration curve and then use that information to print out the associated values from the samples. One should resist this since just because the software lets you do it, doesn't mean that is should be done. A thorough analysis of the regression equation should always be done and this means using appropriate statistical software and evaluating coefficients from a statistical standpoint and examining various residual plots. The calibration experiment is a model and thus an appropriate statistical analysis should be done to verify the model. Furthermore, since this experiment will be repeated at regular intervals, a control chart of the results should be produced and updated after every run and this will provide further insights into the quality of the work and the predictions.

Predicting the appropriate result is more complicated than doing a simple linear regression and allowing the software to report a number. The prediction error on the result depends upon the number of standards in the calibration curve and the number of samples being tested. Running samples in duplicate may or may not provide additional information since it depends upon how the samples were prepared in the first place. Splitting the sample into two gives the error of the machine, not the error on the sample. A complete analysis must have a well delineated standard operating procedure that clearly explains every step of sample preparation and analysis. The standard operating procedure should also define the mathematical and statistical model being tested with the appropriately validated statistical software to be used. Some analyzed examples will be presented using alcohol and ecstasy (MDMA) to show both what to do and what not to do.

Calibration, Prediction Error, Experimental Design

E19 ARMD and Dangerous: Adverse Reaction to Metal Debris, Metal on Metal Joint Replacements, and Present Toxicological and Legal Challenges

Karl G. Verebey, PhD, Ammon Analytical Laboratory, 1622 South Wood Avenue, Linden, NJ 07036; and Samuel L. Davis, JD*, 375 Cedar Lane, Teaneck, NJ 07666-3432*

After attending this presentation, attendees will learn about a newly identified complication of joint replacement surgery currently identified by a number of different and confusing names. The information gap on the toxicology of low levels of heavy metals will have short term and long term consequences for clinical medicine, public health, medical device innovation, and regulatory policy.

This presentation will impact the forensic science community making attendees aware of data that is currently lacking on the biological effects of long term low level heavy metal concentrations in the body. Legal, political, public health, and regulatory debates are filling this vacuum with polemics and speculation. It is recommended that attorneys in this medico-legal debate be mindful of the potential harm yet recognize the limits of

current knowledge. Clinicians and researchers should seize upon this opportunity to advance the state of knowledge and fill this vacuum.

Hypothesis or Proposition: Shedding of metal microparticulates from so-called metal-on-metal joint prostheses is a clinical phenomenon with potentially toxic consequences. Toxicologists must identify the biomedical significance of elevated levels of metals used in joint replacement surgery. Inconsistent naming conventions for the phenomenon are hampering clinical assessment of its import to patients, physicians, and regulators.

Synopsis of Content: Medical science has been experimenting with suitable materials for human joint replacement since 1891 when a German doctor tried to substitute ivory for the head of the femur in a hip joint. Since then, various mundane and ultra sophisticated materials have been tried and tested with varying degrees of success. Use of cobalt-chrome surfaces to replace both the hip and femoral sides of the ball and socket hip joint, so-called "metal-on-metal (MoM)", began in the 1950's and continues today with the application of harder alloys and precision surfacing equipment.

Yet friction forces that degrade the metal surfaces are inevitable. The tribology of friction, wear, and lubrication in these anatomical bearing surfaces dictate the toxicological potential of the bearing materials. Micro particulates and metallic ions migrate from the immediate joint space throughout the body and across the placental barrier. Blood and serum levels of cobalt and chromium that equal or exceed EPA and OSHA permissible exposure limits (PELs) are increasing in frequency. Certain devices using the MoM design are reported with higher than expected failure rates due to component loosening.

Toxicological screening now measures heavy metal levels in the low parts per billion ranges. The pathological significance of these findings is uncertain, but they have become an indication for costly and risky revision surgery in the absence of other signs or symptoms of prosthetic failure.

Local tissue toxic reactions are identifiable by gross visual inspection and characterized by frank tissue necrosis and cellular organization into pseudotumors. Variously names are used to link their pathological features to their identified cause: metallosis, adverse reaction to metal debris (ARMD), arthroplasty-related metal disease (ARMD), periprosthetic cobaltism, aseptic lymphocytic vasculitis- associated lesions (ALVAL), and others. No uniform set of diagnostic criteria has yet been devised.

The actual number of U.S. patients that have received or will have joint replacements with metal-on-metal joint couples is unknown. Medicolegal concerns about alleged design defects and inadequate warnings to patients and physicians have discouraged but not eliminated use of the metal-on-metal design. Public health policies recommending medical monitoring for affected patients will be valued in the millions of dollars.

Diverging, if not conflicting, regulatory pronouncements by the FDA and its European counterparts leave device manufacturers and their customers at a loss to decide what is or is not safe and effective. Political debate over a stricter or more lenient regulatory policy governing device approval reflects the contest between the free market and the public health. Litigation, rather than science, is now driving research into the toxicology of metallic ions widely disseminated throughout the human body.

General Statement of Conclusion: The science of toxicology needs to re-capture the initiative on the biological consequences of a body burden of metallic ions and microparticulates. Pending litigation that is seeking damages for short term and long term medical monitoring is based in part on extrapolation from existing industrial exposure investigations. Defining what are safe and unsafe heavy metal levels have tremendous economic and medical consequences for individual patients, health care providers, medical device innovators third party benefit payors, and litigants.

Metal-on-Metal, Joint Replacement, Cobalt Poisoning

E20 No Hit Left Behind: Getting the Most Out of CODIS

Melissa Mourges, JD, and Martha Bashford, JD*, District Attorney's Office, New York County, One Hogan Place, New York, NY 10013; and Noelle J. Umback, PhD*, Office of the Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016*

After attending this presentation, attendees will understand how use of a NYC-developed email system for the distribution of information about combined DNA idex system (CODIS) hits can prevent match information from falling through the cracks.

This presentation will impact the forensic science community by illustrating deficiencies in most notification systems, where only police agencies get notified of a CODIS match, and where many DNA matches are not acted upon.

Many CODIS matches occur months or even years after the crime scene samples are uploaded into the forensic index. Many public labs routinely send notifications of these matches back to the police officer or detective who originally submitted the evidence. Unfortunately, detectives retire or get transferred, and often the notification sits in a fax machine, tossed into the "circular file" or thrown unread into the original case folder, never to be seen again. Many matches are therefore not acted upon. This creates several serious problems. One is that perpetrators who should be charged with crimes remain free to commit new ones. Second, some CODIS matches serve to exonerate the convicted. Third, in some states, legislators who learn that hits remain uninvestigated are reluctant to budget money for DNA labs or to expand DNA databanks.

To battle this problem, the mayor's Criminal Justice Coordinator in New York City decided to develop a notification system that would accomplish several tasks: notify police and prosecutors simultaneously of DNA matches; eliminate the use of fax machines that could malfunction; and create a system where all stakeholders could view and update information. The result is "DNA Hits", an email system that notifies police and prosecutors simultaneously of DNA matches that occur in the local, state, and national CODIS database. The system, which went online in 2006, also has a "create reports" function to make statistics readily accessible. This is vital in tracking outcomes for policymakers and for grant purposes.

Observe a "real time" notification, which comes in via email to participants' smart phones. The actual information about the match is on a secure database where police agencies, prosecutors, and the OCME all have access. On the opening screen, the database provides the following information: lab case number, convicted offender swab ID number, victim's name, date of crime, police report and precinct number, evidence type, perpetrator name, criminal ID number, and whether he was a named suspect at the time of testing. Any particular "hit" can be opened to reveal the name of the criminalist, contact information in the case of out of state hits, and whatever additional updates prosecutors or police may add. Simultaneous notifications greatly reduce the chance that a DNA match will fall through the cracks and ensures public safety.

CODIS, Matches, Simultaneous Notification

E21 Uncertainty Analysis in Forensic Practice: How to Apply It Wherever Scientific Integrity Demands Its Use

Thomas L. Bohan, PhD, JD, MTC Forensics, 54 Pleasant Avenue, Peaks Island, ME 04108; and Ted W. Vosk, JD*, 8105 Northeast 140th Place, Bothell, WA 98011*

The goal of this presentation is to educate forensic practitioners who have not yet introduced uncertainty analysis into their work and to hone the skills of those who have.

This presentation will impact the forensic science community by providing a general understanding of uncertainty/error analysis, enhancing their ability to quantitatively assess the reliability of forensic evidence, and to knowledgeably demand such assessments in evidence presented by others.

"In science, the word *error* does not carry the usual connotations of the terms *mistake* or *blunder*. Error in a scientific measurement means the inevitable uncertainty that attends all measurements. As such, errors are not mistakes; you cannot eliminate them by being very careful. The best you can hope to do is to ensure that errors are as small as reasonably possible and to have a reliable estimate of how large they are."[1]

Those in the general scientific and engineering communities are astonished when they hear some forensic practitioners claim: "I don't know what error analysis is; I cannot find its definition" or "There are so *many* definitions of error analysis, it cannot have any significance" or "There is no need to use numbers in describing reliability." The fact is that the presentation of the results of a key measurement without a quantitative characterization of its uncertainty is non-scientific, that is to say, meaningless.[2] Now that the courts are increasingly recognizing this truth,[3] all forensic and legal practitioners need to develop a facility understanding of and a facility with uncertainty/error analysis—especially in the wake of the 2009 National Academy of Sciences Report on forensic science. The effort here is directed at facilitating that development, starting and ending with the defusing of a number of mistaken concerns about applying uncertainty/error analysis in the forensic context.

The existence of varying definitions for uncertainty/error is to be expected. As with most important concepts, scientific and otherwise, the definition of uncertainty/error varies with the context in which it is applied. Indeed, different definitions can be used within the same context, as will be described below. The important point is not this variety but rather that one be aware of the specific definition being used at a particular time. A statement of the uncertainty/error in one's results is incomplete without a statement of the method you used for estimating the uncertainty/error.

One often hears concern that once error/uncertainty analysis is universally required in the forensic setting, the practitioner will have to carry it out for every measurement made, no matter how mundane or preliminary. This concern is misplaced, as the results requiring a statement of uncertainty/error are those going to the determinations to be made by a trier-of-fact. Those results can be divided into two broad categories: quantitative and qualitative.

- Quantitative results include such things as the blood-alcohol concentration (BAC), the speed of a car involved in a crash, the time elapsed between time of death and the discovery of a corpse, etc.;
- Qualitative results include such things as the match/no-match determinations encountered in signature, fingerprint and DNA analysis.

Uncertainty/error analysis in the first category is the more amenable to short definitions; however, even here one must take care to ensure that the meaning of a statement is understood. For example, what does the statement "the defendant's BAC was measured to be 0.12±0.02 g/100ml" mean? When dealing with the statement of uncertainty/error, that is, the number following the ±, the wise person will withhold judgment until its definition is revealed. Is this a maximum range outside of which one would not expect the "true" value to fall? Or does it refer to a more rigorously determined range within which the "true" value is expected to fall with a given probability? The answers to these questions will lead to the most important question of all: How was the uncertainty/error determined? Forensic scientists and attorneys must know and understand these issues in order for the results of forensic measurements to be competently presented to the parties to litigation and the ultimate triers of fact.

In the DUI/OUI field, it is common to be presented with a result such as 0.12 g/100ml, with no characterization at all of the number's uncertainty/error. This is an indefensible practice from a scientific perspective, which should be the forensic perspective. The party adverse to the one presenting it is on firm ground in making a motion *in limine* to exclude any statement about this number until its reliability has been revealed through a statement of uncertainty/error.

The determination of the uncertainty/error of a BAC result is relatively simple compared to doing so for the speed of a car involved in a crash, often a key number in criminal prosecutions for vehicular homicide. In general, the ultimate number testified to involves a several independent measurements, each of which carries a its own range of uncertainty/error. Once one has all the individual values for uncertainty/error, there are a number of methods for combining those values so as to determin the uncertainty/error of the final result. The most comprehensive and appealing, but one which most attorneys shy away from identifying by name in court, is the Monte Carlo approach. We will discuss this method as well as two simpler ones, one of which is acceptable and one of which should be attacked when it is introduced. Fortunately or unfortunately, it is the latter that seems to come up most often in court.

When dealing with qualitative tests, such as signature, fingerprint or DNA analysis, the result itself is often of the nature match/no-match, with the ultimate conclusion of whether this implicates or excludes a particular suspect or defendant left to the trier of fact. When the *Daubert* court and its progeny wrote of "reliability" of a forensic result, it was referring to the likelihood that the result was what it purported to be. Thus, reliability of a qualitative statement is usually quantified by stating the probability that it is correct. Conversely, it can be stated in terms of the probability (which should be low) that the result shows a match where it should not ("false positive") or a non-match where it should show a match ("false negative"). How are such probabilities to be determined? To what do they relate? Should one distinguish between the uncertainty/error of the result, that is, the match/no-match, and the ultimate conclusion of association?

Pattern evidence, such as expert testimony that a fatal wound was made by a four-inch blade with a broken-off tip just like the blade found in the defendant's possession, is also to be considered. This evidence is proffered for its indirect role in identifying a perpetrator. The probability of a false positive in this instance necessarily requires at least two questions to be answered. What is the probability that the weapon's characterization is correct? If it is correct, what is the probability that the wound was made by the defendant's knife?

Finally, if the fact is considered that uncertainty/error analysis is never absolute and relies, to a large extent, on judgment and the use of prior measurements and information not necessarily obtained during the course of the forensic test in question. The fact is that one never has complete knowledge concerning anything, including the probability that a particular result deviates from physical reality. Contrary to arguments seeking to block legitimate attempts to characterize uncertainty/error, this state of affairs is precisely what requires such efforts. Rational inferences can be made only when our incomplete knowledge/information is adequately understood and characterized. To see this, reflect on the fact that to one assessing the survey of a particular parcel of land, it is useful to know whether Surveyor A or Surveyor B did the work, in light of the knowledge that Surveyor A has a record of doing very good work and Surveyor B a record of not-so-good work. Even though this knowledge of past events does not tell us with certainty that new work by A will be good or that new work by B will be poor, there are few people who would use that as an argument for not taking account of who did the surveying in question. Indeed, no rational person would do so.

E22 Global Gatekeeping?: A Comparative Analysis of the Judicial Process for Determining the Reliability of Proffered Expert Testimony

Donald E. Shelton, JD, PhD, PO Box 8645, 101 East Huron, Ann Arbor, MI 48107; and Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of Pennsylvania, Erie County Court House, 140 West 6th Street, Room 223, Erie, PA 16501*

After attending this presentation, attendees will have an international perspective on the admissibility of scientific evidence in courtrooms across the globe and will be able to compare and contrast the gatekeeping standards of their own jurisdictions with those in several other countries. Attendees will learn what factors judges in other jurisdictions consider when admitting expert scientific evidence.

This presentation will impact the forensic science community by showing how similar and dissimilar various jurisdictions are across the globe in admitting expert scientific evidence. Members of the forensic community across the globe will learn various types and kinds of factors which can be considered in evaluating whether scientific evidence should be admitted in their courts. The various forensic communities across the globe can learn from each other regarding how to better evaluate expert scientific evidence in order to have the most reliable and relevant scientific evidence enter our courtrooms regardless of the geographic location of the court and science. Science and Law should intersect at the same location or venue regardless of where or who is evaluating the expert scientific evidence in order to render justice—at the truth where reliable and relevant scientific evidence exist.

The American judicial system has developed specific processes to regulate the admissibility of forensic science evidence and has focused on the role of the trial judge as the gatekeeper for such evidence. It is useful to compare those processes and that trial judge role, with the approach of the judicial systems of other nations. This presentation presents some of that comparison.

Initially, this presentation describes the Unites States gatekeeping process as a base for comparison. The 1923 standard announced in *Frye v. United States*, 54 App. D.C. 46, 293 F. 1013 (1923), established a requirement that proffered scientific evidence must have received "general acceptance in the particular field in which it belongs." Some version of *Frye* is still the applicable law in several states. In 1993, the Supreme Court established the trial judge as the gatekeeper for scientific evidence and announced new tests for admissibility in *Daubert v. Merrell Dow Pharm., Inc.*, 509 U.S. 579 (1993). In addition to "general acceptance," *Daubert* requires judges to assess: (1) whether the underlying methodology is scientifically valid; (2) whether it can be and has been tested; (3) whether it has been subjected to peer review and publication; and, (4) whether there is a known or potential error rate. The *Daubert* standards apply to all federal courts and most State courts.

Recently, the role of forensic science has received considerable criticism. The National Research Council Report found serious deficiencies and called for major reforms. Post-conviction DNA testing has exonerated a number of persons who were convicted based on forensic science evidence. This debate over the reliability of forensic science evidence is also a currently active debate in a number of other countries.

In Canada, scientific evidence is also a topic of considerable concern. The Canadian system mostly parallels the U.S. process. While expert testimony is treated as a part of opinion evidence generally, Canadian courts have recognized the "gatekeeping" role of the trial judge. *R. v. Mohan* [1994] 2 S.C.R. 9. They have required evidentiary hearings that are similar to, and perhaps even more demanding, than a typical *Daubert* hearing. The Canadian evidentiary requirements of relevance and balanced probativeness are also similar. The reliability of proffered testimony appears to be decided on factors similar, but not identical, to *Daubert* tests. It appears however that the Canadian courts have, much like the United States, applied those standards less stringently to the prosecution than to the defense.

In England and Wales, the focus was traditionally on the experts rather than the science, although there is a stated requirement that the field of expertise must at least be "sufficiently well established to pass the ordinary tests of relevance and reliability;" *Dallagher* [2002] EWCA Crim 1903, [2003] 1 Cr App R 12 at [29]. Recently, highly publicized and the proposed closure of major forensic science facilities have spawned a movement to a system more resembling *Daubert*. The Law Commission, a government advisory organization, reported this year (2011) recommended statutory action that would require criteria similar to FRE 702, notably omitting however an analysis of error rate. The government appointed "Forensic Science Regulator" and the Forensic Science Society are also working toward the establishment of criteria for analytic procedures, testing and accreditation within the various disciplines.

In Australia expert testimony is regarded as a part of opinion evidence generally. The admission of opinion testimony is controlled by statutory rule, s79(1) of the *Evidence Act* 1995 (NSW). That rule has language strikingly similar to the Untied States rule and provides: "If a person has specialised knowledge based on the person's training, study or experience, the opinion rule does not apply to evidence of an opinion of that person that is wholly or substantially based on that knowledge." The expert must demonstrate to the satisfaction of the Court how the proffered opinion is based upon the training, study or experience and that such training, study, or experience permits the witness to provide an expert opinion (*Dasreef Pty Ltd. v. Hawchar* [2011] HCA 21).

Evidence, Admissibility, International Standards

E23 Australian Bloodstain Pattern Analysis (BPA) Training and Education: A Response to Judicial Scrutiny

Mark E. Reynolds, PhD, Western Australia Police, 2 Clayton Street, Midland, Perth, Western Australia 6152, AUSTRALIA*

After attending this presentation, attendees will understand the Australian education and training levels in place for forensic investigators of major crime who perform bloodstain pattern analysis (BPA) as part of their crime scene examination duties. The rationale and drivers for the training and education package's development will be explained as will the implementation process and the likely future educational direction for Australian BPA practitioners.

This presentation will impact the forensic science community by describing a robust and sustainable education and training model for BPA practitioners, the components of which lend themselves to generic adoption and implementation by most forensic disciplines.

Recent judicial rulings in Australia have clearly articulated the need for robust scientific education and training for those involved in the forensic investigation of major crime. In a system where detectives and pathologists are invited guests to a crime scene controlled by forensic investigators (usually sworn police officers), the need for elevated practitioner training and education standards has never been greater. Further, typically many of the pattern recognition disciplines have been the purvey of 'police officers' who culturally have had little pressure to justify any opinions or conclusions they have derived.

In 2006, under the umbrella of its National Institute of Forensic Science, Australia embarked on a three year journey that resulted in the development of four (4) levels of BPA training and education for its forensic investigators of major crime. Foundational to those levels are: demonstrated competence, continuing proficiency, discipline and practitioner succession planning, sustainability and most importantly, a strong scientific basis. As a reconstructive "crime event" tool, the forensic discipline of BPA necessitates a contextual and holistic investigative approach and as such introduces levels of complexity over and above a number of other forensic disciplines. Subsequently, practitioners require high levels of educational and experiential exposure in order to derive the maximum, but more importantly, reliable results from the discipline.

In late 2009, the following four (4) levels of training and education were universally adopted by law enforcement jurisdictions across Australia:

- BPA Awareness: An introductory training level for all forensic investigators of major crime
- BPA Level II: Equivalent to the Basic 40 Course designed to provide a scene technician level of competence but prevent the provision of expert opinion "reconstructive" evidence
- BPA Level III: An advanced level of training designed for the provision of expert opinion "reconstructive" evidence
- BPA Level IV: LIII Mentor and Senior Instructor

The advanced levels of training (Level III and IV) are based on a curriculum including exhaustive scene analysis and case work exposure, laboratory focused exhibit examination particularly surrounding fabrics and other textiles, hypothesis testing and reconstructive considerations and in a vision for the future, the inclusion of a fluid dynamics curriculum. The adoption of these levels is already assisting to crystallise the judicial acceptance of the forensic discipline of BPA and its practitioners within Australia. Furthermore, the levels have been suggested as a demonstrative model that could be adopted by a number of forensic disciplines such as tyre and shoe outsole identification and forensic investigation of firearm related matters.

BPA, Education, Training

E24 Virtopsy®: Its Associated Legal Parameters and Impact

David A. Zimmermann, LLM, Bern Graduate School of Criminal Justice at the University of Bern, Schanzeneckstrasse 1, Bern 3001, SWITZERLAND; and Noel W.F. Woodford, MBBS, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Victoria 3006, AUSTRALIA*

After attending this presentation, attendees will receive an overview about the legal implications of Virtopsy® and postmortem computed tomography (pmCT) or magnetic resonance imaging (pmMR) in Australian, Swiss, and U.S. American legislation.

This presentation will impact the forensic science community by emphasizing the necessity to legally qualify that state-of-the-art procedure in forensic medicine and serving as its (worldwide) legal approach.

The Virtopsy® project was launched at the Institute of Forensic Medicine in Bern, Switzerland, more than ten years ago with the goal of replacing or supplementing traditional forensic autopsy examination techniques with a multi-modality approach comprising three dimensional photogrammetry-based optical body surface scanning (3D surface scan), pmCT, pmMR, pmCT-guided angiography, and targeted tissue sampling by pmCT-guided biopsy. Virtopsy® is used to document cases of sudden or unexpected death of (unknown cause) or unnatural deaths (homicides, suicides, accidents, medical malpractice) and identification of bodies. Since that time pmCT scanning (and in some centers pmMR) has been incrementally introduced in many forensic death investigation facilities all over the world (e.g., Australia, Denmark, Germany, Japan, United States) and now assumes an important role in case management protocols. Both Virtopsy® and pmCT (or pmMR) scanning allow more sophisticated approaches to death investigation and in many cases may obviate the need for autopsy. Advantages of these imaging technologies include: the ability in some circumstances to determine a cause of death without dissection, visualization of body areas not easily examined at autopsy (e.g., pelvis and base of skull), safer examination of contaminated or infected bodies (e.g., tuberculosis), transmissibility of data for (second) opinions, a permanent digital record of the state of a body at the time of presentation, and 3D pictorial demonstrations of complex pathological processes for evidentiary/court purposes. CT, MRI, and 3D surface scan have also found application in the forensic medical setting of several institutes where they have been used to record and analyze injury patterns, examine areas of trauma (e.g., to the neck in cases of attempted strangulation) and digitally record crime scenes.

The introduction of novel imaging/diagnostic techniques into the time-honored and arguably conservative legal processes associated with forensic death investigation may have interesting and unanticipated consequences although literature on this particular area is sparse. Specific legislative provisions are also uncommon. While traditional court processes such as coronial hearings and criminal prosecutions are increasingly utilizing imaging data derived from Virtopsy® or similar technologies, in the English or German speaking world, no court decrees or published rulings relating specifically to forensic imaging have emerged to date.

This presentation will consider legal issues relating to the current practice of Virtopsy® and pmCT (or pmMR) in a comparative study of three jurisdictions (Australia, Switzerland, and United States), with specific reference to statutory interpretation in different fields of law including criminal procedure and coronial legislation. In conclusion, it will examine whether this new technology is satisfactorily accommodated by current law or whether amendments might be necessary. Thus, the legal issue whether Virtopsy® and pmCT/MR can be qualified as an inspection (external examination) – to triage if an autopsy should be done – or as an autopsy (adjunct) is an important part of that legal analysis.

Virtopsy®, Legal Bases, Australian, Swiss and U.S.-American Legislation

E25 Honor Killings in Turkey: Facts and Figures

Itir Erkan, MSc, Yeni Yuzyil University, Faculty of Health Sciences, Cevizlibag, Topkapi, Istanbul, TURKEY; Rakel Rozant, MA, Maltepe University, Institute of Social Sciences, Psychology Program, Istanbul, TURKEY; E. Hulya Yukseloglu, PhD, Istanbul University, Institute of Forensic Sciences, Cerrahpasa, Istanbul, TURKEY; S. Sebnem Ozcan, PhD, and Gavril Petridis, PhD, Yeni Yuzyil University, Faculty of Health Sciences, Cevizlibag, Topkapi, Istanbul, TURKEY; and Ersi Abaci-Kalfoglou, PhD, Yeni Yuzyil University, Faculty of Health Sciences, Yilanliayazma Cd., No 26 Cevizlibag, Istanbul, TURKEY*

After attending this presentation, attendees will be informed about the idea of honor killings and the way it is covered by the Turkish Law.

This presentation will impact the forensic science community by alerting attendees to this cultural phenomenon.

Many countries all over the world are experiencing honor killings for different reasons. Depending on the culture, the level of education, the environment, the living conditions, the written or simply verbal rules and the position of women in society, this issue is named differently. Honor killings are called "the passion killings," in Europe, whereas Asia and Africa call them "honor killings." Data in Turkey shows that between 2000 and 2006 there has been 1,091 honor killings. The reported reasons for honor killings are vendetta, family conflict, sexual harassment, prohibited intercourse, rape, and simply honor. According to the survey, the number of cases increases as education level decreases. Victims are not solely women and the number of male killed seems to be higher than those of

females. The age of the perpetrator ranges between 19-35 years. The highly populated cities of the country are more likely to host the killings, because the action generally does not take part in its origin but in a big city where the parties have migrated. Particularly inadequate housing facilities, lack of education, unemployment, and poverty are triggering factors. Honor killings vary from country to country. Nearly twenty women are murdered per year because of honor violations despite the opposition of the Royal Family in Jordan. Whereas in Lebanon, the murder of a person based on an honor issue may be saluted. In Europe the situation is somewhat different. The problem in Europe is seen much more in immigrant populations. Germany, Sweden, Italy, Denmark, France, Belgium, Great Britain, and the Netherlands have to face the honor killing issue in their immigrant populations. The reported number of the honor killings by the United Nations Population Fund is approximately 5,000 women victims per year. But it should be noted that a part of honor killings is disguised as suicide or accident which if included would elevate the actual number. Although the old Turkish penal code underestimated honor killings and envisaged a lower penalty in the new Turkish Penal Code, "honor killings" are considered as regular homicides and the perpetrators are sentenced to life in prison. As a result, the economic structure the level of development, the education/training programs and their application, the legal arrangements, the status of women's rights and women's awareness, the cooperation between institutions and organizations, and the media coverage are important factors affecting the issue.

Honor Killings, Woman's Rights, Turkey

E26 Facebook® and the Faceless: Authorship in an Electronic Society

Carole E. Chaski, PhD, Institute for Linguistic Evidence, ALIAS Technology, Limited Liability Company, 25100 Trinity Drive, Georgetown, DE 19947; and Alice B. Lustre, JD, California Department of Justice, 455 Golden Gate Avenue, Suite 11000, San Francisco, CA 94102-3658*

After attending this presentation, attendees will learn about the role of authorship issues involving blogs, emails, Facebook®, and other documents in both high profile and low press cases. Attendees will attain information regarding two different methods of language-based authorship identification forensic stylistics and computational linguistics. Attendees will also gain information on validation test results for these methods and the linguistic community's reaction to these methods since the *2011 Ceglia v. Zuberberg* Facebook-ownership case.

This presentation will impact the forensic science community by being able to accurately assess authorship identification methods by both the *Frye* and *Daubert* criteria, giving them an additional tool for handling electronic evidence.

For most of the general public, many attorneys and most crime laboratories, the term "forensic linguistics" is so unfamiliar that it evokes images of argumentative linguini or the speech of dead people. But anyone who has received an email from a Nigerian scam artist, a vixen selling herbal compounds, has read blog posts that scorch the computer screen, or has received digital applications to fill out over CAPTCHA boxes might also wonder about the reality of email addresses, screennames, and digital documents. Authorship in an electronic society provides pseudonymity, anonymity, and blithe shape-shifting.

Some recent high profile cases which have involved an authorship issue include the JonBenet Ramsey homicide, the 2004 precedent-setting case of *Cahill vs. Doe* (Shaeffer), the 2008 *Best Western International vs. John Doe* (Dial, Furber et. al.), settled for over $2M, and now the latest Facebook® suit, *Ceglia vs. Zuckerberg*. Cases which have little or no press, but are just as pressing for societal concerns and forensic science include, from 2011, the Masters homicide and the Isaacs custody-related trials which focused, in part, on a pseudonymous Facebook post.

There are currently two main methods for author identification: forensic stylistics and computational linguistics. Forensic stylistics has practitioners in the United States, Britain, Australia, and Spain. The computational linguistics approach has practitioners and researchers in the United States, Israel, Germany, France, Greece, Spain, and Ireland. These two methods differ radically in their procedures, data requirements, implementation tools, and most importantly, in the validation testing results. The differences between authorship identification in forensic stylistics and computational linguistics have been documented by Crystal[4], Chaski[2-6], Koppel and Schler[7], Nunberg[8] and now in relation to the latest Facebook® case, Zimmer[9,10] and Liberman[11,12]. In this presentaiton, we review these differences by references to the specific cases mentioned above will be reviewed, highlighting the core difference of validation testing. While computational linguists employ validation testing as a primary means of software and method development, forensic stylistics practitioners have never offered any test results or error rates.

The *Frye* standard of general acceptability has been subsumed by the *Daubert* criteria, not abandoned. The relevant scientific community for both authorship identification methods, forensic stylistics, and computational linguistics, is linguistics. Linguists who function independently of the forensic world and some linguists who do forensic work are not in agreement with forensic stylistics as a method or as a representation of linguistics. The forensic science community, including crime laboratories and the judicial system, should begin to pay heed to what linguists are saying about these methods. Attorneys are the key personnel for presenting the documentation reported to the judges and juries who face issues of authorship in an electronic society.

Authorship Identification, Computational Linguistic, *Frye* and *Daubert* Criteria

E27 International Child Abduction

Serdar S. Kelahmet, MBA, Cumhuriyet Meydani, Besim Yucel Ishani, Kat 1 Daire 1, Iskenderum, 31200, TURKEY; and Mete K. Gulmen, PhD, MD, Cukurova University, School of Medicine, Department of Forensic Medicine, Adana, 01330, TURKEY*

After attending this presentation, attendees will develop an awareness of the Hague Convention on the Civil Aspects of International Child Abduction. Attendees will also learn the importance of integrating the disciplines of law, forensic science, and child psychology when dealing with abduction cases, as well as the problems that can arise when dealing with cultural differences among signatory countries.

This presentation will impact the forensic science community by fostering awareness of the importance of international conventions that create a common language and deal with the humanitarian aspects of child abduction cases, in a way that fosters a child-centered system free from cultural bias.

In a world that reached seven billion people by mid-2011, nearly 2.9 billion, or 42% of the world's population are children up to 18 years-of-age. Not surprisingly, children are often exploited, and in some areas of the world, child labor, child soldiers, and child abductions are rampant.

In addition, ease of travel and communications has affected not only economic and business relations, but has led to an increase in international marriage, and its counterpoint, international divorce. Unfortunately, children sometimes become pawns in these struggles, and one parent, intent on causing pain to the other, may resolve a child custody dispute by kidnapping the child in question. When this happens, everyone suffers.

For parents, there is nothing more terrifying than losing a child in this fashion. Words cannot describe the torture the parent feels—is the child lost, hurt, hungry, afraid, or alone? Will the child ever come back? And the kidnapped child is suddenly isolated from all that is familiar, wrenched from home and thrust into an unknown world. Oftentimes, the child is told that the "left behind parent" no longer wants him, or even has died.

The kidnapped child can face serious psychological and emotional problems. These include anxiety, nightmares, sleep disorders, aggressive behaviors, and phobias as a direct result of being neglected and exploited.

The Hague Convention of the Civil Aspects of International Child Abduction of 1980 aims to create a legal solution to international custody disputes. Often, that results in an order returning the child to his "habitual residence" as being in the best interests of the child. Factors to be weighed include an objective viewing of the child's spiritual, psychological, and educational needs. Indeed, actions of a kidnapping parent who curtails a child's access to a loving "left behind parent" and cuts off his relations with other family and friends could be described as both physical and emotional negligence. Such children may respond to this family stress by exhibiting anti-social behavior and suffer a marked lack of self-confidence. The "habitual residence" analysis, aided by a combined psychological, legal and forensic approach, may help repair the damage inflicted by fractured international families.

Law, Child Abuse, Exploid and Neglect

E28 How Can the Question of Relevancy Ensure an Ethical Use of Forensic Science?

Durdica Hazard, MS, School of Criminal Justice, Ecole des Sciences Criminelles, UNIL-BCH, Lausanne, 1015, SWITZERLAND; Joelle Vuille, PhD*, University of Lausanne, Institute of Criminology Law, Internef, 323, Lausanne, 1015, SWITZERLAND; and Pierre A. Margot, PhD, School of Criminal Justice, Ecole des Sciences Criminelles, UNIL-BCH, Lausanne, 1015, SWITZERLAND*

Often cited, implicitly used, but not clearly defined, relevancy is a concept that may be understood differently depending on the legal structure and proceedings. The goal of this presentation is to define such a concept in the European forensic and legal communities, and what questions such a definition raises in terms of communication between scientific experts and lawyers, and in terms of right to a fair trial for a defendant.

This presentation will impact the forensic science community by raising its awareness to relevancy as a manifold concept that might be understood very differently by scientific experts and lawyers, and this discrepancy in definition can influence the course of a criminal proceeding.

The inquisitorial nature of the European criminal justice systems will be introduced in order to emphasize the importance of the role of the instructing magistrate in the evaluation of the forensic data used as evidence. After confronting the Anglo-American and European notions of relevance in the criminal investigation context, the importance of the concept will be outlined. It will be argued that relevancy from a legal standpoint is a rather vague concept in European criminal justice systems, leaving ample latitude to the investigating magistrate to determine which forensic information is relevant and which is not. Such a "laissez-faire" approach often results in an a priori evaluation of relevancy, which is hardly compatible with the scientific reasoning required by the forensic work and may, in the end, be prejudicial to the defendant.

It will be argued that the legal reasoning applied to a concrete case could be enhanced by the formalization of the concept of relevancy. To achieve this goal, one must go back to the investigative phase, the very beginning of the process, instead of considering only adjudication. Indeed, it is expected that a better understanding of the concept at an early stage of the criminal justice system will allow more relevant questions to be raised and will strengthen the interactions between the different stakeholders (forensic scientists and magistrates). In short, such an approach would produce more relevant clues from the forensic point of view and stronger evidence from the legal point of view.

To do so, it is necessary to go back to the notion of relevancy in science and specifically forensic science. The concept of relevancy represents one of the cornerstones of forensic science. This principle is understood as a key point between three entities: the trace, the clue, and the evidence, that are related within a context. The relationship between these entities will be discussed, and it will be argued that each is specific to a particular step of the forensic reasoning process. They all share a common aspect: they exist within a context specific to a case investigated, and this is aimed finally to insure that the right to a fair trial is safeguarded.

Confronting the legal and forensic definitions of relevancy would, eventually, allow a better definition of the expectations and needs of the instructing magistrate in terms of forensic information. This attempt to formalize such a manifold concept is aimed at showing that focusing on the initial phase of the process will help strengthening the information provided and, thus, the principle of equality of arms. Indeed, the concept of relevancy, if taken from a scientific point of view, is independent of the legal systems, whether European or Anglo-American will be shown. This principle is considered universal and should be considered as a scientific "guardrail" which guarantees an ethical use of forensic information by the justice systems.

Forensic, Legal, Relevancy Concept

E29 Paul Gregory House: Death Penalty Exoneration in Tennessee Through the "Gateway to Innocence" Concept

Linda K. Baden, JD, Law Office of Linda Kenney Baden, 15 West 53rd Street, Apartment 18 B/C, New York, NY 10019*

The goal of this presentation is to provide attorneys with information on how to proceed once a new trial is granted subsequent to a murder or other major felony conviction in order to obtain a dismissal before retrial.

This presentation will impact the forensic science community by providing attendees an avenue to shepherd a case where a defendant may

be innocent and understand the legal procedures and pitfalls in such a case. The presentation will also enhance knowledge about the expert testimony and investigative domains needed in order to properly prepare such a case for both the appellate court and retrial. In 2006, the United States Supreme Court in *House v. Bell*, 547 U.S. 518 (2006) reversed the conviction of Paul Gregory House and remanded to the State Court for a new trial in a case where House had previously been convicted of a death penalty murder and was awaiting execution. Unlike most actual innocence cases, the opinion by Justice Anthony Kennedy in a 5-4 decision, ruled that DNA testing and other investigation may give a defendant the right to argue to a jury that he is innocent even if the DNA did not prove actual innocence. The House decision was unique in two ways: (1) it enveloped the concept of "gateway to innocence"; and, (2) it allowed House to proceed on his claims even though the State Court had previously procedurally rejected him.

In 2009, the Tennessee State Court dismissed the murder indictment against Paul Gregory House. Mr. House had been on death row since 1986 for the brutal murder and alleged attempted rape involving a neighbor, Carolyn Muncey. Mr. House appealed from this conviction and had been rejected by courts for years. DNA testing had been blocked through procedural barriers; however, as a result of the efforts of the Federal Public Defender's Office through a *habeas corpus* petition, House was finally able to obtain DNA testing and also argued through investigation that the evidence presented at the first trial was improper. Even though DNA testing seemed to indicate that House was not the murderer due to the fact that a rape had never been consummated, the Supreme Court was presented with the issues as to whether DNA testing on the clothing of the victim, which could be argued to support the fact that House was innocent, could be cause for reversal of a death penalty conviction and retrial. As a result of additional investigative leads pointing to a third party, Justice Kennedy in a landmark decision sent the case back for retrial in an Opinion of the United States Supreme Court in 2006, *House v. Bell, 547 U.S. 518 (2006)*.

While the federal public defender had been charged with handling the investigation up to the United States Supreme Court decision, the local public defender's office was charged with continuing House's legal representation, the additional testing of forensic evidence, and preparation of the case for retrial. With the aid of additional organizations who assist wrongfully convicted defendants, along with forensic experts and attorneys who donated their time on *a pro bono* basis, the case was prepared for retrial. This resulted in the unique marriage of a branch of the Tennessee Public Defender's Office and the legal *pro bono* assistance. Additional investigative interviews were conducted, additional DNA testing was performed, additional review of the evidence was undertaken, additional unfettered review of the evidence was permitted by all branches of law enforcement, and the Tennessee Court allowed the involvement of all out of state experts and attorneys.

Through the avenues set out in the Supreme Court opinion and the efforts that continued from 2006 through the date given for retrial in 2009, on the eve of retrial, the charges against Paul Gregory House were dismissed. This presentation will discuss the legal parameters that attorneys and experts should be aware of when handling such cases and the actual step-by-step footprints that need to be performed when representing a client in a wrongful conviction case.

Wrongful Conviction, Gateway to Innocence, Paul Gregory House

E30 The Innocent Rapist: The Story of a Prosecution-Led Exoneration

Melissa Mourges, JD, and Martha Bashford, JD*, District Attorney's Office, New York County, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will understand how re-submitting a "negative" rape kit during backlog testing produced an "uploadable" DNA profile, which in turn led to an exoneration.

This presentation will impact the forensic science community by illustrating how a "negative" rape kit in a closed case yielded important results when it was swept up in a "fork lift" backlog testing project, and provides a road map for a fast and efficient prosecution-led exoneration when the results proved the wrong man was in prison.

On March 19, 1991, in upper Manhattan, a 15-year-old girl was attacked by a man who followed her into the elevator of her building, then dragged her onto the roof and brutally raped her at gunpoint. After reporting the crime and giving a detailed description of her assailant, the victim stayed with friends and did not return home for three months. On the date of her return, she saw Michael Mercer outside the building, recognized him as her attacker, and called for help. Neighbors held him for police.

The sexual assault evidence kit was tested, and the vaginal, oral, and anal swabs were negative for sperm. Even the slides retained by the hospital were tested, with the same results. While there was no forensic evidence to corroborate the victim's identification of Mercer, some details did match—the defendant admitted to being in the building on the date of the rape, visiting a friend who lived on the same floor the attacker pressed, and said he recognized the victim as a girl he rode with in the elevator. He also fit the detailed physical description given by the victim. Mercer was convicted after trial and sentenced to 20.5 to 41 years. From prison, Mercer repeatedly requested post-conviction DNA testing, but those requests were denied since the kit results were negative.

In 2003, his kit was part of the NYPD backlog project, which employed a "forklift" approach and tested every kit in storage, even those from closed cases. This time, one of the four swabs in the kit tested positive for sperm, a profile was developed and uploaded to CODIS, where it hit to Arthur Brown, a convicted rapist.

Prosecutors were notified of this "hit" on Wednesday, May 14, 2003. First, it was confirmed that the convicted offender samples from Mercer and Brown were collected in different prisons and developed on different days, so there was no possibility of mix-up. The victim was contacted, who had become a police officer, and determined Brown was not a consensual partner. A DNA swab was taken from her, tested, and confirmed that results were the same as initial testing. This proved the integrity of the kit and contents were intact and had not become comingled with other evidence over the years.

The victim was shown a photo array containing both Mercer and Brown and she identified Brown as her assailant. She recognized Brown immediately as the real rapist and also understood that she had misidentified Mercer. Prosecutors drafted a motion to dismiss and sent detectives to the prison in upstate New York where Mercer had spent 12 years. On Monday, May 19, 2003, he was brought into court and the charges against him dismissed. Five days from the date of the DNA match, Mercer was a free man.

Learn why initial testing was negative, the victim's reaction to her mistake, what the Manhattan DA's office did for Mercer, Mercer's reaction to events, what Arthur Brown had to say for himself, and why Mercer's court-appointed attorney was extremely happy.

Backlog, Exoneration, CODIS

E31 An Expert for the Court: Testimony in the Magdelana Dzubia Case

Mark E. Reynolds, PhD, Western Australia Police, 2 Clayton Street, Midland, Perth, Western Australia 6152, AUSTRALIA*

After attending this presentation, attendees will understand principles governing the role of the expert witness and the difficulties that can be encountered when attempting to fulfill the responsibilities to the judicial process that surround the role of an expert witness.

This presentation will impact the forensic science community by improving practitioner knowledge regarding the provision of expert opinion evidence.

Providing expert opinion evidence within a criminal trial can be a daunting and lonely experience. Often the testimony of an expert becomes

pivotal to the acceptance, or otherwise, of scenario(s) consistent with the guilt or innocence of an accused person and in many instances becomes the decision fulcrum used by the jury in coming to a determination. In this presentation, the forensic component of investigations surrounding a murder case to highlight the value of expert opinion evidence to the criminal trial process and demonstrate the overarching responsibility code those experts must apply to the judicial process, irrespective of party advocacy.

At about 9:00 a.m. on Wednesday, November 30, 2005, Magdelana Dzubia returned home from work to an improvised covert alarm positioned across her entry door with security locks on doors between her and her male housemate which had been rendered inoperable with the insertion of cardboard into components of the doors locking mechanisms. Within five minutes of entering the house she was set upon by her housemate who attempted to bind her with rope thus rendering her incapable of resistance and who then advised her that it was his intention to rape and then kill her. She managed to escape from the bindings, and in fighting for her life she subsequently killed her housemate by stabbing him in the chest with the very knife he intended to use upon her. At postmortem, the deceased housemate was found to have several incised and penetrating injuries to his chest and leg. Dzubia suffered a single superficial incised injury to her left index finger.

The assessment and analysis of the bloodstains and bloodstain patterns along with complementary DNA results from more than 60 of those bloodstains spoke of that fight, particularly when the results were schematically mapped to the floor and wall plans of the house. The physical evidence assessed during the course of investigations surrounding the death of the housemate, and in particular the bloodstains and bloodstain patterns, became vital to the issue of "acting in self defense" that was raised and argued at Dzubia's subsequent trial for murder.

The presentation of this case example, articulates an unlikely "event" scenario proffered by the prosecution and its subsequent attempts to mitigate the evidence of the state's own bloodstain pattern analysis (BPA) expert. A highlight of the trial was the cogent exposé of the bloodstain evidence by the defense team following extensive pre-trial dialogue with that same BPA witness. Following less than five hours of jury deliberation, Magdelana Dzubia was acquitted of murder on the grounds of self defense.

Expert, Evidence, Bloodstain

E32 Who Killed Ruby Jean Johnson? Unleashing the Power of Y-STRs

Melissa Mourges, JD, and Martha Bashford, JD*, Distric Attorney's Office, New York County, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will understand how, despite statistical limitations, the use of Y-STR DNA testing can identify the perpetrator in a rape/homicide case.

This presentation will impact the forensic science community by illustrating the development of Y-STR DNA testing by the New York City Office of Chief Medical Examiner's Forensic Biology lab and presenting its first use in a courtroom, leading to the conviction of Elbert Mitchell for the rape and murder of an 81-year-old woman.

On June 26, 1998, the home health aide for 81-year-old Ruby Jean Johnson was worried. She had been unable to enter Ms. Johnson's Harlem apartment for two days. Police climbed in through a fire-escape window and found Ms. Johnson's body. She was bent double over the bathtub, with a dog's leash wrapped around her neck and a fur coat draped over her body. Decomposition was well underway. Based on her state of undress and dried secretions on her thighs, police suspected she had been sexually assaulted. Although the apartment was cluttered with a lifetime's worth of stuff, police also believed the killer stole property.

A fingerprint in the bathroom led to suspect Elbert Mitchell, a convicted felon who claimed he often helped Ms. Johnson around the house. DNA testing was still pending when Mitchell was first questioned two weeks after the crime, and he vehemently denied harming Ms. Johnson, who he described as "like a mother" to him. He did offer up another suspect; however, a neighborhood man who did maintenance work around the building, and who was easily identified by police.

Meanwhile, serological testing was positive for semen on vaginal, anal, and oral swabs, as well as on the fur coat, but only the victim's DNA was detected through multiplex STR testing. Fearing that any male DNA was "masked" by the victim's female DNA, OCME scientists employed a "home brewed" Y-STR kit validated to attempt to identify male DNA on the crime scene evidence. The results were then compared with exemplars from both Elbert Mitchell and the maintenance man.

Prior to trial, defense attorneys made a motion for a *Frye* hearing to exclude the Y-STR results, claiming the science was novel and the statistics unproven. Prosecutors countered that the technology was exactly the same as traditional STR testing, and that statistics, reached through the "counting method," were the same as those used in mitochondrial DNA testing. The prosecution prevailed.

The presentation includes filmed interviews with participants in the case. The investigating detective, who teaches interview techniques to NYPD investigators, explains the secret of getting a suspect to talk. The relationship between strangulation and sexual assault will be explained. The early attempts at Y-STR testing, how results were achieved in this case will be described, as well as the future utility of Y-STRs. Mitchell's videotaped statements are presented, demonstrating his changing explanations as the unfolded evidence, ending with his claim that sex with the 81-year-old disabled victim was consensual. Finally, prosecutors explain how to prove time-of-death, theft of property, and forcible rape when the only witness to the crime is dead.

YSTRs, Homicide, Rape

E33 Disingenuous Testimony in the Forensic Toxicology Community

David M. Benjamin, PhD, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918*

After attending this presentation, attendees will be able to: (1) define disingenuous testimony; (2) summarize the forensic expert's duties under the testimonial oath; and, (3) recognize why laws on *per se* levels of drugs are oppressive.

This presentation will impact the forensic science community by providing examples of disingenuous expert testimony and prosecutorial misconduct and how it impacts all stakeholders in the administration of criminal justice.

Disingenuous is defined in the dictionary, as "lacking in candor; giving a false appearance of simple frankness." It resembles a lawyer's or police officer's use of subterfuge (claiming the existence of evidence that does not really exist). An appropriate definition of candor, from the same source is "freedom from prejudice or malice, i.e., fairness." When an expert witness testifies regarding his or her opinions about the significance of the scientific evidence, the rules of evidence provide a framework to ensure that such testimony is relevant and reliable. Matters not covered by the rules of evidence may be addressed by the case law or may be left up to the judge's discretion. According to FRE 702, the purpose of expert testimony is to help the jurors understand scientific matters that would typically be beyond their ken. Pursuant to FRE403, even relevant evidence may be suppressed or limited, when such evidence confuses the issues, misleads the jury or is substantially prejudicial.

The Oath: Before testifying, every witness takes the oath. The oath asks witnesses to testify to "the truth, the whole truth and nothing but the truth..." In breaking down these three portions of the oath, "the truth" means, the truth as opposed to a lie. "The whole truth" means, the whole truth as opposed to a half-truth. And, "nothing but the truth" instructs us not

to add or subtract any disingenuous statements that might cause the truth to be misperceived by the jury (Gutheil et al 2003). Not adulterating your testimony pursuant to FRE 403 is what you have sworn not to do, under the last part of the oath.

Why Laws Regarding *per se* Drug Levels Contradict Criminal Jurisprudence: In a Driving Under The Influence of Drugs (DUIDs) the prosecution's evidence of impairment usually consists of: an admission made by the driver, the appearance of the driver, and the way the driver performs standardized field sobriety tests (sFSTs). In an attempt to increase DUID enforcements, many states have taken to passing *per se* laws, developing numeric concentrations for drugs in the blood plasma, or urine above which a citizen is automatically assumed to be the DUID. In these instances, impairment does not have to be proven. The analogy is a *per se* level of 0.08% for blood alcohol. The scientific problems are: the blood levels of drugs and the onset and duration of impairment are not precisely related; people metabolize drugs at different rates casing blood levels to vary widely; people have individual sensitivities to drugs; people develop tolerance to drugs; urine concentrations do not correlate with current impairment; only prior ingestion; and, people produce anywhere from 1200 to 2500 ml of urine a day. Ultimately two identical twins could take the same 25 mg dose of diphenhydramine, if one drank an extra quart of fluid, that person's urine would be twice as dilute as his twin's, meaning that the other twin could be arrested for DUID, because his urine concentration was twice as high as his sibling, even though they both took the same dose. Inter-subject variability is so great that the error rate of offering an opinion is merely speculation and the degree of certainty less than reasonable certainty. If such a "zero tolerance" policy stands, many sober people will be prosecuted oppressively. Impairment must be proven beyond a reasonable doubt, not inferred merely from the presence of a drug.

Prosecutorial Misconduct: Recently, public attention was focused on the "Duke rape cases" where the prosecutor knew he was moving against innocent defendants, and also withheld exculpatory evidence to that fact from the defense, despite a duty to comply with the Brady Doctrine. That man has lost his license to practice law in North Carolina, and will always be remembered as the part of the horse that went over the fence last! The judiciary must take a harder look at prosecutorial misconduct and not permit oppressive prosecution to continue, under the guise of zealous representation. Perpetrating a fraud on the court, suborning perjury, and deliberately withholding exculpatory evidence are unethical and illegal, not zealous advocacy.

Drug Laws, Disingenuous Testimony, Prosecutorial Misconduct

E34 Ethical Implications for the Trial Judge Faced With Disingenuous Expert Testimony

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of Pensylvania, Erie County Court House, 140 West 6th Street, Room 223, Erie, PA 16501*

After attending this presentation, attendees will learn the ethical implications for the trial judge when encountering disingenuous testimony. Judicial sanctions may result from the judge having an ethical responsibility to report the lawyers and their experts providing disingenuous testimony. Case examples will be shared.

This presentation will impact the forensic science community by alerting forensic experts that trial judges are active gatekeepers of scientific evidence whether in a *Frye* or *Daubert* jurisdiction and must take action in the case at hand and report the lawyers and experts who provide disingenuous testimony when appearing before the court.

The United State judicial system relies on reliable and relevant expert testimony to reach the truth of the matter before the courts. In the United Sates, we have state trial court jurisdictions which vary as to whether a state trial court is a *Frye* or *Daubert* jurisdiction or some version of both. The gatekeeper function of the judge differs as to what admissibility standards exist for admitting scientific evidence which is relevant and reliable. Most experts provide valuable testimony and assistance to the courts with honesty and integrity; however, there are always exceptions unfortunately with experts who are disingenuous before the court. Disingenuous experts provide reports and testimony lacking in candor and by doing so give a false appearance of frankness in a calculating fashion. Lawyers have numerous ethical requirements with respect to the experts they bring before the court. State trial court judges in the United States have ethical responsibilities as evidenced in the Judicial Code of Ethics or Judicial Code of Conduct in each of their respective states. Each state has had the benefit of reviewing the American Bar Association's Model Code of Judicial Conduct and adopting a version of this model code with modifications tailored to the needs of their own state jurisdictions. Judicial ethical responsibilities include a disciplinary responsibility to report misconduct from the professional parties appearing before the court including lawyers and experts. Lawyers have a responsibility to ensure that the experts appearing before the court are properly credentialed and their reports do not include false testimony. If a lawyer discovers that an expert has falsified information or has been disingenuous, what duty, if any, does a lawyer have to disclose that new information to the tribunal he or she is appearing before? What is the duty, if any, to opposing counsel? What is the ethical duty of the judge to report lawyers who provide experts having disingenuous testimony? How does a judge handle this situation if the judge finds the expert is not properly qualified to render such a report but has been accepted as qualified for years by fellow judicial colleagues within the same jurisdiction? Examples of cases will be shared where these ethical dilemmas have appeared and how judges have approached these situations.

Judicial Expectations, Ethical Responsibilities, Expert Testimony

E35 The Impact of Gunshot Residue in Military Investigations and Legal Proceedings

Anthony M. Robinson, and David Shadoin*, United States Air Force Academy, 2304 Cadet Drive, USAF Academy, CO 80841; Candice Bridge, PhD, United States Army Criminal Investigation Laboratory, 4930 North 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will have a general understanding of how gunshot residue (GSR) is used in military investigations and legal proceedings, the usefulness of gunshot residue evidence in criminal cases and suicide investigations, and an understanding of some of the caveats that come along with gunshot residue.

This presentation will impact the forensic science community by providing a solid foundation as to the use of gunshot residue in military investigations and trials, and providing a catalyst for more research in GSR analysis.

According to Michael Trimpe, from the *FBI Law Enforcement Bulletin* in 2011, gunshot residue (GSR), like most trace evidence, is not conclusive but supportive and circumstantial.[1] Supportive evidence can only take an investigation so far and the continuing controversy on the usefulness of GSR examinations brings about the debate of how important GSR examinations are to an investigation and/or legal proceedings. Garcia suggested in *The American Journal of Forensic Medicine and Pathology* in 2007 that the results of GSR examinations were crucial to medical examiners but very little has been done to show what it means to investigating agents.[2] Since the initiation of the Innocence Project, there have been several outcome studies that try to identify links and commonalities in criminal investigations/judicial proceedings in an effort to reduce the number of convicted innocent people.[3] Based on the effectiveness of these outcome studies and the circumstantial nature of GSR examination, it is necessary to determine the overall effect that these examinations have in the military system.

This retroactive outcome study started with 154 cases involving a gunshot residue kit that had been sent into the United States Army Criminal Investigation Laboratory (USACIL) since 2008. Cases were collected from all of the military branches. Of those, 68% of the cases were made up of

suicide investigations. The remaining 32% were criminal investigation that involved murders, assaults, and negligent discharge crimes. Even fewer of these ever make it to a judicial proceeding. The forensic information for each case was drawn from the laboratory information management system (LIMS). This information included GSR examination results, case synopses and other pertinent data (rank, location, weapon type, contact numbers). Once all the applicable data was obtained, investigators, defense, and trial counsel were questioned regarding cases that had GSR kits submitted for examination. The questions asked of the agents and attorneys were used to gauge the overall impact of gunshot residue in their investigations and legal proceedings. A rating scale was developed at the end of the study to group responses based on how they used the examination reports. This placed a quantitative value on qualitative data. Statistical data was also determined using a Chi-Square model including items such as interviews before and after the results were released and sentencing outcomes for criminal cases.

The conclusion drawn from the investigative study was broken into two categories: suicide investigations and criminal investigations. Using the rating scale developed from the responses of the investigators, it was inferred that GSR results in suicide investigations had minimal to no impact 84% of the time. The impact of gunshot residue in criminal investigations was contrary to suicide investigations. The results showed that 87% of criminal investigations were impacted in some manner from gunshot residue results. The GSR examination results came back inconclusive on 13% of cases in which the investigators stated there was no impact from gunshot residue.

Most of the attorneys that utilized GSR results in legal proceedings stated that it was a part of the package that was used to either get a conviction or exoneration. There were two cases where the attorneys stated they didn't even look at the results and a few others saying they looked but decided against using it. One attorney said that the results were a big piece in negotiating a plea agreement.

Based on the research thus far, the impact of gunshot residue in military investigations is still circumstantial. However, based on the trends identified in this study, gunshot residue has significantly more impact in criminal investigations than in suicide investigations. Analyzing the data for legal cases reveals that most of the attorneys would like to see more research into the subject or at the very least, see it continue to be used with better training provided to investigators on how to collect GSR kits leaving less room for error in analysis. A decision cannot be made based solely on this study due to the quantity of data collected, but the trend shows that it would be worth looking into the possibilities of making GSR exams more specific before determining if it is still needed.

Gunshot Residue, Military Investigation, Legal Proceedings

F1 Forensic Dental Analysis of Degraded, Fragmented, and Commingled Human Remains

Diana Aparicio, DDS, Servicio Medico Legal, Avenida La Paz 1012 Departamento de Tanatologia, I, Santiago, CHILE; and Soledad Martinez, MD, Servicio Médico Legal, Avenida La Paz N°1012, Independencia, Santiago, CHILE*

After attending this presentation, attendees will be able to recognize the morphological, anatomical and pathological criteria used in forensic dentistry and its application as an important tool in identifying commingled remains of skeletonized bodies in a mass grave intentionally disturbed

This presentation will impact the forensic science community by demostrating that an accurate forensic dental analysis of degraded, fragmented, and commingled human remains can be essential for individual identification even when premortem records are not available.

During the military regime in Chile, thousands of people were killed. In many cases they were caught and killed in groups and illegally buried in mass grave sites. After a period of five to ten years, when some of the graves were discovered, the militars carried out an operation to remove the bodies from the mass graves to make evidence disappear. At that time, bodies were skeletonized so they could not remove all the remains, leaving in place bone fragments, teeth and other small evidence. With democracy, judicial investigation of these cases started and the state forensic institution "Servicio Medico Legal" (SML) was called to perform exhumations of remains in different disturbed burial sites.

This particular case, involves a group of farmers killed in a creek and buried in a mass grave that was disturbed from remotion five years later. Despite this, the SML recovered from this site human bone fragments, dental remains, ballistic evidence, personal objects, and non-human skeletal remains, all commingled, incomplete, and degraded.

Forensic dentistry is a useful tool in human identification, which achieves its goal through the comparison of antemortem and postmortem information. The postmortem examination is affected in this case by the admixture of remains as well as postmortem teeth loss caused by the intentional relocation process. Additional difficulties derived from the long interim from burial to judicial exhumation (thirty years). Performing a thorough dental macroscopic study using morphological, anatomical, and pathological criteria, evidence was organized in skeletal and dental clusters, partially or completely reconstructing the dental arches and providing the minimum number of individuals present in the mass grave.

One hundred twenty seven human remains good for dental analysis were recovered: 111 (87%) consisted of isolated teeth (including crown fragments), 10 (8%) were mandibular fragments (four with *in situ* teeth), five (4%) were maxillary fragments (three with in situ teeth) and one consisted of a removable upper dental prosthesis. All specimens presented taphonomic erosion with the teeth being the least affected due to dental enamel resistance.

Odontological analysis classified 87 of 127 specimens into twenty-one groups obtaining two complete upper arches, one complete lower arch, two partial upper arches and one partial lower arches, and other smaller parts. This led to a minimum of nine individuals for the burial site, considering only the odontological point of view.

The lack of adequate antemortem dental records ruled out postmortem comparison for identification purposes, thus genetic testing appeared as the only possibility to get individual identities. Teeth from some of these 21 groups and eight ungrouped teeth were subjected to nuclear DNA sampling; one to three samples from each group were sent separately. A consistency up to 100% was obtained between odontological analysis and DNA testing: identical genetic profiles in all loci typed for teeth coming from the same group. The genetic testing results confirmed the odontological clusters and also provided other associations between upper and lower arcades and ungrouped teeth.

The dental analysis methodology and evidence organization allowed grouping and adequate selection of samples for genetic analysis that lead to successfull identification of individuals, preserving dental remains suitable to be returned individually to relatives and terminate the grieving process. Multidisciplinary approach integrating judicial information, forensic archaeology, forensic anthropology, forensic odontology, forensic pathology, and forensic genetic was essential for this goal.

Commingled, Odontology, Identification

F2 Digital Enhancement of Dental Radiographs to Facilitate Identifications

Richard M. Weledniger, DDS, 931 Walt Whitman Road, Melville, NY 11747-2297*

After attending this presentation, attendees will understand the difficulties that poor quality antemortem or postmortem dental radiographic images can make impeding victim identification and how readily available simple digital enhancement tools can reduce these challenges in the identification process.

This presentation will impact the forensic science community by giving an overview of image quality issues and the digital enhancement tools that are available to make acceptable and non-acceptable corrections to these images without affecting the evidentiary value of the image.

Whether it is a multiple fatality incident or single person identification, the use of dental radiographs as a tool for biometric comparison and identification is well documented. Dental features can withstand severe conditions and resist the degradation that affects other body tissues. Dental radiographs not only reveal dental restorations but tooth morphology, boney trabeculation patterns, root and crown morphology, tooth size, rotations, spacing between the teeth, and sinus patterns. As dental caries rates decrease, more odontological identification decisions will be based on inherent dental features.[1] Dental radiographs often suffer from poor image quality which can affect the identification process. Development of a stringent protocol of acceptable image enhancement techniques is essential for the forensic odontological community.

Acquisition of diagnostic images requires the use of either a flatbed/transparency adaptor digital scanner to digitize analog dental radiographs or a digital sensor to obtain images directly. Numerous issues exist that can be detrimental to image quality. Equipment issues such as exposure time, MA/KV, film age, film processing chemical quality, and/or the actual storage of the image or images can lead to poor image quality that can increase the challenges of the identification process. If working with analog radiographs, efforts should be made to acquire the original radiographs, as scanned second or third generation images of poor quality can impede the identification process.

By either rescanning analog x-rays with different scanning parameters or by incorporating the enhancement tools available for digital films, many of the difficulties for making identification can be overcome. Current forensic dental standards such as the ANSI/ADA Specification 1058 advocate scanning resolution sizes of 96 DPI for screen viewing, 150 DPI for lower resolution viewing and printing, 300-600 DPI for higher

resolution viewing and laser quality printing and greater then 600 DPI for photographic viewing and printing. [2] This presentation will demonstrate support of these settings as well as color/grey scale depths to aid the odontologist in the understanding of the relevancy of these guidelines. In addition, this presentation will show the effects of additional scanning software settings to show how they can also enhance an image at the time of scanning.

The ANSI/ADA Specification 1058 specifies that a radiographic image should be of sufficient quality to ensure that an enlargement of any section will not result in an unacceptable image.[1] In addition to image resolution, the type of file format used to store the image can also affect image quality. This presentation will expand on the types of file formats that meet the standards criteria while promote ease of data access through the use of standard interoperable file formats. [2]

Essentially, the enhancement of a dental radiograph is the process of producing an improved quality image out of a degraded quality input while preserving the evidentiary value of the radiograph.[2] Although the enhancement process improves the visibility of objects of interest and thereby increases an image's diagnostic yield, it is vital that it does not alter the image in an unacceptable manner to enhance artifacts to the level that they are considered an anatomical feature.

This presentation will show various images reflecting several of the image management tools such as: contrast and brightness, sharpness and clarification, inversion, colorization, relief, subtraction, stereo, and invert logic that can help assist the forensic odontologist in the identification process.

Dental Radiography Enhancements, Forensic Odontology, Unidentified Persons

F3 The Perfect Storm II: The Strengths, Weaknesses of Bitemark Analysis, and Answers to Inquiries Requesting Fact-Based Protocols for This Forensic Discipline

C. Michael Bowers, DDS, JD, Forensic Services, 2284 South Victoria Avenue, Suite 1G, Ventura, CA 93003*

The goal of this presentation is to discuss the current status of bitemark identification opinions in three specific areas: (1) strengths; (2) weaknesses; and, (3) discussion of the future uses of bitemark comparison in criminal investigation.

This presentation will impact the forensic science community by clearly describing the issues regarding the necessity to substitute DNA analysis in cases involving human bitemark evidence.

Three years since the 2009 National Academy of Sciences Report (NAS Report) was published, things have been quiet regarding any revision of the methods and protocols allowed by the recognized forensic bitemark certification organizations. The American Academy of Forensic Sciences has issued a general recognition of the need for improvements in forensic application of certain disciplines. The ABFO has argued that bitemark comparisons still qualify as acceptable forensic science. The available literature on the foundations of bitemark comparisons is currently being reviewed by the ABFO in response to direct questioning by the Congressional Judiciary Sub-Committee tasked to establish the breadth, substance, and gaps in this area of forensic investigation. Reviewers outside this organization have completed their own literature investigation. Do these summaries tell us anything regarding a common ground of proof supporting bitemark comparisons? As of August 1, 2011 the answers have yet to be revealed. The content and status of these reviews will form the core of this presentation.

1. STRENGTHS

- Cases involving biting activity occur during assaults and homicides. Victims can be either children or adults. Sometimes an assailant may be bitten by the victim. In all of these cases, the identity of the biter is the foremost challenge. Currently available DNA technologies have recently changed the hierarchy of investigation of bitemarks. The penultimate resource to biter identification is via collection and processing of DNA containing saliva from both the region of the skin injury and also from clothing worn at the time of the attack. Well informed jurisdictions have adopted this protocol as a standard operating procedure. Nevertheless, this type of evidence must be collected in a timely manner due to its susceptibility to environmental degradation. This makes the identification of the skin injury as a bitemark the paramount task of the initial medico-legal investigation. Forensic dentists are dedicated to educating law enforcement and hospital staff to the appearance of human bitemarks and the proper collection, documentation and preservation of this biological evidence.

2. WEAKNESSES OF BITEMARK COMPARISONS

- Poor to non-existent scientific support regarding scientific issues published in NAS report and questions posed by the Congressional Judicial subcommittee to the ABFO in 2011.
- Multiple analysis methodologies and unrealistic expectation of the validity and judicial presentations of bitemark pattern analysis. Unopposed research now available indicates skin injury patterns are unreliable for comparison purposes.
- General lack of scientific determination of levels of certainty used by dental experts.
- History of expert disagreement in court regarding fundamental levels of bitemark pattern analysis.
- Resistance of odontology organizations to consider the basis of the numerous United States exonerations which overturned opinions of experienced board-certified forensic dentists.

3. ISSUES AND SOLUTIONS

- The weaknesses in Section B are currently unresolved.
- The default solution is to determine that DNA analysis is the best method for bite identification and that bitemark identification opinions should only be used for extra-judicial investigation. It is mandatory to refocus U.S. odontologists towards better training and education of law enforcement, hospital, dental and medical professionals about the basis of bitemark identification and biological evidence collection. The increased use of DNA analysis as a substitute for dependence on bitemark comparison is evident in the numerous cases in the United States and is the hallmark for well informed medical-legal agencies throughout this country and abroad.

Bitemark Research, Bitemark Unreliability, DNA

F4 Exploration of Bitemark Distortion in Human Skin: Effects of Size and Shape Deformation

H. David Sheets, PhD, Canisius College, Department of Physics, 2001 Main Street, Buffalo, NY 14208; Peter J. Bush, BS, Laboratory for Forensic Odontology Research, School of Dental Medicine, SUNY at Buffalo, B1 Squire Hall, South Campus, Buffalo, NY 14214; and Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214*

The goal of this presentation is to describe the extent of distortion, relative to size, in a series of bitemarks with consideration of both maxillary and mandibular teeth. In addition, the ability to predict distortion in one arch relative to the other will also be discussed.

This presentation will impact the forensic science community by exploring one of the basic premises of bitemark analysis, that of reproducible transfer of dental shape to the skin.

The biomechanical nature of skin dictates that distortion will be inevitable, as skin behaves in anisotropic, visco-elastic manner. Given these properties the question then becomes *what is the extent of distortion possible in a bitemark and is distortion with respect to one dental arch predictive of the other?*

In order to explore this deformation of skin, an approach that can statistically evaluate the range and extent of shape change associated with distortion is necessary. A well-developed method to describe shape variation between biological specimens is Landmark based Geometric Morphometric analysis (GM).

In GM, landmarks are placed on digital images. These are preserved as coordinates that describe and preserve spatial information. The landmarks can then be extracted and used to describe shape changes between specimens in a quantitative and statistical manner. Traditionally, GM methods remove scale; however, GM methods can extended to preserve size information. In forensic studies, information about size is generally important, so it was necessary to explore an approach that preserves size. Thus, a size-preserving Procrustes approach (Procrustes S-P) was used in this study, as well as the size independent approaches.

Human Subject Review Board Exemption (HSRIB) was granted for this project. Impressions of the maxillary and mandibular dentition were taken from a single volunteer. The impressions were poured in resin and mounted on a hand held vice grip instrumented with a load cell to monitor force application.

The apparatus was used to inflict 49 bites on unembalmed human cadavers. The cadavers were acquired based on availability and thus gender and age were not controlled factors in this study. Bites were made on the upper arm, lower arm, lateral thoracic wall, and upper thigh. The same examiner created all of the bites.

The resulting bites were digitally photographed with an ABFO scale in place. All photography occurred within two minutes of infliction. In order to avoid photographic distortion, the maxillary and mandibular arches were photographed separately as needed.

Landmarks were placed on the digital images with tpsDig freeware. Landmarks were placed on the mesial and distal extensions of the six anterior teeth as well as the center point of the canines. This resulted in a placement of 14 landmarks. Two additional landmarks were placed on the ABFO scale for size reference. The maxillary and mandibular dentitions were recorded separately.

The landmarks were then extracted from the images and analyzed with IMP freeware. Landmarks were also placed on digitally scanned images of the biter's maxillary and mandibular dental models as described for the bitemarks. Concurrently, a sample population of 297 paired maxillary and mandibular dental models were acquired from the University at Buffalo School of Dental Medicine. This was a sample of convenience. The models were placed on a flat bed scanner and digitally scanned and landmark placement performed. These models were used for comparison purposes to the inflicted bitemarks. Error rates were calculated by repeated measures.

Results show that scale changes appear in the upper and lower arch in a relatively independent way and are not highly correlated. This result is not surprising given the anisotropic nature of the skin. A change in arch width was the largest factor seen with regard to distortion. Variation in arch width caused by distortion in the bitemarks was roughly ten times the measurement error. Arch width variation in the bitemarks from a single dentition was compared to the population of 297 models. The bitemarks span 42% of the population range of arch widths in the mandibular dentition, and 53% of the range in the maxillary.

It was concluded that substantial size variation exists in bitemarks produced by one dentition, as characterized by arch width, as well as by more complex geometric morphometric measurements. Scale changes appear in the upper and lower in a relatively independent way and are not highly correlated. To summarize, cadaver skin produced extensive and rather unpredictable distortions in arch width for the dentition used in this study.

Forensic Science, Bitemarks, Distortion

F5 Ethical Considerations in the Use of Live Human Subjects in Bitemark Research

Kenneth P. Hermsen, DDS, Creighton University, School of Dentistry, 2500 California Plaza, Omaha, NE 68178*

After attending this presentation, attendees will be aware of the ethical considerations that should be taken into account when conducting bitemark research on live humans, including a brief history of human experimentation, the Institutional Review Board process, and the protection of vulnerable populations.

This presentation will impact the forensic science community by laying the ground work for the participants to consider the ethical ramifications in utilizing live human subjects in bitemark research and to move the discussion forward on prohibitions and/or guidelines if bitemark research is to be conducted on live human subjects.

Giving consideration to human research subjects goes back to the days following World War II when 26 Nazi scientists were held accountable for performing experiments on prisoners of war. Their trial at Nuremburg resulted in the first internationally recognized code of research ethics authored by the Nazi War Crimes Tribunal. The "Nuremburg Code" established the principles of voluntary consent which included: consideration of the capacity of subjects to consent, freedom of subjects from coercion, a comprehensive analysis of the risks and benefits of the research, minimization of risk and harm to the subjects, experimentation by qualified investigators, appropriate research designs, and the freedom of the subjects to withdraw at any time.

In 1974, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research was established and the National Research Act was passed by Congress. The Act established the Institutional Review Board (IRB) and required all federally funded research projects involving human subjects be reviewed and approved by the IRB. In 1979, the Commission issued the Belmont Report which revised the principles to include all human research. The principles identified by the Commission fell into three basic categories: autonomy, beneficence, and justice. The Report provided guidelines to ensure research subjects' safety, total freedom of choice, and protection of vulnerable populations from coercion.

Much of the research on bitemarks has been done using live, anesthetized animals, and human cadavers. There has been significant insight gained from this research but there may be a limit to the extrapolation of the results from these models to live human victims. At some point consideration of using live human subjects will likely need to be considered. Currently, opinions by forensic experts on the ethics of this

endeavor appear to be varied. The risks associated with bitemark research falls far short of the risks associated with many other human research projects. However, most would agree that producing a bitemark in a live human subject would require inflicting a brief but significant amount of discomfort. So the question becomes: is bitemark research on live human subjects ethical and if so, what ethical considerations are involved?

One ethical consideration is research design. Will the design provide useful, reproducible results? Have specific parameters been identified and can they be measured? Will it provide a favorable benefit- to-risk ratio? Have sufficient measures been taken to minimize potential harm to the participants? All of these need to be answered to the satisfaction of the IRB overseeing the research. The other, and for most researchers the most important consideration, is the recruitment and selection of volunteers. Great care must be given to this process to ensure absolute autonomy for the participants. This involves recruitment without pressure or coercion, disclosure and explanation of the research design including adverse effects (i.e., pain and bruising), a signed informed consent that includes complete disclosure of the risks, the ability to withdraw at any time without prejudice, and extreme care in the use of potentially vulnerable populations. Vulnerable populations are populations that can be more susceptible to pressure or coercion. These populations include children, the elderly, prisoners, the mentally or socially impaired, and, in the case of research by university faculty, students. IRB oversight is extremely important in any research involving live humans to prevent under-compliance of these critical ethical considerations.

The ethics of using live human subjects for bitemark research is a complex issue that will need to be decided by the forensic dental community. Discussion should be held in an attempt to arrive at a consensus on the ethics of this type of research.

Research, Institutional Review Board, Ethics

F6 Bitemarks in Perishables: 3D Laser Scanner Analysis

Aime H. Conigliaro, MA, Institut de Recherche Criminelle de la Gendarmerie Nationale, 1 Boulevard Theophile, Sueur 93110, Rosny-sous-Bois, FRANCE; and Charles Georget, DMD*, Institut de Recherche Criminelle de la Gendarmerie Nationale, CTGN, 1 Boulevard T Sueur, Rosny Sous Bois, 93111, FRANCE*

After attending this presentation, attendees will understand how new technologies, especially laser scanner 3D modeling of dental casts, can enhance the study of bitemarks. The sectioning performed allows an approach to further development in the study of bitemarks to help investigators and magistrates to identify the perpetrators of such injuries.

This presentation will impact the forensic science community by showing how this photographic technique provides a reliable system to use in the field or laboratory. It is has been tested within the Forensic Science Institute of the French Gendarmerie (I.R.C.G.N). The practical applications presented can be used as a guideline to forensic odontologists.

In 1997, C. Georget and W. Baston compared experimentally produced bitemarks left in food with the dental casts of two suspects.

The pieces subjected to analysis were: (1) a piece of cheese with bitemarks; and, (2) study models of maxillary and mandible dental arches of two suspects.

The first step is to make a molding to duplicate the shape of the bitten substrate. The cast of the impression is then made of resin (resin INTERIM CD / SPAD) and is duplicated.

The observation of cast supporting bitemarks objectives evidence of marks indentations, the traces left on the edge of the food, tearing the material. The cast also specifies the dynamics of the bite (lateral movement and slippage) specific to the individual who has bitten. The meeting point between the upper and lower teeth are visible in the form of a bead. This observation also helps to identify the visible teeth on the food. The shape of the teeth can give the orientation of the object in the mouth.

In 2011, Georget and Conigliaro repeat the previous studies.

The contribution of new technologies and especially the use of laser scanners assist in the production of fast and easy 3D models of the dental casts and perishable substance.

The use of a 3D laser scanner has advantages. The print is done without any risk of deformation due to the pressure of a conventional impression material on the perishable substance. Furthermore, as no impression material is used there is not riks of the material tearing. The average ambient temperature of the enclosure of the scanner is 22°C (74°F). This temperature does not alter the sample to be analyzed during the impression taking. In extreme cases, a fragile sample can be placed on a refrigerated pedestal. The shape of the food is preserved.

This non-destructive method enables the producion of sections according to the needs of the forensic odontologist. The digitalized dental cast is available for further examination due to the non-destructive nature of the methodology.

Bitemark, Perishable, Noninvasive Analyze

F7 The Uniqueness of the Human Dentition: Fact or Fiction?

Mark Page, BDSc, University of Newcastle, Department of Oral Health, Ourimbah, New South Wales, AUSTRALIA; and Jane Taylor, PhD, and Matt Blenkin, MDSc, University of Newcastle, Ourimbah, AUSTRALIA*

After attending this presentation, attendees will be aware of both the difficulty in attempting to prove the proposition that the spatial arrangement of the human dentition is unique as it applies to bitemark analysis as well as the ultimate irrelevance of such a proposition to both forensic scientists and the law.

This presentation will impact the forensic science community by presenting attendees with examples from not only the forensic field, but general mathematical and philosophical principles that support the concept that uniqueness is an unattainable, irrelevant, and unproveable concept in bitemark analysis and other forensic areas. This will serve to highlight the fact that there is no need to resort to uniqueness principles in order to bolster claims of identification in courts of law or elsewhere. Such claims do not strengthen the position of odontologists as expert witnesses and do nothing to increase the reliability of the discipline as required under current evidence law mandates.

Fingerprint and handwriting analysts, firearms and tool mark examiners, and forensic odontologists often rely on the uniqueness proposition in order to support their theory of identification. In forensic odontology, several articles are commonly cited as providing evidence for the geometric uniqueness of the anterior dentition. These articles were reviewed in order to assess this claim, and benchmarked against more than thirty articles claiming to prove the uniqueness of other forensic traits. The literature providing support for uniqueness in forensic odontology is comparatively weak and archaic in its methodology; however, articles in all forensic disciplines suffer flaws that negate the conclusion that any forensic feature is unique. The sources cited as contributing towards the evidence for uniqueness include the anecdotal and experiential, biological, and mathematical, yet all of these approaches suffer disadvantages that result in little faith being able to be afforded to their conclusions. These included the employment of unrealistic assumptions, erroneous mathematics, and the drawing of illogical conclusions from experimental data. The finding of uniqueness in any study appears to be an overstatement of the significance of the results, and in several instances, this claim is made despite contrary data being presented. Recently, studies have been published regarding the uniqueness of the dentition, and these have definitively falsified the notion that the spatial arrangement of the dentition is quantifiably unique.

Both the mathematical and philosophical viewpoint regarding uniqueness is that obtaining definitive proof of uniqueness is considered impossible by modern scientific methods. More importantly, there appears to be no logical reason to pursue such research, as commentators have convincingly established that uniqueness is not a necessary requirement for individualization or identification by the forensic expert. In fact, such questions broach the scope of the expert witness, and should properly be left to the trier of fact. The courts have accepted this in several recent cases in the United States, and have dismissed the concept of uniqueness as irrelevant to more fundamental questions asked of forensic expert witnesses. Current concepts in evidence law mandate that the expert witness's testimony must be found to be relevant and reliable, and neither of these concepts are supported by statements of uniqueness. Odontologists would be better to focus their efforts in both research and the courtroom elsewhere in order to truly improve the reliability of the discipline.

Odontology, Uniqueness, Forensic Science

F8 A Bitemark Classification That Makes Sense

Richard R. Souviron, DDS, Medical Examiner's Office, Miami-Dade County, Number One on Bob Hope Road, Miami, FL 33136*

After attending this presentation, attendees will learn classifications for logical and simple bitemark categories. Attendees will also learn the difference in each of four distinct types of human bites on human skin. The application of a classification in the practice of forensic odontology should help to standardize and better organize the science.

This presentation will impact the forensic science community by simplifying and categorizing bitemarks. When forensic odontologists can all speak the same language in bitemark analysis it will make this science more understandable. By applying a logical classification to bitemark analysis, errors in interpretation should be greatly reduced. Other disciplines all use classifications for logical separation and for impact in identification of specific procedures or categories.

In the literature, bitemarks are usually not referred to by a classification but are described as good, poor, limited evidentiary value, distorted bitemark, high evidentiary value, diffused, healed, etc. How much more professional would it be to group the bitemarks into a logical, simple, and understandable group. In most areas of science similar items are classified. For example; in dentistry, there are classifications of fillings, i.e., Class I, II, III, IV, and V. All dentists understand what falls into these classifications. They are used for the insurance industry and all speak the same languages. The orthodontist classifies occlusion into Class I, II, and III. All those in the discipline understand what the occlusion will look like in these classifications. So why have the forensic odontologists not used classifications for bitemarks? In the 1980's Dr. Ray Rawson proposed a classification for bitemarks which consisted of a total of six classes. To my knowledge it has never been used. Why? Because it was too specific, complicated, and not user friendly. However, bitemarks can be classified into four simple, clear, and logical classifications. If used by all forensic odontologists everyone would for once be speaking the same language. These classifications would make it clear to other disciplines what is being referring to; specifically for the legal profession, pólice, and medical examiners.

The most logical classification for human bitemarks on human skin should be based on appearance or lack there of, of the pattern injury. The following are examples that have proven to be effective in practical application:

Class I: This is the diffused bitemark. The one that lacks individual characteristics and has limited class characteristics, sometimes referred to as a bruise, diffused bitemark, a smoking ring or, a faint bitemark.

Class II: This pattern injury has some individual tooth characteristics, some class characteristics, sometimes referred to as the "single arch bite" or the partial bitemark. This type of bite can be seen in human bites through clothing or where several teeth are recorded such as teeth marks with a fist blow to the face or where the individual has an object over one arch when the bite is inflicted when only the opposing arch would mark.

Class III: In this classification, there are both individual tooth characteristics and class characteristics present. This type of bite is one that is used most often for comparison purposes and has great evidentiary value. This type of bite is usually found on the body part that has the least amount of tissue distortion such as buttocks, shoulder, an upper arm, or the chest. In this classification of bites, the pressure is often held for a long enough period of time and with a deep enough penetration of tissue to record the lingual surfaces of the anterior teeth.

Class IV- In this classification, the bite has caused avulsion or laceration of the tissue. Usually there are no class or individual tooth characteristics present. This type of bite is most common where scarring occurs or where there is avulsion of an ear or finger. This bite is used to demonstrate that in a bitemark, one has a permanent injury which will elevate a charge of battery which is a misdemeanor to a third degree felony aggravated battery.

If one avoids complications by adding sub classifications to the classes then this method of classification of bitemarks is one that all forensic odontologists should be able to live with and more importantly use as part of their analysis and report documentation.

Bitemark, Odontology, Classification

F9 Developing the Evidence Base for Forensic Science – The Systematic Review

Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, South Campus, Buffalo, NY 14214; Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; and Iain A. Pretty, DDS, PhD, Dental Health Unit, Skelton House, Lloyd Street North, Manchester Science Park, Manchester, M15 6SH, UNITED KINGDOM*

After attending this presentation attendees will: (1) understand the nature of evidence hierarchy; (2) understand the principles of systematic reviews; (3) be able to assess a forrest plot; and, (4) be aware of the need for protocol development in reviews.

This presentation will impact the forensic science community by beginning the process of defining topics for systematic review in the forensic sciences to develop a robust research base.

With a rapidly expanding number of journals and publications it is becoming impossible for health care professionals to assimilate new research findings, assess their value and determine if their conclusions should impact on clinical care and practice. In response to this, literature reviews have always been popular methods of presenting summary findings to readers; however, narrative reviews are prone to bias and often reflect the opinions and philosophies of the authors. Out of this concern was developed the systematic review – a review with a robust protocol, inclusion and exclusion criteria for publications, and a statistical approach to meta analysis of results. Leading the field in systematic reviews is the Cochrane Collaboration, an international network which assesses the impact of randomized clinical trials on patient care.

Forensic science, and its application within judicial systems, can have a significant impact on the lives of those it touches and therefore should be held to no lesser a level of scientific scrutiny than medical interventions and therapies. The National Academy of Sciences Report has clearly identified concerns over the quality of research in forensic science and there is a need to take a systematic approach to define the literature, consider meta analyses of findings, and report recommendations. Cochrane reviews have changed the way medicine is practiced and a similar approach to forensic science seems timely.

While peer reviewed scientific evidence in the form of research publications can easily be rated using Sackett's hierarchy of evidence (with

systematic reviews being considered the highest level) forensic science is executed in two arenas – the peer reviewed journals and the judicial system. The opinions, judgments, and reviews that are conducted within the court system cannot be ignored nor can any positive or negative outcomes produced as a result of using a particular forensic science be ignored. One would not adopt a medical intervention that worked in the laboratory but that killed patients in the operating theatre.

Forensic science is rarely appropriate for testing using randomized controlled trials. As such, the Cochrane methodology is inappropriate. However, a sister organization, the Campbell Collaboration offers a review framework that is ideally suited to assessing forensic sciences and providing guidance, recommendations, and future research paradigms that will help strengthen the individual disciplines.

Part of a robust systematic review is the development of a protocol. In this presentation the nature of systematic reviews will be described along with their impact in the medical space and how homogenous evidence is combined in meta analyses. The protocol for a systematic review of bitemark evidence will be presented demonstrating the search protocol, the inclusion and exclusion criteria and the literature areas to be covered. Forensic science needs to meet the highest level of scientific evidence and the development of a suite of systematic reviews, with robust and agreed protocols, is one such way of achieving this.

Odontology, Review, Systematic

F10 Disaster Victim Identification (Dental) Following the Christchurch Earthquake in February 2011

Judith A. Hinchliffe, BDS, 88 View Road, Houghton Bay, Wellington, 6023, NEW ZEALAND*

After attending this presentation, attendees will gain a brief overview of the devastating magnitude 6.3 earthquake in New Zealand, on February 22, 2011, which shook the city of Christchurch to its core, causing death and destruction. Attendees will gain understanding of the successes and difficulties with identification (focusing on dental identification) encountered following this mass fatality incident that claimed the lives of 181 people and injured many more.

This presentation aims to give a brief overview of the disaster and to share with the attendees the difficulties and successes encountered with the dental identifications. It will show the problems facing Christchurch for the future and the importance of having Disaster Victim Identification response plans and personnel in place to respond rapidly and effectively.

This years Academy theme is based around the global reach of the forensic sciences. Odontology's contribution to international forensic efforts is never clearer than when forensic dentists work in teams to assist the identification of victims of mass fatalatity events. While personnel may be local to the disaster, there are many instances when international assistance is gained. Irrespective of the nationality of forensic dentists, all are influenced by the development of standards, protocols, and IT systems that have been developed and enhanced through the efforts of those attending previous DVIs. Indeed, this interative process of development is essential – some good must come from these devasting events.

Within a few moments Christchurch would be reduced to rubble with hundreds of aftershocks during the following months causing further distress and damage. The emotional, structural, and financial devastation will leave its mark on New Zealand for years to come. The collapse of the Canterbury Television Building and subsequent fire would claim the most lives - mainly young people and many from other countries.

New Zealand declared a state of national emergency and teams rapidly deployed to assist in whatever way they could. Recovery teams began the grim task of locating and transportation of the deceased. A temporary mortuary was established at Burnham Military Camp in preparation for the postmortem gathering of information and relatives were approached for antemortem information. The different forensic disciplines worked long hours to establish identification of the victims.

Despite incineration, co-mingling, and trauma of the remains, forensic odontology would prove to be a useful identification method alongside fingerprints and DNA. To date only four persons have not been identified, but the work goes on to return every victim to their families. A devastated city fights to return to a semblance of order from the chaos of that ill-fated morning earlier this year.

Disaster Victim Identification (Dental), Christchurch Earthquake, February 2011

F11 Classification of Human Remains — A New Classification That Describes the Condition of Human Remains in Simple Form

William E. Silver, DDS, 10 Edgewater Drive, #5G, Coral Gables, FL 33133*

The goal of this presentation is to provide a simple method of describing the condition of human remains so that this information may be communicated effectively to other persons in the same or different disciplines. This is particularly applicable within the facial area. The interrelationship between the jaws will also be discussed.

This presentation will impact the forensic science community by allowing professional forensic operators from different areas of interest to describe the condition of human remains within the identifiable facial area by a simple method with the use of a numerical system that would describe those remains in terms that would not require the use of a particular language. This also allows for the entry of descriptive terms for computer entry by using numbers instead of phraseology that might otherwise be confusing to those who speak a different language. Examples of each classification and the dental relationship between the jaws will be demonstrated.

Acceptance of a standard of classification for human remains is essential to communicating among persons who speak different languages as well as those who speak the same language. The reduction of an object's description to a numerical evaluation simplifies and also allows for ready entry into the language of computers.

Orthodontic classification has long been the standard using Class I, Class II, and Class III to describe the anterior-posterior relationship of the maxilla and mandible. This classification system may also be helpful in describing the dental condition for identification purposes as well. When examining the dentition of an individual, the relative position of the upper and lower jaws will be reflected in the facial features, which may assist in the identification process and should be noted in the examination of human remains. In a Class I, dental relationship the upper first molar is slightly distal to the lower first molar. This is considered to be the normal relationship between the jaws and may result in a regular, spaced or crowded alignment of the teeth. In a Class II, dental relationship the upper first molar is mesial to the lower first molar, usually resulting in a maxillary protrusion or mandibular retrusion—except when the upper central incisors are retrusive and the upper lateral incisors are protruded together with a deep vertical overbite. In a Class III, dental relationship the lower first molar is completely mesial to the upper first molar. This condition is referred to as mandibular prognathism and may result in an anterior crossbite when the lower anterior teeth are in front of the uppers.

Class I, Class II, and Class III was used as the basic classification of human remains with particular reference to the dental and facial condition.

Class I: Refers to a fresh condition of the tissues when the facial structures are in good condition and could be readily observed and possibly used for visual identification. Any incision or removal of the facial tissues that would impact the ability to make an identification is contraindicated.

Class II: Would include facial features that had been appreciably lost due to severe decomposition over time, fire, or extended immersion in water. It would also include remains from severe facial trauma as a result

of a free fall, high speed automobile accident, or plane crash. These remains would not be in a viewable condition and would require surgical removal of tissue and debris as well as possible jaw removal procedures for examination of the dentition and possible identification.

Class III: Would be skeletal remains that were no longer covered by soft tissue and the dentition present in its entirety or fragmented.

Classification, Dental, Remains

F12 Dental Ethnic Mutilation

Aime H. Conigliaro, MA, Institut de Recherche Criminelle de la Gendarmerie Nationale, 1 Boulevard Theophile, Sueur 93110, Rosny-sous-Bois, FRANCE; and Delphine Savoie, DDS, 86 Rue des Halles, Tours, FRANCE*

After attending this presentation, attendees will understand how dental mutilation may help identify a victim. They are a sign of identification between the tribes and even within a tribe. For this purpose, a software location of different types of mutilation still practiced today was established.

This presentation will impact the forensic science community by demonstrating how to identify a victim outside the conventional methods of identification based on data characteristics of the different ethnic groups still existing in the world.

The tooth is a particularly powerful symbol. Its exceptional hardness makes it possible to resist the vagaries of time, even over many hundreds of years. Thereby, it has become a symbol of strength, power, and even eternity. The use of intentional dental mutilations in humans only constitutes one chapter of a larger history, the one of body mutilations on the skin (tattoos, scarifications…), the genitals (castrations, excisions…), the feet (deformities, toe cutting…), the neck (the giraffe women), or the head (deformity of the skull…). Dental mutilation can be described as a voluntary partial or full amputation of one or several teeth mainly of the maxillary or mandibulary incisivo-canine teeth.

Although customary dental mutilations are disappearing, they can still be observed in many ethnic groups in Africa and throughout the world. These mutilations, under very various forms from strategic dental extractions to modifications of the shape of the tooth or covering with diverse materials, are highly varied and are of great interest. There is no doubt that these mutilations have several characteristics: standards of beauty, initiation rites, warrior symbols, cultural, and religious character, in a wide meaning or symbolism. Distinguishing signs for some, religious or ethnic for others, the dental mutilations and sometimes the dental adornments can assist in the identification of an individual when one has no dental record or ante radiographs (which unfortunately happens in many countries).

The originality of this topic is in the presentation of software specifically created to associate a dental mutiliation to an ethnic group, in relation to a country in order to identify the dental mutilation(s) with the goal to the identification of the individual.

As examples, there are different shapes of dental cuts existing in Africa and Indonesia:

- The shape of a saw with two separate tips: ethnic group of the Bakougnis in Gabon
- The shape of a saw with 2 or 3 contiguous tips: Congo, Togo
- The shape of an axe: Tchad
- The shape of a tip: the bantou and pigmy ethnic groups of Congo, the Mossi ethnic group of Burkina Faso
- The shape of niches: the Dzems ethnic group of Gabon
- The straight shape: Bali (Indonesia)
- Creation of inter incisive artificial diastema by avulsion between the maxillary and mandibular central incisives: the Massais ethnic group in Kenya, the Wollof ethnic group in Senegal, and the Hereros ethnic group in Namibie.

These multiple dental mutilations have been observed for centuries and in all areas of the world. In this presentation, dental mutilations still occuring today have been regrouped by classifying them according to their type (additive or subtractive dental mutilations) and according to their geographic location. The goal for the odontologist is to determine the ethnic origin of the human with the observed mutilation. For this, odontologists will be able to use the decscribed computer program by completing the different sections describing the mutilation to determine the corresponding ethnic group as well as its geographic location.

Teeth Mutilation, Ethnic, Dental Identification

F13 The Trabecular Bone in Identification — Part 2

Robert B.J. Dorion, DDS, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ieme, Montreal, QC H2K 3S7, CANADA; and Sylvain Desranleau, DMD, 273 Boul Laurier, Mont St-Hilaire, QC J3H 3N8, CANADA*

After attending this presentation, attendees will acquire new information regarding the use of trabecular patterns in the mandible for the establishment of positive identification.

This presentation will impact the forensic science community by providing new scientific evidence regarding the positive identification by trabecular patterns taking into consideration their variations in morphology and a method of calculating its significance.

According to Berkeley's Orthopaedic Biomechanics Laboratory, the trabecular bone can be classified as a porous cellular solid, consisting of an irregular three-dimensional array of bony rods and plates, called trabeculae, which are composed of a calcified matrix. Bone marrow fills the spaces of the pores. In addition, because all free bone surfaces are covered with bone cells, bone is a living tissue that is self-healing and has the ability to adjust its morphology in response to changes in its mechanical environment, the so-called but poorly understood phenomenon of bone remodeling. As such, the mechanical complexity of this two-phase biological tissue surpasses any engineering material making it a fascinating subject of study regardless of clinical applications.

Dental identification compares postmortem to antemortem records. It involves the analysis of different factors such as: the presence and the absence of teeth; crown and root morphology and their interrelationships; the evaluation of the periodontal status; the type and extent of restorative and endodontic materials; fixed, removable, and implanted prosthetics; tori and sinus configuration; anomalies and pathologies of teeth; and, bone as well as trabecular pattern morphology.

Few studies have been completed on the statistical reliability of trabecular bone patterns for identification purpose. Mann's research indicated that radiolucencies and radiodensities in the distal femur and proximal tibia are valid individualizing features for establishing a positive personal identification in human remains;[1] Hiss and Kahana used the densitometric analysis of the trabecular bone pattern as a sole means of identification that was confirmed later with two other methods;[2] Kahana, Hiss, and Smith's research concluded that the trabecular architecture is unique to each individual and stable enough to be used as a forensic marker for positive identification of human remains;[3] and, Couture, Whiting, Hildebolt, and Dixon studied the alveolar trabecular bone in radiographs.[4] On the other hand, other related studies discussing the radiographic recognition of dental implants,[5] the morphometric analysis of intra-oral radiographs of unrestored teeth,[6] the computer-aided dental identification,[7] the sensitivity, specificity and reliability of radiographic periapical diagnosis of posterior teeth,[8] the root morphology and anatomical patterns in forensic dental identification,[9] and the dentists' qualifications affecting the accuracy of radiographic identification have also been carried out.[10]

As a continuation of the preceding research, "*The Trabecular Bone in Identification*," the current research focuses on trabecular bone pattern

morphometric analysis and comparison as a viable and empirical method of positive identification. It involves the collection and analysis of panoramic, apical, and bitewing radiographs from the same patient over a number of years as well as from different patients. Locating, identifying, marking, and measuring common sets of trabecular patterns for each patient's radiographs, and determining whether trabecular patterns are unique to that patient, and if and how they are affected by the turnover rate in bone remodeling.

F14 Forensic Dental Data Standardization for Law Enforcement Applications

Brad Wing, MS, National Institute of Standard & Technology, 100 Bureau Drive, Stop 8940, Gaithersburg, MD 20899-8940; and Kenneth W. Aschheim, DDS*, 44 East 67th Street, New York, NY 10065*

After attending this presentation, attendees will be introduced to the various standardization activities currently underway to specify forensic dental data interchange and to cover the differences, similarities, and proposed harmonization of efforts in this area.

This presentation will impact the forensic science community by highlighting the numerous forums working to develop a standard for forensic dental information exchange: INTERPOL; the American Dental Association; the DVI community; and, the National Institute of Standards and Technology Information Technology Laboratory (NIST-ITL). Although the business users involved in each of these efforts are different, their data needs are similar. The creation of a common dataset among these various bodies would not only coordinate work efforts, but would benefit the forensic dental community by creating a common definition for data and a common way of specifying and defining that data while still allowing different encoding formats. This would lead to greater inter-operability of systems and streamline law enforcement and forensic efforts involving the exchange of dental information.

The American National Standard Institute/National Institute of Standards and Technology-Information Technology Laboratory (ANSI/NIST-ITL) publishes a biometrics-oriented standard known as the NIST Special Publication 500-271 ANSI/NIST-ITL 1-2011 American National Standard for Information Systems—Data Format for the Interchange of Fingerprint, Facial & Other Biometric Information that is used by Law Enforcement Agencies in over 100 countries. This standard defines not only the dataset for forensic information, but the formats and the data specifications to exchange biometric information on such metrics as friction ridge data for fingerprints, palm print, plantar prints, as well as facial metrics, and iris recognition data. It also covers the transmission of scar, needle mark and tattoo images, and related data, as well as DNA information for automated recognition and forensic use. Domestically, it is used by the Federal Bureau of Investigation, the Department of Defense, the Department of Homeland Security, the Department of State, and all state governments, as well as most local police departments to transfer biometric information amongst law enforcement agencies. It also forms the basis for fingerprint submissions to INTERPOL and its member countries.

Following the 2011 update of the standard, ANSI/NIST-ITL would like to address the next biometric modalities such as voice and dental records, as well as define new metrics for describing bitemarks that are submitted for analysis. ANSI/NIST-ITL has established a working group that is currently chaired by a representative of the Government of Argentina, and involves specialists from around the world. The ADA Specification 1058 has served as a starting point for forensics data standardization, but the hope of ANSI/NIST-ITL is to not only define the dataset, but the electronic protocol in which to transfer the information.

The goal of this presentation is to call for the development of a unified set of electronic specifications to submit to INTERPOL and ANSI/NIST-ITL by bringing together all business users to form a common foundation for forensic dental data exchange and to attempt to unify the DVI needs with the needs of law enforcement and government. This will involve several different stakeholders: forensic dental specialists, information technology specialists, standard development organizations, law enforcement, disaster recovery organization representatives, and others in order to ensure that all of the various needs and requirements are met.

Pub. 500-271 ANSI/NIST-ITL 1-2011, ANSI/ADA Specification No. 1058, Forensic Dental Data Set

F15 Contribution of Photographic Techniques in Automated Dental Identification

Charles Georget, DMD, CTGN, IRCGN, 1 Boulevard T Sueur, Rosny Sous Bois, 93111, FRANCE; Anne-Sophie Labyt-Leroy, DDS, Department Of Public Health, Lille 2 University Assistant, 233 rue de Lompret, Lambersart, 59130, FRANCE; and Aime H. Conigliaro, MA, Institut de Recherche Criminelle de la Gendarmerie Nationale, 1 Boulevard Theophile, Sueur 93110, Rosny-sous-Bois, FRANCE*

After attending this presentation, attendees will be able to understand the use of automated photographic techniques of mandibles and maxillas in mass disaster identification.

This presentation will impact the forensic science community by exploring a photographic technique that provides a reliable system for use in the field or laboratory. It is currently being tested within the Forensic Science Institute of the French Gendarmerie (I.R.C.G.N). The practical applications presented can be used as a guideline available to forensic odontologists.

Photography is an important element of dental forensic examination. It is often required by magistrates and investigators because pictures are able to show the mandibular and the maxillary teeth, their characteristics, their pathologies, and dental treatments.

Materials and methods: The digital SLR camera with a 60 mm lens is mounted on a stand equipped with a light source. This device is coupled to a laptop computer equipped with a distance shooting software package. A mouse is activated with the foot. This provides a means of capturing an image. The operator takes the photo hands-free and frames by visualizing on the screen.

Results: The testing environment enabled the identification of some key points.

Automation: On the camera the function, AF coupled with the function S treats the sharpness of the image. Thus, for each shot, the auto focus and sharpness is achieved without any manual intervention from the operator.

Handling: Holding the object to be photographed in their hands, the operator chooses easily the exact plane of the desired image.

Ergonomics: There is no need to use two operators, a clean hand operator and a dirty hand operator, or to continually change gloves between dirty and clean interventions. An operator can easily work alone.

Framing: Direct vision on the screen enables the observation of a greatly enlarged scale image. Details can be highlighted.

Speed: The reduced need for focusing decreases the time taken considerably.

Repeatability: The foot control of the camera permits the repeated shots with ease.

Cleanliness: The issue of the cleanliness of the collection of images and contamination of the photographic material is resolved because at no point does the operator touch the equipment.

Flexibility: The final results can be verified immediately on the screen and the ability to correct mistakes is possible – simply by acquiring another image.

Discussion: The use of photographic equipment and shooting a predetermined four orientations can establish a standardized photographic record.

Thus for each mandible and maxilla an occlusal view, buccal anterior view and two lateral views are taken. Photographs of specific details are made if necessary. A photographic record for each victim is always procuced and it contains all the photographs of the case.

When producing a report, the photographs of the occlusal surfaces are preferably framed and each tooth is identified according to the classifications used in countries where the expertise is conducted (FDI nomenclature, Universal system; Army system...).

Other photographs (front view, left and right side views, and photographs of details) are subject to a layout on a specific page.

The entire photographic record illustrates the dental status of the victim. It will support the comparison, along with radiographs and antemortem records.

Conclusion: A question emerges from this presentation – if sound photographic records can be produced – is a pictorial odontogram required?

Odontology, Photographic Technique, Computer

F16 A Novel Forensic Use of Clinical Odontological Imaging: Geometric Morphometric Analysis of Sexual Dimorphism in the Mandible From Panoramic Scanning X-Ray Images

Emilio Nuzzolese, DDS, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, 70124, ITALY; Patrick Randolph-Quinney, PhD*, Caroline Wilkinson, PhD, and Katie N. Baines, BSc, Centre for Anatomy & Human Identification, College of Life Sciences, University of Dundee, Dundee, DD1 5EH, UNITED KINGDOM; and Giancarlo Di Vella, PhD, Section of Legal Medicine - University of Bari, P.zza G. Cesare 11, Bari, 70124, ITALY*

After attending this presentation, attendees will have a better understanding of the sex determination during the skull assessment.

This presentation will impact the forensic science community by introducing a novel method of sex determination in the process of human identification investigations.

The human mandible is routinely utilized as part of sex assessment in forensic odontological and anthropological practice. Various studies have pointed to the utility of morphological and metrical traits in the mandible, such as symphyseal shape, gonial angle and eversion, and ramus flexure among others in the assessment of biological sex. The research here presented utilizes geometric morphometric techniques to investigate and quantify shape and size variation in the morphology of the mandibular corpus and ascending ramus, and consequently highlights the potential for forensic human identification. The results of a novel morphometric study are presented using clinical panoramic scanning x-radiography, the goal of which was to develop a methodologically and statistically robust means of investigating biological variation in lower jaw morphology from a commonly acquired clinical data source.

As part of proof-of-concept, clinical digital orthopantogram images (OPG's) were acquired from 50 male and 50 female adult participants from a modern Italian sample population. Ten type I and type II landmarks were applied to the symphyseal region and the condylar and coronoid processes of the resulting 2D images in order to anchor a framework of semi-landmark curves. One-hundred equidistant semi-landmarks were established along the inferior border of the corpus, and the posterior border of the ascending ramus, thus encompassing the sympyseal region, gonial region, and posterior ramus – all of which are isolated anatomical regions which have been demonstrated to exhibit significant expression of sexual dimorphism in previous studies. The resulting landmark and semi-landmark configurations were subjected to Generalized Procrustes Analysis (GPA) with Full Tangent Space Projection. Principal Component Analysis (PCA) was applied in order to assess populational variation. Factor loadings were subject to Canonical Variates Analysis with stepwise and leave-one-out classification in order to assess the effects of sexual dimorphism on mandibular shape. The preliminary results showed individuals to be correctly classified for sex in 89.6% of cases (males were correctly classified in 90.1% of cases, and females in 85.6%).

A partial least squares (2-block PLS) method was further applied, in order to examine patterns of covariation between shape variables and the exploration of patterns of functional modularity. In this case, functional modules are assumed to be units within which there is a high degree of integration from many and/or strong interactions, but which are relatively independent of other such units. The nature of the interactions can be, for instance, developmental, functional, or genetic, depending on the context. Most interestingly the results indicate the greatest level of individual and sex-specific variation is found in the shape-curve and pattern of the inferior corpus, in contrast to that of ramal flexure. However, a moderate degree of modular integration between the corporal and ramal regions suggests that functional ties between the units are correlated in influencing sex-based morphological trait expression. Consequently such units may be studied together or in isolation, and this may allow for the development of identification criteria based on modular unit shape variables which may be

applicable for both whole specimens and fragmented remains depending on the forensic situation. Overall, the results are strongly significant and suggest dependently and independently that the shape relationship between the mandibular corpus and the ascending ramus offers significant power for forensic identification purposes.

This investigation was designed to introduce a more standardized method of sex determination in the process of human identification within the field of forensic dental radiology. Orthopantogram images allow an objective and reproducible 2D images reducing observer bias especially when the analysis of the mandible utilizes geometric morphometric techniques. This study confirms that the mandible exhibits significant sexual dimorphism and that skull assessment of unidentified cadavers cannot leave aside the odontological investigation with the benefit of stored radiological images. Nevertheless, further assessment on a wider sample of OPG's should be carried out in order to increase the predictive accuracy of this novel methodology.

Geometric Morphometrics, Sex Assessment, Forensic Odontology

F17 Comparing Cone-Beam CT With Conventional Digital Dental Imaging for Forensic Dental Identification

Denise A. Trochesset, DDS, Stony Brook University School of Dental Medicine, Department of Oral Biology and Pathology, 105 Westchester Hall, Stony Brook, NY 11794-8702; Richard B. Serchuk, DDS, 5 Valentines Lane, Old Brookville, NY 11545; Rose Katz, BS, Stony Brook School of Dental Medicine, Rockland Hall, Stony Brool, NY 11794; and Daniel C. Colosi, DDS, PhD, Stony Brook University School of Dental Medicine, Department of Prosthodontics and Digital Technolog, Westchester Hall, Stony Brook, NY 11794*

After attending this presentation, attendees will gain knowledge of the use of cone beam CT in forensic identifications.

This presentation will impact the forensic science community by understanding how the use of cone beam CT derived images in forensic identifications is a viable time saving and a resource sparing technique.

Studies have previously presented evidence showing the ease of use of cone beam computed tomography (CBCT) derived images for dental identifications. The data gained from CBCT can be formatted into images that appear similar to periapical, bitewing, and panoramic radiographs. To further test the hypothesis that CBCT derived images are similar enough to conventional digital images to allow use in forensic identification, an IRB approved survey was developed.

The survey presented sets of images, each with a CBCT-derived periapical or bitewing image ("postmortem") as an unknown as well as five conventional radiographs (either bitewing or periapical, "antemortem") which may or may not be a "match" to the unknown, all on a one page sheet of paper. The five radiographs reviewed for each case are from the same anatomic location, but may be from a different individual; or taken from a different angle; or include fewer or more teeth; or be a bitewing instead of a periapical. The survey will be administered to multiple groups of dental practitioners, including dental students, post doctoral residents, practicing dentists and forensically trained dentists.

Five human jaw dissection specimens were scanned using an i-CAT cone-beam CT system and digital periapical and bitewing radiographs were taken of all dentate alveolar bone areas of the specimens. For each conventional radiograph, an image representing the same anatomical area was generated from the CBCT data set, as described previously. CBCT-derived images were cropped to the field of view of a conventional dental radiograph and to an aspect ratio of 4:3. CBCT-derived and conventional images of same anatomic areas of the specimens are presented in a survey alongside de-identified conventional radiographs of the same general region from patients with similar clinical dental situations (distracter images).

The results of the survey study will be presented and show the matching accuracy of the CBCT-derived image with the correct conventional image of the same specimen. In addition, each subgroup will be evaluated against the others to determine if the ability to correctly identify the "match" image with the unknown is a factor of years of experience in dentistry, experience as a forensic dentist or if a dental knowledge base is not required.

It is believed that CBCT derived images are similar enough to the conventional digital radiographs to allow their effective use in forensic identifications. Furthermore, it is believed that in situations such as mass disasters, the use of CBCT derived images would allow for rapid imaging of the deceased, allow reviewers to be located at a distance from the disaster site and allow for adjusting the viewing angle of the CBCT-derived ("postmortem") images to approximate that of the comparison ("antemortem") images.

Cone-Beam CT, Dental Identification, Radiographs

F18 Posthumous DNA Analysis Proves Equivocal Bitemark Analysis

Roger D. Metcalf, DDS, JD, Tarrant County Medical Examiner's District, 200 Feliks Gwozdz Place, Fort Worth, TX 76104*

The goal of this presentation is to remind attendees that not all high-profile post-conviction DNA analyses result in exoneration of the convicted person.

This presentation will impact the forensic science community by serving as a cautionary tale by recalling the facts around a case where the bitemark and palm print evidence used to secure a conviction in a capital murder trial might be considered equivocal, but, ultimately, post-conviction and posthumous DNA analysis showed the conviction was not improper.

In July 1989, Jesse Joe Patrick broke into the home of a neighbor, 80-year-old Nina Rutherford Redd, through a bathroom window. Redd was sexually assaulted before having her throat slashed. Patrick ransacked the home before leaving and was later arrested in Mississippi. A blood-soaked sock was found in the home of Patrick. DNA matched the DNA in Redd's blood sample. Patrick's live-in girlfriend identified the knife found at the scene as theirs. Patrick confessed to the crime shortly after his arrest, but later recanted. Patrick had previously been convicted of aggravated assault in 1986 and sentenced to four years probation, which was later revoked.

Patrick was convicted of capital murder in the 282nd District Court of Dallas County and sentenced to death on April 16, 1990. His conviction and sentence were affirmed by the Texas Court of Criminal Appeals on June 28, 1995, and his petition for *writ of certiorari* was denied by the United States Supreme Court on March 25, 1996. Patrick also filed a state *habeas corpus* application, which the Court of Criminal Appeals denied on April 22, 1998.

Patrick then filed a federal *habeas* petition, which the district court denied on Aug. 23, 2000. After the district court disposed of several post-judgment motions filed by Patrick, he attempted to appeal to the United States Court of Appeals for the Fifth Circuit, but both the district court and the Fifth Circuit denied him a certificate of appealability to do so. He then filed a petition for *writ of certiorari*, which was denied by the Supreme Court on September 12, 2002. Patrick's motion for a stay of execution was also denied on Sept. 12, 2002.

In addition to his appeal and *habeas corpus* proceedings, Patrick filed a motion for DNA testing in the state trial court. Although sperm had been found on the victim, a DNA analysis had not been performed. Following a hearing, the trial court ruled that Patrick was not entitled to testing under Chapter 64 of the Texas Code of Criminal Procedure because there was no reasonable probability that favorable DNA results would have led to an acquittal—Patrick had not been charged with a sexual assault.

Since Patrick was willing to pay the costs of DNA testing, the court did rule he could have testing at his expense. The State appealed that ruling

to the Court of Criminal Appeals and also filed a petition for *writ of mandamus* to force the trial judge to rescind her order. On September 11, 2002, the Court of Criminal Appeals dismissed the State's appeal but also granted the requested *mandamus* relief. The court held that because Patrick did not meet the statute's requirements, he was not entitled to testing regardless of whether he was willing to bear the costs. Jesse Joe Patrick was executed by lethal injection on Sept. 17, 2002.

Craig Watkins was elected Criminal District Attorney for Dallas County in 2006. Mr. Watkins promptly established the Conviction Integrity Unit at the Dallas DA's office in 2007, the first of its kind in the country. This Unit is responsible for the post-conviction review of more than 400 Dallas County cases in conjunction with the Innocence Project of Texas (IPOT) and in accordance with the Texas Code of Criminal Procedure, Chapter 64 (Motion for Forensic DNA Testing). In addition to the IPOT project, the Conviction Integrity Unit investigates and prosecutes old cases (DNA and non-DNA related) where evidence identifies different or additional perpetrators.

Dallas County has been at the forefront of testing and retesting DNA evidence from old criminal cases. One important reason for this, it is believed, is that the Southwest Institute of Forensic Sciences in Dallas has historically been very diligent about retaining and properly storing evidence—evidence that might well have been discarded in other jurisdictions.

Patrick's case was one of the initial 400 Dallas cases selected for review for potential DNA testing/retesting of biological evidence. The review was by IPOT student volunteers supervised and directed by the Conviction Integrity Unit's attorneys. The initial IPOT volunteers participating in this project were primarily from Texas Wesleyan University's School of Law. Even though Patrick had been executed in 2002, his case was nonetheless included in the initial 400 cases because it met a threshold screening criteria of apparently having suitable biological evidence still available for testing. As his case was being investigated by the law students, it was discovered that the physical evidence that had been admitted at trial—a palm print analysis and a bitemark analysis—might be considered equivocal by some, and it was decided to proceed with a DNA analysis of the remaining biological evidence (*please note: the original bitemark analysis was* ***not*** *performed by any current Diplomate of the ABFO or member of AAFS)*.

Ultimately, results of DNA analysis of the sperm found on the victim's body "could not exclude" Patrick as a potential DNA contributor. It is left to wonder "in the end, did we arrive at the correct result, but by the wrong route?"

Bitemark, DNA Analysis, Postconviction

F19 Guide of International Dental Chartings Translated to English – Decoding International Antemortem Dental Chartings for INTERPOL Disaster Victim Identification Forms (F2)

Scheila Manica, MSc, University of Glamorgan Wales, 53 Street Dunstans Avenue, London, W3 6QD, UNITED KINGDOM*

After attending this presentation, attendees will be aware of a wide variety of symbols and abbreviations in different languages present in various dental chartings from INTERPOL member countries.

This presentation will impact the forensic science community by presenting a guide that could be a source of consultation for different needs such as: dental identification on foreign patient in mortuaries (when previous dental records are not written in English); and, additionally by aiding dental teams working for the antemortem dental records section in disaster victim identification in international scenarios while decoding international dental records.

The INTERPOL Disaster Victim Identification forms have a global standard of application for mass disasters and the collection of international antemortem dental records could be optimized by a guide of dental terminology applied on dental chartings from several languages to English.

The goal of this study was to analyze the tooth numbering system, symbols, and abbreviations used on dental charting worldwide. The countries studied are composed of the 188 INTERPOL member countries.

The logical approach to obtain current dental chartings from those countries was contacting national dental associations through the FDI (*Fédération Dentaire Internationale*) website. The letter addressed the goals of the project and requirements of samples of dental chartings. They were sent to the national dental associations email addresses and additionally by mail. In order to complement the amount of information, the letter was also sent to the twenty-one IOFOS (The International Organization for Forensic Odonto-Stomatology) members.

A total of 50 countried replied to the query. There was a wide variety of dental notations applied in a same country or the absence of those in other countries. Some of the samples were of little value; however, a fair amount of information and detail was present in most of them.

A literature review summarized the spoken language and density of dentists in each country as well as all the received information from the replies. This pointed out the two most used tooth numbering system in use namely: the FDI and the Palmer notations.

Focusing on the gathering of information for the filling of the INTERPOL DVI form F2 where the most important dental information is.

Twenty-four common dental alterations were selected such as: decay, fillings and prosthesis, and their symbols and/or abbreviations were summarized in ten languages. Some findings were very surprising, for instance: one determined symbol has two different meanings in different countries. Another example is the tooth surface nomenclature named "vestibular" which is not widely used in Europe.

This report also compares most of the historical tooth notations from Zsigmond (1861) to FDI two-digit (1971). After the results, it is also shown a percentage of the tooth numbering system most commonly used today.

This guide could be useful when the handwriting, symbols, and abbreviations on the antmortem dental chartings are not clear and this is paramount when antemortem x-rays and casts are not available.

Disaster Victim Identification, Antemortem Dental Record, INTERPOL DVI Form

F20 Protocol for a Systematic Review of Human Dental Age Estimation Studies

Patrick W. Thevissen, MSc, Katholieke Universiteit Leuven, School of Dentistry, Forensic Odontology Department, Kapucijnenvoer 7, Leuven, 3000, BELGIUM; and Guy Willems, PhD, Katholieke Universiteit Leuven, School of Dentistry, Kapucijnenvoer 7, Leuven, International B-3000, BELGIUM*

After attending this presentation, attendees will be informed step by step how a review of human dental age estimation studies can be performed and reproduced in an unbiased way.

This presentation will impact the forensic science community with a guideline classifying the different age estimation studies and related methods. It will reveal tools to compare and evaluate within each category the age predicting accuracy of the included study outcomes.

Teeth are assessed for age estimation because their changes in development, morphology, and biochemical structure can be related to the chronological age of an individual. Divers dental age predictors can be registered in a tooth conserving or tooth destructive way. The sampled data are statistically approached and analyzed to develop specific age estimation methods. Supplementary information related to the gender, ethnical or geographical origin, medical history and living condition of the sampled

individuals influences with variable weight the applied dental age estimation methodology. The different dental age estimation methods can be divided in specific groups: (1) methods based on developing teeth can be divided on the one hand in methods based on growth of all teeth except third molars and on the other hand methods based on third molar maturation; (2), methods based on mature teeth, contain a group of methods analyzing intact teeth and methods destructing teeth for age estimation examinations; and, (3), age can be predicted comparing a presented dental variable with a corresponding variable listed in common age related tables or atlases. In each of previous groups age is predicted following a particular method. This protocol aims to describe step by step the procedures to perform a systematic review of dental age estimation method studies in an attempt to classify the studies in defined groups enabling to evaluate the diagnostic accuracy of the included dental age estimation methods.

The systematic review will include studies presented to the scientific community by publication in a peer-reviewed journal, a book or in a doctoral thesis. All included studies should be written in English. They should describe the development, the evaluation or the comparison of dental age estimation methods, or they should report relations between dental variables and chronological age by means of common tables or a (n) atlas(es).

Two reviewers will screen, independently, in a first stage the titles and abstracts of all collected records and select papers for inclusion. In a second stage, full text of the studies selected in stage one will be screened and a lists of detected inclusion and exclusion criteria will be composed. Disagreements between reviewers will be resolved by mutual discussion.

The quality of each accepted study will be assessed, independently by two reviewers, using the Quadas tool. An initial search of Pubmed will be undertaken followed by an analysis of the text words in the title, abstract and the index terms used to describe the articles. Next, a search term will be established and used across the considered digital archives.

Out of each included study following characteristics related to the used dental age estimation method, together with related specific criteria will be extracted: the sample size; the considered teeth; the used dental variables; the dental variable outcomes; and, the study outcomes.

Specific outcome analyses will be established for each of the obtained dental age estimation study group in an attempt to compare the accuracy of age predictions between studies within a group and possibly between groups.

Forensic Odontology, Age Estimation, Systematic Review

F21 Dental Age Determination – A New Software Tool

Kenneth W. Aschheim, DDS, 44 East 67th Street, New York, NY 10065*

After attending this presentation, attendees will become familiar with a flexible new software tool that automates the process of determining dental age from birth through the completion of third molar eruption.

This presentation will impact the forensic science community by exploring the next generation of dental forensic software for prototype programs that are being developed for proof of concept testing. One area of interest is the ability to automate the dental aging process. The goal of this presentation is to present a proposed dental age determination software prototype system for possible inclusion in a future version of morgue management software that is being developed.

The use of dental radiographs for age determination has been well documented. Tables, by Moorrees, Fanning and Hunt (1963) and Demirjian, Goldstein and Tanner (1973), have been a common references for the forensic odontologist in determining dental age. However, they are not routinely used in daily morgue operations because a simple software package to aid in visualizing tooth bud development does not exist, and the mathematical calculations are often tedious. Previous software for age determination analysis based on third molar development is available; however, it does not do calculations based on succedaneous teeth in individuals with either a deciduous or mixed dentition.

The need for a software tool that was designed to automate the dental age determination process, as well as accommodate a greater range of ages, has led to the development of the Dental Age Determination (DAD) prototype software. Designed as a proof of concept project, it is hoped that it will ultimately be incorporated into currently available full forensic management software packages.

The software is divided into four sections: the demographic information section, the image manipulation section, the current dental assessment section, and the dental age calculation section. In addition, the software allows for user supplied “age-tables” based on ethnicity, sex, or any other custom metric.

The demographic information section utilizes standard fields for specimen familial data. It currently supports the Familial Data Set of ANSI/ ADA Specification No. 1058, the Forensic Dental Data Set. By allowing a one-to-one relationship with recognized data fields, future data transfer to other software products will be supported.

The image manipulation section allows for importation of multiple radiographic images and contains standardized tools to allow for magnification as well as scrolling for better visualization of the tooth bud stage determination. Importation of multiple images of standardized image formats (jpg, bmp, etc.) is currently supported. Future DICOM importation support is anticipated.

The key section for age determination is the algorithmic or current dental assessment section. Because recent studies have questioned the accuracy of the standard dental age estimation charts for children of different ethnic groups, DAD allows for the importation of user supplied multiple data sets which may be more accurate. The current prototype also displays both line drawings and radiographic samples of individual tooth bud development stages to assist in dental stage determination. This allows for the visual comparison of tooth bud stages to known standards.

The dental age calculation section is the final section of the software. This section performs an average dental age determination based on the forensic odontologist’s assessment of tooth bud development. In addition, it calculates simple statistical analysis of the data based on individual tooth bud development stage estimates. A final output screen displays the final calculation.

At the time of submission, the current version of DAD only contains a rudimentary reporting output, although a more robust system is anticipated as prototype development continues.

Dental Age Determination, Computer Software, Dental Informatics

F22 Dental Age Estimation Combining Developmental and Morphological Age Predictors

Patrick W. Thevissen, MSc, Katholieke Universiteit Leuven, School of Dentistry, Forensic Odontology Department, Kapucijnenvoer 7, Leuven, 3000, BELGIUM; Dimitra Galiti, Msc, Katholieke Universiteit Leuven, bus 7000, Kapucijnenvoer 7, Leuven, Belgium B3000, BELGIUM; and Guy Willems, PhD, Katholieke Universiteit Leuven, School of Dentistry, Kapucijnenvoer 7, Leuven, International B-3000, BELGIUM*

After attending this presentation, attendees will be informed on the age predicting effect combining age related dental variables based on third molar development and on tooth morphology.

This presentation will impact the forensic science community by providing knowledge that, observed on orthopantomograms, data combining developmental variables of third molars and morphological changes of other teeth is not improving age predictions based only on third molar development.

Most frequently asked questions from judicial authorities regarding age estimations in living individuals is whether or not the age of majority

is reached. In most countries this age threshold is set at 18-years-old. For this sub-adult age category dental age estimations are most commonly based on developmental changes of the third molars. Compared to all other maturing teeth, third molars have the highest human variability, resulting in age estimations with wide prediction intervals. For the adult age category, dental age can be estimated examining divers morphological tooth variables. One of them, apposition of secondary dentine on the walls of the pulp cavity can be evaluated in living individuals using radiographs. This technique was developed on periapical radiographs by Kvaal et al. (1995). Divers authors studied the feasibility of the Kvaal technique on orthopantomograms. The goal of this study was to detect on panoramic radiographs if additional tooth morphological measurements according to the Kvaal technique ameliorate the accuracy of age estimations based on scores of third molar development.

Retrospectively, 450 digital orthopantomograms from individuals with a Belgian nationality and Caucasian origin were collected from the dental clinic files of the Katholieke Universiteit Leuven. In the age range between 15 and 23 years, 25 radiographs were selected in each age category of one year for both genders. All available third molars were classified and scored according to the ten stage system proposed by Gleiser et al. (1955) and modified by Köhler et al. (1994). The Kvaal technique was applied on the upper central and lateral incisor and second premolar, as well as on the lower lateral incisor, the canine, and the first premolar from the left side. On the obtained measurements, the mean of length and width ratios (M), and the difference of mean width- and mean length ratios (W-L) were calculated separately for each tooth, for all upper, for all lower, and for all six teeth. After one month, twenty randomly selected orthopantomograms were rescored and measured again by the same and another observer to detect a high intra- and inter-observer reliability. Linear regression models with age as response and third molar scores as explanatory variables were established for the whole sample and for males and females separately. To these models M and W-L measurements were added for each of the six measured teeth, for all upper, all lower and all six teeth together. From the models the determination coefficient (R^2) and the root mean squared error (RMSE) were calculated.

The regression models calculated on the whole sample and including only third molar scores information revealed a R^2 of 0.60 and RMSE of 1.63 years. Adding the Kvaal information (M, W-L) maximally increased R^2 with 1% and decreased RMSE with maximally 0.02 years (for FDI tooth #22). The regression analyses performed separately for males showed comparable results. In the regression analyses based on females less accurate predictions were detected, most supplementary Kvaal information was observed adding the measurements of all six teeth.

Adding radiologically observed morphological secondary dentine apposition information to developmental third molar information was not providing more accurate age predictions. Moreover, the Kvaal technique was time consuming and not applicable on all panoramic radiographs.

Forensic Odontology, Age Estimation, Third Molar Development and Kvaal Technique

F23 Anthropological Measurement of the Juvenile Mandible and Dental Assessment Using Multi-Detector Computed Tomography

Alison L. Brough, BSc, University of Leicester, Forensic Pathology Unit, RKB, Leicester Royal Infirmary, Leicester, LE2 7LX, UNITED KINGDOM; Bruno Morgan, PhD, Leicester Royal Infirmary, Imaging Department, Leicester, UK LE2 7LX, UNITED KINGDOM; Sue Black, PhD, University of Dundee, Centre for Anatomy and Human Identification, Dundee, UK DD1 5EH, UNITED KINGDOM; Guy N. Rutty, MD, University of Leicester, Forensic Pathology Unit, Robert Kilpatrick Building, Leicester, LE2 7LX, UNITED KINGDOM; and Catherine Adams, BDS, Cardiff Medicentre, Heath Park, Cardiff, CF14 4UJ, UNITED KINGDOM*

After attending this presentation, attendees will understand the principles of odontological and anthropological identification of juvenile remains, multi-detector computed tomography (MDCT), three-dimensional imaging, and the necessary research required for the implementation of a virtual anthropological examination for juvenile age determination.

This presentation will impact the forensic science community by providing vital data which supports the implementation of a virtual/near virtual anthropological examination for the identification of juvenile remains. As the primary demographic feature used in the identification of juvenile remains is age estimation, determining the accuracy and repeatability of measurements derived by traditional and MDCT measurements would be a vital preliminary step in validating the utility of MDCT analysis in special situations such as forensic and disaster victim investigations (DVIs). This would accelerate the process of anthropological assessment and remove the necessity to deflesh remains, which may also be more ethically and morally acceptable, particularly when dealing with young victims and offers significant health and safety benefits for practitioners.

Anthropological examination of defleshed bones is routinely undertaken in medico-legal investigations to establish an individual's biological profile (age, sex, stature and ethnicity). However, when dealing with the recently deceased the removal of soft tissue from bone can be an extremely time consuming procedure that requires the presence of a trained anthropologist. In addition, due to its invasive nature, in some disaster victim identification (DVI) scenarios the maceration of bones is discouraged by religious practices and beliefs, or even prohibited by national laws and regulations. Radiological imaging modalities have been used in forensic practice as an adjunct to traditional anthropological techniques for many years. Currently, three different radiological techniques may be used in the investigative process; plain x-ray, dental x-ray, and fluoroscopy. However, recent advances in multi-detector computed tomography (MDCT) means that it is now possible to acquire morphological skeletal information from high resolution images, reducing the necessity for invasive autopsy procedures. Currently there is no standardised protocol for MDCT measurement of juvenile remains. In order for this "virtual approach" to be implemented and accepted internationally as part of a forensic investigation, accuracies must be shown to be comparable to that of traditional anthropological techniques. A series of studies conducted by the Developing Human Research Group, based at the University of Leicester, utilises skeletal material from the Scheuer Juvenile collection in order to construct a protocol for the measurement and age assessment of the entire immature human skeleton.

In this study, twenty juvenile mandibles were scanned using a truck mounted 16-detector CT scanner. This simple was used to construct a protocol for the measurement and age assessment of the immature human dentition. The results of this study illustrate that there is no significant difference between the measurements taken by MDCT and those by direct osteometric methods. MDCT had greater flexibility of measurements and offered the opportunity to take measurements not easily made on dry bone.

This research assesses the value of these new measurements in addition to considering the limitations and the potential applications of this virtual approach.

Forensic Anthropology, Multi-Detector Computed-Tomography, Imaging

F24 Technological Advances in Forensic Odontoloygy

Irena Dawidson, DDS, PhD, The National Board of Forensic Medicine, Retzius v. 5, Solna, 17165, SWEDEN*

The goal of this presentation is to enhance the performance of the postmortem odontological investigation.

This presentation will impact the forensic science community by improving the equipment standards resulting in a swifter and safer forensic odontology investigation.

DMORT teams that exist in the United States are an exception that has no real counterpart in other parts of the world**.** In many countries the disaster victim identification organization is put together *ad hoc* when the fatal event occurs. Among the disciplines involved in the identification effort, the forensic odontology seems to have the least official affiliation in spite of its fundamental contributions to the establishing of identity. Subsequentely, there's often little involvement of the proper agencies in the developing and modernization of the equipment and facilities to suit and enhance the forensic odontologists' working environment. That is ultimately left to the individual forensic odontologist with whatever means that are available, presenting finacial problems as the forensic odontology quite often is a sideline occupation for dental professionals in academia or in private or community practice. Since their services are required infrequently it has not been possible to consistently develop the technology needed in the identification work, especially when large efforts are necessary in cases of mass disasters. The odontological identification work requires quite a lot of instrumentation, including x-ray machines as well as the radiographic reception media and very good illumination. All these devices have been traditionally gathered and/or built by the forensic odontologist, comprising among other things "home-made" portable x-ray machines on tripods, which would fall and break all too easily, portable "dark-rooms" for developing analogue radiographs, headlamps, and flashlights. All these things were heavy, cumbersome, and generally difficult to haul around as well as unrelible.

During the last decade the technology of the forensic odontology has gone through a dramatic progress diminishing the amount of equipment that has to be moved by about 75% in volume as well as in weight. Since the combined international effort in identification of the December 26, 2004 Bengal Bay Tsunami victims, there has been a swift innovation in the field of the forensic odontology.

The portable x-ray machine has become a handheld device that works on batteries. Also, replacing the analogue radiographs with digital radiography has reduced both the time needed for obtaining good quality radiographs as well as the the quantity of machinery. A battery operated intraoral lamp that can be placed inside the oral cavity will provide bright lighting. Another common feature of these devices is that they can run on batteries for several hours making the forensic odontologist independant of external power supplies for at least a working day at a time. There is however, the drawback of the costs of these devices prohibiting many of the forensic odontologists from acquiring them. Neither the policemen nor the pathologists have to pay for their own equipment.

Conclusion: In order to improve the ability of the forensic odontologists to carry out their part of the identification process the concernered national authorities should be encouraged to obtain the modern equipment needed. Another advantage would be that compatible pieces of equipment can be assembled.

Forensic, Odontology, Equipment

F25 Quality Assurance in an International Perspective and IOFOS Recommendations

Tore T. Solheim, University of Oslo, Blindern, Box 1052, Oslo, 0316, NORWAY*

After attending this presentation, attendees will understand the importance of quality assurance in forensic odontology. Also the difficulties of quality assurance on an international level will be appreciated and knowledge of the IOFOS' work and recommendations will be acquired.

This presentation will impact the forensic science community by increasing awareness of quality assurance and systems for such assurance. Also the IOFOS recommendations may not be so well known in the United States, but could be of use also for American forensic odontologists.

According to the law in many countries, medical and dental work should be subject to quality assurance. Thus also forensic medicine and forensic odontology has a duty to implement systems for quality assurance. What quality assurance actually is may be considered differently and it also may consist of many different elements. All efforts to make sure the quality fulfill a minimum requirement and also effort to improve the quality may be called quality assurance. Most important may be descriptions of procedures to be followed in the work; however, also important is the quality of how the presentation is, for instance in the form of the quality of the written report.

Other aspects of quality assurance are quality improvement, registration of deviation from normal, and registration of accidents. Education of the expert and level of competency is part of quality assurance. Quality assurance may be a so called "paper tiger" if it is not implemented and followed up in some way. Quality assurance is the responsibility of leaders. Except for within an ID-commission, forensic odontologists operate on an individual basis. Thus there is no authority to control if procedures are followed.

To agree upon procedures on a national level is difficult. Therefore, in most countries each dentist must have his own procedure descriptions. It is even more difficult to establish procedures on an international level that people may agree upon to the extent that they are willing to follow them. Except for ethical rules there have been no known attempts to establish international systems of quality assurance. From the beginning, It was clear it would be difficult when the IOFOS decided to come up with recommendation for procedure descriptions in the various fields of forensic odontology in 2003.

In 2004, an international meeting was held in Norway with participating forensic odontologist from a number of countries representing all continents except America and Australia. It showed that they could agree upon very little and some would thing one step was important others would thing a different step was important. To reach some degree of agreement it was decided that only procedure steps should suggested on an international level, not how each step should be carried out. We felt that should be left to quality assurance in each country or society.

There was a great deal of disagreement about the steps. Only those where there was full agreement is a stage recommened as obligatory. Others, although reasonable enough, are only recommended and may be omitted. To implement the recommendations we advise each forensic odontologist to write in their report that they are following the IOFOS recommendations for quality assurance. Also we advise each society to see if they may accept these recommendations for their members and thus sign a contract with IOFOS.

Quality Assurance, International, IOFOS

F26 A Twenty-Two Year Old Cold Case Homicide With Bitemarks

William T. Lichon, DDS, 4028 State Street, Suite A, Saginaw, MI 48603*

After attending this presentation, attendees will realize that even a 22-year-old cold case can contain bitemark evidence which can be processed.

This presentation will impact the forensic science community by examining how even after many years, a cold case homicide can contain forensic odontology evidence that may be useful in the conviction of a long time suspect.

The year was 1989. Kim Currington was found by two of her children bludgeoned in her bedroom. Earlier that morning, the children, nine-year-old, seven-years-old, and a six-year-old, related they saw the boyfriend of their mother, stab her in the right leg during an argument. She screamed to the children to run to school. When two of the children returned from school near noon, they found their mother lifeless in the bedroom. They ran across the street for help and police were notified. The Saginaw Police Department arrived and secured the scene. They confirmed the fact a homicide had occurred. The crime scene investigators arrived and began to process the scene. Photos were taken of the exterior of the house and surrounding area. Following that, the interior of the house was processed. There were two entrances to the home. The entrance on the driveway side of the house revealed the door was locked. The front porch entrance door had a full size sofa placed directly in front of the door. The first responding officer related they had to push the sofa away from the door to gain entrance. There was no sign of forced entry on this door, plus the other house door was locked. Photographs were taken of the complete interior of the home. The windows in the home were all secure and no signs of a forced entry. There were two bedrooms; one for three children and a master bedroom. The children's bedroom appeared to be orderly and undisturbed. The master bedroom doorway was partially covered with a thin curtain. Upon entering, the bed was to the right with the victim lying face up on the bed with her feet near the floor. On examination of the victim, there were two large openings in the right lateral forehead, with other visible lacerations to the mid and left forehead. There was a large pool of blood around her head with blood splatter on the wall directly in the back. The victim was dressed in thin pink top and black dyed jeans. After crime scene photographs were completed the victim was transported to the hospital for an autopsy. After the clothing was removed, the pathologist noted a bitemark on the right upper arm and on the left breast. Swabs were obtained from both bitemarks. Photographs of both of the suspect bitemarks were taken with the ruler in place. Also noted was a stab wound on the right leg. There were multiple impacts to the head.

At the time, living in the house was the victim, the victim's three children, along with the victim's boyfriend. The boyfriend was questioned by the police and a signed search warrant was obtained for dental information. A local dentist at the time, who is now deceased, took upper and lower impressions of the suspect's teeth along with wax registrations. Photographs were also taken of the suspect's teeth. Later the photographs and dental models were taken to a forensic dentist in the Pontiac, Michigan area for evaluation. This dentist is now in poor health and has left the state. This was done on February 17, 1989. The case for a number of reasons was put on hold and not litigated. In 2009, the case was activated by the Michigan State Police Violent Crime task force, Cold Case Unit. The bitemarks evidence which had been stored in the evidence locker for over twenty years was examined. The dental models were wrapped in bubble wrap and in excellent condition. This interesting case was litigated in April of 2011 and concluded with a verdict of first degree murder.

Cold Case, Homicide, Bitemarks

F27 The Joplin Missouri Tornado Disaster

John E. Filippi, DDS, 1325 North 127th Avenue, Omaha, NE 68154; and Peter W. Loomis, DDS*, New Mexico Office of the Medical Investigator, 700 Ranchitos Road Northwest, Los Ranchos de Albuquerque, NM 87114*

After attending this presentation, attendees will better understand how the forensic sciences supported the identification process in this particular mass fatality Incident (Joplin Tornado). The main focus of the presentation will be directed to the utilization of forensic dentistry in the human identification process.

This presentation will impact the forensic science community by enhancing a forensic team's knowledge (specific to odontologists) and the ability to better prepare and respond to future mass fatality Incident events.

The goals of this presentation are to familiarize and help the attendees understand the following:

- The destruction an EF5 (Enhanced Fujita Scale) Tornado can produce to a community and utilizing a short video.
- Discussion regarding who directs a forensic operation of this magnitude, via the Stafford Act, ESF #8 (Emergency Support Function), federal team assistance, and the assets that were deployed to Joplin.
- The timeline of the disaster, logistics and morgue operations, forensic science work stations, with special attention to the dental comparison analysis, utilization of the WINID3/DEXIS system and final identification results.
- How the federal disaster team supported the local coroner system with forensic services, family assistance, and multi-forensic science supported victim identifications.

Background: The 2011 Joplin tornado was a devastating EF5 multiple-vortex tornado that struck Joplin, Missouri late in the afternoon of Sunday, May 22, 2011. It was part of a larger late-May tornado outbreak sequence and reached a maximum width in excess of one mile (1.6 km) during its path through the southern part of the city of Joplin Missouri.

The Joplin tornado ranks as one of America's deadliest tornadoes and is likely to be the costliest, with an estimate of $3 billion to rebuild Joplin. It was the first F5 or EF5 tornado in Missouri since the Ruskin Heights tornado struck south of Kansas City in 1957. It is also only the second F5 or EF5 tornado in Missouri history dating back to 1950. The May 2011 tornado was the deadliest tornado to hit the United States since 1947—the seventh-deadliest single tornado in U.S. history, and 27th-deadliest in world history. As of July 8, officials reported that 158 people died from the tornado, with another killed by a lightning strike during cleanup operations the next day.

The tornado intensified greatly as it entered a densely populated portion of the city at about 5:41 p.m. (C.S.T). Damage was widespread and catastrophic in residential subdivisions in the southwest portion of Joplin, which included the St. John's Regional Medical Center. Virtually every house in that area (near McClelland Boulevard and 26th Street) was destroyed and some were literally blown away in the area as well. Trees sustained severe debarking, a nursing home and a church school in southwest Joplin were also destroyed, and several other schools were heavily damaged along with numerous dental and medical offices.

As the tornado traveled across the southern portion of the city, heavy objects, including concrete parking bumpers, and large trucks, were tossed a significant distance, as far as 1/8 mile (200 m) away from a parking lot and some tornado debris was recovered as far as 75 miles away from Joplin. The tornado dissipated east of Joplin at 6:12 p.m. (CST) after approximately twenty-five minutes on the ground and the tornado's total track length was at least 14 miles long.

Conclusion: The presentation will also review the organization of the dental team, including the postmortem, antemortem, and comparison sections and the methodology used by them.

The experience gained from this unfortunate mass fatality incident (MFI) has enhanced the forensic team's knowledge and the ability to better prepare and respond to future MFI events.

Forensic Odontology, Mass Disasters, Human Identification

F28 The Identification of Burned Human Remains

James McGivney, DMD, 346 Tulip Drive, Webster Groves, MO 63119; and Eric S. Wilson, DDS, PO Box 50, Cole Camp, MO 65325*

After attending this presentation, attendees will; (1) understand the steps necessary to fully document the dental features of burned human remains; and, (2) will appreciate the difficulties encountered when working with burned human remains.

This presentation will impact the forensic science community by demonstrating the importance of step by step documentation of burned human dental features.

The identification of burned human remains is one of the most difficult tasks faced by forensic odontologists. In cases where there is extensive burning, the skin is charred and flakes off, bones become discolored, brittle, and fracture, and the crowns of teeth may crack or at times explode.

At initial recovery, the thermal destruction makes retrieval of all biological fragments difficult. In many cases small, yet important portions are missed, disturbed, or even destroyed during scene processing. A systematic, conservative approach to recovery and examination is needed to prevent the loss of valuable dental information before a thorough dental charting, intra-oral photographs, and radiographs can be obtained.

The lips, tongue, and cheeks initially insulate the oral cavity and present a barrier to heat and fire. The teeth can remain relatively undamaged while the rest of the body shows signs of extensive fire damage. This pattern is seen in cases where an accelerant is used to burn a body in an attempt to hide a homicide.

When a fire burns long and hot, the insulating tissues are consumed by the fire and the damage to the oral structures will be extensive. Teeth will be completely consumed in a hot fire. While teeth do not survive the cremation process, certain dental restorative materials such as porcelain and stainless steel can be found in cremains.

Delattre has described a four stage process to follow when examining burned human remains. First photographs are taken of the undisturbed remains. Then soft tissue is removed to allow better visualization and additional photographs. The third step is to carefully obtain access to the oral cavity to allow exposure of radiographs and photographs. Lastly loose dental specimens are placed in suitable containers to avoid further damage and loss.

In the spring of 2011, an extensively burned set of human remains was recovered from a car fire. Investigation by medical examiner's personnel allowed the formation of a putative identity and contact was made with the suspected victim's mother who was able to provide an antemortem dental chart. The mother was also able to provide a decorative tooth grill and a dental model from which the grill was fabricated. In hip hop culture, a grill (to include front or golds) is a type of jewelry worn over the teeth. Grills are made of metal and are generally removable. Grills are fitted to a dental model of the wearer. The long term safety of grills is debatable, as is their effect on oral health and hygiene. Grills can be obtained online and from beauty and barber shops.

The body was examined, photographed, and digitally radiographed. Examination of the body disclosed a loose crown and a tooth grill.

A positive identification was confirmed by several methods. Antemortem and postmortem radiographs of a root canal filling in an anterior tooth compared favorably. The grill found on postmortem examination fit the dental model obtained from the mother. The tooth grill obtained from the mother fit the postmortem dentition; and a loose metal crown found postmortem, fit a tooth on the dental model.

Care used in the examination and documentation of severely burned human remains made possible a positive dental identification via several modalities.

Odontology, Identification, Human Remains

F29 Remains of Climber Identified After 21 Years on a Glacier: A Case Report With Discussion of the Need for an International Missing Persons Database That Includes Dental Records

Lowell B. Riemer, DDS, 8-25102 TWP RD 542A, Sturgeon County, AB T8T 0C4, CANADA*

After attending this presentation, attendees will understand the circumstances and factors involved in a climbing accident, which resulted in rescuers being unable to locate a missing mountain climber for 21 years. Positive identification of the recovered remains was possible because of dental records retained by the local police agency.

This presentation will impact the forensic science community by reinforcing the importance of retaining dental records of missing individuals for an indefinite period of time. Priority must also be placed upon consensus and implementation of a national and international missing persons database that includes accurate dental records.

The American Alpine Club states that between 1951 and 2005 there were 1,686 deaths in Canada and the United States related to climbing activities with 18 and 59 fatalities occurring each year. The report, Accidents in North American Mountaineering, provides statistics regarding injuries and fatalities in all reported climbing incidents and the factors involved.

This case report concerns a pair of experienced winter climbers in the Canadian Rocky Mountains. Upon reaching the summit of the mountain the climbers unclipped from their ropes. One climber proceeded to move about to locate their desired descent route. While venturing too far onto an unsupported snow/ice cornice, the climber disappeared from view as he fell 300 feet before likely striking the face of the mountain and another 1,800 feet before striking a snow slope, which then fanned out over a 160,000 square foot area of glacier. Due to deteriorating weather and snow conditions, the body could not be recovered. Dental records were acquired by the local police agency and retained on file in anticipation of a future recovery of the body of the deceased. Twenty-one years later, a body was observed partially embedded in glacial ice and was subsequently identified as the missing climber though comparison with the dental records.

The body, still clothed in climbing gear, was desiccated and mummified. The remains showed evidence of being trapped and compressed within the glacier for the 21 years. The right foot had been disarticulated at the level of the ankle and was located in close proximity to the rest of the body. Some bony fractures and adjacent soft tissue discoloration were suggestive of possible antemortem trauma. The cause of death has been attributed to multiple blunt injuries.

The head and climbing helmet were extensively compressed in a midline sagittal plane resulting in a compressed thickness of approximately 6.5 cm in width. Brown head hair and a moustache were still evident. The teeth were still in good condition and position with only one tooth displaced through avulsion despite the lateral compression of the dental arches. A considerable amount of previous dental work aided the comparison with antemortem dental records.

The Royal Canadian Mounted Police are to be acknowledged for their record keeping and readily accessible antemortem dental records for this individual. This case emphasizes the importance of comprehensive antemortem records, including dental, being compiled, stored, and being accessible for all missing persons cases.

Dental Identification, Mountain Climbing Fatality, Glacial Compression

F30 A Study of Bitemark Characteristics in Live Human Subjects

Kenneth P. Hermsen, DDS, Creighton University, School of Dentistry, 2500 California Plaza, Omaha, NE 68178; Eric S. Wilson, DDS*, PO Box 50, Cole Camp, MO 65325*

After attending this presentation, participants will understand the issues associated with performing bitemark research on live human subjects, including the Institutional Review Board process and the challenges encountered in doing research on live human subjects.

This presentation will impact the forensic science community by reporting on the latest attempt to move the study of bitemarks into the realm of research on live human subjects, providing insight into the issues encountered in the endeavor.

Thirty-two live human subjects volunteered for the project which was designed to compare the bitemarks that resulted from a bite. The bite was delivered by a device that was fitted with a set of denture teeth provided by the prosthetics laboratory at Creighton University School of Dentistry. The decice was outfitted with a pressure sensor that could measure the amount of pressure being exerted by the bite. The intent of the project was to administer a bite with the same amount of pressure to each volunteer and compare the marks created. It was an attempt to determine if all the marks were similar in appearance or if there were significant variations that might be related to individual characteristics of the volunteers, like gender, stature, or muscle mass. During the IRB process, the project was altered to first determine the minimum amount of pressure that would be required to produce a mark in all the volunteers.

To accomplish this, fifteen volunteers from the original group of thirty-two were selected to participate. The forearm was selected for the site of the bite for this initial phase of the project. The volunteers were subjected to incremental increases in pressure until a mark was produced that lasted for a minimum of twenty-four hours. Based on the unexpected results of the initial phase, it became apparent that proceeding with the original research design would be extremely difficult and would bring into question some ethical issues that should be resolved before proceeding.

The results of the initial phase showed a significant variation in the amount of pressure required to produce a mark that lasted for twenty-four hours as well as significant variations in how the marks were manifest. The least amount of pressure to create a mark was in an Asian female who was the smallest in stature of the group. She exhibited a bruise at the site of the bite at a reading of 60 lbs. as indicated on the pressure sensor. It was not a pattern bruise but rather a round bruise approximately 10 mm in diameter in the area of the maxillary central incisors. The last two volunteers to mark were two males who did not exhibit a mark that lasted for twenty-four hours until the pressure sensor had indicated a pressure of 235 lbs. Neither of these marks were bruises, per se, but rather red marks corresponding to the incisal edges of the teeth. One of the males was the largest in stature of the group. The length of time the indentations made in the skin by the bite was also noted.

In all volunteers, the indentations left by the teeth had clinically disappeared within two hours of the administration of the bite with only one exception. In that exception, a female reported that the indentations were clinically detectable for approximately six hours. However, in spite of the persistence of the indentations, she did not exhibit bruising or marking of the bite for the required twenty-four hours. It should be noted that in previous and subsequent bites, her indentations disappeared within two hours. She reported having been working out prior to the application of the bite and suggested perhaps she was dehydrated. It is unknown whether this could be a factor. This study revealed a variation from 60 to 235 lbs in pressure required to produce a mark lasting twenty-four hours, it also showed a wide variation in the manifestations of the mark even though the volunteers were all young, healthy adults. Further study is required to draw any conclusions, but there are ethical issues that should be considered before moving ahead with further human studies.

Bitemark, Human, Live

F31 Bitemark Analysis in Hungary

Armin A. Farid, DDS, Avicenna Med & Dent Bt., Podmaniczky Utca 33, III Floor, 8, Budapest, 1067, HUNGARY*

After attending this presentation, attendees will gain a clearer understanding of bitemark analysis in Europe as it is becoming more and more an integral and vital part of police investigation work.

This presentation will impact the forensic science community by raising awareness that violent biting happens all over the world despite not gaining the attention it deserves.

Hungary has a long history of bitemark recognition, study, and analysis. The Forensic Institute of Semmelweis University, one of the most traditional and renowned centers of medical education in Europe, undertook the work of bitemark analysis as early as 1904. Medical textbooks make reference to bitemark analysis conducted by Dr. Laszlo Harsanyi in 1968; however, due to the low rate of criminal activity in socialist countries such as Hungary, little attention was given to this topic in the past. Although animal bitemark analysis was conducted frequently, the occurrence of human bitemarks was considered rare or nonexistent.

Beginning in 2008 as a result of an aggressive media campaign, effort and a special educational program aimed at raising awareness among the Hungarian Crime Scene Technicians, the importance of bitemark analysis was brought to light among not only the police force but also the general public resulting in the reporting of several bitemark cases within a short period of time.

The most prominent case occurred in December 2010 in a suburb of Budapest and shocked the Hungarian nation. A two-month-old infant was beaten by her father and then bitten twice to be silenced. The police were called in once the infant was admitted into the hospital twelve days after the initial abuse had taken place. During the initial medical assessment it was apparent that additional abuse had taken place. Since this case involved a "closed population" suspect pool, a forensic odontologist was called in to analyze the dental evidence obtained from both parents of the infant. A thorough examination and analysis of the bitemarks ruled out the mother as a suspect and concluded that the father was the probable offender. The highly individual characteristic of the bites helped strengthen the father's conviction. The forensic dentist in Hungary involved in this case collaborated closely with his mentor in the United States who offered valuable advice and guidance during this process.

A few weeks later, another case was reported of a child bitten multiple times by a neighbor who was babysitting him while his mother was at work. Soon after this report reached police investigators, an elderly woman attacked in her home was reported to have bitten her attacker in self defense. In both of these cases, bitemark analysis served as strong evidence in the respective criminal investigations.

It is believed that the education of not only the police force and agencies concerned with children and women's welfare, safety, and protection, but also that of the general public of the significance of bitemark analysis, which will result in an increase of reported cases ultimately serving to protect the general population as well as providing the justice system with critical evidence in solving crime.

Hungary, Bitemark, Police Investigation

F32 Bitemark Analysis — The First Step Utilizing Bitemarks as Evidence

Richard R. Souviron, DDS, Medical Examiner's Office, Miami-Dade County, Number One on Bob Hope Road, Miami, FL 33136*

After attending this presentation, the attendees should be able to implement a systematic and logical approach to analyzing a human bitemark with the objective of providing useful information to the authorities.

The presentation will impact the forensic science community by providing a comprehensive and useful description of a human bitemark. The proper analysis of a bitemark will impact the use of this evidence for later comparisons.

The terminology used in describing bitemark evidence is confusing at best and misleading in many cases. The confusion has to do with the term analysis which means "separation into component parts, qualitative, and quantitative." The term comparison means to examine for similarities or differences.

In real time, the odontologist is often presented with a photograph of a pattern injury. He may or may not have scene photos, the photos may or may not have a ruler or scale present. He may have no information as to the circumstances of the event. If it is a Class I bite, the odontologist may give an opinion such as "diffuse bitemark with no evidentiary value in bitemark analysis." However, there is valuable evidence and analysis should be conducted of a Class I bite. The analysis consists of breaking the bitemark down into logical parts. The most important factor to decide is whether it is a human Bitemark; andm if so, is this a child or adult dentition? Further analysis may be able to determine when it was made in relation to time and the circumstances of the event, i.e., an old healing bite, peri-mortem bite, postmortem bite or a fresh bite. If possible to locate and differentiate upper and lower arches so one may be able to determine the position of the biter in relation to the victim. Analyzing the bite may also determine whether the bite was made through clothing. Evaluation of the bite should help to determine whether or not pain was inflicted on the victim. In Class II and Class III bites more definitive opinions can be given. These opinions may or could include a profile of the biter, positions of the biter to the victim, arch form identification, adult versus child bite, or more. Transillumination of the bite may give more details of the individual and class characteristics of the teeth.

All of this analysis does not take place in a vacuum but with knowledge of the circumstances of the event, scene photographs, orientation photographs, scaled photographs, etc. The analysis phase of a bitemark has nothing to do with a comparison to anyone or to the ID of a biter.

The comparison phase may rule in or rule out (exclude) a potential biter and is separate and apart from the analysis of the injury pattern. In the case of a good bitemark (a class III) with both arches and distinct individual tooth characteristics present and with a closed population, an odontologist can state "within reasonable medical/scientific certainty of a match." However, "scientist may have a high level of confidence if there is abundance evidence but they wont ever claim absolute truth or absolute certainty" (GLY.UGA.EDU).

Analysis, Comparison, Odontology

F33 Patterns of Variation and Match Rates of the Anterior Biting Dentition With Regard to Size and Shape: Characteristics of a Database of 3D Scanned Dentitions

Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; Peter J. Bush, BS, Laboratory for Forensic Odontology Research, School of Dental Medicine, SUNY at Buffalo, B1 Squire Hall, South Campus, Buffalo, NY 14214; and H. David Sheets, PhD, Canisius College, Department of Physics, 2001 Main Street, Buffalo, NY 14208*

The goal of this presentation is to describe dental shape variation and shape matches in a large population of three-dimensional (3D) dental models.

This presentation will impact the forensic science community by addressing one fundamental premise of bitemark analysis, that of "uniqueness" of the human anterior dentition.

Critics of the concept of "uniqueness" claim that individuality cannot be proven since examination of every individual that exists, and has existed, is not possible. To this end, it might best to describe "uniqueness" as "sufficiently similar" such that two objects cannot be measurably distinguished once impressed in a substrate.

To state that two objects are indistinguishable requires a definition of measurement resolution and error. In any given system, these parameters may be determined by repeated measures of an object in question. Any two (or more) objects that fall below this defined error threshold, when compared with each other, may be said to be indistinguishable.

An established means to study size variation in shape in biological systems is landmark based Geometric Morphometic analysis (GM). It is a multivariate approach and allows statistical comparison of the change in shape in large datasets. With this approach, shape information can be visualized by plotting landmark positions in Procrustes superimposition, a method of optimally matching one shape to another. This technique can be performed with or without scale and for this study both approaches were used. Procrustes distances can be used to summarize variations in populations, to express the degree of similarity of individual specimens, means of populations, or to search for matches between specimens.

Another statistical tool available in the GM framework is Principal Component Analysis (PCA). This allows for determination of which shape aspect is responsible for the most variation. Finally Partial Least Square (PLS) was utilized to observe patterns of covariation in maxillary and mandibular data.

In this study, the anterior human dentition was examined in 3D data using size-preserving Procrustes (Procrustes-SP) methods, as well as scale-independent Procrustes methods.

A collection of 1,099 distinct paired sets of 3D scanned maxillary and mandibular dentitions were obtained from a commercial dental laboratory, which produced these scans for the production of occlusal guards (night guards). Of these, 497 pairs were taken from an earlier data set (Bush, Bush, and Sheets, 2010) and 602 pairs were newly measured for this study. The individuals involved were private practice patients from dental practices across the United States. All patient identifying information was stripped from the data prior to any additional processing. This was a sample of convenience, containing a wide range of alignment patterns, from relatively straight to fairly mal-aligned. All necessary Human Subject Institutional Review Board protocols were completed for this project and exemption was granted.

Curves were placed which delineated the incisal edges of the six anterior teeth in both uppers and lowers. Each curve contained 10 landmark data points on each incisal edge. A total of 60 data points in 3D were obtained for each arch.

Following landmark data point extraction, statistical analysis was completed to describe the variation in these human biting dentitions and to determine match rates in the population studied. The statistical tools, as described above, were used in conjunction with LM methods to produce a summary of the variation present in this large data set, as an initial approach to understanding the types of variation present in the population of dentitions.

Results indicate that, measurably indistinguishable maxillary and mandibular dentitions could be found (defined as a match rate). The paired dentitions were also evaluated as a set. Two specimens (one pair) with just shape information, and four specimens (two pairs) with size and shape were found to be indistinguishable in the dataset. PCA revealed definite patterns of common mal-alignment, allowing exploration of the variation that exists in this population.

The sensitivity of match rate on measurement error was also determined by searching for matches as a function of assumed error level, indicating rapid increases in match rate as measurement error increased. The nature of the relationship of arch width and centroid size among and between the maxilla and mandible was examined. Lastly, Principle Components Analysis and Partial Least Squares revealed readily interpretable patterns of variation and covariation in the data, with both dominated by the variation in relative arch width.

It was concluded that arch width was the principal factor in variation. A number of specimens were found to be measurably indistinguishable

when investigating the maxillary and mandibular arches separately. When investigated as a set, incorporating size caused an increase in the number of specimens that were indistinguishable.

Forensic Science, Dental Uniqueness, Bitemarks

F34 Couplers for Scale Combination and Orientation

James C. Schneider, DDS, Cuyahoga County, Coroners Office, 8660 Columbia Road, Olmsted Falls, OH 44138*

After attending this presentation, attendees will be able to better use currently accepted scales for forensic documentation.

This presentation will impact the forensic science community by allowing better use of forensic scales while demonstrating photographic documentation more accurately in a court of law.

For many years, the field of forensic Odontology has had the luxury of using scales (rulers) in the forensic community that have been proven to be of high accuracy. This is undoubtably of utmost importance when portraying evidence in a court of law, and obviously important when one studies and interprets a photographed patterned injury such as a bitemark.

However, until now, it has been difficult to professionally "surround" a patterned injury for accurate measurement recording. In the past, it has been advised that when one wished to photograph a patterned injury from multiple sides concurrently, two or more scales could be laid end-to-end or corner-to-corner. For a number of reasons, it is recommended that this technique no longer be used. When one places multiple scales end to end, or corner-to-corner, there is no assurance the scales will be in the same plane. Further, there is no assurance the scales will meet in an end-to-end relationship with no space between. And further yet, there is no assurance the scales will not overlap or be at an improper angle.

By using the scale couplers, the above-mentioned problems are solved. It has already been noted that the forensic community uses scales that have been proven to be of high accuracy, and are accepted by the legal and judicial communities. The use of the scale couplers enables existing scales to be used in a better and more professional manner. These couplers eliminate the need for the fabrication of other scales by putting to better use our already proven and most accurate scales.

The scale couplers have been fabricated in a variety of shapes with which to orient two or more scales; however, the two most common used couplers are the "corner" or 90° coupler, and the "straight" or 180°coupler.

To use, existing straight or right angle "L" shaped scales are simply inserted into the couplers that firmly hold the scales oriented. By doing so, a patterned injury, or other such displays needing to be photographed can be completely encircled. Thus, easier and more accurate measurements can be made. As one may imagine, a multitude of patterns can be photographed this way, but not limited to tire patterns, shoe prints, blood, and other body fluid spatter, gun shot residue etc.

These couplers allow scales to be oriented in the same plane and brought together to an end-to-end or corner-to-corner relationship. These couplers maintain the accuracy of the "joint" or "joints" of two or more scales for accurate measurement. These scale couplers allow the forensic community to use scales already proven accurate in yet a better manner.

Simple, and yet fabricated of high quality and standards, these scale couplers are already being used in many locations. As an advantage to photographic departments, these scales further allow the use of iridescent scales to be oriented for ultra violet imaging.

In conclusion, the scale couplers are easy to use, reusable, and enable the forensic community to better use scales already trusted.

Scale Couplers, Couplers, Photographic Couplers

F35 Bitemark Analysis in an Italian Judicial Case: Dentists – Do They Bite Off More Than They Can Chew?

Emilio Nuzzolese, DDS, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, 70124, ITALY*

After this presentation, attendees will have a better understanding of the expert witness testimony in the Italian legal system.

This presentation will impact the forensic science community by raising awareness of the importance of the involvement of trained and experienced odontolgists when a life sentence is at stake.

The purpose of bitemark analysis is to retrieve both distinct individual and class characteristics of teeth on the bitten skin. The odontologist compares the dentition of the suspect's with the injury pattern and draws a conclusion as to whether or not they were compatible using a variety of methods. The expert witness assessment of a bitemark pattern injury commissioned by the defendant is presented. The framework is a twenty-year-old homicide cold case, where only one suspect has recently been found guilty.

The purpose of the presentation is to promote a discussion among experts about who should perform a bitemark analysis, thus reducing potential errors and observer bias. At this point dentists and odontologists cannot be considered of equal forensic ability, thus suggesting two separate expert witness categories in civil cases related to professional litigation and/or dental traumatology and judicial cases related to crimes.

The case presented is suggestive of a partial bitemark where the forensic significance is crucial. This provides the basis for a controversial comparison with only one suspect, although it is well understood that, except specific cases, the comparison should be carried out within a sample of suspected biters. Poor quality of evidence, primary and secondary distortion of the bitten skin, combined with the lack of a direct assessment on the human specimen, plus absence of a proper metric scale, make it impossible to decide upon the correct orientation of the biting teeth. In view of this, the results of the forensic evaluation should be restricted to exclusion. The analysis of the bitemark injury by the forensic odontologist, in conjunction with the forensic pathologist, remains of unquestionable value for the investigation of this criminal case.

The case presented is not designed to provide an account of how a bitemark comparison should be undertaken but raises concerns of the validity of bitemark evidence that is dramatically connected to those involved in the technical analysis of a bitemark. This case confirms the importance of involving a forensic odontologist, rather than a general dentist, in the analysis of a bitemark injury pattern to reach a technical conclusion and reduce to the minimum the risk of subjective conclusions. The need of education, training, and updating in forensic odontology, which goes beyond everyday dentistry and dental training, suggests the need of a periodical review of those professionals registered in court for expert testimony. In the Italian legal system, as in other European countries, it may be worth considering the institution of a subcategory (or a separate one) of experts in forensic odontology and legal dentistry, within the actual single category board of court experts/consultants who only have a degree in dentistry. Many dentists involved in the judicial system in Italy are still not sufficiently aware of the extent of forensic odontology as an autonomous discipline within the forensic science field, least of all how a bitemark assessment should be performed.

The use of non-peer reviewer techniques, the lack of formal training in forensic odontology, poor quality evidence, and prosecutorial interference are some of the possible pitfalls that the review of this cold case reveals.

Bitemark Analysis, Forensic Odontology, Cold Case

F36 Lens Correction, White Balance, and Other Photographic Prerequisites to Bitemark Interpretation

Robert B.J. Dorion, DDS, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ieme, Montreal, QC H2K 3S7, CANADA*

After attending this presentation, attendees will be briefed on new scientific evidence regarding the requirement for lens correction caused by optical aberrations of a particular lens and the necessity for "white balance" and methods used to accomplish the tasks as well issues surrounding different file formats.

The theme of this year's Annual Meeting is *Global Research: The Forensic Science Edge*. This presentation will impact the forensic science community by providing forensic odontologists with the leading edge of knowledge on the subject of bitemark evidence.

Bitemark analysis is by far the most complex and difficult subject matter in forensic dentistry.[1] Following bitemark recognition, the analysis involves a series of noninvasive procedures that includes photography regardless of whether the bitemark recipient is alive or deceased. The conclusions are, at times, solely based on this analysis. It is therefore paramount to understand the factors that influence photographic evidence and which may ultimately contribute to erroneous conclusions.

A search of the Journal of Forensic Sciences between 1972-2010 reveals not a single article dealing with the issue of lens correction or "white balance" in forensic photography.

Lens aberrations are deviations from a norm of an optical system that leads to image blurring. Even if the image is sharp, it may be distorted. Ideally, the magnification of an object is inversely proportional to its distance to the camera. Distortion can result from non-uniform stretching of an image. The most prominent form of distortion is referred to as "barrel distortion" where the center of the image is magnified more than the perimeter.

"White balance" in a photo reflects the lighting condition under which it was taken. It is influenced by daylight, cloudiness, shading, tungsten, fluorescent and flash conditions, and so on.

This presentation will focus, in part, on methods of correcting lens distortion and "white balance" using Adobe® Photoshop® CS5 Extended.

RAW file format is a class of formats and each manufacturer creates its own version of a RAW file format for each camera model. This data block contains unprocessed pixel readings from the camera metadata and sensor chip. The standard for RAW image format is ISO 12234-2, TIFF/EP. Adobe's Digital Negative (DNG) specification is an attempt to standardize a RAW image format for cameras.

File compression is the process of reducing the size of a file to facilitate storage and transfer. The resulting file may retain all of the data or there may be data loss. Compression algorithms that retain all of the original data are referred to as "lossless" compression, and those with a loss of data as "lossy." When using the former, the compressed file uses fewer bits to represent the information. The original data when re-opened is reconstructed despite a compression ratio of approximately 2:1. Digital files such as ZIP and LZW (Lempel-Ziv-Welch) are examples of lossless compression files. There are various types of compression encoding including Quantization, Run-length and Lexicographic.

This presentation will concentrate, in part, in comparing various file formats and its influence on photographic quality and ultimately on bitemark interpretation.

Bitemark, Lens Correction, White Balance

F37 Bite Wafers for Additional Analysis of Patterned Injury Bitemarks

James C. Schneider, DDS, Cuyahoga County, Coroners Office, 8660 Columbia Road, Olmsted Falls, OH 44138*

After attending the presentation, attendees will understand an additional method to use with patterned injury analysis.

This presentation will impact the forensic science community by giving the investigator of the patterned injury another tool to use to interpret the injury.

In the attempt to better analyze and interpret patterned injuries, in particular bitemarks forensics depended on various methods to aid in the collecting and presentation of data.

The purpose of this presentation is to provide the attendee with additional method to be used. This is not a method intended to be used in place of currently used methods, but rather to be used as an adjunct. Thus, when one is required to present in a court of law, he or she will now have yet an additional display to aid in the explanation to those of the nonscientific community. Further, this method will help the forensic odontologist to interpret the patterned injury bitemark.

Methods: This method uses a standard sheet of aluminum wax which is spray painted with white latex paint. It does not matter if the paint is gloss or flat. What matters is that the paint "blocks out" one side of the wax. Next a sheet of white impression wax is sprayed on one side with contact cement. This side is then adhered to the already dry painted side of the aluminum wax to create a "Bite Wafer." The impression wax is then trimmed and luted to the circumference of the aluminum wax. Once dental models have been made of the suspected biter, the models are then impressed on the impression wax side of the wafer. By impressing a model in the softened wafer, a pattern will occur which will resemble a pattern capable of being made by said subject. The incisal edges and cusp tips will be denoted as darker areas. The layer of paint prevents bleaching or burn through of pressure areas not caused by the dentition.

Similar to fingerprint analysis, this technique compares an image of a bitemark to an image of a possible pattern created by a suspected dentition. This technique does not require any flipping or transposing of images. This is obviously easier for the non-scientificly educated person to understand and trust. Though untrue, people sometimes believe an image has been altered when it is demonstrated to them that transposition has taken place in order to complete the analysis and subsequent demonstration.

As with other similar methods, one to one overlays can be made and simply placed on images of the pattern injury and images of the wafer.

This method is already being used and has been used with success in the courtroom. As stated above, this method is not recommended as a substitution for currently used techniques, but rather as an adjunct. This technique allows the forensic odontologist yet another tool for use in his/her ability to better interpret and explain a patterned injury bitemark in question.

Bite Wafers, Wafers, Bite Sheets

F38 Suggested Use of a Hand-Held Scanning Device to Produce Accurate Evidentiary Measurements in Bitemark Analysis

Henry J. Dondero, DDS, 2 Emerald Drive, Glen Cove, NY 11542*

After attending this presentation, attendees will learn how the forensic odontologist must be capable of presenting evidentiary accurate measurements and documenting such measurement by photographic and/or digital images. This presentation will explore the use of a hand-held scanning device to facilitate a more accurate means of documenting bitemark evidence.

This presentation will impact the forensic science community by exploring how the utilizing of a hand-held scanner in bitemark analysis is examined.

Previous studies discussed how the forensic odontologist relies on highly accurate measurements to facilitate evidentiary quality bitemark analysis. Reasonably accurate Alginate or the more stable and accurate polyether or polyvinyl siloxane impression materials are capable of producing measurement friendly dental stone study models. All these measurements are usually taken in a flat plane linear environment. For example the inter-canine cusp measurement is accomplished by simply placing the standard ABFO #2 ruler across the model and recording the appropriate dimension. Such data accurately translates to photographs (both film and/or digital) through specialized scanning techniques and photo processing software. The resultant images are generally accepted as evidence in litigation. Analysis of the bitemark is more problematic.

Bitemarks by their very nature are subject to either *in vivo* healing or postmortem decomposition. Elastomeric impressions, methacrylate tissue excision techniques, and specialized 1:1 close-up photographs or digital images all serve to preserve the bitemark as evidence. Measurement problems occur because bitemarks are rarely made in a truly flat plane environment. It is the natural curves of the human body that lends itself to exhibiting a bitemark that has been made around a curved surface. If one should photograph the bitemark with the #2 ruler in view all objects are in a two dimensional posture and all measurements taken of a curved surface with a straight ruler with have some inherent inaccuracies. It was determined that such inaccuracies could be as high as 36.31% if one considered a bitemark on a perfectly round body part. It is the recording of analytical and subsequent evidentiary documentation that this paper will address.

Methodology for this analysis will be based on comparisons of measurements taken from digital photographic images produced by a standard professional close-up camera and lens and a digital image produced by a hand held scanning device with measurements taken in vivo on a test subject.

Several measurable marks were made on a volunteer utilizing a non-permanent marking device. Digital photographs were taken with a single lens reflex digital camera fitted with a 105mm macro lens and close-up strobe lighting apparatus. An ABFO #2 ruler was placed in some of the photographs and a self-adhesive flexible measuring tape was used in other photos. An eight and one-half inch hand-held scanning device was used to obtain similar images. All photographs taken with the digital camera were in color and at a high resolution. The scanner was also set for color scanning at a resolution of 600 DPI (dots per inch). Results showed a comparison of measurement differences and similarities by the various recording modalities. It is noteworthy that under certain circumstances such as a curved flat-plane area the measurements elicited by the scanner and the adhesive tape were more accurate than the camera with the ABFO #2 ruler.

This analysis suggests that measurements along a curved surface should be made by rotating the ABFO #2 ruler along the arc, by using some flexible measuring device, or by using a hand-held scanner.

Measurement, Scanner, Bitemarks

F39 Validation of Three Methods of Estimating Age-at-Death From the Dentition of Modern Colombians

Clara I. Valderrama, DDS, and Edna M. Buitrago, DDS*, National Institute of Legal Medicine and Forensic, Bogota, COLOMBIA*

After attending this presentation, attendees will understand the principles and application of research in dental age determination by validating the original method proposed by Lamendin et. al (1992), as well as updates proposed by Prince and Ubelaker (2002) and González-Colmenares et al. (2007), on a modern Colombian sample of documented individuals.

This presentation will impact the forensic science community by demonstrating that the dentition can be used with some degree of success in modern Colombian populations. In addition it demonstrates that the methodology of Prince and Ubelaker (2002) performs with slightly more accuracy than the technique of González-Colmenares et al. (2007).

In the identification process, forensic practitioners are often required to estimate age-at-death from skeletal and dental tissues. While numerous methods utilize morphological structures of the post-cranial skeleton, various methodologies utilizing the dentition estimate age based on dental development, time of eruption, dental attrition, and root translucency. These methods have been developed for different populations on the basis of various morphological features and have been modified and/or applied and validated for other populations over time; however, with the exception of González-Colmenares et al. (2007), few have been specifically developed or tested on modern Colombians.

Therefore, this study validated three techniques that each utilize periodontosis and root translucency to estimate age-at-death. The techniques included Lamendin et. al (1992), Prince and Ubelaker (2002), and González-Colmenares et al. (2007). The sample used was the Collection of Modern Colombian Skeletal Remains curated by the National Institute of Legal Medicine and Forensic Sciences in Bogotá, Colombia. Both male and female individuals were utilized and age-at-death ranged from 19 – 93 years with a mean age of 47.5 years. Although 133 individuals were examined, only 88 were included in this study, due to either poorly defined root translucency or entirely edentulous individuals.

All data were collected blind to real age and the teeth utilized included maxillary and mandibular incisors and canines which met the requirements of root translucency, level of periodontosis, and root length. The usable dental structures were cleaned with a 0.05% sodium hypochlorite solution for 60 seconds, dried with gauze, analyzed on a light box with electronic caliper, and finally packaged in plastic bags, labeled, and filed with the case file. A subset of the original sample was measured twice by each author so that intra and inter-observer could be assessed.

Correlation coefficients were calculated for root translucency, periodontosis, and root height and age-at-death was calculated with each method. Not surprisingly, root translucency and periodontosis were significantly correlated with age (r_S = 0.515 and 0.612, respectively; $p <$ 0.001) but root height was not (r_S = -0.025; p = 0.820). Such results mirror those of González-Colmenares et al. (2007) who also found that root height did not increase with age.

The mean difference between real age and estimated age were as follows: Lamendin (+0.25 years, standard deviation 15.01 years), González-Colmenares et al. (+0.17 years, standard deviation 14.84 years) and Prince and Ubelaker (+3.52 years, standard deviation 13.82 years). Simple scatterplots which plotted estimated age against real age generated the following R^2 coefficients: Lamendin (0.406), González-Colmenares et al. (0.413), and Prince and Ubelaker (0.532). Moreover, overall results fit a consistent pattern of over-aging young adults and under-aging old adults. These results indicate that dental estimation methods may inform overall age-at-death estimates, particularly in younger adults, and that population-specific standards should continue to be developed for Colombia.

Dental Age Estimation, Colombian Population Standards, Teeth

F40 Odonto-Listics

Diane T. Penola, MA, 54 Fayson Lakes Road, Kinnelon, NJ 07405*

After attending this presentation, the attendees will become familiar with the similarities between victim identification and criminalistics.

This presentation will impact the forensic science community by drawing attention to the fact that many of the steps taken by the forensic odontologist in the process of making a dental ID are the same as those taken by a crime scene investigator.

During the 2011 proceedings of the American Society of Forensic Odontology, AAFS President Joe Bono commented that an elementary program in dental identification would be a good thing. He indicated that there is interest, by the other members of the Academy, in the subject.

There is a level of research and innovation that defines the odontology section presentations. The goal of this research is to provide new information, support previous research, and explore current initiatives. These presentations are wonderful for the members of the section and those who choose to follow new developments. However, they do not educate the members of other sections on the most basic responsibilities.

Last year one presentation, quantified the various duties of the forensic odontologist. By far, the most frequent task performed is the identification of unknown human remains. This being the case, it seems incumbent to provide meaningful information for the non-dental professionals who are attendees and Academy members.

Of all the sections in the American Acacemy of Forensic Scineces, the one which has the most in common with Odontology is Criminalistics. The sequence and rationale behind the procedural steps is actually identical, in general terms. Both sets of professionals are expected to recognize material of evidentiary value. They preserve and collect that evidence, taking care that in transport it is protected and remains in the condition in which it was found. They document that evidence with photography, radiography, and other means. The material is analyzed for significant findings. The findings are compared with known samples.

For example, a bullet is removed from a murder victim. The bullet is carefully collected, with attention being paid to the entrance and exit wounds and the position and damage to any clothing the victim may have been wearing. The forensic pathologist will have dictated, or in some other way, recorded these findings. The suspected murder weapon will be test fired in such a way as to protect the projectile from damage. The two bullets can then be examined side by side with a comparison microscope. In a best case scenario, the striations on the outside of the bullets will match, confirming the identification of the murder weapon.

The scene in which the forensic odontologist is called might involve the collision and subsequent explosion of a motor vehicle. The driver is burned beyond recognition and a dental identification is necessary. The dentist must recognize what is of evidentiary value, as the impact and explosive forces may have dislodged dental material. All dental structures will be carefully examined and radiographed after being collected and transported. Please note, in most cases of this type, the dentition will usually be preserved within the oral cavity.

The dental findings will be analyzed for characteristics that have particular significance. The findings will then be compared to known records provided by the dentist who rendered treatment. This can actually be a difficult or impossible step if there is no information available regarding the name of the treating dentist.

Members of both the odontology and criminalistics sections should expect to come away with a greater appreciation for the challenges that face their colleagues across the hall.

Odontology, Criminalistics, Comparison

F41 Human Skeletal Remains Found During Excavation of Rufisque's Town Hall Annex in Senegal

Khalifa Dieng, DMD, PO Box 6622, Dakar Etoile, SENEGAL; and John M. Williams, DDS, 1011 West Broadway, Minneapolis, MN 55411*

After attending this presentation, attendees will understand how to utilize multiple methodological approaches for identifying human skeletal remains.

This presentation will impact the forensic science community by establishing that the reliability of scientific evidence based opinions may be overlaped by experts from various disciplines.

The construction of an annex to the Rufisque Town Hall building necessitated excavation and removal of earth to allow for the annex's foundation. Once underway, the removal unearthed a large stone that halted progress until it could be broken up. Underneath the stone, human remains were found. On the second day of the project, the Attorney General of Senegal ordered excavation to continue where a second pit revealed additional human bones and four bottles of dubious liquid. The third day of excavation unearthed a third pit containing an entire human skeleton along with the smell of putrefaction.

The commissioned forensic pathologist, anthropologist, and odontologist were assigned to determine race, age, and sex, as well as the manner and likely date of death for those interred in the pits. Photographs of bone fragments, teeth, a skull, and a black, cord-like substance were cataloged for study. The teeth were x-rayed and sand samples were extracted from the spaces between teeth and the eye orbits to cross reference with soil samples from the immediate area.

In this investigation, each discipline is trying to determine the sex, race, and age of the skeletal remains. The odontologist will examine the skull, teeth, and postmortem radiographs that will reveal the status of the person's oral health and can be compared to antemortem dental records if they can be located. The odontologist is one of the best person to work up skeletonized, decomposed, and macerated bodies to arrive at a confirmation or unknown identification.

The anthropologist would arrange and study the skeletal remains to also make an analysis as to age, sex, race, and height. All human are unique and an analysis will make the compared groups smaller. The more unique the characteristics the smaller the group become by eliminating other groups.

The pathologist is concern with race, sex, disease, DNA, trauma, and cause of death.

In conclusión, the first body found in pit one was Black in race from Africa. The upper canine appeared to be 50 years of age according to Gustafson's analysis. In the second pit, there were only human bones and four bottles of liquid substance. The race, sex, and origin are undetermined. In the third pit the human remains is that of a Black African male. The determination of average age according to Gustafson is 30 years of age. A longitudinal section of an upper premolar was use to determine the age.

This is not a case of murder but a case of some mystic practices.

Excavation, Human Remains, Forensic

F42 Contributions of a Forensic Odontologist in a Criminal Child Abuse Dog Bite Case

Kenneth F. Cohrn, DDS, 422 Teague Trail, Lady Lake, FL 32159*

Forensic odontologists are often a part of a team effort to investigate criminal bitemark cases. Cases can involve human-human, animal-animal, or animal-human abuse situations.

After attending this presentation, attendees will have an appreciation of the contribution of a forensic odontologist in a criminal child abuse dog bite case spanning three years involving multiple agencies, the law enforcement officer suspect, the infant victim, and a dog.

This presentation will impact the forensic science community by adding to the knowledge of case investigation and trial results.

In 2007, the State's Attorney requested the examination of injuries on a two-month-old female who was admitted to the hospital with life threatening injuries. The infant was in the care of her father, a police officer, at the time of the incident. He indicated that the family dog had injured his daughter and he drove her in the family car to the hospital for emergency care. The emergency room physician noted numerous superficial scratches, linear red marks, bruising, and a number of superficial

circular lesions on the trunk of the infant as well as severe life threatening internal injuries. The child protection team was alerted.

There were a number of red flags associated with the parent's version of the events. First, the child was seriously injured and the father, a police officer, indicated that he "did not trust EMS" and decided he would drive the near death child to the hospital rather than use emergency services. The visual injuries were superficial yet the child had multiple posterior rib fractures, a lacerated spleen and liver, and was in respiratory distress. The emergency room physician indicated that her external examation was inconsistence with the parent's history that she sustained her injuries as a result of an attack by the family dog. The CTP medical examination suggested physical abuse.

This case evolved over three years involving multiple agencies, experts, including an animal psychologist and bitemark expert, culminating in a trial with unexpected results. The prosecution's case alleged child abuse by the father blaming the dog. The defense position was that the dog was entirely responsible. There was contentious testimony from the experts, including several medical examiners, about the cause and nature of the injuries. Were the deep crushing injuries the result of the dog or the father squeezing the torso out of anger and frustration? Could the dog have applied enough force to lacerate organs and break pliable ribs yet leave only very superficial marks with virtually no bleeding or puncture wounds? How did the one-zee pajamas end up off the infant almost unscathed if the dog viciously attacked the infant? With the child in extreme distress, why did the father elect to drive the infant to the ER rather than call 911? Were the circular marks of the skin from the dog's teeth or another source? Certainly the demeanor of the parents was inconsistent with the severity of the situation. The entire emergency room staff felt that the parents were hiding something. This case had a number of difficult issues that were difficult to prove with certainty that ultimately led to a controversial result.

Forensic Odontology, Animal Bitemarks, Child Abuse

F43 The Case of the Frustrating Floater

Thomas V. Brady, DMD, 1823 Boston Post Road, PO Box 622, Westbrook, CT 06498*

After attending this presentation, attendees will gain an appreciation of the multiple avenues of investigation in missing/found persons. This case involves an extensive array of medical, dental, communicative, and investigatory procedures in an attempt to identify a found unidentified dead body.

This presentation will impact the forensic science community by stressing the multiple ways an investigation of an unidentified dead body can be conducted. It will introduce the attendee to little known resources and will stress the value of persistence in an investigation.

The Connecticut River runs north to south separating the eastern third of Connecticut from the western two thirds. The Town of Old Saybrook is at the mouth of the Connecticut River where it runs into Long Island sound. It is about 45 miles southeast of Hartford, Connecticut. It has a population of approximately 11,000 people. The police department has 21 sworn officers. In late March 1998, the Hartford police informed the Old Saybrook police that they had a report of a body floating in the river. Hartford reported they were unable to find the body after a "cursory search." The normal current and tides would indicate that the body, unimpeded, would arrive in the Old Saybook area in three or four days.

On March 31, 1998, the Old Saybrook police received a phone call that a fisherman spotted the body 1.1 miles north of the mouth of the river. Police responded to the scene to find a badly decomposed body floating face up in the river. With the help of the Coast Guard, DEP pólice, and a local towboat operator the body was brought to shore. The body appeared to be male, wearing a tan jacket, dark pants, and black sneakers. There was no wallet, jewelry, or other means of identification on the body. The local medical examiner spotted two holes on the back of the skull possibly indicating bullet holes but stated the sites needed further examination.

While the body was on the dock a silver cigarette lighter fell out of the coat pocket.

The body was sent to the medical examiner's office in Farmington, Connecticut for autopsy. The autopsy revealed that the victim was probably a white/Hispanic male, approximately 68 or 69 inches tall, and weighing approximately 200 lbs. A local oral pathologist completed the dental charting and took a full mouth set of x-rays. Evaluation of the skull by a forensic antrophologist confirmed the sex but also confirmed the holes to be anatomically normal orifices for large veins. The body was determined to have been the water for several years. Marsh grass in and around the body indicated it had been hung up in swampy ground before floating free. Due to the badly decomposed state of the body, a cause of death could not be determined. Fingerprints were also not possible.

The time and ingenuity spent on this case by a small police department with limited resources is admirable.

An extensive type went out via NCIC to all police agencies regarding the found person. A request was made of the Department of Defense through Senator Leiberman's office for a review of the dental chart for possible identification. Copies of the dental charting were sent to many dentists in the Connecticut and Massachusetts area asking for help. There were no matches found. The investigators focused on the cigarette lighter. Several lighter manufacturers were contacted to no avail. There is a National Lighter Museum in Guthrie, Oklahoma, the museum was contacted and was very helpful. They determined that the lighter was of Chinese origin, most likely made between 1992 and 1995. It was a very cheap model most likely sold to young people at flea markets or at convenience stores. In effect it had no individual characteristics to make a source for narrowing down an investigation.

The police then contacted the Center for Missing and Exploited Children in Alexandria, Virginia who agreed to do a facial reconstruction of the skull. The results now gave a face to the victim - giving him a persona. The facial reconstruction picture and pertinent information was placed on the America's Most Wanted website. The case went cold.

In 2003 the investigation was reopened. The skull was brought to the office where the teeth were photographed and recharted to update NCIC records. The dental chart and a picture of the facial reconstruction was submitted to the Connecticut State Dental Association newsletter requesting information from any dentist who might know the victim. A similar request was sent to all the New England state dental associations and the American Dental Association for publication. To date there has been no response.

The victim's dental chart has been resubmitted to NCIC and NAMUS. There has been no successful matches found on the $M reports as of this date but attempts will continue to be made. Everyone deserves a name.

Floater, Cigarette Lighter, Communication

F44 ID – The Unknown – A Piece to the Puzzle

Charles S. Mandell, DDS, 3220 Stirling Road, Hollywood, FL 33021*

After attending this presentation, attendees will understand how that the field of dental implantology can provide the dental forensics division an invaluable tool in the identification process of the unknown and missing.

This presentation will impact the forensic science community by pointing out the grossly overlooked possibility for a new identification tool in the field of dental forensics.

The design and production of dental implants began 34 years ago with Leon Shaw, one of the first prodcers of dental implants. Since this time, implants have undergone various transformations in relation to design, shape, architecture, and metallurgy or component consistency. Today, there are literally hundreds of different dieigns and components.

Dental implants were introduced in the U.S. in 1940 with Gustavo Dahl presenting the first dental implant – a subperiosteal design. Since its inception in 1940, the field has gone from subperiosteal to blade-type or endosteal implants invented by Dr. Leonard Linkow of New York City, mucosal inserts (Park Dental's Jack Wimmer). Endodental stabilizers,

screw-type implants, mini implants, with each type promoting different restorative options in the field of dental implantology. All of these, when located in the unknown, can provide a useful tool for the forensic dentist to utilize as a possible piece of the puzzle in the identification process.

Serving on the IAPC (International Organization of Police Chiefs) Forensic Committee and the committee to ID the missing, one simple goal presented itself– the placement of ID numbers on all dental implants. This may sound simple; however, for six years after contacting congressional members to no avail (Markey, Boston; Schultz, Broward County, Florida), progress has not been made. Unfortunately, there is now 69 years of dental implants being placed in this country without any IDs located on them. The cost factor, with today's technology, would be insignificant, amounting to less than 50 cents per implant. The ID numbers are not visible to the naked eye and can only be read with a special reader, which many companies already have, and would not influence the success or failure of the implant, but would provide an invaluable tool in the ID process.

This past year approximately 600 million dollars were spent on dental implants in the U.S. The significance of this figure speaks volumes as to this piece to the puzzle. However, all is not lost. At this time dental implants without IDs to help ID unknowns can still be utilized.

Recently a mandible (lower jaw) was found on a beach in California. After x-rays were taken, it was found to have a dental implant and a referral was made for identification of the type and manufacturer of the implant. With the cooperation of several people in the industry, the identity the manufacturer, type, and approximate year it was produced were identified. This reduces the number of dentists in the U.S. who might be able to provide an ID in this case from 165,000 to 200 (only those customers on the list from the manufacturer); and reduces it even further down to the one customer who might have purchased this type of implant. If this implant had an ID number, this process would have been immediate.

At this time, the goal is to expand this process to all orthopedic implants inserted in a human body (hips, knees, shoulders, etc.) with hopefully someday a central bank – perhaps located in UCF under the direction of Carrie Whitcoff for the registration of all implants.

Resolutions from the IAPC and the committee to ID the missing have been granted regarding this matter, with both organizations giving their unconditional support to this ongoing process.

The goal is to provide any and all information regarding: (1) type; (2) manufacturer; (3) metallurgy; and, if possible, (4) year manufactured.

Implantology, Missing, IDs

F45 Challenging Odontological Identification of Severely Burned Remains

Glen A. Smith, DDS, 2136 North Cole Road, Boise, ID 83704*

After attending this presentation, attendees will illustrate the collaborative effort between forensic odontologist and death investigator to find the evidence that was needed to make a positive dental identification on a severely burned set of remains. Attendees should also learn some of the unique antemortem records available from an orthodontist, and how to clean cyanoacrylate cement off of teeth.

This presentation will impact the forensic science community by demonstrating how detective teamwork between the odontologist and death investigator can find the evidence needed to make an identification. It will demonstrate the use of orthodontic antemortem records in the identification process where there was insufficient postmortem material available to use common odontology techniques. The presentation will also demonstrate a technique on how to deal with cyanoacrylate residue on charred dental remains.

In a remote area in Southern Idaho, human remains were found burned beyond recognition in a vehicle fire. The coroner with primary jurisdiction in the case processed the remains and then transferred them to the Ada County Coroner's office in Boise, Idaho for a more in-depth work up by a forensic pathologist and forensic odontologist.

Coroner's office personnel collected and fixated dental structures with a cyanoacrylate product to help preserve those structures from further damage. Even with this effort, not all of the dental skeletal remains were recovered and only one intact tooth remained for odontological examination. This one tooth was an unrestored maxillary second molar and was difficult to examine and evaluate because it was covered with deposits of burned material sealed in place with cyanoacrylate.

Local law enforcement used the vehicle identification information to arrive at a likely identification of the victim who turned out to be a local resident. Detectives contacted the victim's family and they were able to provide information as to who the family's general dentist was. That general dentistry office was able to provide antemortem dental records, which local law enforcement then sent as "the dental record" to the forensic odontologist.

The antemortem dental record consisted of chart notes and two sets of bitewing radiographs. The postmortem dental evaluation included radiographic, photographic, alternate light, and visual examination. To be able to fully examine the sole surviving intact tooth, various materials were used in an attempt to clean the sealed burn material off of the tooth. In the end, standard hardware store acetone was the most effective solvent. An analytical comparison of antemortem and postmortem dental information showed that there were no significant inconsistencies between these records. Unfortunately, there was insufficient information available to be able to confirm the suspected identification of the victim.

The odontologist's review of the antemortem records discovered that third molars had been extracted at some point in time at another dental office, most probably by an oral maxillofacial surgeon. The odontologist contacted law enforcement with this information and they were able to identify the oral surgeon who had extracted the teeth, collect the surgeon's records, and send them on to the odontologist so that he would have "all of the victim's dental records." Within these records were copies of radiographs taken by a local orthodontist. Again, local area law enforcement was contacted, and the orthodontic written records, original radiographs, and plaster models were obtained for the odontologist. These orthodontic materials provided the record of a unique collection of intracranial anatomic structures and dental crown morphology by which a odontological identification was made.

Odontological Identification, Orthodontic Records, Cyanoacrylate

F46 Child Abuse Reporting by Pediatric Dentists in Texas

David R. Senn, DDS, University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Drive, Mail Code 7919, San Antonio, TX 78229-3900; Paula C. Brumit, DDS, PO Box 608, Nocona, TX 76255; Roger D. Metcalf, DDS, JD, Tarrant County Medical, Examiner's District, 200 Feliks Gwozdz Place, Fort Worth, TX 76104; Bruce A. Schrader, DDS, 4414 82nd Street, Unit 212, Lubbock, TX 79424; and Shirley Miranda, MScD, Baylor College of Dentistry, 3302 Gaston Avenue, # 711, Dallas, TX 75246*

After attending this presentation, attendees will understand the attitudes, knowledge and practices of Texas pediatric dentists in reporting child abuse.

This presentation will impact the forensic science community by exploring how this research could help in the implementation and dissemination process of child abuse information for medical, dental and legal professionals.

Objectives: The data produced from this study identified: (1) the clinicians' training and management strategies for children with injuries suspected as related to unreported abuse; (2) the factors weighed by clinicians when deciding whether to report injuries suspected to be abuse; and, (3) how clinicians explained reasons for not reporting suspicious injuries. This research could help in the implementation and dissemination process of child abuse information for medical, dental, and legal professionals.

Discussion: One previous study reports that approximately 1% of general dentists had reported cases of suspected abuse while a larger percentage had suspected abuse. This suggests that the information gained from dental schools may be insufficient and contribute to the lack of knowledge of the signs of abuse and the legal responsibility to report.

The Prevent Abuse and Neglect through Dental Awareness (PANDA) coalition has trained dental personnel through continuing education. According to this program, "the extremely low reporting rate by dentists seems to be related to the lack of training dentists receive in how to recognize and report abuse and neglect, and concerns about the ramifications of becoming legally involved in such cases."

Methods: Surveys were sent out to all 115 pediatric dentists in Texas who had provided an email address to the American Academy of Pediatric Dentistry (AAPD) 2010 directory. Fifteen questions were included in the survey that was conducted by email. The online service, Survey Monkey (www.surveymonkey.com) was used to facilitate the survey. The interviews were analyzed for the rationale utilized for the decision to report suspected child abuse as well as management strategies, bitemark cases, most common signs observed, and the level of training of the dentist in identifying abuse.

Results: The response rate, distribution by gender, and professional associations will be reported in the oral presentation. The collection of data was ongoing at the time of submission of the abstract. Early responders indicated that the most common sign of abuse observed was bruising of the skin. Data on this and on the other signs of abuse listed are reserved for the presentation.

Conclusions: Dentists should consider all relevant factors when deciding whether or not to report cases of suspected child abuse. Pertinent factors include history and circumstances of the injury, knowledge of and experience with the family, consultation with others, and previous personal training and experiences with child abuse and bitemark cases. Data on bitemark reporting as a form of child abuse can provide valuable reference material for forensic odontologists to present to their local medical examiners, emergency room personnel, law enforcement agencies, and prosecutors.

Child Abuse, Odontology, Bitemarks

F47 A Dental Identification Without Teeth

James C. Schneider, DDS, Cuyahoga County, Coroners Office, 8660 Columbia Road, Olmsted Falls, OH 44138*

After attending this presentation, attendees will learn how teeth are not always necessary to make a dental identification.

This presentation will impact the forensic science community by demonstrating how a dental identification can be made with the use of analysis of restorations.

A man and woman met in Toronto in the year 2000. After some time together, they relocated to a south eastern subburb of Cleveland, Ohio called Maple Heights. Prior to becoming involved with each other, the man had a list of charges including: domestic violence, drug use and posession, drug trafficking, and armed robbery.

On a day in 2001, a tennant who was living below the couple noticed a liquid dripping from their balcony to his. Upon reporting this to the landlord, and when the above apartment was notified, there was no answer. When the landlord entered the apartment, there was nobody present. While searching the balcony, a large plastic trash barrel was found with a soupy liquid and what looked to be a blanket or comforter of some type contained inside.

It had immediately become apparent that something was awry and the police were called. Upon inspection it was found that the contents of the barrel was some type of liquid mixed with what was most likely a human body. When retreived, a body was in fact what was found. However, one arm, one leg, and the head had been severed off. These body parts were found in the barrel as well. After further analysis, it was noted that the liquid was an acid of some type; a form of hydro-flouric acid.

At the time and even now, it is not exactly known how long the body was in the vat. The body was identified to be that of a woman. An interesting note to take into account is that the body and bones were somewhat "rubbery." The skin and hair remained intact, but the teeth were missing, causing one to believe that the victim was edentulous.

X-ray analysis using film showed what appeared to be six fragments most probably from a fragmented bullet in the skull. These were noticed on a lateral skull X-ray film. Once the fragments were retreived, they were found to actually be six seperate dental restorations. The acid had dissolved the teeth but had not harmed the amalgam restorations or the composites, of which there were three of each.

The suspected victim's family was notified and the victim's dentist in Toronto was located.

Though unsure of exactly which teeth the restorations belonged to, it seemed evident that the three amalgams were all from maxillary teeth, two from molars and one from a pre-molar. This was deduced from the shape and size of the restorations. The three composites seemed to be of the shape and size that would be found in mandibular molars. When the dental chart was forwarded to the Cuyahoaga County Coroner's office (some of which was in French), it was discovered that the numbering system used had to be converted to our commonly used international system. Further, it was found that the suspected victim did in fact have six charted restorations, three amalgams and three composites. And lastly, the three maxillary amalgams were of two molars and one pre-molar, while the three mandibular composites were all from mandibular molars. Viewing of the restorations from the side indicated all six to match with the shaped of the bite-wing films also forwarded.

With DNA, fingerprinting, and visual identification not possible, this dental restoration identification indicated with a high degree of probability who the victim was.

As a conclusion to the story, the suspect was apprehended shortly after in the western United States with a receipt found in his glove compartment for—driveway cleaning acid.

Dental Identification, Identification, Restoration Analysis

G1 The Significance of Ventricular Volume Measurement in the Macroscopic Evaluation of a Postmortem Heart

Joo Young Na, MD, Department of Forensic Medicine, Chonnam National University Medical School, 5 Hak-dong, Dong-gu, Gwangju, 501-746, KOREA; and Byeong-Woo Min, MD, Hye-Jeong Kim, MD, Seung Hyun Chung, BS, Hyung-Seok Kim, MD, PhD, Jong-Tae Park, MD, PhD, Chonnam National University Medical School, 5, Hak-Dong, Dong-gu, Gwangju, KOREA; and Jong-Pil Park, MS, National Forensic Service, Western District, 111, Daedeok-ri, Seosam-myeon, Jangseong, KOREA*

After attending this presentation, attendees will understand how measuring the ventricular volume at autopsy could be a new indicator used in forensic pathology, one that can complement the limitation of classical evaluation methods of the postmortem heart.

This presentation will impact the forensic science community by proposing a new indicator for evaluating a postmortem heart macroscopically.

A normal heart maintains its structure by being very well adapted to its role of supplying blood to the pulmonary and the systemic circulation systems. But, in various conditions, the heart goes through a remodeling process resulting in reduced cardiac contractility and ultimately cardiac failure. During this process, hemodynamic and morphological changes occur concurrently. The morphological changes can be clinically categorized into cardiac hypertrophy and cardiac dilatation. An accurate evaluation of the heart during autopsy is critical. The weight, shape, and consistency of the heart and the thickness of the ventricular wall are used as parameters for evaluation of the postmortem heart and diagnosis of cardiomyopathy at autopsy.

A total of 58 hearts were categorized into four groups: 13 cases in the control group; 14 cases in the dilated heart group; 9 cases in the hypertrophied heart group; and, 22 cases in the undetermined heart group by using conventional evaluation methods. In addition, the ventricular weight and volume were measured and analyzed.

The weights of male and female hearts in the control group were 329.2±30.2g and 277.9±30.7g, respectively, and the ventricular weights were 271.5±34.4g and 219.3±23.9g. Left ventricular and right ventricular volumes for male were 25.8±9.7ml and 34.3±13.2ml; and they were 15.7±8.2ml and 35.6±9.0ml for females. The thickness of the left ventricular free wall in males and females were 1.4±0.1cm and 1.3±0.1cm, respectively, and for the interventricular septum they were 1.3±0.3cm for both males and females.

In the group of dilated hearts, the ventricular weight, the ventricular volume, ventricular volume/ventricular weight, and left ventricular volume/right ventricular volume were increased and the thickness of the ventricular wall was decreased. Such a result is the consequence of excess increase of ventricular volume, particularly of the left ventricle. In the group of hypertrophied hearts, the ventricular weight, ventricular volume, the thickness of the ventricular wall were increased; but, ventricular volume/ventricular weight and left ventricular volume/right ventricular volume did not change significantly. Such a result is the consequence of ventricular hypertrophy exceeding ventricular dilation in the hypertrophied heart group. The increase in ventricular volume was thought to be mostly due to the increase in right ventricular volume. The most evident morphological characteristics that distinguish hypertrophied hearts from dilated hearts were a more obvious increase in ventricular weight than volume, and in right ventricular volume than left in the hypertrophied heart. Such characteristics were revealed using ventricular volume to weight ratios and left ventricular volume to right ventricular volume ratios in this study.

In the group of undetermined hearts, compared with the control group, ventricular volume showed only a slight increase, but the ventricular weight increased by approximately 400g. Additionally, the ventricular volume to weight ratio and the ratio of left and right ventricular volume remained relatively similar with those of the control group and hypertrophied heart group. It was thought that secondary myocardial changes in the undetermined heart group would have progressed to a dilated heart through cardiac hypertrophy. In the group of undetermined hearts, it was later found that four of the cases should have been included in the dilated heart group and another two cases in the hypertrophied heart group according to aforementioned characteristics.

This study concludes that measurement of the ventricular weight and volume may be an objective parameter that can aid in distinguishing between dilated and hypertrophied forms of secondary cardiomyopathies, as well as providing an objective indicator for evaluating the degree of change in cardiac remodeling at autopsy.

Ventricular Volume, Postmortem Heart, Cardiac Remodeling

G2 Acute Respiratory Insufficiency During Computed Tomography Procedure for Pituitary Adenoma

Elizabeth Ventura, MD, Baylor University Medical Center, 3500 Gaston Avenue, Dallas, TX 75246; and Joseph M. Guileyardo, MD, 2911 Turtle Creek Boulevard, Suite 300, Dallas, TX 75219*

After attending this presentation, attendees will understand that potentially fatal respiratory insufficiency can result from procedural sedation in patients with upper airway narrowing due to lymphoid hyperplasia.

This presentation will impact the forensic science community by demonstrating the relevance of autopsy examination to accurate certification in cases involving adverse events during medical therapy.

A case is presented of a 39-year-old man who underwent an outpatient CT scan for recent headaches. His past medical history included mental retardation due to a penicillin reaction during childhood. He also had recurrent viral infections and a seizure disorder which was previously treated with phenytoin. Currently, his seizures were controlled with oral levetiracetam (Keppra) 1,000mg twice daily, and 5mg diazepam, three times a day. Prior to his CT scan, he received 1,000mg IV levetiracetam over 15 minutes and 5mg of IV midazolam slowly; however, due to continued agitation in the scanner he was slowly given 75mcg of intravenous fentanyl. He was then administered IV contrast, but four to five minutes after contrast injection he appeared to have a "vagal" reaction which was treated with increased IV fluids. He did not respond, and full cardiopulmonary resuscitation was initiated. His mother informed caregivers of his "do not resuscitate" status; however, he had already regained spontaneous respiratory and cardiac activity. Unfortunately, he was found to have profound and irreversible hypoxic-ischemic encephalopathy, and he was discharged home to hospice care where he died the next day. The local Justice of the Peace declined to order an autopsy, and the family allowed the body to be embalmed; however, they later requested a private autopsy in hopes of obtaining a better understanding of the cause of death.

Autopsy Findings: The sella turcica was expanded by a friable and uniformly grey-tan, 2.0cm mass which compressed the adjacent optic chiasm. Microscopically, the normal pituitary histology was effaced by a monomorphic population of cells which were strongly positive for prolactin by immunohistochemistry. At the periphery of the tumor there was a compressed rim of normal pituitary tissue. Within the thalamus there were

scattered red neurons. The upper airways were markedly narrowed at the laryngeal inlet by thickening and induration of the epiglottis and aryepiglottic folds. The epiglottis was also folded towards the midline, resulting in transverse airway narrowing to approximately 4 millimeters. Microscopically, the epiglottis contained prominent lymphoid infiltrates with germinal centers containing numerous tingible bodies. Plasma cells were also increased within the subepithelial tissues.

It is the opinion that this man died of anoxic encephalopathy due to multifactorial acute respiratory insufficiency during computed tomography for evaluation of headaches due to pituitary adenoma. The respiratory insufficiency was due to the combined effects of upper airway narrowing associated with lymphoid hyperplasia and respiratory depression associated with procedural sedation.

The effects of phenytoin on lymphoid tissues have been known for some time and airway compromise due to lingual tonsil hyperplasia causing laryngeal obstruction has also been previously associated with phenytoin therapy. In addition, treatment-emergent adverse events reported with levetiracetam therapy have included pharyngitis and this patient was also reported to have recurrent viral infections. Therefore, multiple factors may have contributed to laryngeal narrowing in this case. Furthermore, studies indicate that safe procedural sedation is best ensured by careful presedation risk assessment and monitoring during the procedure. It is the opinion that "accident" is an appropriate manner of death in this case, since death was not solely due to natural disease; however, others may certify such deaths as "natural" (based on predictable or foreseeable consequences of treatment for a medical disorder). The "death certification and manner-of-death classification require judgment, and room must be allowed for discretion on a case-by-case basis." In conclusion, this autopsy provided helpful clarification regarding the multiple complex and inter-related factors which were contributory to this man's death.

Lymphoid Hyperplasia, Procedural Sedation, Airway Compromise

G3 Case Report of a Death Involving Methylenedioxypyrovalerone (MDPV) From Bath Salt Use

Diane C. Peterson, MD, Office of the Jackson County Medical Examiner, 660 East 24th Street, Kansas City, MO 64108; C. Clinton Frazee III, MBA; and Uttam Garg, PhD, Children's Mercy Hospital, Department of Pathology, 2401 Gillham Road, Kansas City, MO 64108; and Mary H. Dudley, MD, Jackson County Medical Examiner's Office, 660 East 24th Street, Kansas City, MO 64108*

After attending this presentation, attendees will be aware of the rise in use of bath salts as an alternative to methamphetamine use. Attendees will understand that one potential active drug in bath salts is methylenedioxypyrovalerone (MDPV) and how to include it in drug screens. Attendees will understand the effects of MDPV and its potential contribution to death.

This presentation will impact the forensic science community by alerting attendees to a relatively new designer drug in use across the nation and the world.

A 41-year-old white male was found unresponsive in his bed. He had a history of hypertension, anxiety, and bipolar disorder. He also had a history of chronic ethanol abuse and methamphetamine use. The decedent had recently stopped using methamphetamine and had begun using bath salts approximately two weeks prior to his death. According to his wife, he had been "high" and awake for the previous three days.

Autopsy revealed superficial ulcers of the mucosa of the upper and lower lips. Head and neck cyanosis was also observed. Linear discontinuous healing superficial excoriations as well as an apparent needle puncture site with adjacent ecchymosis were on the skin of the arms. The coronary arteries were mildly to markedly narrowed by atheroma. The lungs exhibited moderate edema. Mucosal erosions were also at the mid and lower aspects of the esophagus. Histologically, no definitive contraction band necrosis was identified.

Femoral blood, heart blood, vitreous fluid, urine, liver tissue, brain tissue, gastric contents, and a packet labeled "Blue Magic 350 mg" were submitted for toxicological analysis. The femoral blood was used for all drug and volatile testing and the remaining biological samples were stored in a freezer at -20°C.

Using gas chromatography with a flame ionization detector, two separate aliquots of femoral blood tested negative for ethanol, acetone, isopropanol, and methanol. A 0.5mL aliquot of femoral blood was extracted with methanol and analyzed for nine drugs of abuse using enzyme immunoassay (EIA). A 1mL aliquot of femoral blood was extracted using bicarbonate buffer (pH 11.0) and n-butyl acetate. The aliquot was then analyzed by gas chromatography/mass spectrometry (GC/MS) for more than 150 drugs. Benzodiazepines, diphenhydramine, tramadol, and MDPV (methylenedioxypyrovalerone) were detected. Benzodiazepines analysis showed the presence of alprazolam. All of the drugs except diphenhydramine were quantified by liquid chromatography-tandem mass spectrometry (LC-MS/MS). O-Desmethyltramadol, an active metabolite of tramadol, was also quantified. Quantification of diphenhydramine was deemed clinically insignificant. Toxicological analysis of femoral blood revealed MDPV at a concentration of 130ng/mL. Tramadol and its metabolite, o-desmethyltramadol, were identified at concentrations of 9000ng/mL and 320ng/mL, respectively. Alprazolam was detected at a concentration of 26ng/mL.

The packet submitted, "Blue Magic 350mg," had a zip lock closure with the inscription "Bath Salts, Novelty Bath Salts, Not for human consumption" on the back aspect of the packet. The packet contained a broken blue capsule with an unknown white powder. Approximately 10mg of white powder was dissolved in deionized water and analyzed by EIA, thin layer chromatography (TLC) and GC/MS. MDPV was determined to be present.

The concentration of tramadol is markedly above the therapeutic range and is sufficient alone to cause death. At this concentration, tramadol causes respiratory depression, hypertension, tachycardia, and seizures. MDPV is a synthetic stimulant, or designer drug. It is sold in the form of bath salts and is known to cause insomnia, severe agitation, tachycardia, and hypertension. The final cause of death was ruled as tramadol overdose with MDPV intoxication as a contributing factor. The manner of death was accident.

Scene investigators should be aware that the use of bath salts is increasing as an alternative to methamphetamine. Any packets of bath salts should be collected with the body. Bath salts may be ingested, injected, or inhaled. In the case above, the exact method with which the decedent used the bath salts is unknown. He had evidence of ingestion and injection. Oral mucosal (aphthous) ulcers have not been previously reported as being a potential adverse effect of bath salt use. With evidence of bath salt use, the pathologist should notify the toxicology lab of the suspicion. MDPV may or may not be detected on typical drug screens. The bath salt packet may also be sent to toxicology for evaluation.

MDPV (methylenedioxypyrovalerone), Bath Salts, Intoxication

G4 Fatal Waterhouse-Friderichsen Syndrome: Crime Scene, Autopsy, Pathology, Bacteriology Microscopic, and Toxicology Features

Gilles Tournel, MD, PhD, Institut de Médecine Légale de Lille, 1, place de Verdun, Faculté de Médecine, LILLE, 59045, FRANCE; Christophe Demarly, MD, Institut de médecine Légale, rue andré Verhaeghe, Lille, 59037, FRANCE; Raphael Cornez, MD, Institut de Médecine Légale, rue andré Verhaeghe, LILLE, 59037, FRANCE; Jocelyn Pollard, MD, IML de Lille, Place de Verdun, LILLE, 59045, FRANCE; Yann Delannoy, MD, Institut de Médecine Légale, place de verdun, LILLE, 59045, FRANCE; Anne Becart-Robert, IML de Lille 1, place de Verdun, Faculté de médeci, Lille, 59045, FRANCE; Valéry Hedouin, PhD, IML de lille, Lille, 59045, FRANCE; and Didier Gosset, MD, PhD, Institut de Medecine Legale, Faculte de Medecine, Lille, 59045, FRANCE*

The goal of this presentation is to educate the attendees about the differential diagnosis between infectious disease syndrome and battered child syndrome.

This presentation will impact the forensic science community by the collection of information before performing an external examination or an autopsy.

Introduction: Waterhouse-Friderichsen syndrome is adrenal gland failure due to bleeding into the adrenal gland. It is caused by severe meningococcal infection or other severe bacterial infection. Symptoms include acute adrenal gland insufficiency and profound shock. It is deadly if not treated immediately. However, the infection leads to massive hemorrhage into one or (usually) both adrenal glands. It is characterized by overwhelming bacterial infection meningococcemia, low blood pressure, and shock, disseminated intravascular coagulation (DIC) with widespread purpura, and rapidly developing adrenocortical insufficiency.

Materials and Methods: A fatal case of Waterhouse-Friderichsen syndrome resulting from bacterial infection in a 4-year-old boy is reported. The course is rapid and the clinical symptoms are serious (hyperthermia, *purpura fulminans*, dyspnea). The clinical symptoms are not known by the forensic pathologist during the external examination. The presence of purpura (numerous skins' petechial haemorrhages) evoked a potential "battered child syndrome."

Results: External examination: numerous ecchymosis are observed, principally located on thoracic and abdominal area. The anamnesis is incomplete and an autopsy is performed. Autopsy findings: included numerous petechial haemorrhages on the heart, the pancreas, the thymus gland, and the bowel. Macroscopic examination showed encephalic edematous, hemorrhagic and edematous lungs, and mainly a bilateral acute hemorrhagic necrosis of the adrenal glands. Toxicology: negative results. Pathology: showed fragments of pulmonary parenchyma with alveolar necrosis. Adrenal glands presented parenchyma complete apoplexy. Bacteriology: the origin of the WFS is pneumococcal meningitis.

Discussion: The autopsy findings (a bilateral acute haemorrhagic necrosis of the adrenal glands) are typical of Waterhouse-Friderichsen syndrome (WFS). Without complete anamnesis (hyperthermia, dyspnea, no traumatic lesions), an error of diagnosis is possible. Indeed, a "battered child syndrome" could be evoked. With numerous petechial hemorrhages on the body and infectious context, the forensic pathologist has to think about the WFS and rapidly perform a lumbar puncture to lead to the good diagnosis. The diagnosis of WFS as the cause of death will be established postmortem based on autopsy findings and additional tests (pathology, bacteriologic cultures). The death of a child with numerous ecchymosis has to be considered as suspicious and an autopsy should be systematically required and performed to confirm or invalidate the diagnosis of WFS. Moreover, the largest number of information must be collected by police (infectious context) before the external examination and the autopsy. Indeed, these important elements of context and anamnesis guide to the best diagnosis and avoid legal implications for the parents if "battered child syndrome" is kept.

Waterhouse-Friderichsen Syndrome, Adrenal Glands, Autopsy

G5 Diatom Analysis From Suspected Drowning Cases

Chun-Yen Lin, PhD, Tsun-Ying Huang, MS, Chao-Ching Huang, MS, Fang-Chun Chung, MS, and Hsuan-Cheng Shih, MS, Institute of Forensic Medicine, Ministry of Justice, Taiwan, ROC, 123, Min-An Street, Zhonghe District, New Taipei City, 235, TAIWAN, ROC; Jiunn-Tzong Wu, PhD, and Chuan-Ling Chou, BS, Biodiversity Research Center, Academia Sinica, Taiwan, ROC, 128 Academia Road, Sec. 2 Nan Kang, Taipei, 115, TAIWAN, ROC; and Wen-Chien Yen, MS, and James Chun-I Lee, PhD, National Taiwan University, College of Medicine, 1, Jen Ai Road Section 1, Taipei, 100, TAIWAN, ROC*

After attending this presentation, attendees will become familiar with the utility and value of the diatom test for the assistance of drowning diagnosis, including the quantitative and qualitative analysis of 105 suspected drowning cases.

This presentation will impact the forensic science community by demonstrating how diatom analysis from sphenoid sinus fluid, lung tissue, and bone marrow is valuable for the diagnosis of drowning.

Many rivers cross the crowded cities, and Taiwan is surrounded with sea. Thus, cadavers were commonly found in water or river banks. In Taiwan, 9.2% autopsy cases per year are found to be a result of drowning. Whether cause of death is actually drowning is the first question raised on these cases. The place where the corpse was discovered in water may not be the initial site of drowning, so it is a challenge to identify the cause and the manner of death for drowning victim. An autopsy conducted by a medical examiner is the essential method for the identification of drowning cases so far. Currently, there are various methods for drowning diagnosis. Diatom screening is one of the methods which can link the cadaver to the natural waters. The cell wall of diatom (also known as frustule) is made of silicon, which is acid-resistant and thermostable. A forensic investigator is capable of doing diatom test by using these characteristics. Diatoms found in sphenoid sinus fluid, lung tissue, and bone marrow can provide an excellent evidence to determine the cause of death. This study was also compared with the findings of autopsy and evaluated the applicability of diatom test for forensic use. There are 105 suspected drowning cases and 20 non-drowning cases collected from Institute of Forensic Medicine, Taipei, Taiwan. Sphenoid sinus fluid, 5g peripheral lung tissue, and rib/clavicle bone marrow were collected during autopsy for diatom analysis. After strong acid digestion, a quantitative and qualitative analysis was conducted by counting the number of diatoms under phase contrast microscope. Diatoms can be observed in most samples from drowning corpses. The percentages of positive diatom results from sphenoid sinus fluid, lung tissue, and rib/clavicle bone marrow were 84.7%, 69.2%, and 6.2%, respectively. The sensitivities of diatom analysis from the same tissues were 84.7%, 84.7%, and 6.2%; the specificities were 81%, 89%, and 100%, respectively. All non-drowning samples showed negative results in the diatom test. The environment of sea water and the seasons of winter and spring could cause the higher false positive rate of diatom analysis in lung samples. Five cases with positive diatom tests in rib/clavicle have the diatom density of lungs above 70 diatoms /per 5g lungs. The qualitative results showed *Nitzschia, Navicula, Cyclotella,* and *Thalassiosira* are most commonly genera in all samples. The results demonstrated that diatom analysis from sphenoid sinus fluid and lung tissue is valuable for drowning identification. The diatom test for suspected drowning cases is a routine screening in Taiwan. For accurate identification of the cause and the manner of death, the results of diatom test from suspected drowning have to be integrated with the investigation from the scene of death and other autopsy findings with careful consideration.

Cause of Death, Drowning, Diatom

G6 Fatal Pulmonary Fat Emboli Following First Trimester Elective Abortion: Is This Amniotic Fluid Embolism

Kenneth D. Hutchins, MD, Miami-Dade County, Medical Examiner Department, #1 on Bob Hope Road, Miami, FL 33136; Erin A. Barnhart, MD, Mississippi State Medical Examiner, 1700 East Woodrow Wilson Avenue, Jackson, MS 39216; and Briza V. Walter, MD, Morristown Medical Center-Atlantic Health System, Department of Obstetrics and Gynecology, 100 Morris Avenue, Morristown, NJ 07962*

After attending this presentation, attendees will understand the clinical presentation, pathophysiology, differential diagnosis, and histological diagnosis of fat and amniotic fluid embolism.

This presentation will impact the forensic science community by reminding attendees of the different approaches to post-abortion deaths and the steps needed to accurately determine the cause of death.

A healthy 28-year-old G5P1041 Haitian woman underwent an elective first trimester abortion at a licensed clinic. The procedure lasted four minutes and there were no complications. During the procedure, she was administered diazepam, meperidine, and propofol. In the recovery room, vital signs taken at five minute intervals were normal. At five minutes after the last vital sign check, 20 minutes into recovery, she was found in asystole. Cardiopulmonary resuscitation lasted 82 minutes with the patient in asystole throughout. At autopsy, the patient was not obese and there were no significant external findings. The right and left lungs were 590 and 530 grams respectively. No thromboemboli were seen grossly. The uterus was 190 grams and approximately 5 milliliters of blood and blood clot, were in the uterine cavity. There was no uterine perforation. A small laceration was on the ectocervix. Accompanying the decedent were two surgical specimens consisting fragmented placental and membranous tissue. The fetus was reported approximately eight weeks gestation. Osmium tetroxide staining of lung tissue revealed obstruction of pulmonary capillaries by fat globules. Mucin stains were negative and no intravascular squamous cells, trophoblasts, or bone marrow elements were identified. There was no polarizable material. The surgical specimens consisted of chorionic villi, gestational endometrium, and membranous tissue. Testing for drugs of abuse was negative, though diazepam, temazepam, and meperidine were detected. Postmortem hemoglobin electrophoresis revealed the decedent to have sickle cell trait. The cause of death in this case was non-traumatic pulmonary fat embolism associated with therapeutic abortion procedure and the manner of death is natural.

Fat embolism syndrome and amniotic fluid embolism syndrome (AFE) have similar clinical presentations though their causes are distinctly different. Fat embolism is usually associated with skeletal trauma but has been described in acute pancreatitis, extensive burns, liposuction, decompression sickness, orthopedic procedures, parenteral infusion of lipids, and sickle cell disease. AFE usually occurs in term childbirths or in the early postpartum period. Risk factors include cesarean section, vacuum and forceps delivery, increased maternal age, diabetes, fetal macrosomia, placenta previa or abruption, and cervical laceration or uterine rupture. Deaths from AFE have been reported following abortion in the first or second trimester of pregnancy but none have been reported in therapeutic abortions performed at as little as eight weeks gestation. In fact, advanced gestational age at the time of abortion is a powerful risk factor for AFE and no deaths have been reported to have occurred at or prior to 12 weeks gestation. Postmortem diagnosis of AFE is made microscopically. One can see amniotic debri in the pulmonary microvasculature including lanugo hair, epithelial squamous cells, granules of bile pigment, meconium, as well as abundant fatty globules. Special stains for mucin and cytokeratin may be of use. In this case abundant fat is seen in the pulmonary microcirculation in a patient who died after a therapeutic abortion at eight weeks gestation. The patient was found to carry sickle cell trait after postmortem hemoglobin-electrophoresis. Rarely have complications during pregnancy been described in patients with sickle cell trait. Case reports have described pulmonary thrombo-embolism following delivery and probable peripartum cardiomyopathy aggravated by intravascular sickling. Sickle cell trait has also been reported to possibly be associated with acute chest syndrome which may be due to fat embolism while sickle cell anemia is definitely associated with fat embolism syndrome caused by bone marrow necrosis and infarction. This patient had diffuse multifocal fat in the pulmonary microcirculation without evidence of other amniotic fluid constituents and at present it is unknown whether the fat emboli are due to amniotic fluid or associated with her sickle cell hemoglobinopathy.

Amniotic Fluid Embolism, Fat Embolism, First Trimester Abortion

G7 Normal Isn't What It Used to Be — The Spectrum of Liver Abnormalities in an Australian Autopsy Population

Johan A. Duflou, MMed, Department of Forensic Medicine, PO Box 90, Glebe, Sydney, New South Wales 2037, AUSTRALIA; and Kate Howson, BSc, and Julia Williams, BSc, University of Sydney, The Sydney Medical School, Sydney, AUSTRALIA*

After attending this presentation, attendees will gain an appreciation of the spectrum of liver normality and disease in an autopsy population.

This presentation will impact the forensic science community by providing updated information, including the range of disease normality, and normal and abnormal weights of relevant organs in the body.

The autopsy is an excellent method for cataloguing disease, whether minor or very serious, and whether incidental or directly related to the cause and manner of death. Autopsy reports should describe pathology in great detail, and even minor pathology is therefore often graced with a detailed description. However, what is normal and what is disease? Is normal the absence of any pathological change or is it what is found in the majority of the population who appear to be healthy? This paper examines the problem of what is a normal liver in a population where aetiological factors for liver abnormalities are present in more than half of all deaths reported for medicolegal autopsy in Sydney, with excessive alcohol consumption, obesity, and hepatitis B and C virus infection predominating. Many abnormalities of the liver are clinically silent, although they can have a significant role to play in the death. For example, a person with an enlarged fatty liver is much more likely to sustain a liver laceration in blunt abdominal trauma than a person with a morphologically normal liver.

This study evaluated the prevalence of liver abnormalities in an autopsy population at the Department of Forensic Medicine, Sydney. Data was extracted from 1,472 autopsy reports from the year 2008. Analysis was performed on the data collected, producing demographic information, cause of death, information on the nature and extent of liver abnormality at autopsy, and information on organ weights in this population.

In this analysis, structural liver abnormalities were very common, with the liver not described as normal in 83.4% of all reports examined. Almost one third of cases had histologically diagnosed steatosis and in the morbidly obese (body mass index greater than 35kg/m^2) this approached 50% of cases. There was steatohepatitis in a further 4% and cirrhosis in 5.6%. In those cases where the history provided documented excessive alcohol consumption, there was steatosis in 36.4% of cases and progression to cirrhosis in a further 24%. There was hepatitis C positive serology in 5% of cases and cholelithiasis was reported in more than one in seven cases.

The mean liver weight for men was found to be 1,747 grams and 1,472 grams for women, with a minor increase in mean liver weight in those where pathology was identified. The mean spleen weight in men was 210 grams and 153 grams in women, with only a modest increase in splenic weight to a mean of 289 grams in cases with hepatic fibrosis and cirrhosis, both of which can be expected to cause portal hypertension with associated significant splenomegaly.

This study of liver pathology in a medicolegal autopsy population provides useful information on the extent and nature of liver abnormalities

which can be expected to be seen. Despite there being a very high prevalence of liver abnormalities in this series, only a small number of cases were considered to have directly or indirectly died as a result of their liver disease. Although this series is not representative of that expected in Australian deaths in general, given the understandably higher rates of death due to physical injuries, poisonings and other external factors than in the general population, this study nevertheless provides useful data which can also be extrapolated to the living general population. It is questioned whether more than four out of five cases in this series had liver disease, or whether in fact many of the changes seen in the liver at autopsy can be reasonably accepted as normal morphology.

Autopsy Pathology, Normal Range, Liver Pathology

G8 Mesenteric Venous Thrombosis as a Cause of Rapid and Unexpected Death

Ana E. Lopez, MD, Harris County Institute of Forensic Sciences, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; Cory J. Broehm, MD*, University of New Mexico Health Science Center, Department of Pathology, MSC08 4640, 1 University of New Mexico, Albuquerque, NM 87131; Jennifer L. Ross, MD, The Methodist Hospital, 6565 Fannin Street, Houston, TX 77030; and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, Harris County Medical Examiner's Office Houston, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will learn about mesenteric vein thrombosis as a rare cause of abdominal pain and death. Attendees will review a case report of a middle-aged woman that presented to the emergency room with abdominal pain and died approximately three hours after admission.

This presentation will impact the forensic science community by discussing the underlying causes of mesenteric vein thrombosis and reviewing the general work up for thrombophilic states in the context of the postmortem examination.

Mesenteric venous thrombosis is an unusual cause of abdominal pain and bowel ischemia that may not be initially suspected because of its vague clinical presentation. In this presentation, a fatal case of a woman with extensive abdominal venous thrombosis who died within a few hours of her arrival to the emergency department is reported.

A 45-year-old Hispanic female was transported to the hospital for abdominal pain of three days duration. Earlier that day, she had presented to an outside clinic with the same complaint, where she was diagnosed with a urinary tract infection and given an intramuscular injection of ceftriaxone. Throughout the day, her abdominal pain became increasingly severe requiring hospitalization. On admission, she was oriented but complaining of severe abdominal pain and nausea. She was afebrile and tachycardic. Physical examination showed a pale, distressed female with diffuse abdominal tenderness and moderate distension, without guarding or rebound. The patient was nulliparous, took no medication, and had no past medical or surgical history. She denied tobacco, alcohol, or illicit drug use.

Laboratory testing showed an elevated white blood cell count (36.0 K/mm^3) and anemia (hemoglobin - 6.9g/dL; hematocrit - 24.9%). Her platelet count was within normal range (246 K/mm^3). Additional laboratory studies were unrevealing. She was given intravenous fluids and morphine for pain. Antibiotics were ordered. The patient refused blood products on religious grounds. A CT scan of the abdomen was ordered; however, she suddenly became distressed, bradycardic, and hypoxic. Following intubation she became pulseless. Despite resuscitative efforts, she was pronounced dead two hours and 50 minutes after admission.

An autopsy was performed at the county medical examiner's office. She weighed 133 pounds and had a body mass index of 28.8 kg/m^2. Diffuse ischemia and infarction were evident in the small intestine, from the ligament of Treitz to the proximal ileum, and in the cecum, ascending colon, and the corresponding mesentery. The spleen and right lateral lobe of the liver were also infarcted. Thrombi occluded the superior mesenteric vein, the portal vein, and its branches throughout the liver parenchyma, and the splenic vein. Thrombi were also noted in the smaller peripheral branches of the mesenteric vein. Additionally, the uterus was enlarged, weighing 625 grams, and contained multiple leiomyomata, the largest measuring 9cm. The left ovary was enlarged, weighing 550 grams and measuring 14cm in greatest dimension, and contained a benign cystic teratoma. The liver was not cirrhotic. Postmortem laboratory testing of hospital blood revealed mild to moderate prolongation of the prothrombin and partial thromboplastin time (PT - 14.9 seconds, PTT - 45.9 seconds) with an INR of 1.5. A lupus anticoagulant screen was negative. Upon further questioning of the family, the patient had no history of deep venous thromboses, abdominal trauma, oral contraceptive use, or prior malignancy.

Mesenteric venous thrombosis (MVT) has been described in the medical literature since 1895. It was first characterized as a clinical entity in a 1935 publication by Warren and Eberhard. Primary forms occur when there is no underlying etiology or associated condition. Secondary forms have an associated condition such as thrombophilia associated with antithrombin III deficiency, protein C or S deficiency, factor V Leiden or prothrombin gene mutations, and the antiphospholipid antibody syndrome. Other associated conditions include liver cirrhosis, prior abdominal trauma, asplenia, oral contraceptive use, malignancies, pancreatitis, intraabdominal infections, and congestive heart failure.

The signs and symptoms of MVT are nonspecific and mimic a large number of abdominal processes. Patients can present with diffuse abdominal pain of several days duration, abdominal distension, nausea and vomiting, and bloody diarrhea in cases that have already progressed to intestinal infarction. Laboratory studies are nonspecific; however, may reveal an elevated WBC count. Diagnosis of MVT is made by CT, MRI, or mesenteric angiography.

In this patient, the thrombosis was extensive, which led to visceral infarctions. No underlying etiology was established; however, coagulation studies were limited by postmortem samples. Venous stasis secondary to her enlarged uterus and left adnexal mass may have been factors. It has been suggested that MVT is a heterogeneous disease, whereby both hereditary and local factors may play a role in the development of the thrombosis. With an early diagnosis and appropriate medical and surgical intervention, the mortality of mesenteric venous thrombosis can be reduced.

Venous Thrombosis, Mesenteric Ischemia, Thrombophilia

G9 Unexpected Death Due to Undiagnosed Medulloblastoma in Twin Pregnancy: A Case Report

Federica Portunato, MD, Manuela Botto, MD, Maria Celeste Landolfa, MD, and Enrico Pizzorno, MD, University of Genova, Department of Legal and Forensic Medicine, Via de Toni 12, Genova, I-16132, ITALY; and Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, Via de' Toni, 12, Genova, 1-6132, ITALY*

After attending this presentation, attendees will learn about a peculiar case of unexpected death due to a brain tumor in a young pregnant woman.

This presentation will impact the forensic science community by stressing the importance of a complete forensic approach to ascertain the causes and means of death and to evaluate possible profiles of professional liability.

A case is presented of unexpected maternal death due to an undiagnosed medulloblastoma in a 28-year-old woman at the 33rd week of bigeminal pregnancy with neurologic symptoms which had been going on for the month prior to her death.

A woman in her 33rd week of twin gestation, presented at hospital with headache, nausea, and vomiting. She had a history of gastritis one month beforehand.

During the last hospitalization there was the onset of vertigo and nystagmus. Following a consultation with a neurologist and an

otolaryngologist; vestibular neuritis was diagnosed. She didn't undergo any instrumental examination since she was pregnant. Two weeks after the diagnosis while she was still hospitalized, she presented with acute frontal headache and died approximately three hours later.

An emergency cesarean section was attempted but it failed to save the twins. A forensic autopsy was performed four days later, which showed a non-encapsulated neoplastic mass between the left lobe of the cerebellum and the vermis (70 x 30mm) surrounded by massive edema. At histology the neoplasm was identified as a medulloblastoma with a IVth grade of malignancy (Louis D.N. et al, 2007).

Death was ascribed to acute cardio-respiratory failure caused by the compression of the brainstem carried out by the tumoral mass.

The twins didn't present with any pathology that could have possibly lead to death, so the cause of their death may be attributed to hypoxia following the maternal cardiac arrest.

Although pregnancy is considered a normal biologic process, it is associated with various physiologic and anatomic changes resulting in an increased risk of death.

The most common types of maternal death include vascular accidents, ranging from 10 to 20%, along with pulmonary embolism, cervical and coronary thrombosis, cerebral hemorrhage, as well as rare events such as rupture of the splenic artery aneurysm (Sharma BR et al, 2009 - He MX et al, 2010).

The incidence of unexpected death due to primary intracranial tumors in forensic practice is low. Particularly, medulloblastomas are relatively rare in adults accounting for only 2.4% of all intracranial tumor types (Merchant TE et al, 2010).

In an analysis of 10,995 medicolegal autopsies in only 19 (0.17%) resulted in an unexpected death due to an intracranial neoplasm of which only one (0.01%) was a medulloblastoma (Di Maio S et al., 1980).

Brain tumors tend to become larger and show accelerated growth during pregnancy due to fluid retention, increased blood volume or pregnancy hormones (Chang L. et al., 1999).

In conclusion, in this case the autopsy was paramount in order to ascertain the cause of death. It is questionable whether a prompt medical intervention with a cesarean section would have allowed the survival of the twins. However, considering the advanced stage of pregnancy, the absence of any sign of pathology regarding the two babies and the availability of perinatal intensive therapy care unit it is highly probable that the two would have survived.

Pregnancy, Medulloblastoma, Unexpected Death

G10 Contribution of Histo-Pathological Examination in Electrocutions: Report of Two Cases and Review of Literature

Camille Franchet, 1 Avenue du Professeur Jean Poulhès, Toulouse Cedex 9, 31059, FRANCE; Céline Guilbeau Frugier, MD, Service d'Anatomie Pathologique, Hôpital de Rangueil, 1 avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE; Fabrice Dedouit, PhD, Service de Médecine Légale, Hôpital de Rangueil, 1 Avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE; Norbert Telmon, MD, PhD, Service Medico-Judiciare, CHU Rangueil, 1 Avenue Jean Poulhes, Toulouse, F-31054, FRANCE; Daniel Rouge, PhD, Service de Médecine Légale, CHU Toulouse-Rangueil, 1 avenue Professeur Jean Poulhès, Toulouse, 31059, FRANCE; and Bernadette Delisle, PhD, Service d'ANATOMIE PATHOLOGIQUE, Hôpital de Rangueil, 1 avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE*

After attending this presentation, attendees will learn the most specific features and the role of histo-pathological examination in the cases of high and low voltage electrocutions. Furthermore, each lesion will be compared with their main differential diagnoses, especially for the skin examination.

This presentation will impact the forensic science community by a clarification of the most specific features of histo-pathological examination and its medico-legal relevance in cases of electrocutions.

High-voltage electrocution is an uncommon cause of death. Few articles describe histo-pathological findings in deaths by electrocution and those that do usually focus on a single organ, without medico-legal relevance or interest, because of lack of specificity of histo-pathological signs.

Two cases of electrocutions observed in the Medico-Legal Institute of Toulouse Hospital, France are reported. For each case, this study reports autopsical and histo-pathological findings of viscera and skin. A review of the literature concerning the pathological examination of deaths secondary to electrocutions is performed, and establish the contribution of reported findings to the medico-legal purpose.

In the first case, the victim was found lying in a wet footpath near a 380 volts bare electric cable (low voltage), which was on the ground. The autopsy found several burns consistent with electric burns. The points of contact of electric current were on the abdomen and on the right upper limb. Notes was cyanosis of the head and neck and reddish foam in the airway suggesting asphyxia. Each internal organ appeared congested. The pathological examination found some features of electric current marks, particularly an iron deposition in the abdominal burn (identified by the Perl's Prussian Blue staining). This histological finding confirmed direct contact with the electric cable. The lungs presented some features of mechanical asphyxia suggestive of respiratory spasms in the context. The heart showed no signs of ischemia.

The second case concerned a man who was climbing on a metallic ladder to take down a hornet's nest in a tree. According to the eyewitness account, the ladder felled a power line carrying 20,000 volts (high voltage). The man was given emergency treatment and then was sent to the hospital, where he died. The autopsy found electric current marks on the upper and the lower limbs. The left-ventricular myocardium macroscopic examination revealed full-thickness diffuse circumferential hemorrhagic alterations. The pathological examination found a pseudo-asphyxic aspect of the lungs, an ischemic and hemorrhagic aspect of the heart with features of ventricular fibrillation, and distinctive ischemic liver injury. Since there was no doubt about the mechanism of the skin lesions, the electric current marks were not sampled.

A review of the literature had allowed the clarification of the role of the histo-pathological examination in the diagnosis and medico-legal classification of death by electric shock. The pathology of the skin (electric current marks), heart, lungs, and liver were studied in an effort to establish specific criteria defining death by electrocution. It appears that there is no pathognomonic sign of electrocution for each organ individually. However, we establish a list of arguments which, added to the accident investigation data, are highly suggestive of the cause and mechanism of death by electrocution shock. Pathological findings in high and low voltage electrocutions were compared, differences between direct contact with the electric source, and arcing injuries were discussed. Skin metallization is presented as a particularly useful histopathological feature for the diagnosis of electrical burns.

It appears that the histo-pathological examinations, in association with the investigation data and the autopsy findings, are helpful for clarification and determination of deaths when death secondary to electrocution is evocated.

Electrocution, Pathology, Medico-Legal Relevance

G11 Sudden Unexpected Death Due to Acute Myeloid Leukemia: A Case Report

Francesca Fossati, MD, Michela Cicconi, MD, Sara Candosin, MD, Roberta Carrossino, MD, and Francesco Ventura, MD, Univeristy of Genova, Department of Legal and Forensic Medicine, via de Toni, 12, Genova, 16132, ITALY*

After attending this presentation, attendees will have learned about a case of unexpected sudden death due to undiagnosed acute myeloid leukemia.

This presentation will impact the forensic science community by stressing the importance of performing an accurate necropsy examination completed by a thorough histopathological study in all cases of unclear sudden death.

Acute myeloid leukemia (AML) is characterized by an increase in the number of myeloid cells in the marrow and an arrest in their maturation, frequently resulting in hematopoietic insufficiency (granulocytopenia, thrombocytopenia or anemia), with or without leukocytosis.

The clinical signs and symptoms of AML are diverse and nonspecific, but they are usually directly attributable to the leukemic infiltration of the bone marrow, with resultant cytopenia.

Typically, patients present with signs and symptoms of fatigue, hemorrhage, or infections and fever due to decreases in red cells, platelets, or white cells, respectively. Pallor, fatigue, and dyspnea on exertion are common. Leukemic infiltration of various tissues, including the liver (hepatomegaly), spleen (splenomegaly), skin (leukemiacutis), lymph nodes (lymphadenopathy), bone (bone pain), gingiva, and central nervous system, can produce a variety of other symptoms.

The primary diagnosis of AML rests on the morphologic identification of leukemic myeloblasts in preparations of peripheral blood and bone marrow stained with Wright–Giemsa. The presence of more than 30 percent leukemic blasts in a bone marrow aspirate is required for a definitive diagnosis of acute leukemia.

AML has typically been categorised with the FAB system, which is based on cytomorphology and cytochemistry. The current WHO classification system incorporates cytogenetic data and defines four major categories of AML. At least 20% of the blasts must have surface antigens associated with myeloid differentiation.

A case is presented of a woman of 67-years-old died in Hospital of Genoa's emergency room for unknown clinical causes. The day before his death, she had been visited at home by doctor for symptoms of diarrhea and vomiting which had persisted for several days. The doctor gave antiemetic and antidiarrhoeal therapy and rehydration.

The body's autopsy was performed by Institute of Forensic Medicine of Genoa. External examination highlights numerous small purplish ecchymosis on the whole body surface. Small and diffuse hepatic nodules were also found at autopsy.

Histopathologic examination performed on the tissue samples, confirmed the presence of neoplastic cells in cerebral, heart, lungs, pancreas, kidney, and spleen blood vessels. Neoplastic elements at immunohistochemical examination showed weak expression of myeloperoxidase and molecule CD 34, absent expression of molecule CD 20 and CD 3. This immunohistochemical profile identified a neoplastic proliferation of immature granulocytic elements. The multiorgan neoplastic involvement was due to acute myeloid leukemia (FAB M1/M2).

The data obtained at autopsy and histopathology attributed the death due to multiple organ failure secondary to acute myeloid leukemia.

In the literature are other examples of unexpected death secondary due to complications of undiagnosed acute myeloid leukemia, but in these cases, the cause of death was hemorrhage secondary to disseminated intravascular coagulation.

In conclusion, the present case is interesting especially because unexpected death, came after non-specific symptoms, caused by a multiple organ failure (MOF) secondary to acute myeloid leukemia, stresses the importance of postmortem examination complemented by histopathological investigations, to define cause of death.

Acute Myeloid Leukemia, Sudden Unexpected Death, Multiple Organ Failure

G12 Homicide During Police Procedures: From Crime Scene Investigation to Reconstruction — The Long Way to the Truth

Francesco Vinci, MD, Maricla Marrone, MD, and Sabrina Leonardi, MD, Section of Legal Medicina - University of Bari, Piazza Giulio Cesare n. 11, Bari, 70124, ITALY*

After attending this presentation, attendees will understand that ballistics investigation is the prerogative of several professionals. Among them, forensic pathologists are essential to ensure a correct reconstruction of the dynamics of events in cases of murder or injury. In fact, a multidisciplinary approach combining the specific skills of different professionals will guarantee the best results.

This presentation will impact the forensic science community by showing how pathologists are irreplaceable in forensic ballistics. Their knowledge, enabling an objective assessment, can integrate and complete the conclusions of other ballistics experts, and assess the compatibility of the bodily injuries and the reconstructed dynamics.

A case is presented of a 47-year-old man who died of a gunshot wound during capture by the police. The victim was driving down a city street in the wrong direction when he was spotted by policemen. A chase by two police cars began and three policemen fired several shots at the victim's car, one of which killed the victim. During the crime scene investigation, a different military force found nine cartridge cases on the tarmac, several bullet fragments in the car (back and front right), and two bullets (a deformed bullet on the floor of the left front seat and an intact bullet on the right front seat). Fragments of glass were found on the tarmac at a distance of two to three meters from the car and the right front window was broken.

The agents reported the following dynamics: the man entered a dead-end street, so he tried to re-enter the main road probably intending to run over the three policemen. Two gunshots were fired against the back wheels and several shots toward the front right of the car. The victim's car started to move again and a policeman broke the front window with a gun. The car stopped immediately and when the policeman opened the front door where he found the victim slumped lifeless in his seat.

A team of forensic pathologists performed autopsy, genetic, and toxicological examinations as well as a ballistic investigation. Autopsy findings showed a single through wound with entry in the victim's left shoulder and exit on the right chest, then striking the arm. The gunshot course was from left to right and back to front at a downward angle of 18°. The bullet struck the left lung and the heart, causing massive hemothorax and slight hemopericardium. The victim also showed a bruise on the left cheek, consistent with a blow from the firearm magazine.

Examination of gunshot residues on the jersey sleeve revealed a shooting distance of 40-60cm. Ballistic examinations were made of the bullets, bullet fragments, cartridge cases, three guns, and on the victim's car: the findings were compared with the evidence markers at the crime scene. The two bullets in the car were 9mm caliber gun. Genetic investigations revealed the victim's DNA on the intact bullet. Firing tests identified the weapon which fired the fatal bullet and studied the decrease of Vo and gunshot residue after firing against the window of a similar car. The victim's car had been hit by at least seven bullets: five shots against the front left (one of which ended on the floor of the left front seat) and two shots against the back wheels.

The following event dynamics were reconstructed: during the capture, the policemen shot at the back wheels and front left of the victim's car. Then a policeman broke the car window with the gun muzzle; meanwhile, a bullet was fired from the same gun and hit the victim's shoulder. It is not known whether the shot was intentional. The car traveled on a few meters while the man died. The blunt injuries to the head probably occurred when the victim was forcibly removed from the vehicle.

In conclusion, serious discrepancies were highlighted between the crime scene reconstruction by the pathologists and what had been reported by the policemen: the man's death was not due to an accidental gunshot fired at

the car wheels, but to a gunshot fired directly at the victim, probably accidentally. Finally, ballistic investigations identified the weapon and the policeman responsible for the death.

Ballistic Findings, Forensic Pathology, Shooting Reconstruction

G13 Minimal Submersion Period Estimation Using Freshwater Benthic Fauna and Wagner's Parsimony Method (WPM): Tools for Forensic Investigations in Different Lotic and Lentic Environments

Yves Schuliar, MD, PhD, and Myskowiak Jean-Bernard, PhD, IRCGN, 1 Boulevard Theophile Sueur, Rosny-sous-Bois, 93110, FRANCE; Fanton Laurent, MD, Institut de Médecine Légale, 12, rue Rockefeller, Lyon, 69008, FRANCE; and Masselot Gerard, PhD, 46, rue Abel-Guyet, Plaisir, 78370, FRANCE*

After attending this presentation, attendees will learn information about a new method to estimate a minimal submersion period for a corpse found in freshwater.

This presentation will impact the forensic science community by possibly providing a PMI estimate in freshwater by studying fauna using Wagner's parsimony method.

The forensic investigations are generally very difficult when a body is discovered immersed for an undetermined period of time in freshwater. Due to long periods of immersion and a high level of putrefaction, the estimation of the time since death is problematic. Classical forensic entomology is based on existing links between necrophagous insects and the state of decomposition, in order of appearance of necrophagous insects on the cadaver. This science does not allow a pertinent evaluation of the time since death for a crime scene technician. It is indeed impossible to reach any conclusions based on the underwater colonization process once the cadaver has resurfaced. The purpose of this work was to analyze from February 2001 to October 2002, the different cases of cadaver discoveries in order to isolate pertinent bioindicators. The database consists of a medicolegal set, ecological, and judicial observations recorded on 30 freshwater. This study gathered the following data: freshwater loci (lotic or lentic), geographical location, first elements on discoveries, season, and the postmortem interval (PMI) recorded by pathologist during autopsy. In all cases, the PMI was estimated between half a day and three years and only involved adult victims.

Two types of mathematical methods can offer an ecological data processing: phenetic's methods and parsimony method. Phenetic' methods, based on the total inter-sites similitude, give calculations of distances and links between sites.

Because of the risk of confusion due to the infinite mathematical distances, number, and computational tools, phenetic' methods seem inappropriate for this type of investigations. So, Wagner parsimony method which does not authorize scenarizations but does allow a strict objectivity between diagram and data matrix was chosen.

Forensic application of WPM allows analyzing presence/absence of aquatic and terrestrial invertebrates on different crime scenes according to the method described and respectively applied by Masselot et al. to freshwater biomonitoring and Coiffard et al. to taxon lists of fossil plant assemblages of the Cretaceous. Leaves of the trees were considered as crime scene "localities." There were gathered according to their environmental or taphonomic states of characters (synapocoenoses sensu Nel et al.). Attributes are independent sets of information (e.g., "victims" parameters).

For corpses found after a one to three weeks period of partial submersion (floating) in a lotic or lentic freshwater environment, attributes required for colonization were the accessibility to the surface, the presence of clothing, a high decomposition level, and the presence of algae and mud. In the 30 cases studied (PMI from one day to three years), invertebrates were systematically absent on fresh (low PMI of under two to three days) and on very decomposed cadavers (skeletal remains). Evidence of a colonization process had disappeared on unclothed cadaver or when postmortem changes occurred. In the laboratory, correlation was explained between the development rate reached by each arthropod specimen and the stage of decomposition recorded at the autopsy. Study of the parsimonious biocenogram demonstrated different gradients associated with increasing postmortem delays:

- Specimens of the order of Gasteropoda were the first colonizers on a cadaver submersed for one week or more. Gasteropoda sampling is particularly congruent with a lotic environment, partial submergence, and presence of clothing. Fist gastropods were collected from carcases just after five days of immersion.
- Second contributors to cadaver coloniszation were immature forms of Diptera. They were mainly collected from the muddy clothing on the cadavers. At the same time, the presence of species of Diptera was found during Spring on submerged cadavers (PMSI from three weeks to two months). Totally submerged corpses were mainly attractive to aquatic species of Chironomidae or Simuliidae, and floating cadavers had a concomitant colonization of aerial Diptera and aquatic fauna.

With regard to the colonization by aerial Diptera, it appears wrong to use necrophagous insects alone for the estimation of PMI. In fact, the aquatic environment was able to defer oviposition (egg-laying), to reduce larval density on emergent parts of the corpse and to slow down the development rate of insects (influence of lower water temperatures and washing effect of the corpse).

A simple but effective sampling protocol to get a real solution to the problem of estimating the postmortem submersion interval (PMSI) of a cadaver found in lotic or lentic water was created.

Postmortem Submersion Interval, Freshwater Invertebrates, Wagner's Parsimony Method

G14 Insect Timing and Succession on Buried Carrion

Emily C. Pastula, BS, 3434 Schlee Street, Lansing, MI 48910*

After attending this presentation, attendees will have a better understanding of how insect succession is used in forensic work, which insects are present on buried carrion as opposed to exposed, and how long it takes insects to arrive on buried carrion.

This presentation will impact the forensic science community by enabling forensic entomologists to better understand the interaction between insects, carrion, and the soil environment. The understanding of insect succession on buried carrion could lead to the development of a post-burial interval estimation. This estimation would be similar to the postmortem interval (PMI) used on surface carrion to determine time of colonization. With this development, it would be possible to date a buried body based on the insect evidence present.

Burial is a popular technique chosen by assailants when looking to dispose of a body. Rarely are bodies buried very deep since digging requires a great amount of time and effort. The longer the assailant is in contact with the body, the more likely they are to be found with the body or leave evidence linking them to the crime. Therefore, assailants usually dig shallow graves to dispose of their victims with depths ranging between zero and three feet, the most common depth being two and one-half feet. A difference in the insect fauna has correspondingly been found when comparing exposed and buried carcasses, yet very little is known about when exactly these insects arrive. The time it takes insects to travel to carcasses at different depths has not been readily studied. It is also unclear how far insects are able to travel through the soil to colonize a carcass because most experiments only looked at a depth of one foot.

By increasing the frequency of sampling and placing out a large number of replicate pig carcasses (42), it was hoped to narrow down the time range

in which certain insects arrive at carcasses buried at one foot and two feet, with the bottom of the hole measuring the depth. A predetermined number of pig carcasses were exhumed after three, five, seven, fourteen, twenty-one, thirty, sixty, ninety, and one hundred twenty days. Insects were collected off of the carcass itself, as well as from the soil above the carcasses via excavating and sieving, and then placed in ethanol for later identification. It was postulated that insects would be able to colonize a carcass at two feet, that it would take one week for insects to reach a depth of one foot, that it would take two weeks for insects to reach a depth of two feet, and that insect succession would progress similarly to exposed remains with fly larvae from the family *Calliporidae* being the first to colonize.

The results indicate that insects are capable of colonizing a carcass at both one and two feet and arrive after five days and seven days, respectively. The insects present do not correspond with those normally found on exposed remains. Instead, fly larvae from the families *Sarcophagidae* and *Muscidae* are the first to colonize buried remains. From these results we hope to aid in the possibility of dating buried bodies based on the insect evidence present.

Forensic Entomology, Insect Succession, Buried Carrion

G15 Stab Wound in the Neck: An Unusual Case of Suicide

Cristina Cordeiro, MSc, Instituto Nacional De Medicina Legal, Largo Da Se Nova, Coimbra, 3000-213, PORTUGAL; and Duarte N. Vieira, PhD, MD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

The goal of this presentation is to report an uncommon case of suicide by stab wounds in the neck and to underline the need of a complete forensic approach through autopsy with special techniques for the dissection and examinations of the neck structures, histological, and toxicological ancillary examinations, as the only way for a better understanding of the mechanism of death.

This presentation will impact the forensic science community by showing how useful a formaldehyde fixation of the neck organs could be allowing an easier dissection of this area and better identification of the injuries.

In forensic contexts, stab wounds usually have a homicide etiology. The severity of the wounds is based mainly on the location, depth of penetration, the type of weapon (knife length, shape, straight or serrated), and manner of assault.

Stab wounds to the chest are usually lethal. They can result in rupture of the lung, marked bleeding within the chest cavity, or penetration of the heart. Stab wounds to the abdomen could result in trespassing internal organs or vessels with fast or slow bleeding inside the abdomen. In the neck, even a single stab wound, because of the multitude of organ systems in this part of the body, is capable of producing considerable harm.

Suicide caused by a stab wound in the neck is unusual in the forensic literature. A case of suicide is presented, in which the victim, resident in a retirement home and with amputation of lower limbs, uses a small penknife with a 6.5cm blade to commit suicide. He was found in his room, still conscious, bleeding from the neck and expressing his suicide intentions – "*I want to die, I want to cut the carotids*."

When admitted at the emergency room he has hemodynamically stable but with respiratory distress and hemoptysis. He developed hypoventilation and bradycardia and died after two hours. Resuscitation procedures were carried out.

During the autopsy the external examination found a single fusiform wound in the anterior view of the neck and two superficial wounds, affecting only the epidermis. However, the internal examination shows multiple injuries at the cervical fascia and at the muscles of the anterior cervical region. Injuries at the thyroid cartilage were also found but none at important vessels. The lungs had a mottled appearance. The neck organs were removed *en bloc* and subjected to formaldehyde fixation. A posterior and careful dissection allowed to better identified the paths of the blade and the injuries, some of them located at the oesophagus and pharyngo-laryngeal mucosa. Histological exams were performed as well as toxicological. The last ones revealed the presence of drugs (midazolan, lidocaine, amitriptyline, carbamazepine, and paracetamol) at therapeutic levels.

This study underlines how in cases of stab wounds of the neck, a careful autopsy involving special techniques of neck dissection must be adopted and combined with the examination of the neck organs after fixation. This previous fixation could be very useful, particularly when no vessel or spinal cord trauma was found, to explain the mechanisms of death.

Stab Wound, Neck, Formaldehyde Fixation

G16 Atypical Hanging Occurring in Two Sisters Within a Short Period of Time: Incidental, Sympathetic, or Something Else?

Khalid Jaber, MD, Firebrigade Training Centre, Malahide Road, Marino, Dublin 3, IRELAND*

After attending this presentation, attendees learn two cases of atypical hanging occurring in two sisters within a relatively short interval. Both sisters belonged to the Travellers' community of Ireland. Both were married and had sporadically difficult relationship with their husbands. When the paramedical staff first encountered these females separately, ligatures were not found around their necks.

This presentation will impact the forensic science community by presenting the unusual death of two sisters through atypical hangings. Autopsy and scene photographs will be presented showing the atypical features of both deaths.

Case 1: The first sister was living with her husband (partner). She had experienced some fertility problems over the past two years prior to her premature death. Her husband somehow was never similarly and or concurrently investigated. She was brought to the near-by hospital, by her husband, clinically in a near hanging situation with unusual burn marks on her left thigh. She was unconscious, with Glasgow coma score of three, with no ligature *in situ*. She remained comatose for less than 24-hours before she expired. The husband's story was that he returned to the house after being away for 20 minutes and found his wife hanging by a rope from the pipe of a boiler unit in a small storage/utility room in an incomplete suspension. Her feet were on the floor. He rushed to remove the noose and loosen the alleged simple slip knot with no apparent difficulty, with one hand while supporting his wife with the other. Upon hearing gurgling noises he realized she was not dead so he called for help from neighbors and began administering CPR. He and his neighbor drove the wife to the hospital. She was admitted and an initial CT scan showed diffuse brain edema and features of hypoxic ischemic encephalopathy. She remained in hospital for less than 24-hours and expired the following day. Upon admission the hospital, nursing staff noted an unusual burn marks on the side of her left hip and thigh area. The features of the hanging marks and the burn marks are presented and discussed.

Case 2: Her sister, a mother of one child, was found dead in her Aunt's house where she sought shelter from her allegedly aggressive husband (partner). The latter apparently had physically assaulted her a few days earlier in her mother's home where she lived with her child. She was drinking with her alcoholic aunt the afternoon when she was found slumped on the floor with her head near the radiator in the center of the wall and her left leg leaning on the edge of the bed positioned along another wall. She was found with ligature marks around her neck by the residents of the house, but with no ligature *in situ*. The scene revealed two TV cables running along two corners of the room and coming from the attic space. The nearest cable to the body was found split at a previously cut point which was taped. The other cable was not considered by the scene investigators as a possible ligature. The features of the hanging marks and the burn marks are presented and discussed.

These two sisters were young females from the Travellers' community in Ireland. Both were married and had experienced uneasy and, at least, sporadically difficult marital life. Both were regular consumers of alcohol and both have been possibly clinically depressed.

Atypical, Hanging, Sisters

G17 Detection of HCV in a Body Exhumed After Four Months Followed by a Phylogenetic-Tree Analysis Allows Identification of the Origin of a Nosocomial HCV Transmission Associated With the Use of a Multi-Dose Vial

Alessandro Bonsignore, MD, University of Genova, Department of Legal and Forensic Medicine, Via de Toni 12, Genova, 16132, ITALY; Andrea Gianelli Castiglione, MD, Regional Network Organ Transplant, San Martino Hospital, Largo Rosanna Benzi 10, Genova, 16132, ITALY; Saverio Parisi, MD, and Giorgio Palù, MD, University of Padova, Deptartment of Histology, Microbiology, and Medical Biotechnologies, Via A. Gabelli 63, Padova, 35121, ITALY; Oliviero E. Varnier, PhD, Laboratory of Microbiology and Virology-Advanced Biotechnology Center, Largo Rosanna Benzi 10, San Martino Hospital, University of Genova, Genova, 16132, ITALY; and Francesco De Stefano, MD, and Francesco Ventura, PhD, University of Genova, Department of Legal and Forensic Medicine, via De Toni, 12, Genova, 16132, ITALY*

The goal of this presentation is to focus on an outbreak of nosocomial transmission of hepatitis C virus (HCV) in a hospital in northern Italy. After attending this presentation, attendees will gain knowledge of a case where a forensic approach by means of exhumation, autopsy, microbiological studies, phylogenetic-tree analysis, and circumstantial evidence led to the conclusion that the outbreak was linked to a patient-to-patient transmission occurred when a multidose vial was contaminated with blood from an HCV-infected patient.

This presentation will impact the forensic science community by demonstrating how important a thorough forensic investigation and a multidisciplinary approach are in order to provide an adequate and high-quality service to the judicial authorities. It will also impact the forensic science community by showing how long HCV can remain active even in a dead body in particular environmental conditions.

Since the introduction of routine screening of blood for anti-HCV and the steep decrease in the incidence of post-transfusional hepatitis, patient-to-patient transmission has become the commonest mode of nosocomial HCV infection.

HCV infection is frequent among patients with hematologic malingnancies, especially those with lymphoproliferative disorders, and unapparent routes of infection may be important in this setting. Indeed, many patients acquire HCV infection in the environment in which they receive treatment for their disease.

Outbreaks of HCV nosocomial transmission have been linked to breaches in standard precautions for blood-borne infections during nursing procedures or interventions such as surgery, dialysis, and colonoscopy.

An outbreak of patient-to-patient transmission of HCV through the use of a multidose vial during the rinsing of central or peripheral venous catheters is reported. At the beginning of 2006, acute HCV infection was diagnosed in six patients hospitalized in a hematology ward and a look-back study identified two other HCV-positive patients. Analysis of the events pinpointed the period in which the contamination occurred due to a single episode of exposure from a unique source between 7:00 a.m. and 8:30 a.m. on December 14, 2006. Circumstantial evidence suggested that the only patient having a known HCV chronic infection in this period was the index case; however, since she died on December 29, 2006, there were no samples available to document the source of the outbreak.

It is well known that HCV, like all viruses, is gradually inactivated in the body of a dead host and the presence of heat can have a drastic impact on the lifespan of the virus. Particularly, the virus is referred to be infectious for about sixteen days at 25°C and two days at 37°C, while it can remain active for more than six weeks at temperatures less than or equal to 4°C.

Regardless of this lability of HCV and the lack of similar cases described in the literature, the cadaver was exhumed four months after burial.

The HCV RNA genome was surprisingly amplified, identified, and genotyped in liver and spleen samples. Genotyping of HCV strains, amplified in various clinical samples from the eight patients, was performed by sequence analysis. The comparative phylogenetic analysis of the strains identified in the patients studied with those from other HCV patients allowed identification of the source of contamination, which was the same for five patients. Moreover, a definite route of transmission has been identified as well as the specific cause-effect relationship for the multidose vial procedure.

Particularly, nursing was found to be inconsistent with recommended safety standards.

In conclusion, the exhumation and appropriate microbiological and phylogenetic investigations allowed for the Identification of the outbreak origin and a correct analysis of the professional liability profiles.

Outbreak of HCV Nosocomial Transmission, Active HCV in an Exhumed Body, Phylogenetic-Tree Analysis

G18 The Virtual Hydrostatic Test

Dori M. Franco, DO, Edward L. Mazuchowski, MD, PhD, Philip J. Berran, JD, MD, and Howard T. Harcke, MD, Armed Forces Medical Examiner System, 116 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will understand the techniques and procedures available to distinguish a stillborn fetus from a liveborn neonate.

This presentation will impact the forensic science community by demonstrating another tool in the determination of live birth.

The hydrostatic test has been used for hundreds of years to help determine if there has been a live birth. Criteria for live births include respiration, heartbeat, food in the stomach, or a vital reaction of the umbilical stump or any injury. The hydrostatic test involves placing the lungs in water to see if they float. If the lungs float, it could be due to aeration or putrefactive gas from decomposition. To exclude decomposition, a portion of liver is also placed in water. If the liver also floats, the test is inconclusive. If the liver sinks, the floating lungs are considered to be aerated. Aeration can also be caused by artificial respiration due to resuscitation efforts and such information should be sought. Histology of the lungs has also been used to assess respiration. Expanded alveoli are consistent with respiration and collapsed alveoli with stillbirth; however, microscopic examination should not be the sole criterion used. Reportedly, there have been stillborns with expanded alveoli and live births with collapsed alveoli.

Computed tomography (CT) is being increasingly used in the practice of forensic pathology. CT is helpful in determining fractures, especially of bones not normally examined during autopsy (e.g., spine), detecting foreign bodies and their trajectories, and detecting air (e.g., pneumothorax). CT can also aid in estimation of gestational age by measuring the femur length.

Presented are two cases of fetal deaths of estimated gestational ages 21-23 and 23-25 weeks in which both the hydrostatic test and CT were performed. In one case, the lungs sank in water and there was no air seen in the lungs or gas in the liver on CT. Histology of the lungs showed collapsed alveoli. In the other case, the lungs floated in water, the liver sank, and air was seen in the trachea, bronchi, and both lungs on CT; and no gas was present in the abdomen. Histology of the lungs showed areas of expanded alveoli and collapsed alveoli. In both cases, the CT was used to corroborate the estimated gestational age.

Because assessment of live birth is a critical and difficult decision, as many factors as possible should be taken into consideration. Postmortem CT offers another assessment to consider in this determination. Further study and correlation with existing methods seems warranted.

Hydrostatic Test, Postmortem CT, Virtual Autopsy

G19 Methylenedioxypyrovalerone "Bath Salts" Related Death: Case Report and Review of the Literature

Kilak Kesha, MD, and Cassie Boggs, MD, Office of the Chief Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21201; Mary G. Ripple, MD, 111 Penn Street, 900 West Baltimore Street, Baltimore, MD 21223; Carol Allan, MD, and Barry S. Levine, PhD, Office of the Chief Medical Examiner Maryland, 900 West Baltimore Street, Baltimore, MD 21223; Rebecca Jufer-Phipps, PhD, 6804 Maple Leaf Court, Apartment 101, Baltimore, MD 21209; Suzanne Doyon, MD, Maryland Poison Control Center, 20 North Pine Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of the Chief Medical Examiner Maryland, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will be familiar with methylenedioxypyrovalerone (MDPV), a new designer drug more commonly known as "bath salts," and its significance as a current public health trend.

This presentation will impact the forensic science community by increasing awareness of "bath salt" use, the clinical presentation of a MDPV-related death, and the importance of monitoring its emergence as a possible new epidemic in substance abuse.

"Bath salts" are white, tan, gray, yellow, or brown odorless powders sold in "head shops", gas stations, and convenience stores and on the Internet where they are marketed under multiple names. They also retail as plant food, pond water cleaner, odorizers, research chemicals, potpourri, and incense. "Bath salts" are recreational designer drugs of abuse that are injected, ingested, or inhaled, which unlike traditional cosmetic bath salts have no legitimate use for bathing. These products contain stimulant compounds such as 3,4-methylenedioxypyrovalerone (MDPV) or 4-methylmethcathinone (mephedrone) whose effects are similar to methamphetamine, amphetamine, and cocaine.

MDPV is part of the phenethylamine class of drugs and is structurally similar to cathinone (khat), found in both schedule I hallucinogenic substances and schedule I stimulants. MDPV is currently not scheduled by the DEA; however, many states have banned the sale of "bath salts." Clinical effects of MDPV include tachycardia, chest pain, hypertension, increased body temperature, diaphoresis, seizures, agitation, paranoia, hallucinations, delusions, aggression, excited delirium, and suicidal thoughts. The psychogenic effects can be prolonged. Symptoms may also progress to rhabdomyolysis and renal or liver failure. Currently MDPV is not found by routine immunoassay toxicology screens.

In April 2011, a 39-year-old white male with a history of depression, back pain, drug, and alcohol abuse was found outside his residence delusional and wandering around in clothing inappropriate for the weather. He was taken to the emergency department (ED) by law enforcement officers under emergency petition for a drug overdose and psychiatric disorder. In the ED, the staff noted whitish powder around his mouth and he admitted he had used "bath salts." He subsequently became agitated, tachycardic and hyperthermic (106.8ºF), and eventually went into asystole. Resuscitation was unsuccessful and he died approximately 12 hours after presenting to the ED. Hospital urine drug screen was positive for benzodiazepines and phencyclidine (PCP). Upon inquiry with the hospital, it was determined that the PCP was most likely a false positive and diazepam and diphenydramine were given at the hospital.

Autopsy was basically unremarkable except for toxicology. Comprehensive alcohol and drug testing were performed in this case. Therapeutic and abused drug testing was performed on the bile. This included: (1) acid/neutral drug screen by gas chromatography(GC)-nitrogen-phosphorous detection (NPD); (2) alkaline drug screen by GC-NPD; (3) acetaminophen and salicylate by color test; and, (4) morphine and benzodiazepines by enzyme-linked immunosorbent assay (ELISA). The salicylate color test was positive and the alkaline drug screen was positive for diphenhydramine, MDPV, promethazine, diazepam, and nordiazepam. Salicylate was confirmed by ELISA. The alkaline extractable drugs were confirmed by full scan electron ionization gas chromatography/mass spectrometry. MDPV was quantitated using the alkaline drug screen routinely employed by this laboratory. The heart blood contained 0.1mg/L diphenhydramine, 0.2mg/L promethazine, 0.1mg/L nordiazepam and 0.7mg/L MDPV and the peripheral blood MDPV concentration was 1.0mg/L. Based on the investigative, autopsy, and toxicology findings in this case, the cause of death was methylenedioxypyrovalerone intoxication and the manner of death was accident.

As of July 2011, it is believed that this is the first reported MDPV related death in the United States. Louisiana and states in the Midwest have reported that almost all of their MDPV deaths are traumatic in nature and not due to the drug alone. MDPV is an emerging drug trend in the United States and medical examiner and coroner's offices need to be aware of the limitations of routine toxicology testing in detecting MDPV. One should consider testing for MDPV in cases with a history of polysubstance abuse with stimulant type and psychogenic symptoms of acute onset and those individuals in a hyperthermic excited delirium type state. Further research on MDPV related deaths is necessary to assist in the determination of emerging drug trends of public health significance.

G20 Retinal Hemorrhages Associated With Non-Abusive Sudden Unexplained Deaths in Infants

Christina J. Tatum, MD, and Patrick E. Lantz, MD, Department of Pathology, Wake Forest University School of Medicine, Medical Center Boulevard, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn how ocular hemorrhages can occur in infants who are found unresponsive and have received cardiopulmonary resuscitation but have no evidence of abuse.

This presentation will impact the forensic science community by increasing the attendees' awareness of non-traumatic retinal hemorrhages in infants and emphasize that retinal hemorrhages can occur after cardiopulmonary resuscitation and are not specific for abusive head trauma.

Retinal hemorrhages (RHs), considered by many physicians as a key finding in abusive head trauma (AHT), have been reported in about 85% of fatal AHT cases. Published reports have stated that the number, location, and distribution of RHs are significant for differentiating RHs observed in AHT as compared to RHs occurring in accidental head injuries or natural disease processes. A number of studies have indicated that bilateral multiple RHs extending to the ora serrata have particular diagnostic specificity for AHT.

Ten cases are presented of sudden, unexplained infant deaths that had RHs following cardiopulmonary resuscitation (CPR) but no evidence of abusive or accidental head trauma. Postmortem monocular indirect ophthalmoscopy (PMIO) detected the RHs in all cases. Only one infant, who had bilateral RHs detected by PMIO, had a documental clinical fundal examination by a non-ophthalmologist 41 hours after CPR had been initiated. Investigative and autopsy findings revealed no natural diseases, craniocerebral trauma, or other injuries that caused or contributed to the deaths. The cause of death was certified as Sudden Infant Death Syndrome or unexplained infant death.

The infant ages ranged from seven weeks to ten months of age, with a median age of 18 weeks and a mean age of 16.7 weeks. Four infants were born premature at 32 to 36 weeks estimated gestational age. All but one infant was found unresponsive after being placed down to sleep; one was taken to the emergency department after a witnessed episode of loss of consciousness. Four infants who were placed to sleep in a bed or crib were found prone. CPR efforts lasted less than 15 minutes to one hour. Four infants experienced return of spontaneous circulation and survived for 6-56 hours after CPR efforts were started. Resuscitation-related rib fractures

occurred in three infants. Ophthalmologic findings ranged from a single superficial retinal hemorrhage in one eye to diffuse retinal hemorrhages with extension to the ora serrata and optic nerve sheath hemorrhage. The four infants with multiple retinal hemorrhages with extension to the ora serrata all had spontaneous return of circulation and survived between 6-56 hours following the initiation of CPR. The infant with the optic nerve sheath hemorrhage had the longest survival time. Diffuse systemic ischemic and reperfusion injuries affecting the kidneys, adrenal glands, liver, myocardium, intestines, lungs and brain were observed in four cases; focal hypoxic-ischemic organ damage was present in three cases. Neuropathological findings included cerebral edema, intra-falcine and intra-dural extravasated blood, and focal subarachnoid hemorrhage.

Infants found unresponsive invariably undergo resuscitative efforts, often for prolonged periods of time. Forensic pathologists must be aware that RHs can be seen in infants who die suddenly and unexpectedly, following cardiopulmonary resuscitation, and are not specific for abusive head trauma. Infants found unresponsive without evidence of head trauma or natural disease processes that have had CPR, especially those with restoration of circulation, can have RHs that may be few in number or numerous with extension to the ora serrata. It is important for forensic pathologists to perform postmortem ocular examinations on all infants dying suddenly and unexpectedly to identify conditions associated with RHs and not equate RHs solely with AHT.

Retinal Hemorrhages, Sudden Unexplained Infant Deaths, Cardiopulmonary Resuscitation

G21 Postmortem Artifactual Perimacular Retinal Fold

Stephen Lenfest, MD, Wake Forest University, Medical Center Boulevard, Winston-Salem, NC 27157; and Patrick E. Lantz, MD, Wake Forest University, Department of Pathology, School of Medicine, Medical Center Boulevard, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn that perimacular retinal folds can develop as a postmortem artifact and should not be viewed as pathognomonic or highly specific for abusive head trauma.

This presentation will impact the forensic science community by emphasizing how ocular abnormalities found at the autopsy must be interpreted with caution and never as an isolated finding without appropriate clinical correlation and thorough death investigation.

The classical triad associated with abusive head trauma (AHT) includes subdural hemorrhage, retinal hemorrhages (RHs), and encephalopathy. Several other ocular findings have been described as virtually pathognomonic or highly specific for AHT. These findings include perimacular retinal folds (PRFs), traumatic retinoschisis, optic nerve sheath hemorrhages, and peripheral RHs abutting the ora serrata. There have been numerous cases reports in the last decade of accidental head injuries that have produced these ocular abnormalities. In particular, perimacular retinal folds and traumatic retinoschisis have been increasingly identified in case reports of accidental head injury. However, these cases are considered by many to be rare outliers and the ocular findings continue to be treated as highly specific for AHT. We present a case of accidental head injury with the development of an artifactual PRF during the postmortem interval that could potentially be interpreted as an antemortem PRF.

Case Description: The decedent was an 11-year-old girl who was crossing the road to get the mail when she was struck by an oncoming automobile. Emergency Medical Services responded, secured an airway, and transported her to the nearest trauma center. Upon arrival in the emergency department the patient's Glasgow Coma Scale was 3 and CT scan showed subdural hemorrhage, intraventricular hemorrhage, and diffuse cerebral edema with herniation. She was ultimately declared brain dead and life support was withdrawn.

At autopsy, multiple blunt force injuries of the head included subscalpular hemorrhage, subdural hemorrhage, subarachnoid hemorrhage, intraventricular hemorrhage, Duret hemorrhages, bilateral multilayered RHs, and bilateral optic nerve sheath hemorrhages. Other injuries included a fracture between C7 and T1, a sternal fracture, a splenic laceration, and multiple scattered abrasions and contusions. The left posterior leg had the greatest concentration of subcutaneous hemorrhage 13-17 inches above the left heel, consistent with a site of impact.

Indirect ophthalmoscopy was initially performed four hours after death. The autopsy was done the next day, at which time indirect ophthalmoscopy was repeated and the globes were removed and placed in 10% neutral buffered formalin. The first exam found numerous bilateral multilayered retinal hemorrhages over the posterior pole in all four quadrants extending to and past the equator but no retinal folds. The second exam 22 hours after death revealed artifactual retinal folds. The right eye had an artifactual perimacular fold extending to the fovea and then continuing temporally from the fovea as a linear papillomacular fold, and the left globe had an artifactual papillomacular fold.

These folds are not Lange folds, which are well-known artifacts of fixation in the eyes of infants and children. Lange's folds are described as an inward fold of the neural retina present at the very periphery of the retina and extending to the ora serrata. The folds in this case were perimacular and papillomacular. The folds in the right eye surround the macula in a circumferential pattern that is not consistent with the description of Lange's folds. The folds in both eyes were located primarily between the optic disc and the fovea and did not extend to the periphery.

If the first retinal exam had not been performed and the perimacular retinal fold was identified following ocular enucleation, it may have been interpreted as sequelae of her head trauma. The more concerning aspect would be if the PRF was identified in an infant or young child, in which case, it might be viewed as highly specific for AHT instead of a postmortem artifact. This case further illustrates that ocular findings identified at autopsy cannot be viewed as pathognomonic or even highly specific of AHT without appropriate clinical correlation, a thorough death investigation, and routine postmortem ocular examinations in all infants and young children.

Forensic Science, Perimacular Retinal Fold, Postmortem Artifact

G22 Sudden Cardiac Death in a Young Male With History of Tako-Tsubo (Stress) Cardiomyopathy: A Case Report

Vadims Poukens, MD, Deparatment of Coroner, Los Angeles County, 1104 North Mission Road, Los Angeles, CA 90033; and Lakshmanan Sathyavagiswaran, MD, Los Angeles County, 1104 North Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will learn of a case showing unusual cardiac cause of sudden death in a young male due to stress cardiomyopathy and its clinicopathologic features.

This presentation will impact the forensic science community by educating the attendees on an uncommon disease entity which is usually associated with postmenopausal females, but can also affect younger males.

This case involved a 20-year-old Black male who had a history of a stab wound of the left chest in May 2010. In the hospital a chest tube yielded 750ml of blood. Chest x-rays and a CT scan showed a stab wound perforating left pectoral muscle with hydro- and hemothorax. There were no injuries to the mediastinum, including the heart, great vessels, trachea, and esophagus. The patient subsequently had chest pain. Cardiac enzymes and EKG showed ST elevation and elevated troponin. A cardiologist made a diagnosis of Tako-Tsubo cardiomyopathy secondary to the stress from his stab wound of the chest. He was discharged six days after the stab wound. Four months later he collapsed at home and was transported to a hospital, where he expired.

The autopsy showed that the decedent was 185cm tall, weighed 77.5kg, and had a linear one-inch scar in the left chest area consistent with the previous stab wound. Mild cardiomegaly (460g) with focal pericardial

adhesions was noted. The heart had extensive apical transmural circumferential left ventricular and septal scarring (8 x 5 cm area) with thinning of the myocardial wall (1.0 – 0.5cm) and attached mural thrombus (5 x 5cm). The scarring far exceeded the territory of any single coronary artery. Dissection of the coronary arteries showed no significant atherosclerosis and no narrowing or stenosis. Toxicology analysis revealed the presence of carboxy-tetrahydrocannabinol in the blood. A cardiac pathologist was consulted. He reviewed autopsy findings, previous medical records, and microscopic slides, and he concurred with the diagnosis of Tako-Tsubo cardiomyopathy as a cause of death.

Tako-Tsubo (stress) cardiomyopathy is a non-ischemic cardiomyopathy in which there is a sudden temporary weakening of the heart muscle. Tako-Tsubo cardiomyopathy is a well-recognized cause of acute heart failure, lethal ventricular arrhythmias, and ventricular rupture. It most commonly occurs in postmenopausal women and is frequently precipitated by an emotionally mediated or physically triggered stressful event. Chest pain and dyspnea are typical presenting symptoms. Transient ST-segment elevation on ECG and a rise in cardiac biomarkers are common. Systolic dysfunction with marked left ventricle contraction abnormality, extending beyond the geographic territory of a single coronary artery, and absence of obstructive coronary artery stenosis are characteristic. The hallmark of this disorder is bulging of the apex of the heart with preserved function of the base. The echocardiographic appearance of this syndrome earned the name "tako tsubo," or octopus trap, in Japan, where it was first described.

In conclusion, this case brings to light an unusual cause of sudden cardiac death in a young male. After literature review it is reported the youngest male (20-years-old) who was diagnosed with and died due to Tako-Tsubo cardiomyopathy.

Sudden Death, Takotsubo Cardiomyopathy, Stress Cardiomyopathy

G23 Sudden Cardiac Deaths Related to Ischemic Heart Disease in Postmortem MDCT and MDCT-Angiography

Katarzyna Michaud, MD, Centre Universitaire Romand de, Medecine Legale, Rue du Bugnon 21, Lausanne, 1005, SWITZERLAND; Silke Grabherr, MD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND; Francesco Doenz, MD, 2Department of Diagnostic and Interventional Radiology, CHUV, Rue du Bugnon 46, University of Lausanne,Switzerla, Lausanne, SWITZERLAND; and Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND*

After attending this presentation, attendees will learn about the utility of postmortem radiological imaging of coronary arteries in cases of ischemic heart disease, along with their possibilities and limitations.

This presentation will impact the forensic science community by showing that the interpretation of postmortem radiology, especially in the cardiovascular field, is a new field for both forensic pathologists and radiologists. Information obtained from both parties can help to further the understanding of CT and CT-angiography in postmortem examinations and enable its integration into the classical autopsy protocol.

Although postmortem radiology is very useful in demonstrating traumatic lesions, its application is still limited for deaths resulting from cardiovascular pathologies. The goal of this study was to evaluate the diagnostic potential of postmortem angiography for deaths related to ischemic heart disease by comparing findings of native postmortem cardiac multi-detector computed tomography (MDCT), multiphase postmortem CT-angiography (MPMCTA), and conventional autopsy.

Twenty three cases were selected based on clinical history, including 21 men and two women. The age of the victims ranged from 35 to 89 years (mean age 52.3 +/-12.2). All cases underwent a postmortem MDCT, MPMCTA, and complete autopsy which included histological examination of the coronary arteries and myocardium.

MDCT-angiography was carried out using the standardized protocol of MPMCTA, in which a native CT-scan was performed prior to any manipulation of the corps. Liquid samples for toxicological and biochemical analyses were collected under CT-guidance before cannulation of the femoral vessels. Radiological interpretation of all images was performed by both a board certified radiologist specialized in vascular radiology and a board certified forensic pathologist trained in forensic radiology.

Postmortem MDCT and MDCT-angiography showed calcifications of coronary arteries in 18 cases (78%). The findings could be more easily detected and documented with postmortem MDCT or MPMCTA than with classical autopsy, where the calcifications were not systematically described by the pathologist. MPMCTA allowed much better visualization of coronary arteries than MDCT and permitted the evaluation of stenoses and occlusions. In 13 cases, MDCT-angiography revealed at least one coronary artery that was not perfused or had a stenosis greater than 75%. Conventional autopsy of 11 of those 13 cases detected an acute or subacute coronary thrombosis, in one case, a postmortem clot led to a perfusion stop. From 14 cases of coronary thrombosis detected at autopsy, 11 were identified as stop of perfusion during CT-angiography, two acute thromboses related to eroded plaques and an old recannalised thrombus were visualized as partial occlusions. Some artefacts were identified using multiphase postmortem MDCT-angiography: in one case a postmortem clot was suspected in a non-perfused coronary artery and in three other cases a postmortem clot imitated pulmonary embolism. These artifacts were confirmed upon autopsy. A hemopericardium was easily identified by all techniques in one case, but the exact localization of the rupture was better visualized in MPMCTA than in MDCT.

This study shows that native postmortem MDCT has limited value for the diagnosis of ischemic heart disease as only calcifications of coronary arteries or evident cardiac pathological findings, such as cardiac tamponade, can be identified. This technique can not estimate the degree of stenosis or occlusion. Postmortem angiography enables identification of coronary occlusion and significant stenosis, and seems also to be promising to detect signs of myocardial ischemia by evaluation of myocardial enhancement.

This study finds that, coronary postmortem MDCT-angiography, if correctly interpreted, is a useful tool to view the morphology of coronary arteries, rule out coronary artery stenoses and to indicate vascular occlusions suspicious of thrombosis, thereby directing the sampling for histological examination. It is, however, too early to postulate if this technique can provide sufficient evidence to determine if the cause of death was related to an acute or chronic ischemic event.

The goal of this presentation is to present the diagnostic potential of postmortem multi-detector computed tomography and multiphase postmortem CT-angiography in cases of sudden cardiac deaths related to atherosclerotic coronary artery disease.

Sudden Cardiac Death, Ischemic Heart Disease, Postmortem Imaging

G24 Sudden Cardiac Testosterone-Related Death in a Young Bodybuilder

Stefania C. Bello, MD, Carmela Fiore, MD, University of Foggia, Department of Forensic Pathology, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia, 71100, ITALY; Alessandro Bonsignore, MD, Via de Toni 12, Department of Legal & Forensic Medicine, University of Genova, Genova, 16132, ITALY; and Francesco Ventura, MD, PhD, Department of Forensic Pathology, University of Genova, Via de' Toni, 12, Genova, 16132, ITALY*

The goal of this presentation is to examine the cardiovascular effects of AAS chronic abuse. In all cases of sudden death in apparently healthy bodybuilder an accurate circumstantial investigation in necessary to confirm the AAS abuse and then the autoptic, histological, and toxicological investigation can ascertain the cardiac pathological features correlated to the abuse of these various substances.

This presentation will impact the forensic science community by communicating the pathological relationship between androgenic-anabolic steroids and sudden cardiac death, underlying the necessity of an accurate anamnestic, circumstantial, histological, and toxicological investigation in cases of unjustified death involving apparently healthy young man to ascertain AAS abuse.

Androgenic anabolic steroids (AAS) are synthetic derivatives of testosterone used in therapeutic dosages in medical practice. In addition, AAS are used worldwide to help athletes gain muscle mass and strength, although the prohormones of testosterone and nandrolone are on the list of forbidden substances of the International Olympic Committee (IOC). To minimize the risk of developing tolerance to any particular agent, AAS are taken as a cocktail of different agents taken at one time. There are several reports in the literature regarding the adverse effects of AAS on various organ systems including endocrine, cardiovascular, and hepatic pathologies. The heart is one of the most frequently affected organs by the chronic and acute administration of AAS. Although the topic is still being debated, and most of the evidence is anecdotal, a consensus is beginning to emerge that chronic AAS abuse may be associated with an increased risk of sudden cardiac death (SCD), myocardial infarction, altered serum lipoproteins, and cardiac hypertrophy.

A case of sudden cardiac death is reported in an apparently healthy bodybuilder who was chronic androgenic-anabolic steroids abuser.

A 28-year-old male was found collapsed in his bedroom early in the morning and he was pronounced dead by an emergency physician called by his father few minutes later. He was an amateur but he had weight lifting workouts at the gymnasium for few hours each day. According to father of the deceased he had been taking anabolic steroids parenterally for several years mainly in an effort to improve his appearance. His room contained a veritable arsenal of drugs, in particular several glass vials, most of which fell into the AAS category, and seven used 2.5-ml syringes.

The body was that of a well-built man (weight 87kg, length 176cm). External examination revealed needle marks on the upper external part of the right buttock and on the anterior part of the left forearm. The autopsy revealed abnormal muscle development and hepatomegaly. The heart had a normal shape and was normal in size (13cm x 11.5cm x 3.5cm) but it weighed 470g. The left and right coronaries showed 75-80% lumen reduction. At the section the left ventricular wall was moderately increased.

Histologically, the myocardial samples showed wide fields of myocardial necrosis characterized by hypercontraction of the myocell with a breakdown of the whole contractile apparatus with markedly thickened Z-lines and extremely short sarcomeres. Foci of disarray with star-like disposition of adjacent myocytes, aligned obliquely or perpendicular to one another, and joined together by short, generally hypertrophic myobridges, with interconnecting myofibrils were observed. Small groups of disappearance of myofibrils with intramyocardial oedema resulting in empty sarcolemmal tube and with any type of reaction (colliquative myocytolisis grade 1) were also observed.

Histological examination of coronary arteries confirmed 80% lumen reduction in anterior discending branch, left circumflex, and right coronary artery sections, characterized by nodular hyperplasia of smooth muscle cells and elastic tissue with progressive fibrous replacement, associated with calcium salts accumulation. Both gross and histological examinations of other organs did not reveal any pathology, except for pulmonary oedema and polyvisceral stasis.

Complete toxicological examination was negative for drugs of abuse, including ethanol, but positive results for testosterone and metabolites in blood, liver, and kidney were confirmed. The examination of content in six syringes confirmed the presence of testosterone.

In conclusion, in this case the combined effects of vigorous training and the i.m. administration of testosterone led to a stimulation of the sympathetic nervous system and predisposed the young man to myocardial injury and subsequent sudden cardiac death.

Anabolic Steroids, Sudden Death, Toxicological Findings

G25 Traumatic Pericardial Rupture

Sara H. Zydowicz, DO, and Vernard I. Adams, MD, Hillsborough County Medical Examiner's Office, 11025 North 46th Street, Tampa, FL 33617*

After attending this presentation, attendees will understand the frequency, spectrum, and associated injuries occurring with traumatic rupture of the pericardial sac caused by blunt impact.

This presentation will impact the forensic science community by expanding knowledge base of blunt impact thoracic injuries and help autopsy pathologists recognize traumatic rupture of the pericardial sac as a marker for energy loading of the heart by presenting data from a series of autopsies in which pericardial laceration was associated with high velocity impact trauma.

A retrospective review was conducted of 145 consecutive blunt injury autopsies performed by one pathologist from 2007 through the first quarter of 2011, comprising all traffic fatalities and suicides who leaped from high structures. One-hundred-fourty were traffic accidents and five were suicides by leaping from a height. The age range of the study cases was 17-80 years with a median age of 29 years and a mean of 37.4 years. Thirty-eight cases were selected for review because they had lacerations or contusion of the heart or laceration of the pericardial sac; 17 were motor vehicle operators, six were motor vehicle passengers, six were pedestrians, five were motorcycle operators, and four were suicides who leaped from a height. Of the 38 study cases, 28 had laceration of the pericardial sac, of which 24 had associated cardiac contusion or laceration. A single pericardial laceration was present in 22 of the cases. In five of 13 pericardial lacerations involving the left side of the sac, the heart was statically herniated through the defect. In three of eight pericardial lacerations on the right side of the sac, the heart was statically herniated through the defect. One case has a single pericardial laceration on the anterior sac without herniation. Multiple pericardial lacerations were present in six cases, one with static herniation of the heart. Fractures of the ribs, sternum or ribs and sternum were associated with pericardial laceration in six cases.

The most likely mechanism causing lacerations of the pericardial sac involves the heart being forced through the sac when the space between the sternum and the vertebral column is reduced by impact. Pericardial lacerations are frequently associated with wounds of the heart, great vessels, lungs and skeletal structures; lacerations of the pericardium infrequently occur in isolation and most subjects with pericardial lacerations died rapidly; only five of the 22 cases with pericardial lacerations were transported to the hospital. Isolated surgical case reports have described this type of injury; however, no case series were found in a search of the relevant literature.

Pericardial Sac, Traumatic Herniation, Laceration

G26 Histologic Variation in Cardiac Rupture Complicating Myocardial Infarction: A Forensic Experience

Brandy Shattuck, MD, Mary L. Anzalone, MD, Merrill O. Hines, MD, and Dwayne A. Wolf, MD, PhD, Harris County Medical Examiner, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the spectrum of histologic changes associated with cardiac rupture, particularly in those who do not have preceding medical intervention.

This presentation will impact the forensic science community by providing a range of histologic findings associated with cardiac rupture that presents as sudden and/or unexpected death.

Cardiac rupture as a complication of myocardial infarction is a rare but well known cause of mortality. Traditional thought has placed the danger period of this complication at five to seven days post infarct with up to 25 percent of the events occurring in the first 24 hours. The accompanying histologic findings of granulation tissue that one would expect at five to seven days after the initial event have been used to describe the most common

background of rupture. This natural time course; however, has changed as medical intervention has altered the timing of rupture and did not fully describe the 25 percent who ruptured in the first day after infract.

Along with improved cardiac survival, there has been a revision of infarct complications due to medical intervention. Research has shown that thrombolytic therapy decreases the overall rate of rupture from four percent to less than one percent; however, it causes many of those who do experience a rupture to do so within the first 24 hours after the initial infarct. Similar research on direct percutaneous coronary intervention placed the danger period for rupture in the first two days. This research, while clarifying the clinical course of the treated infarct and incidence of associated complications, still does not address the spectrum of histologic findings associated with survival less than five days.

The acceleration of the natural time line will change the cellular milieu that can be seen upon histologic examination, making it similar to those patients who do not have medical intervention. Those patients who present with death due to cardiac rupture without intervening medical intervention are most frequently seen in the forensic pathology setting. An examination of the histology seen in this setting can help explain the lack of the classical presentation of fibroblasts, blood vessels, lymphocytes, and macrophages that histology teaching has classically associated with ruptures.

A review of all forensic autopsies performed in Harris County, Texas from January 2006 to July 2011 revealed 37 patients who were found to have cardiac rupture as a complication of myocardial infarction listed as cause of death. Of these 37 patients, nine had evidence of classical histology, i.e., granulation tissue with fibroblasts, macrophages, and blood vessel formation. The remainder did not have the same infiltration of fibroblasts and early blood vessel formation in the area of myocyte death. Signs of early myocyte death, including minimal to extensive neutrophilic infiltrate, dissecting hemorrhage, and varying amounts of lymphocytes and macrophages were present in those who had witnessed collapse, were found unresponsive, or had complaints of chest pain less than 48 hours before death. None of these patients had active medical intervention such as thrombolytic therapy or percutaneous intervention according to available medical records. Many patients, both with and without classic histology, did not have a reported history of chest pain.

These findings provide a histologic correlate to both the originally described 25 percent of patients who present with cardiac rupture in the first 24 hours after infract and to those who may have an accelerated time to rupture due to medical intervention. These results, even with a small sample size, can provide an explanation for the spectrum of histologic findings associated with cardiac rupture in patients who have no medical intervention and those who have an accelerated time course due to therapy.

Histology, Cardiac Rupture, Myocardial Infarct

G27 A Comprehensive and Systematic Evaluation of Sudden Cardiac Death in a Diverse Urban Population

Ellen Moffatt, MD, City & County of San Francisco, Office of the Medical Examiner, 850 Bryant Street, San Francisco, CA 94103; Dan Steinhaus, MD, Massachusetts General Hospital, Department of Medicine, 55 Fruit Street #410, Boston, MA 02114; Philip Ursell, MD, University of California, San Francisco, 513 Parnassus Ave, Medical Sciences, Box 0102, Room 546C, San Francisco, CA 94143; Eric Vittinghoff, PhD, University of California, San Francisco, Box 0560, 185 Berry Street, Room 5700, San Francisco, CA 94143; My Linh Van, MS, University of California, San Francisco, 500 Parnassus Avenue Millberry Union, Box 1354, Room E434, San Francisco, CA 94143; Felipe Fernandez, BS, and Amy P. Hart, MD, San Francisco Office of the Chief Medical Examiner, 850 Bryant Street, North Terrace, San Francisco, CA 94103; Jeffrey Olgin, MD, University of California, San Francisco, 505 Parnassus Avenue, Moffitt Hospital, Box 0124, Room 1182, San Francisco, CA 94143; and Zian Tseng, MD*, University of California, San Francisco, Electrophysiology and Arrhythmia Service, 400 Parnassus Avenue Floor B1, Room 094, San Francisco, CA 94143*

After attending this presentation, attendees will understand the definition of sudden death and its relationship to atherosclerotic coronary artery disease. Atteedees will also gain new insight into sudden death and its causes.

This presentation will impact the forensic science community by showing how the background incidence of sudden death due to coronary artery disease is decreasing and is lower than had been reported in the literature previously.

Despite decreases in overall mortality of death from cardiac causes due to better treatment and interventions over the past decade, sudden cardiac death (SCD) remains a significant public health problem in the United States. The true burden of SCD; however, remains unknown; variable definitions and inconsistent ascertainment methods in previous studies have resulted in widely divergent estimates of its incidence. The common paradigm is that sudden death is most likely cardiac (particularly due to coronary artery disease) in origin. However, commonly cited epidemiologic data on SCD are now a generation old, predate modern advancements in cardiac care, and were drawn from homogenous populations. Many relied on retrospective records review and/or death certificate review, which did not require autopsy-proven heart disease in the vast majority of cases, and may overestimate the prevalence of coronary artery disease in the community. Prior gold standard autopsy studies defining the underlying causes of SCD indicated that coronary artery disease (CAD) is the underlying cause of death in 80% of cases; however, these data are similarly outdated and hindered by referral bias of only a small subset of SCD cases. The contemporary epidemiology and pathology underlying SCD in the rapidly diversifying U.S. population is therefore unknown.

In a unique collaboration, the Cardiac Electrophysiology Section at the University of California at San Francisco and the San Francisco Office of the Chief Medical Examiner have worked to establish a robust surveillance method and comprehensive evaluation of all consecutive incident SCDs in San Francisco, a prototypic diverse U.S. community that presages near-term national demographic shifts. The population of San Francisco numbers 700,000 residents and increases to 1.5 million persons during working hours. The annual mortality rate in San Francisco is approximately 6,000 with half of these reported to the Office of the Chief Medical Examiner. Of these cases, approximately 1,400 decedents come under the jurisdiction of the Medical Examiner, including the vast majority of sudden deaths which include those dying outside of a physician's recent (within three weeks) care. The cases accepted by the office are completely investigated with review medical records, statements from witnesses, and evaluation by a American Board of Pathology certified forensic pathologist.

In this study funded by the National Institutes of Health for five years, which officially began in February 2011, all deaths reported to the office are

screened by two physicians (a forensic pathologist and a cardiac electrophysiologist) for circumstances fitting World Health Organization (WHO) sudden death criteria (witnessed death within one hour or unwitnessed without symptoms 24 hours before). These cases then undergo complete investigation, including comprehensive autopsy incorporating a specially designed cardiac protocol, toxicology, and histology. The cardiac protocol includes measurements of the left ventricular compact and full thickness myocardium, and the short axis of the left ventricle at the level of the origin of the papillary muscles. Coronary artery stenoses are assessed systematically at 5mm sections, and microscopically if evidence of plaque rupture is seen. Histology is reviewed by two pathologists and assessed for degree and nature of cardiac fibrosis, as well as other pathology (i.e. myocarditis, cardiomyocyte disarray, etc.). Frozen tissue (heart, blood in EDTA tubes, and skin) is obtained and with next of kin consent, will form a genetic and molecular tissue bank for future study.

To estimate the prevalence of cardiac pathology in the general population, comprehensive autopsy evaluation of a frequency-matched sample of geographically and demographically similar accidental trauma death controls are also performed over the same period. Accidental trauma deaths are those who die with an accidental manner of death (such as falls or motor vehicle collisions) who die at the scene or shortly after transportation to the hospital. Findings from autopsy of these trauma death controls will be compared to SCDs to allow for the evaluation of CAD, other pathology, and cardiac indices (all thickness, mass) as risk factors for SCD.

As of July 2011, approximately 110 SCDs and 14 trauma controls have been evaluated in the study, representing over 85% of all SCDs occurring in San Francisco over the six months since study inception. Of these cases, approximately 40 cases have been reviewed by two pathologists and two cardiac electrophysiologists. Approximately 40 percent of the reviewed "SCDs" so far have had non-cardiac causes of death. At the time of presentation, the study will have been performed for one year (out of a total of three years of autopsy study) and many more cases will have been reviewed with resultant information.

This novel study fulfills a critical need for the precise characterization of the contemporary epidemiology and underlying causes of sudden cardiac death in population subgroups heretofore underrepresented. These data may allow for the elucidation of new independent risk factors for sudden cardiac death and direct new insights into the clinical therapy of this lethal disease.

Sudden Death, Coronary Artery Disease, Public Health

G28 Osseous DNA Sampling Procedures and Success Rates at the Pima County Office of the Medical Examiner

Angela Soler, MA, Michigan State University, Department of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Angela L. Williamson, PhD*, Bode Technology, 10430 Furnace Road, Suite 107, Lorton, VA 22079; Bruce E. Anderson, PhD, Forensic Science Center, Office of the Medical Examiner, 2825 East District Street, Tucson, AZ 85714; and Lindsay H. Trammell, MA, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996-0720*

After attending this presentation, attendees will learn the results of a study examining the success rates of an osseous DNA sampling procedure.

This presentation will impact the forensic science community by providing procedural guidelines for a successful, scientifically rigorous, and economical sampling procedure for obtaining DNA profiles from osseous elements recovered from an arid desert environment. Furthermore, it presents the results of a study on the success of these sampling procedures in providing DNA profiles from skeletal elements in varying stages of decomposition.

Over the years, DNA analysis has become elemental in the positive identification of individuals in mass fatality situations and for decedents without appropriate antemortem records for comparison. Increasingly, forensic anthropologists are responsible for obtaining osseous tissue samples from decomposed, burned, mummified, and skeletonized remains. There are over one hundred cases each year of unidentified decedents without sufficient antemortem records. Due to the extreme climate and desert environment, many of these individuals are in varying stages of decomposition and require an osseous sample for DNA testing. With the large number of cases and the high cost of sampling and testing samples, efforts have been made to apply a procedure that is scientifically rigorous, while simultaneously prompt and economical.

The first step in laboratory preparation at PCOME is the adornment of basic personal protective equipment, such as gloves and a mask. All osseous DNA samples are taken at the analytical table using a non-disposable Stryker saw blade that has been soaked in bleach and cleaned with a brush. Osseous elements with the thickest portion of cortical area are typically selected for sampling, such as the posterior femur, anterior tibia, and parietal. When these are unavailable, samples are taken from other osseous elements, including the humerus, occipital, and mandible. Some skeletal elements may have been processed in simmering water with Alconox and Sodium Carbonate prior to sampling; however research demonstrates that this technique has no affect on DNA extraction rates (Rennick *et al.* 2005; Lee *et al.* 2010). A rectangle of bone weighing approximately 15-25 grams is resected, wrapped in filter paper, placed into a manila envelope, and sealed into a plastic heat-and-seal bag. All samples are then cooled for varying periods of time to await shipment in chilled transport containers. After shipment to Bode, the osseous samples are decontaminated by using a dremel tool to sand the top layers and then put through bleach and ethanol washes. The osseous samples are then re-sampled and powdered using a blender cup or by drilling a hole, depending on the size and quality of the bone. The bone powder (input amount ranging from 0.2g - 2.0g) then undergoes a decalcification step prior to DNA being extracted using a proprietary extraction method, which has been optimized and validated for use on skeletal samples.

For this study data was collected on osseous samples submitted from the past several years (n = 420). Information regarding the estimated postmortem interval (PMI), freshness of the bone sample, quality of the cortical surface of the bone, and skeletal element sampled was collected for analysis. These variables were then compared with the number of STR loci reported and the mtDNA region developed for each sample.

Results demonstrate a high success rate for both STR and mtDNA extraction. In total, 73.5% of all samples developed at least 8 STR loci, the minimum necessary for entry into the Missing Person's DNA Database, and 58.3% of the total sample developed a full STR profile. Of those tested for mtDNA, 93.7% developed an adequate profile. Predictably, there is a statistical relationship between the success rates for developing a full STR profile and the freshness of the bone, the estimated postmortem interval, and the quality of cortical surface of the osseous sample. Regardless, 59% of skeletal remains with a PMI estimate of one to two years, and 37% of remains with a PMI estimate of more than two years developed an STR profile of at least 8 loci. Furthermore, 41% of the samples with sunbleached and weathered cortical surfaces developed at least 8 STR loci indicating the success in obtaining STR profiles from even highly degraded osseous samples.

Forensic Anthropology, Osseous Sampling, DNA

G29 What Can a Cartridge Case Tell us When There is no Gun? Interpreting Extractor and Ejector Marks on Ammunition That has Been Inserted in a Gun but not Fired

Francesco Vinci, MD, and Maricla Marrone, MD, University of Bari, Section of Legal Medicine, Piazza Giulio Cesare n.11, Bari, 70124, ITALY; Felice F. Carabellese, MD, University of Bari, Section of Forensic Psychiatry, Policlinico Univ, p.za G. Cesare, 11, Bari, 70124, ITALY; and Chiara Candelli, MD, PhD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will understand that comparing spent cartridges with unfired cartridges found at the crime scene in cases of suspected murder is a nightmare even for an expert firearms consultant. To obtain a good, positive match in such cases, it is important not to confine the identification to a simple comparison but extending the analysis to other parts of the bullet.

This presentation will impact the forensic science community by showing that in many cases after shooting, a criminal may throw away or destroy the gun but often forgets unfired bullets at home that have at one time been inserted in the gun but not fired perhaps, on a whim or to check the correct function of mechanical devices, especially the loading and ejection mechanisms. This generally leaves marks on the cartridge (often very evident) caused by the extractor and ejector, but not by the firing pin, of course, that at most may leave slight signs that are useless in such a comparison.

This case reports a 34-year-old man involved with the "camorra" (a variety of mafia), was killed in a narrow but very crowded street in Naples. Several shots were fired by different guns. None of the people present were willing to testify but the presence of a well known "boss" at the crime scene at the time of the murder was confirmed. No gun was found at this criminal's home but 23 unfired cartridges were found in a drawer, of the same caliber and brand as the spent cartridges found at the crime scene.

The man was convicted, and for this study, by surveying the evidence, obtained surprising results that demonstrated that the cartridges found at the suspect's home were undoubtedly inserted in the weapon, never recovered, that had been used for the mafia killing two months before.

Beginning by examining the characteristics of the class of spent cartridges found near the victim; this examination was done with a comparison microscope. Even at first sight, the marks of the extractor appeared very distinct, and to vary very little from one cartridge case to another, whereas the ejector marks seemed less useful for comparison. Naturally, firing pin marks were not useful. The class and individual characteristics of all the cartridges, spent or not, were perfectly superimposable, as were the breech marks.

The results of this analysis are illustrated and discussed, specifying the potential and limitations of this type of investigation that has never previously been described in literature. It is believed this case may shed light on new possibilities in forensic investigations, which should be kept in mind as further elements to be used by trained experts, especially in cases with a shortage of evidence that otherwise often remain unsolved. In particular, strategies are proposed for resolving disagreements between experts and thus avoiding contention during the trial that may lead to an unsatisfactory conclusion. It should be kept in mind that considerable experience is required to recognize the true concordance of marks on spent and unfired cartridges, and differentiate them from accidental and not individual marks visible on extraneous cartridges.

Firearms Investigation, Unfired Cartridges, Mafia

G30 Foreign Emboli to Multiple Organs Following Catheter Ablation

Lori A. Proe, DO, New Mexico Office of the Medical Investigator, MSC07 4040, 1101 Camino de Salud NE, Albuquerque, NM 87102; Michelle B. Aurelius, MD, Office of the Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131; and Katherine Lindstrom, MD, 720 Albany Street, Boston, MA 02118*

After this presentation, attendees will be aware of an unusual complication to the common procedure of cardiac ablation involving trans-atrial catheterization. Attendees will understand the possible clinical presentation and the likely histopathologic findings seen in patients whose intravascular procedures are complicated by embolization of foreign material from the devices used in these procedures. Attendees will also understand how to investigate and report a possible medical device safety problem.

This presentation will impact the forensic science community by alerting the autopsy pathologist to the possibility that an intravascular procedure may directly contribute to death. This presentation will inform the pathologist as to the likely gross and microscopic findings in cases of foreign material emboli from catheter devices. Finally, this presentation will highlight the role of the forensic pathologist in product safety surveillance.

Catheter ablation is indicated as therapy for patients with symptomatic supraventricular tachycardia, symptomatic ventricular tachycardia, and atrial fibrillation. In patients with atrial fibrillation, catheter ablation is indicated for those who do not tolerate anti-arrhythmic drugs, in whom pharmacologic therapy is ineffective or who have lifestyle-impairing atrial fibrillation. The simplest ablation therapy for atrial fibrillation is radiofrequency ablation of the atrioventricular nodal junction only. However, it is common to ablate more extensive areas of cardiac tissue, including the muscular connections between the pulmonary veins and the left atrium. These procedures may employ a technique in which the cardiac catheter crosses the atrial septum. Embolization of foreign material as a result of catheterization procedures is an uncommon complication.

This case study is a 63-year-old male who developed Streptococcus anginosus sepsis and suffered a progressive frontoparietal stroke complicated by extensive pneumocephalus within three months of his catheter ablation procedure for atrial fibrillation. Clinically, he was suspected to have septic emboli from heart valve vegetations. However, at autopsy, his heart valves appeared normal. His brain had bilateral infarctions with subfalcine herniation. On microscopic examination, there were foreign material emboli in his lungs, kidneys, heart, liver, brain, and esophagus. The foreign material was basophilic, non-polarizable, PAS positive, trichrome negative, and had no defined shape. The foreign material in his cerebral vasculature was associated with areas of infarction as well as foreign body giant cells with a granulomatous reaction. In other organs, the foreign material was associated with chronic inflammation and foreign body giant cells, but not necrosis. The histologic appearance of this foreign material is similar to that described in other literature reports of foreign material emboli from intravascular procedures. This case appears to be unique among reported cases of foreign material emboli from intravascular procedures in that this previously healthy patient had a single intravascular procedure that produced foreign material emboli to every organ examined at autopsy and contributed directly to his demise.

The autopsy findings and their implications were discussed with the cardiologist who performed the procedure and with the manufacturer of the device. The cardiologist was unaware of this complication in other cases. The manufacturer of the catheter used in this patient's procedure was unaware of reports of similar complications from this device. This case was also reported to the Food and Drug Administration as a medical device problem.

This case report details an unusual complication of intravascular procedures and highlights the importance of the forensic pathologist in surveillance of potential product danger to the community.

Foreign Material Emboli, Catheter Ablation, Cardiac

G31 Extrapulmonary Tuberculosis — Rare Autopsy Findings

Urmila Khadilkar, MD, Department of Pathology, Kasturba Medical College, Mangalore, 575001, INDIA*

The goal of this presentation is to show how the involvement of heart and pancreas although rare, can be seen at autopsy in multi-organ tuberculosis in developing countries. Tubercular myocarditis can remain clinically asymptomatic, or can present with sudden death, ventricular arrhythmia, heart block, or congestive heart failure. Tubercular necrotizing pancreatitis is an atypical form of the disease, and can result in shock.

This presentation will impact the forensic science community by showing how cardiac and pancreatic tuberculosis is associated with increased fatality rate in systemic tuberculosis affecting both immunocompromised and immunocompetent individuals.

Autopsy study of the heart and pancreas is important in suspected cases of multiorgan tuberculosis although the disease is generally believed to spare these organs as well as skeletal muscle and thyroid. Many times, diagnosis of tuberculosis is made only at autopsy, especially in developing countries. Multi-organ tuberculosis, historically a disease of infants and young children, currently predominates among the elderly and immunocompromised individuals especially those infected with both HIV and Mycobacterium tuberculosis. The involvement of myocardium and pancreas could be considered as potentially lethal especially in multiorgan tuberculosis.

Tuberculous pericarditis with tamponade, myocarditis, and necrotizing tuberculous pancreatitis can be fatal. Systemic tuberculosis with multi-organ failure should be considered as a possible cause of septic shock especially in patients with typical high risk factors such as advanced age, diabetes, alcoholism, and immunosuppression. Extrapulmonary tuberculosis was seen in three males who were not hospitalized and aged twenty to fifty years in the present study.

Cardiac tuberculosis most commonly affects the pericardium, while endocardial, myocardial, valvular, or coronary artery involvement is exceedingly rare. It is estimated that 1% of all cases of tuberculosis have cardiac involvement. Before the introduction of chemotherapy, the overall incidence of cardiac tuberculosis, as detected by autopsy was less than 3%. Tuberculous caseating myocarditis usually results from direct hematogenous seeding from pericardium or mediastinal lymph nodes via lymphatics. The three distinct forms of myocardial tuberculosis are nodular tuberculomas, miliary tubercles, and an uncommon diffuse infiltrative type. In the present study, multifocal areas of caseous myocardial necrosis were seen in three cases. The pericardium showed tuberculoid granulomas in all the three cases.

Pancreatic tuberculosis was seen in 4.7 to 14% of deaths from miliary tuberculosis. Higher incidence of this entity is related to increased frequency of abdominal tuberculosis in immunocompromised patients. Pancreas is biologically protected from infection by Mycobacterium tuberculosis because of the presence of pancreatic enzymes. Hematogenous dissemination from the pulmonary focus or direct spread from adjacent peri-pancreatic lymph nodes causes tuberculous pancreatic abscess, though large lesions are not so common. In the present study, tuberculous pancreatic abscess with necrosis of the large vessels was seen in one case. In all the three cases, there was concurrent infection in the lungs, kidneys, liver, and spleen, with the presence of caseating granulomas. Ziehl Neelsen stain showed tubercle bacilli in these organs.

Mortality from systemic tuberculosis is high and death due to multi-organ failure and septic shock has been reported in both immunocompetent as well as immunocompromised individuals. In conclusion, although myocardial and pancreatic involvement by tuberculosis is rare, it should be suspected as a cause of congestive heart failure and shock, respectively.

Tuberculosis, Heart, Pancreas

G32 Patterns of Injury in Fatal Coyote Attack: A Case Study From Nova Scotia, Canada

Marnie J. Wood, MD, 5670 Spring Garden Road, Halifax, B3J 1H8, CANADA; Tanya R. Peckmann, PhD, Saint Mary's University, Department of Anthropology, McNally South 208, 923 Robie Street, Halifax, NS B3H 3C3, CANADA; and Ashleigh M. Pringle, BSc, Saint Mary's University, 923 Robie Street, Halifax, NS B3H 3C3, CANADA*

After attending this presentation, attendees will: (1) gain an understanding of the rarity of lethal coyote attacks on human populations; (2) gain an understanding of patterns of injury in coyote attacks; and, (3) be educated about distinguishing animal attacks from postmortem predation and inflicted injuries.

This presentation will impact the forensic science community by presenting a unique and very rare case report on coyote attack fatalities. There have only been two recorded fatalities in North America from Coyote attacks. The presentation will also provide a unique examination of coyote attack patterns during autopsy.

The typical activity pattern of coyotes in the absence of human harassment seems to be largely crepuscular and diurnal, but when predator control activities are under-taken, coyotes shift their activity mainly to nighttime to avoid humans. Conversely, a lack of human harassment coupled with a resource-rich environment that encourages coyotes to associate food with humans can result in coyotes losing their "normal" wariness of humans.

Several factors may have led to the recent increases in predator attacks on humans in North America. Among them are human population growth, suburban sprawl, and protection of predator species that were once harassed. Male coyotes in the wild generally have home ranges from 8.1 to 16.1 square miles (21 to 41.6km^2) and females 3.1 to 3.9 square miles (8 to 10km^2).

The motive for attacks by coyotes is not always hunger or protection of dens. Movement, particularly escape behavior, is a key stimulus for eliciting orientation and attack; children's play and running behavior, particularly when running away from a coyote may provide a strong stimulus for attack.

There are only two recorded fatalities in North America from coyote attacks: in 1981, a female toddler in Glendale, California, and, in 2009, an adult female in Cape Breton, Nova Scotia, Canada. This is the case of an adult female who was attacked by at least three coyotes while hiking in the Cape Breton Highlands National Park in Nova Scotia, Canada.

The offending animals included a 32-pound female, 34-pound male (likely a brother of the female), and one 50-pound male (genetically unrelated to the other two animals). During the attack, a group of four hikers scared away the coyotes and called "911."

When emergency crews arrived, she was transported to a regional tertiary care center where she died overnight. An autopsy was performed by the Nova Scotia Medical Examiner Service.

The offending coyotes were captured, euthanized, and necropsied by a wildlife pathologist at the Atlantic Veterinary College, University of Prince Edward Island. All animals were healthy, free of apparent disease and infection, and well fed on postmortem examination. The female coyote contained human remains in her stomach.

This case report will describe the patterns of injury seen at autopsy and consider them in the context of usual coyote attack behavior. It will include considerations of distinguishing animal attacks from postmortem predation and inflicted injuries.

Coyote Attack, Injury Patterns, Forensic Pathology

G33 Takotsubo Cardiomyopathy Following Jeweler's Hold Up: Forensic Considerations

Frederic Savall, MS, Service de Médecine Légale, Hopital de Rangueil, 1 avenue Professeur Jean Poulhès, Toulouse Cedex 9, 31059, FRANCE; Fabrice Dedouit, PhD, Service de Médecine Légale, Hôpital de Rangueil, 1 avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE; Norbert Telmon, MD, PhD, Service Medico-Judiciare, CHU Rangueil, 1 Avenue Jean Poulhes, Toulouse, F-31054, FRANCE; and Daniel Rouge, PhD, Service de Médecine Légale, CHU Toulouse Rangueil, 1 avenue Professeur Jean Poulhès, Toulouse Cedex 9, 31059, FRANCE*

After attending this presentation, attendees will understand the causual link between a physical assault and a stress-induced cardiomyopathy.

This presentation will impact the forensic science community by providing an example of a stress-induced pathology rarely described in the forensic literature.

Takotsubo cardiomyopathy (TTC) is also known as transient apical ballooning, apical ballooning cardiomyopathy, stress-induced cardiomyopathy, and simply stress cardiomyopathy. The name refers to the morphological features of the left ventricle which look like the Japanese Takotsubo ("fishing pot" used to trap octopuses). It was initially described in Japan by Dote et al. and subsequently recognized in the United States and Europe. The prevalence of stress cardiomyopathy among patients with symptoms suggestive of myocardial infarction is 0.7–2.5%.

The mechanisms of disease remain unclear and the cause has not been established. Hormonal disturbances, diffuse microvascular spasm, multivessel epicardial coronary artery spasm, hidden coronary disease or aborted myocardial ischemia, focal myocarditis, structural changes and oxidative stress theory, hypercontraction of the basal segments, have been suggested as possible causes of this disorder.

The typical presentation of a patient with TTC is a sudden onset of congestive heart failure or chest pain. On the ECG the most common changes are ST segment elevation in two or more leads and T-wave inversion. Markers of myocardial damage and heart failure are moderately elevated.

Left ventricular function was assessed by echocardiography, left ventriculography or cardiac Magnetic Resonance Imaging (MRI). Typically, dyskinesis of the left ventricular apical or midventricular segments with a hyperkinetic basal region was demonstrated. In 2009, a systematic review showed that cardiac MRI is very useful, first for diagnosis, but also for visualization of apical thrombus, left ventricular abnormalities and analysis of the right ventricular function.

The prognosis of stress cardiomyopathy is good, although fatal complications, such as cardiogenic shock, malignant arrhythmias, and free wall rupture of the left ventricle, have been reported.

Case presentation: This case is about an 80-year-old man who was victim of confinement during the hold up of his jewlery store. His arms and legs were tied with adhesive tape. He was maintained by three unknown male individuals, first in a vehicle with his wife, and then in a room where he was released. The hold up lasted eight hours.

Following the hold-up and confinement, he vomited and felt a gripping pain with a feeling of tightness that led him to consult a physician. On arrival he presented a badly tolerated tachycardia with low blood pressure at 80/60. The physical examination found subcrepitant rales but no lower limb oedema. No skin lesions were found.

The cardiac troponin presented a small and rapid increase. The ECG showed a sinusal rhythm, left bundle branch block and a ST segment elevation of 1mm in lead D1 to VL. On the echocardiography, the left ventricular ejection fraction was 35%, there was an apical akinesis with apical ballooning pattern. On the coronarography, no significant epicardial coronary artery disease was found. He was hospitalized in cardiology department for a TTC.

Two weeks after the admission, a cardiac MRI was performed, showing normalization of the apical wall motion and of the ejection fraction.

Discussion: One of the goals of the forensic expert was to establish the link between the assault and the cardiomyopathy.

It is well known that TTC arise after an acute emotional stress and examples of incidents are: after an electroconvulsive therapy, after an earthquake, following dobutamine stress echocardiography, after caesarean delivery.

In this case, all of the four criteria were present:

- Transient hypokinesis, akinesis or dyskinesis of the left ventricular mild segments with or without apical involvement; the regional wall motion abnormalities extend beyond a single epicardial vascular distribution; a stressful trigger is often, but not always present.
- T Absence of obstructive coronary disease or angiographic evidence of acute plaque rupture.
- T New electrocardiographic abnormalities (either ST-segment elevation and/or T-wave inversion) or modest elevation in cardiac troponin.
- T Absence of pheochromocytoma, myocarditis.

Furthermore, a physical assault is unquestionably an intense emotional and physical stress. Only three cases reported of a TTC in a judiciary context has been found: in an elder abuse case, following a physical assault and after use of electric weapons.

Considering the alleged facts and the unquestionably link between the stress situation and the TTC, the expert reasonably accepted the direct, certain and exclusive causal link.

Although no studies were found in reference to the maximum time for onset of the appearance of symptoms, they classically appeared quickly after the initial complaint.

In case of death and considering the classic complications, except the free wall rupture of the left ventricle, it is possible to find no macroscopic lesion during the autopsy.

Conclusion: Forensic pathologists could be led to discuss the imputability of stress induced cardiomyopathy to a physical assault.

Takotsubo Cardiomyopathy, Physical Assault, Imputability

G34 Two Unusual Cases of Homicide Involving Heterosexual Erotic Hypoxic Games

Iana Lesnikova, PhD, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Jytte Banner, PhD, Department of Forensic Pathology, University of Aarhus, Denmark, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK*

After attending this presentation, attendees will gain understanding about deaths, occurring after hypoxic heterosexual erotic games. The important points of this presentation are that hypoxic erotic games are rarely seen in forensic pathology and that the hypoxic games prior to death are not necessarily the cause of death.

This presentation will impact the forensic science community by improving the knowledge about accidental erotic asphyxia and homicide, involving hypoxic erotic games. Knowledge about injuries associated with eroticism is important for forensic pathologists. The incidence of erotic asphyxiation, occurring after or as a result of hypoxic heterosexual erotic games is low and almost every case is highly individual. It is believed that the actual presentation can contribute to improving the diagnosis and differentiation between self-inflicted, accidental sexual activities, and homicide in cases where hypoxic heterosexual erotic games are involved.

Fatal autoerotic asphyxiation is not uncommon, but deaths due to homicidal attended behavior or after accidental erotic asphyxias involving heterosexual partners are rare. Cases, where the hypoxic games were practiced before or as a part of the homicide are difficult to diagnose due to difficulties in separating features of accidental and inflicted injuries. It is even more difficult to differentiate if the diagnosis of death is due to mechanical asphyxia or non-deadly asphyxia, taking place shortly before the death.

This study addresses two cases of homicidal deaths occurring after or due to asphyxiation during heterosexual erotic games. Both cases were routinely autopsied at the Department of Forensic Medicine University of

Aarhus, Denmark. The drug testing was performed at the Department of Forensic Toxicology of University of Aarhus, Denmark.

The main role of forensic pathologists is to give a reasonable hypothesis regarding the cause of death. In the vast majority of cases the asphyxia can easily be diagnosed. The diagnosis of asphyxia is traditionally based on morphologic findings and nonspecific signs, such as ligature marks, fingernail marks, bruises on the neck, petechial hemorrhages, facial congestion, edema, cyanosis, bruises in soft tissue, fracture of hyoid bone, thyroid- and cricoid cartilage. These findings are all characteristic for death caused by asphyxia, but almost in non-deadly asphyxia, taking place shortly before the death. Additionally fractures of hyoid bone, thyroid- and cricoid cartilage can occur after death.

Two cases are presented in order to provide new knowledge and to improve the forensic diagnosis of causes of deaths, occurring after hypoxic erotic games involving heterosexual partners, which are relatively rare events in forensic pathology. The presented cases illustrate that the presence of morphologic signs of asphyxia at autopsy provide evidence of asphyxia shortly before death, but it cannot provide evidence for asphyxia causing the death.

It is realized that even though such complicated cases are highly individual there is some similarity of findings and signs. Since such cases are extremely rare, the collection of knowledge regarding the case history, forensic examination, police investigations, and court records is an important tool, providing an evidence based interpretations of the findings.

Sexual Asphyxia, Death, Homicide

G35 Antipsychotic Polypharmacy: Lessons to be Learned From Forensic Toxicological Screening

Lisa F. Michaelsen, MD, Department of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Ingrid Rosendal, MSc, and Jørgen B. Hasselstroem, PhD, Department of Forensic Toxicology, Aarhus University, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Birgitte Brock, MD, PhD, Department of Clinical Farmacology, Aarhus Universityhospital, Noerrebrogade 44, Aarhus C, 8000, DENMARK; and Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgårdsvej 100, 8200 Aarhus N, DK-8000, DENMARK*

After attending this presentation, attendees will understand the challenge of medical treatment of psychiatric patients with several drugs and the importance of the forensic autopsy in psychiatric patients dying suddenly

This presentation will impact the forensic science community by showing an example of what can be revealed from routine forensic toxicological screening and toxicological interpretation and how it can help understanding drug intoxication in psychiatric patients.

The prevalence of antipsychotic polypharmacy among schizophrenic patients is high and increasing internationally although a considerable difference in prescription practices exists. To estimate the overall risk of polypharmacy for the patient, pharmacodynamics, pharmacokinetics, as well as pharmacogenetics (how genetic differences influence patient's response to drugs) also have to be taken into consideration.

A 62-year-old schizophrenic man treated with several antipsychotic drugs died suddenly and unexpectedly. Beside his psychiatric diagnose he was once hospitalized with atrial flutter and ventricular extrasystoles (VES). No cause of death was found. The autopsy was performed and blood samples were taken from the femoral vein in accordance with standard procedures. Toxicological screening revealed the following: a lethal concentration of sulpiride (4,6mg/kg blood), concentrations of amitriptyline (0,43mg/kg blood) and the active metabolite nortriptyline (1,1mg/kg blood) were in levels where symptoms of lethal intoxication are seen, clozapine (1,3mg/kg blood), zuclopenthixole (0,16mg/kg blood) and procyclidine (1,2mg/kg blood) were found in concentrations where symptoms of intoxication are seen, levomepromazine (0,13mg/kg blood) and metoclopramide (0,13mg/kg blood) were both found in therapeutic concentrations. Alcohol was not detected in blood or urine.

Histology showed a simple pneumonia and slightly myocardial fibrosis. The cause of death was stated to be intoxication due to polypharmacy with several drugs. The manner of death was accident. All drugs were found to have been prescribed in recommended doses, and findings at the crime scene did not disclose intended intake or overdose.

The high drug concentration could according to toxicological interpretation not be explained by hepatic metabolic interactions, whereas pharmacodynamics may have played a role; the influence of potential pharmacogenetics was not examined.

Sulpiride is poorly absorbed from the gastrointestinal tract leading to low bioavailability of 25-35%. The patients constipation may have increased the absorption of sulpiride and thereby his serum concentration.

Metoclopramide was prescribed to the patient due to complaints of nausea, a well known symptom of intoxication of the drugs he was treated with. Metoclopramide which share side effects with antipsychotics is; however, not recommended in combination with other antipsychotic drugs. A majority of the drugs this patient was treated with share prolonged QT-interval and cardiac arrhythmia as side effects among others. This, in combination with the history of atrial flutter and ventricular extrasystoles, gives a high risk of cardiac arrhythmia. Furthermore, sulpiride is not recommended in combination with other drugs that may cause prolonged QT interval

This study presents this case illustrating that the potential fatality of polypharmacy in psychiatric patients should be considered and explored. Furthermore, it will reveal hypotheses of how this patient, treated with medication in recommended doses, could reach these high serum concentrations.

Antipsychotic Polypharmacy, Drug Intoxication, Psychotropic Drugs

G36 Nucleic Acid Degradation and the Postmortem Interval

Arpad A. Vass, PhD, Oak Ridge National laboratory, PO Box 2008 MS6120, 1 Bethel Valley Road, Oak Ridge, TN 37831-6120; Rachel I. Fleming, PhD, and SallyAnn Harbinson, PhD, Institute of Environmental Science and Research, Private Bag 92-021, Auckland, NEW ZEALAND; James M. Curran, PhD, The University of Auckland, Department of Statistics, Private Bag 92-019, Auckland, NEW ZEALAND; and Eletra Williams, MS, University of Auckland, Department of Chemistry, Private Bag 92-019, Auckland, NEW ZEALAND*

After attending this presentation, attendees will be updated on how to capitalize on the utilization of modern molecular biology techniques, providing new and powerful statistically based tools uniting forensic biology and forensic pathology together with the potential to reveal crucial information regarding the circumstances surrounding a potential crime.

This presentation will impact the forensic science community by providing understanding of how the analysis of DNA and RNA from aged and/or degraded samples may reveal vital information about processes involved in decomposition, as these also affect nucleic acids. This has the potential to be of benefit in the analysis of samples that may traditionally be compromised and difficult to analyze.

While DNA has been used for over twenty years in forensic biology the potential applications for RNA have only recently received attention after the revelation that RNA is more stable than previously thought. By studying DNA and RNA from aged and/or degraded samples we expect to learn more about the processes involved in decomposition, as these also affect nucleic acids. This has the potential to be of benefit in the analysis of samples that may traditionally be compromised and difficult to analyze.

This study measured the systematic rate of decay of nucleic acids (DNA and RNA) in hard tissues such as nails, teeth, and bone. These tissues are more stable against environmental conditions due to the inherent biochemical structure of the tissue. The rate of degradation of nucleic acids in these tissues will be less influenced by external environmental factors and utilization of the rate of nucleic acid degradation found is likely to lead to the development of

postmortem interval indicators for longer time periods. A unique aspect of this research is the ability to take multiple samples from various human cadaver tissues at different time intervals without interfering with the decompositional process. This methodology, incorporating various time intervals, has not been studied before in relation to the degradation of nucleic acids in a systematic manner using human cadavers.

A critical aspect of assessing nucleic acid degradation was the recovery of RNA and DNA without any further fragmentation. Previously studies have shown that the DNA isolation and quantitation extraction system can be successfully adapted to allow the co-extraction of RNA and DNA without compromising the quality of either nucleic acid. An important practical aspect of this work is the further adaptation of this method to co-extract RNA and DNA from bone and nail samples. This will ease implementation into forensic laboratories as many already have the necessary skills and capacity to perform this adapted extraction strategy.

This initial research has identified the most useful genetic markers and established the experimental system required for analyses to assess whether ribs, nails or teeth are preferred as tissues for PMI estimation using this technique.

It was found that nails contain relatively high levels of DNA and RNA. Using reverse transcriptase PCR (RT-PCR), we have amplified four keratin mRNA transcripts and 18S rRNA from nail samples. After placement of nail samples in different environments, including submerged in water, soil, and at room temperature we have found that all four keratin mRNA transcripts are stable under different environmental conditions for significantly long time periods. Using these results, a statistical model has been developed to correlate the rate of degradation of the different keratin mRNA transcripts and 18S rRNA with the time since the material was sampled (PMI). Using nails collected from cadavers, we have applied the statistical model to determine the PMI in real-life situations. This work has shown that DNA and RNA in nails are stable and suitable for use in estimating the PMI.

DNA, RNA, Postmortem interval

G37 Typical Contrecoup Injury of Fixed Head by a Blow: A Case Report

Jong-Pil Park, MS, Bong-Woo Lee, PhD, and Sung-Ji Park, MS, National Forensic Service, Western District, 111, Daedeok-ri, Seosam-myeon, Jangseong-gun, 515-822, KOREA; Seonjung Jang, BS, College of Medicine, Yonsei University, 250, Seongsanno, Seodaemun-gu, Seoul, 120-752, KOREA; Tae-Hoon Kang, BS, Scientific Investigation Laboratory, Criminal Investigation Command, Ministry of National Defense, Seoul, 140-701, KOREA; and Joo Young Na, MS, Chonnam National University Medical School, Department of Forensic Medicine, Chonnam National University Medical School, 5 Hak-dong, Dong-gu, Gwang-ju, 501-746, KOREA*

After attending this presentation, attendees will be able to learn an unusual case demonstrating a prominent contrecoup injury of fixed head which is caused by a blow and get a lesson about how to identify a cause of head injury through examining a cerebral contusion.

This presentation will impact the forensic science community by presenting an exceptional practical point regarding on how to interpret the occurrence of coup and contrecoup injury, and contributing to a study about the mechanism of the coup and contrecoup injuries by suggesting that several factors including anatomical position of the deceased, a surface area of a blunt weapon, damaged area and etc should be considered together to distinguish between two injuries.

It is critical to distinguish between coup and contrecoup injuries because it provides important information about the cause of the head injury. It is well known that coup injury is more dominant by a blow and contrecoup by a fall. However, several exceptions have been reported, and one of them is that contrecoup would be more prominent when a fixed head to a ground or a wall is struck by a heavy blow

A 45-year-old man was found dead in a prone position on a cabin of his village with a severe head injury. The police investigation proved his son's crime associated with a gambling debt.

On the postmortem examination, there were multiple bruises with semi-circular lacerations on occipital area and posterior portion of left temporal area of the scalp, and small bruises on right forehead and zygomatic region. Widespread subcutaneous hemorrhage and communicated and depressed skull fracture with several linear fractures on occipital bone of calvaria were identified. On the skull base, front to back fracture, which run occipital bone, right side of foramen magnum, right temporal bone, sellar turcica and right frontal bone, and small linear fractures on both orbital roof of frontal bone were noted. The brain showed multiple and large contusions on poles and undersurface of both frontal lobes and poles of both temporal lobes, and relatively small and weak contusions on both occipital lobe and right lobe of cerebellum. The remaining body was unremarkable except a contusion with intramuscular hemorrhage of left shoulder and small abrasions of right elbow.

The deadly weapon used in the crime was a hammer with an octagon-shaped surface, which is 35.0cm in an overall length, 10.0cm in length of the head, 10.2cm^2 in surface area and 978g in weight, and it turned out that he was hit by a hammer on the occipital area in a sitting posture, and then more than 10 times in a prone position.

There were several factors which were associated with injury pattern such as anatomical position of the deceased, a type and a surface area of a blunt weapon, damaged area, material quality of the floor, and the number of impacts. This deceased placed a face on wooden floors and received repetitive blows on the occipital area by a heavy hammer with relatively large surface.

In conclusion, this case showed that a blow can cause contrecoup more significantly than coup injury and this was more likely to be interpreted when several factors, particularly that head is fixed to a ground or a wall, were considered together.

Cerebral Contision, Coup, Contrecoup

G38 Man With a Blue Brain: A Case of Hydrogen Sulfide Poisoning

Todd M. Luckasevic, DO, Baiyang Xu, MD, Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222*

The goal of this presentation is to illustrate an unusual case of suicide within a closed vehicle by mixing household chemicals to form hydrogen sulfide gas.

This presentation will impact the forensic science community by illustrating an unusual case of suicide that results in a hazardous materials (Hazmat) situation for first responders and medical examiner personnel.

Introduction: Suicide is one of the most important public health issues and represents the eleventh leading cause of death in the United States. Suicides comprise approximately 12% of the caseload of the Allegheny County Medical Examiner's Office in Pittsburgh, Pennsylvania. Suicide rates for this country have been relatively stable over the past decade averaging approximately 10 per 100,000 populations. The most common method of suicide in the United States is the use of a firearm.

Chemical suicides have plagued the United States since 2008, and continue to be on the rise. This method of suicide originated in Japan in 2007, where they have seen over 2,000 such cases. Chemical suicide, or detergent suicide, involves mixing common household chemicals to create deadly hydrogen sulfide (H2S) gas, which is lethal in contained areas. Hydrogen sulfide, H2S, is a colorless gas that has a strong odor of rotten eggs or sulfur. H_2S inhibits enzymes in mitochondria by binding with Fe^{3+} of cytochrome oxidase. This reaction blocks cellular respiration, and interferes with oxygen utilization at the cellular level.

Materials and Methods: The case involved a 32-year-old Caucasian male with a history of a recent suicide attempt via sleeping pills. The decedent was recently depressed over losing his job and the threat of his car being repossessed. He was last seen alive the previous night.

The decedent was located by his father the next evening in his car in the rear of a large parking lot. The father recognized that his son was unresponsive and smashed the car window to gain access to his son. He then drug his son partially out of the car before being overcome by noxious fumes. First responders arrived at the scene and pronounced the son dead. His father was evaluated by medics and taken to a local hospital for observation.

There was a note taped to the driver's side window of the car stating "Danger! Hydrogen sulfide gas! Call police! Stay away!" There was a large size plastic container in the back seat of the car containing a blue liquid.

Results: The body was decontaminated at the scene by local fire department and Hazmat crews by dousing with water.

The external examination revealed a Caucasian male that had a blue-gray hue to his skin color and wet clothing. There were areas of skin slippage to his trunk and extremities. There were no detectable noxious smells or gases detected with a Hazmat CAD device. The autopsy revealed bilateral congested lungs and white froth in the airways. Upon removal of the skull cap, a rotten egg smell was observed and the brain was blue.

The household chemicals used to produce the hydrogen sulfide gas were lime sulfur spray (containing the active ingredient calcium polysulfide) and a strong chlorine acid.

Conclusions: Responders must do a thorough scene safety check before attending to a vehicle with unresponsive patients. Responders should take extra time to peer into the vehicle and look for buckets or other mixing containers in the front or rear seats, containers of acids and pesticides, a yellow or green residue in the vehicle, and vents that may be taped off. Responders need to be extremely cautious when investigating suspicious odor calls inside a structure. Once recovered from the vehicle, the body should be thoroughly washed with water and transported in a body bag to the morgue. During the autopsy, decedents may off–gas from their lungs and in this case their brain.

Hydrogen Sulfide Gas, Hazmat, Suicide

G39 Application of Single Nucleotide Polymorphisms (SNPs) to Forensic Casework in Malaysia

Sharizah Alimat, MSc, University of Central Lancashire, Darwin 254, School of Forensic & Investigative Sciences, Corporation Street, Preston, Lancashire PR1 6JU, UNITED KINGDOM; and William Goodwin, PhD, School of Forensic Medicine and Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will learn another reliable SNPs panel developed from the SNP*for*ID markers that can be applied for population study or forensic human identification. Data obtained showed the SNP markers and platform chosen are informative and suitable to be used in forensic casework, where samples with minute amount of DNA input (as low as 30 picogram) can be detected.

This presentation will impact the forensic science community by introducing reliable and sensitive SNaPshot assays in order to genotype the population or to be used in human identification. Data obtained from the study will provide knowledge about the allele frequencies distribution in three major ethnic groups in Malaysia (Malay, Chinese, and Indian).

The analysis of degraded DNA can be problematic. Recent advances in the identification and analysis of single nucleotide polymorphisms (SNPs) have demonstrated the advantage of these markers over short tandem repeats (STRs) in that they only require small amplicons. However, before applying to casework, it is important to develop allele frequency databases from relevant populations. The purpose of this phase of the study is to characterize three Malaysian major ethnic groups: Malay, Chinese, and Indian, using 52 autosomal SNP markers that have been identified in the SNP*for*ID project.

Sanchez et. al., 2006 reported a multiplex of 52 SNP markers in one PCR reaction with two single base reaction (SBE) in the detection of SNPs using capillary electrophoresis (CE). The amplicons for PCR ranged from 59 bp to 115 bp. Whilst for SBE reactions ranged from 16 nt to 92 nt. In their study, full complete profile was obtained from 500 pg DNA input. The study was carried out on three major populations: African, Asian, and European.

As in this study, a total of 150 Malaysian samples (50 samples from each ethnic group) were genotyped. In order to genotype the population samples reliably and robustly, four sets of 13-plex SNPs were developed. Sensitivity and reproducibility studies demonstrated that the assays were highly sensitive, requiring as little as 30 pg of DNA. Full, complete, and clear profiles were generated. Data were collected and evaluated statistically for forensic usefulness.

Across the three ethnic groups, few significant departures from HWE were observed in Malay, Chinese, and Indian ethnic groups. At marker rs2107612, no heterozygosity was observed at all in Malay group (Ho=0) but the Indian group showed higher heterozygosities (above 80%). Whereas, for marker rs1413212, Malay group showed higher heterozygosities (above 80%) compared to Chinese or Indian groups. Major departure from HWE also was observed in both Chinese and Indian ethnic groups at rs1528460 marker.

The combined mean match probabilities for the 52 SNPs of Malay, Chinese, and Indian are 2.1974^{e-18}, 6.0042^{e-18} and 1.1756^{e-18}, corresponding to a combined power of discrimination of >99.99999999%, respectively. Paired F_{st} values obtained in the study showed, as expected, that Malay group is closely related to the Chinese population, with the Indian population being more distant.

SNPs Marker, Malaysian Population, SNP for ID

G40 Firearm Suicide Demographics in Harris County, Texas

Brandy Shattuck, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Sara N. Doyle, MD, and Merrill O. Hines, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; and Dwayne A. Wolf, MD, PhD, Harris County Medical Examiner's Office, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will have a better understanding of the rate of firearm suicides among the different racial groups in Harris County, Texas.

This presentation will impact the forensic science community by providing insight into the rate of firearm suicides amound different racial groups, particularly Hispanics, in an urban setting with high firearm ownership rate.

Suicide continues to be a common cause of death among all ethnic groups in the United States and using firearms to complete suicides is the most frequent method. As has been previously documented, White and African American males are more likely to complete suicide by firearm than males of other ethnic groups. It has also been found that nationally, Hispanics have a lower overall suicide rate than either Whites or African Americans. Studies have shown that regions that have a high prevalence of firearm ownership have a higher rate of suicide by firearm over other methods.

The literature has had fewer assessments of Hispanic suicide statistics; however, given the growing population of Hispanics, confirming these results or finding regional trends is useful to better understand this segment of society. To that end, a review of the suicide cases in Harris County, Texas was performed to see if these national statistics were applicable, given both the large Hispanic population and the high prevalence of firearms.

All deaths classified as suicides by the Harris County Institute of Forensic Sciences from January 2006 until July 15, 2011 were reviewed for age, sex, race, and method of suicide. Statistical analysis using student chi-squared testing with contingency tables was performed. In line with previous

research, a significance value of $p < 0.05$ was used. All statistical analysis was performed using spreadsheet software. The total number of suicides classified during that time period was 2,411, with males comprising 1,827 or 75.6 percent and females comprising 584, or 24.4 percent. The ethnic composition was 1,610 White (66.8 percent), 434 Hispanic (18 percent), 261 African American (10.8 percent), and 106 Asian (4.4 percent). These numbers vary from the ethnic distribution of Harris County according to the 2010 census. The percentage population is as follows: White (33.0 percent), Hispanic (40.8 percent), 261 African American (18.9 percent), and 106 Asian (6.2 percent).

Statistical analysis shows that Hispanics in Harris County are less likely than both Whites and African Americans to commit suicide by firearm (p value <0.04). Results also show that females of all races are less likely to commit suicide by firearm than their male counterparts, confirming previous research. There was no statistical significance to women of any ethnicity using firearms. It was found to be statistically significant ($p<0.004$) that Hispanic men are less likely than men of all other ethnicities to use firearms to commit suicide. Interestingly, Hispanic women were just as likely as women of other ethnicities to use a firearm to commit suicide ($p= 0.41$). It had been hypothesized that the given the prevalence of firearms in this geographic area that both genders of all ethnic groups would be more likely to use firearms but the analysis did not show this to be the case.

These results were surprisingly in line with previously documented research. While this analysis does not provide any additional information on the trends in Hispanic suicide, it does confirm the national data from a region with both a prominent Hispanic population and a large population that owns firearms.

Suicide, Firearms, Demographics

G41 Reconstruction of Homicide by Stabbing Through Clothing Position

Khudooma S. Al Na'imi, MSc, Abu Dhabi Police GHQ, Abu Dhabi, Al Ain, PO Box 66722, Al Ain City, 66722, UNITED ARAB EMIRATES; Zainat N. Al-Hattali, BSc, Abu Dhabi Police GHQ, PO Box 253, Abu Dhabi, UNITED ARAB EMIRATES; and Sumaia J. Al-Swaei, BSc, Abu Dhabi Police, PO Box 253, Abu Dhabi, UNITED ARAB EMIRATES*

After attending this presentation, attendees will understand basic principles of recording clothing position in homicide cases involving stabbing. A case example will be discussed

This presentation will impact the forensic science community by providing information on the importance of analysis of clothing position in homicide cases involving stabbing.

Stabbing is the most common method of homicide and it represents several investigative challenges. Its reconstruction is a complex process where factors such as stabbing site, body position and dynamics, type of clothes, knife type, blood distribution, crime scene condition, pathology, and psychology are important information parameters to be considered. Major questions required to be answered in stabbing cases are differentiating between homicide and suicide, the victim and perpetrator positions, and the sequence of stabbing.

There is little attention directed towards clothing position analyses. This factor can be lost or affected during or after moving the body in the crime scene or the morgue which could produce changes in the clothing position profile.

Clothing position can be divided into three stages which are before stabbing, during stabbing, and after stabbing positions. This research will attempt to reveal clothing position during the stabbing process. It will be achieved mainly through matching stabbing sites in clothes and body tissues. The stab sites will be assessed individually and in relation to each other. This will help to determine the movement and the interaction of the victim with the perpetrator during the stabbing process and help to determine the sequence of wounding. In addition, other evidence such as blood distribution on the victim and the perpetrator's clothing can help to indicate clothing position during stabbing.

A case of a son with a history of psychological disorder, who killed his father by stabbing is presented.

Examining the victims t-shirt showed seven stab sites. In correspondence there are six stabs sites in the left chest and left back areas of the body. The clothing position analysis demonstrated differences in the t-shirt alignment after matching stab sites in the clothing and the body. This can be explained by different pulling forces applied vertically and horizontally on the t-shirt during the stabbing process. The son confessed that he held his father after stabbing to prevent his movement which could produce the pulling force that is supported by the blood distribution evidence.

Understanding clothing position and blood distribution on the victim and the perpetrator helped to elucidate some of the events during the stabbing. Clothing position and blood distribution should be recorded and analyzed in the crime scene first then at the mortuary and in the laboratory. There is a need of more research in this vital area of stabbing reconstruction.

Reconstruction, Stabbing, Clothing Position

G42 The Prevalence of Hepatitis Among the Forensic Autopsy Population of the South Alabama Region

Andrea G. Kahn, MD, LeRoy Riddick, MD, and John Nelson, MD, University of South Alabama, 2451 Fillingim Street, Mobile, AL 36617*

The goal of this presentation is for attendees to become familiar with the prevalence of hepatitis among the forensic autopsy adult population of the South Alabama region in a cross section study.

This presentation will impact the forensic science community by determining the estimated prevalence of hepatitis among the forensic autopsy adult population in the South Alabama region.

From 887 cases investigated by the Alabama Department of Forensic Sciences (ADFS) during the calendar year 2003, demographic information was obtained and all adult cases that had had a postmortem examination were included in the study. Of the 887 cases, 775 had an autopsy and of these 711 were over 18 years of age. From the 711, 580 liver hematoxylin and eosin slides were available and retrieved from the ADFS files.

A total of 550 slides have been reviewed by at least one reviewer, 127 by two reviewers and 75 by three reviewers. The reviewers include one pathology resident, one surgical pathologist, and one medical examiner/forensic pathologist. The Batts-Ludwig modification of the Scheuer grading system designed for chronic hepatitis cases was used by the reviewed to standardize the information, acknowledging that most of these cases may not represent chronic hepatitis in the first place or that the information needed to make such diagnosis is not available. The information obtained includes the degree of inflammation (grade) and the degree of fibrosis (stage). The presence or absence of steatosis was also recorded and graded if present and any other significant pertinent findings recorded.

Paraffin embedded blocks were retrieved from 75 of the cases that had shown morphologically some degree of inflammation. Four micron sections were obtained on coated slides and immunohistochemistry for the hepatitis B core antibody was performed.

From the 550 reviewed, 229 (41.6 %) had no significant inflammation or fibrosis scored by one or two pathologist, indicating no morphologic evidence of hepatitis. Another 48 (8.7 %) cases had no significant inflammation or fibrosis by one reviewer and variable degrees of inflammation or fibrosis by additional reviewer/s. An additional 122 (22.1 %) cases by one, two or three reviewers had minimal inflammation and mild fibrous portal expansion; this pattern with no clinical information may only represent chronic triaditis, a common finding in liver tissue from medical examiner adult autopsy with no clinical significance. The remaining 145

(26.3 %) cases had mild to severe portal and lobular inflammation and fibrosis that ranged from fibrous portal expansion to cirrhosis. Six cases has marked autolysis and were not graded for inflammation or staged for fibrosis.

Cases with minimal to marked changes were included in the group that was selected for immunohistochemistry. All except one case were negative for Hepatitis B core antigen. The positive case had cirrhosis.

This study shows that approximately one fourth of the cases had morphologically features that would indicate chronic hepatitis in the appropriate clinical setting. The prevalence of hepatitis B appears to be low in this cohort. The prevalence of hepatitis C remains to be investigated in this group.

Prevalence, Hepatitis, South Alabama

G43 Fatal Latrogenic Pseudomonas Aureginosa Meningitis After Epidural Anesthesia: A Case Report

Mario Rascon, MD, New Mexico Office of the Medical Investigator, MSC07 4040, 1101 Camino de Salud NE, Albuquerque, NM 87102; Erin G. Brooks, MD, Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131; Julie Adams, DO, Saint Louis University, 1234 Big Bend Crossing Drive, Valley Park, MO 63088; and Michelle B. Aurelius, MD, Office of the Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131*

After attending this presentation, attendees will become familiar with the risk factors associated with iatrogenic meningitis, as well as the proper approach to follow by the forensic pathologist.

This presentation will impact the forensic science community by emphasizing the importance of: (1) a thorough investigation in potential infection-associated fatalities: and, (2) surveillance for infections in medico-legal cases.

Case report: A 22-year-old pregnant woman at her 35th gestation week was admitted to the hospital after spontaneous rupture of membranes. She had a past medical history necrotizing faciitis during childhood and a previous episode of meningitis. An emergency cesarean section was performed due to failed labor induction. Epidural anesthesia was placed at this time. The baby was born with low Apgar scores and was taken to the intensive care unit (ICU). The patient was discharged three days later and soon developed headaches, agitation, and altered mental status. A lumbar puncture performed at the ED showed a very elevated white blood cell count on her cerebrospinal fluid (CSF). She was admitted to the ICU, where she had rapid decrease in consciousness, and erratic breathing, and needed to be intubated shortly thereafter. A magnetic resonance imaging (MRI) showed severe cerebral edema, suggestive of meningitis. CSF cultures grew Pseudomonas aureginosa. A ventriculostomy was performed; her condition continued to deteriorate to the point where there was no sign of brain activity. The family withrew care and she was pronounced dead.

Autopsy revealed bacterial meningitis with fibrinoid necrosis and multiple intraparenchymal microabscesses. Postmortem CSF cultures were negative for Pseudomonas aureginosa

Latrogenic meningitis, along with epidural abscess and vertebral osteomyelitis, are rare but clinically important known complications of spinal anesthesia. Some of the potential patient-associated risk factors to develop meningitis after spinal procedures include: bacteremia; diabetes; immunodeficiency; alcoholism; chronic renal failure; malignancy; and, spinal trauma. Other described causes include: poor antiseptic technique; starch powder from gloves; and, aerosolized oropharyngeal secretions from medical personnel.

Almost half the cases of postdural puncture meningitis are caused by Streptococcal species. Pseudomonal species are an infrequent cause of meningitis and occur almost exclusively as a nosocomial infection.

Clinicians should maintain a high index of suspicion in a patient with altered mental status that has undergone spinal anesthesia, since early diagnosis is key to a successful treatment regimen. Equally important is to follow strict aseptic techniques during all spinal procedures.

Being a preventable entity, each case of potential iatrogenic meningitis should be investigated thoroughly by the forensic pathologist with specific inquiry regarding the circumstances surrounding the death, and postmortem CSF cultures as to try to elucidate a specific cause.

Only a minority of deaths due to infections fall under the jurisdiction of medical investigators. This makes communication between forensic pathologists and clinicians essential because the sentinel case of an outbreak can often be detected at a medical examiners office.

Surveillance for infections in medico-legal cases is of utmost importance for medical examiners; it can frequently help achieve an organism-specific diagnosis, and may also identify potential high risk populations.

Meningitis, Pseudomonas, Epidural Anesthesia

G44 An Unusual Case of Whipple's Disease With Fatal Outcome in a Young Woman: A Rare Disease and Diagnosis Failure

Francesco P. Busardo, MD, Institute of Legal Medicine, Via del Vespro, 129, Palermo, ITALY; Emiliano Maresi, PhD, Via del Vespro 127, Palermo, 90100, ITALY; Francesca Portelli, MD, Via dei Nebrodi 64, Palermo, ITALY; Paolo Procaccianti, PhD, Palermo University, Via del vespro, n. 127, Palermo, Sicily 90100, ITALY; and Antonina Argo, PhD, Via Narbone n°13, Palermo, ITALY*

After attending this presentation, attendees will gain knowledge on macro and microscopic aspects of the rare disease, Whipple's disease, in order to make the difficult diagnostic process of this illness easier.

This presentation will impact the forensic science community by showing how a "diagnosis failure" which does not always imply a professional negligence; it stresses the importance of not relying only on the epidemiological evidence for the diagnostic prediction of the disease.

Introduction: Whipple's disease is a rare, systemic infectious disease caused by the bacterium *Tropheryma whipplei*. First described by G.H. Whipple in 1907 and commonly considered a gastrointestinal disorder, Whipple's disease primarily causes malabsorption but may affect any part of the body including the heart, lungs, brain, joints, skin, and eyes. Weight loss, diarrhea, joint pain, and arthritis are commonly presented symptoms, but their presentation can be highly variable and approximately 15% of patients do not have these classic signs and symptoms. Whipple's disease is significantly more common in men (87% male) and the incidence has been estimated in around 1/1,000,000, even if no valid estimate of the incidence is available. The disorder has been described most frequently in white people and in Western Europe. For these reasons, in Italy the disease is naturally placed on the National Register of Rare Diseases (RNMR) of ISS.

When recognized and treated, Whipple's disease can usually be cured with long-term antibiotic therapy; untreated the disease is ultimately fatal.

The case: The case of a 27-year-old woman who died six days after admission in a Sicilian hospital for persistent fever, anaemia, and weight loss is presented. For the symptoms presented, doctors evaluated a broad spectrum of diagnoses, not identifying this rare disease. For this reason, the court ordered an autopsy, to clarify the causes of death and any professional liability. The autopsy, together with the histological and microbiological investigation, allowed the diagnosis of Whipple's disease, with systemic manifestation and predominant intestinal involvement (lipodystrophy), heart (fibroadhesive pericardial disease), brain (lipid thesaurismosis), pulmonary and renal fat embolism and erythrophagocytosis.

Discussion and Conclusions: After explaining all aspects of forensic pathology, accompanied by macro and microscopic investigations, the exclusion of other causes of death, attention was focused on the concept of "diagnosis failure" of a rare condition such as Whipple's disease, which does not always imply a professional negligence, as in this case.

What is stated above, doesn't want to mean that a "rare disease" is the same as a "failed diagnosis", rather it wants to point out that a rare illness must be carefully investigated and therefore needs a manifold elaboration "differential diagnostic path" (with other more common pathological conditions) which require more time and more specific examination.

Moreover, it stresses the importance of not relying only on the epidemiological evidence for the diagnostic prediction of the disease.

Whipple's Disease, Diagnosis Failure, Autopsy

G45 A Freak Human-Human Collision: Application of MSCT 3D Modeling to Incident Reconstruction

Paul P.S. Chui, MRCPATH, Health Sciences Authority, Singapore, Forensic Medicine Division, 11 Outram Road, Singapore, 169708, SINGAPORE*

After attending this presentation, the attendee will be able to appreciate the usefulness of MSCT as an adjunct tool to the routine forensic autopsy in providing valuable objective and more detailed documentation, and the value of 3D reconstruction of MSCT data in understanding the mechanism of injury in cases of trauma, and its application in assisting the investigation into circumstances and accident reconstruction.

This presentation will impact the forensic science community by showing how 3D reconstruction of MSCT information provides better spatial and orientation information in the total understanding of pattern of injuries, aiding in accident reconstruction.

3D reconstruction of CT scan damage is a useful method in assisting in medicolegal death investigation and scene reconstruction, particularly in traumatic deaths.

The use of MSCT has become more common place. Multiplanar reconstruction (MPR) is the usual mode of reviewing of CT images in the identification and 2D documentation of skeletal injuries. This case study of two simultaneous deaths arising from a human-human collision demonstrates the application of 3D reconstruction in understanding the pattern of injuries, which might have otherwise required painstaking and lengthy forensic anthropological preparations.

While 2D CT MPRs provide a basic documentation of injuries, application of 3D reconstruction provides additional spatial information in a speedy and non-destructive manner. Its use should be considered in more routine forensic work.

In traumatic deaths with severe skeletal injuries, while identification of first level documentation of presence of fractures may be easily done through the routine autopsy method, it is not often possible, without significant effort to examine deep seated structures, such as the pelvis, scapula, and transverse processes of vertebrae. Much painstaking effort is also required if one desires to examine the pattern of fractures so as to understand the mechanism of injury. Additional steps involving further mutilation of the body, recovery, and retention of body parts, and forensic anthropological processing in a laboratory are required. This takes time and additional resource such as a proper anthropological facility. This is made more complicated where retention of human tissue becoming more sensitive medicolegal and ethical issues in the community at large.

Further, removal of the material for processing involves the loss of original spatial orientation and related information. For example, recovery of a severely comminuted fractured skull will disturb the original orientation of the pieces, run the risks of loss of minute fragments, and incur the loss of information on the original fracture pattern. Severe comminution also makes reconstruction difficult due to generation of numerous similar looking pieces and loss of 'fit' characteristics.

In recent years, CT scanning has been used in more and more jurisdictions. Multiplanar reconstruction (MPR) tends to be the most common manner in which CT information is viewed and findings gleaned. The Forensic Medicine Division, Health Sciences Authority Singapore, acquired a multi-slice helical CT scanner and operationalised it in late 2010/early 2011, using it to scan cases of traumatic deaths routinely. Besides reading the MPR images, 3D reconstruction of the skeletal system is routinely carried out. The bulk of traumatic deaths in Singapore are accounted for by self-inflicted fall from a height (tall buildings), road traffic accidents, and hangings.

3D reconstruction has been found to be very helpful in understanding the pattern of skeletal injuries, in cases where severe trauma has been afflicted. To illustrate its application, a case study will be presented to demonstrate the value of 3D reconstruction in a freak accident involving two adult Chinese females who were found side by side dead at the foot of a block of apartment flats, both sustaining serious injuries. There was a lack of eye-witness accounts and investigators were not certain how both women could have come to rest in that situation. Initial investigations appear to suggest that one or both deceased could have fallen from a substantial height. A suicide pact scenario was considered. There has been no previous documented incident where a human falling from a height had impacted another individual.

Prior to the autopsies, both deceased persons were scanned and forensic autopsies were conducted. Following the scanning, 3D reconstruction of CT data was carried out. Analysis of the 3D reconstructions enabled the medical examiner to postulate the mechanism of injuries in both individuals, by looking at the overall patterns and direction of injuries. It was then possible to subsequently make a determination on the relative postures and positions of both deceased persons at the time of impact and form a conclusion that one of the deceased persons had fallen from a height and contacted the other deceased in a back to back manner, resulting in severe injuries to both individuals and instantaneous deaths.

MSCT, Fall From Heights, Human-Human Collision

G46 Heart Study in Magnetic Resonance: Birth of a Protocol

Christine Bruguier, University Center of Legal Medicine Lausanne-Geneva, Ch. du Bugnon 21, LAUSANNE, SWITZERLAND; Coraline Egger, MD, Centre Uneviersitaire de Médecine Léagle Romand, Lausanne-Genève, Suisse, R. Gabrielle Perret-Gentil 4, Geneva, SWITZERLAND; Jean-Paul Vallée, MD, Hôpitaux Inuversitaires de Genève, R. Gabrielle Perret-Gentil 4, Geneva, SWITZERLAND; Xavier Boulanger, MD, Centre Hospitalier Universitaire Vaudois, R. du Bugnon 41, Lausanne, SWITZERLAND; and Patrice Mangin, MD, PhD, and Silke Grabherr, MD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND*

After attending this presentation, attendees will understand the specific approach to create a protocol for ex-situ cardiac MRI (Magnetic Resonance Images) based on the clinical experience

This presentation will impact the forensic science community by showing which elements (physics, materials) must be considered to create an easy applicable and reproducible protocol for examining a heart ex-situ by MRI.

In recent years, MDCT (Multi-detector Computed Tomography) and MRI (Magnetic Resonance Imaging) are becoming increasingly important tools for investigations in forensic medicine. Both modalities can be used on the same case. In the Institute of Legal Medicine, Lausanne-Geneva, multi-phase postmortem CT-angiography (MPMCTA) using the oily contrast agent mixed with paraffin oil is executed regularly. Because of this technique, the complete vascular system can be examined in detail, which is especially important in order to investigate the coronary arteries in cases of ischemic heart disease. However, MDCT is not appropriated to investigate cardiac tissue. Cardiac MRI could solve this problem. Additionally, no adequate scanning protocol and no guidelines for interpreting postmortem cardiac MRI are available at this time. The purpose of this study is: (1) to create a protocol for an ex-situ study permitting the systematic examination of cardiac tissue of patient suspected of heart attack; and, (2) to investigate the performance of the oily contrast agent used for MPMCTA for its application on MRI.

This study was performed on a MRI unit using a 32 channels-head coil. Different scanning protocols were tested using six porcine hearts and one human heart. The protocols included: a) the preparation of the organ including contrast-agent injection and the positioning of the heart inside the coil, b) the scanning parameters used for the MRI acquisition. The following detailed the protocols:

a) In order to define a reproducible position of the heart inside the coil, different samples were tested made of plastic and glass containing paper, sand, or flour to avoid vibration artifacts due to the low weight of the examined heart. To unfold the left ventricular wall, different materials were inserted through the aortic valve such as a balloon catheter, polystyrene balls, or modeling clay. Different positions of the heart have been tested and a material for marking anatomical landmarks had been searched. During contrast agent injection into the coronary arteries, different types of catheters were inserted, the influence of vascular ligature, and the concentration of the oily contrast agent were tested.

b) As we performed the MRI sequences with a 32 channels-head coil, we had opportunities to use a small slice thickness (0,6 mm to 3 mm), a relative small field of view (180-250 mm) with a good signal-to-noise ratio. The choice of the different T1-or T2-weighting sequences depended on the original software equipment of the MRI unit and of the suspected pathology.

This study shows that the oily contrast agent had a good signal in T1-weighed sequences, which makes this contrast agent adequate for the MRI examination. This can be explained by the fact, that it is an oily liquid. The filling of the coronary arteries with the oily contrast agent depended on the morphology of the vessels and on their size. In some cases, the result was disappointing; however, this problem could be solved by the use of an angiographic catheter and the dilution of the contrast agent with a solvent in order to decrease its viscosity.

To find consequential edema of cardiac infarct, T2- weighted sequences were performed in the small axe of the left ventricle, in analogy to clinical examinations and the cardiac dissection technique used in our center. In some sequences we observed a bad image quality due to the movement of the heart produced by radiofrequency waves and the gradients. This problem could be overcome by the filling of the recipient with heavy materials. A glass recipient filled with flour turned out to be optimal because it didn't interact with the magnetic field and therefore no artifacts were observed.

For an easy orientation on the resulting images of the heart, a tablet of vitamin E was used (oily contrast in MRI) as landmark that was introduced in a cork stopper which was inserted into the aorta.

This study demonstrates: (1) that an optimal scanning protocol for cardiac ex-situ MRI contains the performance of T1-weighted sequences to evaluate the coronary arteries and of T2-weighted sequences for the imaging of the cardiac tissue, and that the preparation of the organ is essential for the quality of the exam; and, (2) the application of an oily contrast agent is providing an excellent contrast for coronary arteries on MRI.

Postmortem MRI, Cardiac MRI, Forensic Imaging

G47 Logistic Challenges in the Initiation and Development of a Forensic Computed Tomography Scanning Service at a United States Medical Examiner's Office

Jamie Elifritz, MD; Mike Spinoe RT, Barry Daly, MD, Zabiullah Ali MD, and David Fowler, MD, State of Maryland Office of the Chief Medical Examiner, 22 South Greene Street, Baltimore, MD 21201*

After attending this presentation attendees will become familiar with the process that the medical examiner's office (OCME) went through to develop protocols for specific forensic indications, in order to train autopsy technicians and forensic investigators and to initiate scanning of decedents.

This presentation will impact the forensic science community by demonstrating how the early experience gained from the development of a PMCT service in a medical examiner's office will be valuable for other forensic institutions planning to introduce a similar service.

The use of postmortem CT (PMCT) examination as part of the investigation of death is gaining interest in the forensic community.[1-6] PMCT may be utilized to complement and in some selected instances, to replace conventional autopsy. PMCT has potential in cases of blunt or penetrating trauma, elder or child abuse, drowning, burns, suicide, unknown cause of death, unidentified remains, decomposed remains, as a triage tool in mass fatalities, and in cases of cultural or religious opposition to autopsy. In suspected accidental or natural death, PMCT can be used as a triage tool to determine if cases may or may not need conventional autopsy. It can also be used as a tool for 3D documentation of complex findings, especially in blunt trauma. To date, several medical examiners offices in the United States have implemented PMCT scanning as part of their practice.

There are many variables to consider when incorporating CT scanning into forensic practice. One must consider economic factors including the purchase or lease cost of the scanner, maintenance contracts, and the operational expenses of scanning. The need for availability in a 24/7 operational environment prompted the initiation of a training program to teach autopsy technicians and forensic investigators how to operate the CT scanner. This training program was supervised by a part time CT technologist with forensic experience. Input was also provided by forensic radiologists from the University of Maryland.

A Lightspeed RT16 Widebore CT scanner with a wide aperture gantry was installed in January 2011. Three basic scan protocols were created, (whole body, head only, dental), adaptable for a wide variation in body sizes. All protocols were tailored to be completed in a 15 minute timeframe. Most 3D reconstructions were created as needed on a separate dedicated 3D server by forensic pathologists or radiologists. All protocols were easily accessible in electronic format on the scanner desktop for step-by-step reference by the autopsy technicians and forensic investigators both during and after training completion. PMCT training was provided in real time by the CT technologist and backed up by a visual presentation on the scanner desktop.

After installation of the CT scanner, nine staff members (six autopsy technicians and three forensic investigators) successfully completed the training program in PMCT applications in an 8-10 hour period each. In order to assure that all trainees produced high-quality diagnostic images upon training program completion, a grading system for technical quality of trainee-performed examinations was used, coupled with ongoing quality assurance. Establishing a radiation safety program and guidelines was an important additional component of the training program. Interpretation of PMCT studies has been performed by on-site forensic imaging fellows and state medical examiners with oversight by off-site forensic radiologists with internet access to the imaging studies. As experience accrues, more complex techniques such as postmortem angiography may be introduced.

In summary, this experience describes the development of forensic indications and basic protocol development for PMCT in a U.S. medical examiner's office. It also demonstrates that autopsy technicians and forensic investigators can be appropriately trained in the technical aspects of PMCT in a short timeframe, thus addressing the economic challenge of providing this service over a 24/7 timeframe. Close co-operation between the OCME staff and both an experienced CT technologist and radiologists interested in forensic imaging has been an important part of this process.

G48 Replica Remains: The Current State of Virtual and Physical Conservation Methods in Forensic Medicine

Summer J. Decker, PhD, University of South Florida College of Medicine, Department of Pathology & Cell Biology, 12901 Bruce B. Downs Boulevard, MDC 11, Tampa, FL 33612; Jonathan M. Ford, MSBE, University of South Florida College of Engineering, Department of Chemical & Biomedical Engineering, 4202 East Fowler Avenue, Tampa, FL 33620; Stephanie L. Hilbelink, PhD, Deptartment of Pathology and Cell Biology, University of South Florida College of Medicine, 12901 Bruce B. Downs Boulevard, MDC11, Tampa, FL 33612*

After attending this presentation, attendees will have an understanding of the variety of cutting edge technologies available to forensic medicine for the reproduction and conservation of fragile human remains.

This presentation will impact the forensic science community by serving to increase scientific knowledge of new technologies and methods available to the forensic community for the protection of human biological specimens. It will also attempt to advance the state of conservation techniques by proposing alternative methods to the usage of actual human specimens in forensic research.

Many collections of human skeletal remains are exhibiting evidence of wear and tear from years of handling by researchers. Damage to often fragile specimens by repeated analyses from calipers has increased the likelihood of biased data and conclusions. Additionally, evidentiary concerns by law enforcement agencies regarding the documentation and preservation critical physical evidence call for conservation techniques that protect the specimen while providing an anatomically accurate alternative to the actual remains, particularly for use in the courtroom.[1] The goal of this study was to document the process of developing an anatomically accurate virtual and physical reproduction of a human skull that could be used for legal, educational, and research purposes.

In this study, a complete Caucasian male skull with intact dentition was utilized for computed tomography (CT) scanning, three dimensional (3D) computer modeling, 3D laser scanning, rapid prototyping, and casting. Using protocols developed and presented previously by the researchers,[2] the skull was 3D modeled and specific regions of interest were highlighted (ex: individual teeth and selected cranial bones) in order to maintain fine anatomical detail. Visualization and texturing of the final 3D model was completed in a 3D rendering software package. After the completion of the virtual 3D skull, stereolithographic models were exported for rapid prototyping using two different commercially available printers.[3] The actual specimen was 3D surface laser scanned and then shipped to a bone-casting expert for a proprietary reproduction process. After a museum quality replica cast was produced, the virtual and physical models (rapid prototypes and France cast) were compared quantitatively and visually to the actual specimen.

Using a binocular surgical microscope with a micrometer precision measurement reticle, the physical replicas were inspected at all regions of interests for the quantification of anatomical features. The replicas were also examined in the areas in which a high level of anatomical detail is required for biological profile analysis, such as suture lines and dental features. The results of this study suggest that accurate anatomical replicas can be made both virtually and physically to substitute for handling of actual osteological specimens. It was discovered that all of the imaging techniques were all useful tools, and that they were useful in somewhat different ways for different applications.

The benefit of this study is that there is an open discussion of the strengths and weaknesses at each stage of the invasive and noninvasive analyses, which will in turn increase the understanding and scope of forensic conservation. With both virtual and physical replicas, these resources can be used in court as visual aids for juries and also for teaching purposes in osteological labs.[1] The detailed replicas also address the need of existing osteological collections to preserve their materials for long-term display and study. Validated replicas such as those used in this study are providing a reliable alternative to the everyday use of actual osteological specimens.

Virtual Remains, Rapid Prototyping, Physical Evidence

G49 Investigation of Sharp Trauma by Postmortem Multi-Phase CT-Angiography

Silke Grabherr, MD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND; Francesco Doenz, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, SWITZERLAND; Sebastien de Froidmont, MD, University Center of Legal Medicine Lausanne-Geneva, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; Cristian Palmiere, MD, Centre Universitaire Romand de Médecine Légale, 21 rue du Bugnon, Lausanne, 1011, SWITZERLAND; Stefano Binaghi, MD, Service of Radiology, University Hospital Lausanne, Rue du Bugnon 46, Lausanne, CH-1011 Lausanne, SWITZERLAND; and Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND*

After attending this presentation, attendees will understand the advantages and limitations of investigating cases of sharp trauma by postmortem multiphase CT-angiography.

This presentation will impact the forensic science community by showing how the performance of a pre-autopsy postmortem CT-angiography can increase the quality of the medico-legal exam. It also shows the importance to complete the radiological exam by a conventional autopsy and the necessity to further develop this new approach.

While the performance of postmortem Multi-detector Computed Tomography (MDCT) has already become a routine investigation in some institutes of legal medicine, postmortem CT-angiography is still a field of research. At the University Center of Legal Medicine in Lausanne, a

standardized technique to perform this kind of exam has recently been developed and is already getting its way into daily routine. The so called multi-phase postmortem CT-angiography (MPMCTA) consists in the performance of a native (without contrast-agent injection) MDCT scan and at least three angiographic phases (arterial, venous, and dynamic phase). As a result of this technique, the vascular system of the head, thorax, and abdomen can be investigated in detail and in a minimally invasive way. Also the examination of soft tissue (musculature, subcutaneous tissue) is significantly increased.

The goal of the presented study was to investigate the performance of MPMCTA on cases of sharp trauma.

More than 170 medico-legal cases have been investigated by postmortem MDCT angiography. From this collective, cases with sharp trauma on which the standardized protocol of MPMCTA has been performed were selected. The findings obtained by native MDCT, postmortem CT-angiography and conventional autopsy have been compared. Additionally, the impact of the radiological findings on the final interpretation of these cases was explored.

Ten cases (six Suicides, four Homicides) were selected for this study. Subjects were primarily men (seven male, three female) and age varied from 17 to 64 years (mean age=37.7). Causes of death were mostly due to exsanguination and hemorrhagic choc (n= 6). Three persons died due to a cardiac tamponade and one victim, on whom the sharp trauma was combined with manual strangulation, died due to asphyxia. More than 75 lesions due to sharp trauma were described in the final autopsy reports (including radiological and autopsy findings). They consisted of 49 stab wounds, 26 cuts, and multiple scratches.

While native MDCT could only identify major injuries due to the presence of air in the soft tissue or due to bone lesions visible on the trajectory, the sensitivity of the radiological examination could be significantly increased by performing postmortem multi-phase computed tomography angiography (PMPCTA). Due to the enhancement of the injured soft tissues, trajectories of stab wounds and even superficial cuts could be rendered visible. The 3D-software of the CT-workstation permitted also different reconstructions that could be used to explain the lesions to medical laypersons and to plan the conventional autopsy. While in most of the cases, the depth of the injury could be measured easily, it was underestimated in some cases because smallest lesions were not visible in the radiological images (e.g., small impact on a vertebra, lesion of the pericardium). On the other hand, the radiological exam revealed vascular lesions that have been missed during the autopsy and could detect the exact source of bleeding. Such findings can be important and can even explain the cause of death (e.g., cardiac tamponade due to a small lesion of branches from coronary arteries).

The sensitivity of PMPCTA to detect mayor lesions (stab wounds, cuts) in the head, thorax, and abdomen was extremely high (100 %). The protocol of PMPCTA allows a complete opacification of the vascular system in these regions; however, the examination of the limbs is not included in the scanning protocol. Therefore, the opacification of the vessels in these regions is not regular and, until now, no standardized protocol exists for the limbs. In cases where their vessels were perfused, the lesions could be identified. Without an optimal perfusion, the radiological exam failed to visualize the morphology of the lesion.

In conclusion, postmortem CT-angiography using the protocol of MPMCTA is a powerful tool to investigate lesions due to sharp trauma localized in the head, thorax and abdomen. The detection of the exact source of bleeding represents an advantage over conventional autopsy. However, this exam should be followed by a conventional autopsy, as smallest lesions could be overseen and the depth of stab wounds can be underestimated. In order to investigate also the limbs, standardized protocols have to be developed that permit the filling of their vascular system.

Postmortem CT, Sharp Trauma, Forensic Imaging

G50 Postmortem Multi-Phase Computed Tomography Angiography: Investigation of "Hemodynamic" Perfusion Parameters and Their Utility in Forensic Cases

Alain Bass, BS, HECVSante, Beaumont 21, Lausanne, 1011, SWITZERLAND; Alexandre Dominguez, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaument 21, Lausanne, SWITZERLAND; Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; and Silke Grabherr, MD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND*

After attending this presentation, attendees will understand the interest of monitoring the "hemodynamic" pressures while performing a postmortem multi-phase computed tomography angiography in order to optimize the vascular filling of the corpse.

This presentation will impact the forensic science community by showing the significance of monitoring the "hemodynamic" perfusion pressures in order to understand their relation to parameters of the examined body and for developing an optimized injection protocol for the perfusion.

Since November 2008, the University Center of Legal Medicine performs postmortem Multi-detector Computed Tomography (MDCT) angiography on autopsy cases in order to complete the autopsy report by a detailed investigation of the vascular system. The recently developed method of Postmortem multi-phase computed tomography angiography (PMPCTA) permits to use a standardized protocol and includes the perfusion of the body with an oily contrast-agent mixed with paraffin oil using a specialized perfusion device. This method reveals its advantages in cases showing vascular lesions or abnormalities. Until now, the attention was focused on the obtained images for the forensic radiological interpretation. The quality of the radiological interpretation depends, among others, on the filling of the vascular system that remains in some cases incomplete, especially concerning the venous system of the head.

The present study focuses on the examination of the perfusion parameters. Employing the PMPCTA protocol, standardized injections parameters for each of the three phases (arterial, venous, and dynamic) are used. During each phase, the hemodynamic pressures can be measured. This study shows interest of investigating these pressure data, in order to determine: (1) if they are related to the filling of the vascular system; (2) if they could be useful to optimize the angio-CT perfusion protocol; and, (3) if they are related to the cause of death.

In order to answer these questions, the data of 64 PMPCTAs, realized between February and November 2010, were analyzed. They included especially the measured perfusion pressures (visual observation of pressure indicator on the perfusion device) during the three different phases, the filling of the venous system, the radiological interpretation of the images and the cause of the death determined by the forensic pathologist. In order to compare the filling of the vascular system, a grading system was used, assessing the opacification of the venous system of the head. The radiological diagnosis was extracted from the radiological report, performed jointly between a forensic pathologist trained in forensic imaging and at least one radiologist, specialized in vascular imaging. Cause of death was determined by the forensic pathologists in charge of the cases after conventional autopsy and additional analyses (histology, toxicology, neuropathology, etc.).

The different data was reported on a computer spread sheet for statistical analysis.

The comparison of the hemodynamic data revealed a relation between the pressure and the filling of the vascular system. Therefore, the necessity of exploring the possibility of performing the acquisitions with specific "intelligent" injection protocols seems evident. It was hypothesized that better filling could be reached by developing a new software for the perfusion device that adjust in real time the injection parameters in conjunction with the measured pressures instead of using fixed injection parameters. Concerning

the relation between perfusion pressures and the cause of death, we noticed an indirect influence that could be observed in a better filling of the vascular system in persons who died without long periods of agony (cases of polytrauma, instant death, etc.).

The measurements of the pressure during the injection for the different phases lead to a software upgrade of the perfusion device which will include the automatic measure of pressure values and their backup. Additionally, new injection protocols could be calculated by the perfusion device depending on the perfusion pressure measured in the body.

In conclusion, our study showed that the measured perfusion data are related to the filling of the vascular system and indirectly to the cause of death. The development and implementation of intelligent perfusion software, based on real-time pressure monitoring, will be the next step to optimize the vascular filling during postmortem multi-phase computed tomography angiography.

Postmortem CT-Angiography, Vascular Perfusion, Pressures Monitoring

G51 Postmortem Vertebral Arteriography in Forensic Investigations

Philip J. Berran, JD, MD, Howard T. Harcke, MD, and Edward L. Mazuchowski, MD, PhD, Armed Forces Medical Examiner System, 116 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will understand the techniques and applications of postmortem vertebral arteriography using computed tomography (CT) as a supplement to the forensic autopsy.

This presentation will impact the forensic science community by detailing methods to evaluate verterbral artery injury and pathology using CT that may obviate the need for tedious dissection and/or removal of the neck block.

Pathology and injury to the vertebral arteries are often difficult to detect and document at autopsy. Traditionally, the vertebral arteries are injected with a radio-opaque dye and a radiograph taken. Extravasation of contrast indicates a defect in the artery wall and the area is further explored with either *in situ* or en bloc dissection. A limitation of this technique is the inability to view the artery and surrounding structures in three dimensions. Using CT in place of radiography overcomes this limitation.

A retrospective review of a series of 14 postmortem vertebral arteriograms in 10 individuals was conducted to clarify the optimal technique for antegrade and retrograde vertebral arteriography using CT. Location and method of vascular access, injection volume, and timing were varied. Arteriography was incorporated into the autopsy protocol and findings correlated with the procedure.

In six of 14 studies the vertebral artery injections were done retrograde following removal of the calvarium and brain. Cannulation of each intracranial portion of the vertebral arteries was done with a 5F angiocatheter. Injection volumes of 15-30 cc were used. All six injections were diagnostic. There were five intact arteries and one lacerated artery. In 8 of 14 studies injections were done antegrade following cannulation of the vertebral artery at its take-off in the neck. Both 5F catheters and embalming cannulas were used with some injections made before organ block removal and some made after block removal. Both techniques were satisfactory. All antegrade injections were performed before opening the cranium. A single injection of one vertebral artery with 60cc filled the contralateral vertebral artery and segments of both internal carotid arteries. Bilateral vertebral injections of 30cc achieved better generalized filling. There were four lacerations and five intact vertebral arteries. In one case retrograde filling of the left vertebral following right vertebral injection showed a left vertebral laceration.

Successful postmortem vertebral arteriorgraphy can be done during autopsy using an antegrade or retrograde approach. The antegrade technique done before opening the cranium is preferred since it offers the advantage of perfusing the Circle of Willis. Incorporating vertebral arteriography with CT into the autopsy protocol aids assessment and may negate the need for an intricate dissection of the vessels.

Postmortem CT, Vertebral Artery, Arteriography

G52 Postmortem Computed Tomography (CT): A Tool for Assessment of Emergency Medical Intervention

Howard T. Harcke, MD, Philip J. Berran, JD, MD, and Edward L. Mazuchowski, MD, PhD, Armed Forces Medical Examiner System, 116 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will be able to explain the value of postmortem CT in assessing medical devices used by first responders to emergency events.

This presentation will impact the forensic science community by demonstrating that postmortem CT affords the opportunity to evaluate some aspects of the use of emergency medical devices. These observations can improve design and application of devices and the training of first responders.

Medical examiners are increasingly using postmortem CT as a preliminary to autopsy. The Armed Forces Medical Examiner System (AFMES) has done this since 2004 and learned that CT can yield helpful information about the use of medical equipment by first responders in the attempt to save a life. However, this requires that resuscitative equipment not be removed from the body until after imaging.

Intraosseous intravenous devices (e.g., tibial, sternal, humeral), cricothyroidotomy devices, thoracentesis needles, and supraglottic airways have been studied by the AFMES in conjunction with autopsy. The CT images non-invasively show precise location of devices in areas not routinely incorporated into the internal examination. Placement of tibial devices in 44 cases has been 95% successful, sternal device placement in 98 cases has been 80% successful and humeral device placement in 24 cases was 83% successful. Recommended length of thoracentesis needles was changed from 5cm to 8cm. It should be noted that military first responders are typically in environments that differ appreciably from civilian emergency situations, results of intervention attempts may therefore differ. Feedback communication of autopsy observations to the military medical community has been used to improve design of devices and upgrade training in device use.

It is important to point out that the postmortem observations do not assess function of a device with regard to its effectiveness in resuscitation or stabilization because the conditions and circumstances surrounding placement of the devices is not always known. Also for any data gathered from postmortem CT consideration must be given to the possibility a device position may have changed during transport and handling of the body.

Attention to details of emergency medical interventions seen on postmortem CT can result in observations that aid first responders in assessing equipment and procedures used in pre-hospital emergency care.

Postmortem CT, Emergency Medical Treatment, First Responders

G53 Development and Validity of a Postmortem Radiological Alteration Index: The RA-Index

Coraline Egger, MD, University Center of Legal Medicine, Lausanne – Geneva, University of Geneva, Rue Michel-Servet 1, Genève, CH - 1211, SWITZERLAND; Paul Vaucher, MSc, University Center of Legal Medicine, Lausanne – Geneva, University of Geneva, Rue Michel-Servet 1, Geneva, CH - 1211, SWITZERLAND; Francesco Doenz, MD, University Hospital Lausanne, Department of Diagnostic and Interventional Radiology, Rue du Bugnon 46, Lausanne, CH - 1011, SWITZERLAND; Cristian Palmiere, MD, University Center of Legal Medicine, Lausanne – Geneva, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, CH - 1011, SWITZERLAND; Patrice Mangin, MD, PhD, University Center of Legal Medicine, Lausanne – Geneva, University of Geneva, Rue Michel-Servet 1, Geneva, CH - 1211, SWITZERLAND; and Silke Grabherr, MD, University Center of Legal Medicine, Lausanne – Geneva, University of Lausanne, Rue du Bugnon 21, Lausanne, CH - 1011, SWITZERLAND*

After attending this presentation, attendees will understand that it is possible to quantify the state of alteration of bodies using postmortem multidetector computed tomography (MDCT) imaging and will learn how to use the new Radiological Alteration-Index.

This presentation will impact the forensic science community by showing that presence of gas from only seven sites is a valid mean to measure the distribution of gas in the entire body. The RA-index is a rapid and easy to use instrument to indicate radiologically the alteration state of the body, which remains reliable for non-experienced users and valid for non-traumatically and traumatically deceased.

Postmortem imaging examinations, performed before autopsy, are more and more used in forensic medicine. Multidetector Computed Tomography (MDCT) is the most often used technique, and preferred to MRI for a number of reasons, including the rapid achievement of the examination, its relatively easy handling and its lower cost. Furthermore, the spatial resolution and high sensitivity of MDCT allows the detection of small collections of gas in bodies which is relevant because such small quantity of gas cannot be detected during standard autopsy techniques.

When investigating cause of death, it is fundamental to be able to distinguish gas formed during postmortem cadaveric alteration and gas due to a vital air embolism. It has previously been shown that cadaveric alteration and gas formation can thus be quantified. This procedure is nevertheless time consuming and requires qualified personnel. There is a need to simplify procedures to detect gas and make them accessible to non-trained physicians.

The objective of the present study was therefore to develop an easy to use radiological alteration index (the RA-index) adapted for cases seen in forensic medicine and verify whether this index can reliably be measured by non-experienced forensic pathologists.

The RA-index, ranging from 0 to 100, quantifies the state of cadaveric alteration analysing only seven sites. It was derived from postmortem MDCT data from 119 non-traumatically deceased people. One hundred additional scanned bodies (including 50% traumatically deceased) were retrospectively examined by two independent observers. Presence of gas on 82 sites was assessed by a radiologist, whereas a forensic pathologist only investigated the seven sites used for the RA-index.

The RA-index was derived using seven sites that were shown to be highly predictive of the overall presence of gas in all 82 sites (R2=0.979 in the derivation set, and R2=0.843 in the validation set). From the 119 cases analyzed in the derivation set, 25 had a RA-index of 0, 64 had a RA-index of 15 or less (no or slight alteration), 18 had a RA-index of over 30 (heart cavity full of gas), and six over 80 (invasion of gas to all tissues). Even if assessment semi-quantitative evaluation of gas presence in each site showed moderate reliability (Cohen's kappa ranged from 0.406 to 0.781), the overall RA-index was very reliable ($ICC_{2,1}$ = 0.945; CI95% 0.919 to 0.962).

This study derivates and validates an index quantifying the state of cadaveric alteration of bodies exclusively based on postmortem MDCT imaging, and ascertains the reliability of the results obtained by a radiologist and a forensic pathologist with no experience in postmortem imaging. Furthermore, the results were extended to traumatic deaths. Indeed, the seven selected sites for calculating the RA-index are sufficiently distributed all over the body to overcome the bias due to gas expansion from open wounds. Therefore, the RA-index is also applicable in cases of trauma such as gunshot or sharp trauma.

The RA-index, presented in this study, is the first approach that allows quantifying the alteration in an objective way. It can be used to indicate the state of the examined body for radiological reports and cases included in different research studies. This means that the selection of cases for different studies could depend on the RA-index and some diagnosis such as the presence of gas embolism should only be made in cases showing a low RA-index. The RA-index can also be important to decide if a body should undergo further examinations such as postmortem CT-angiography.

Thanatology, Postmortem MDCT, Putrefaction Gas Index

G54 Biochemical Characteristics of Diffuse Axonal Injury by Fourier Transform Infrared Micro-Spectroscopy

Tiantong Yang, MD, Key Laboratory of Evidence Science, 116, Lugu Road, Shijingshan District, Beijing 100040, China, Beijing, ROC*

After attending this presentation, attendees will learn a new method of Fourier transform infrared (FTIR) Micro-spectroscopy to study the diffuse axonal injury.

This presentation will impact the forensic science community by providing participants with a better understanding of the biochemical and histopathological characteristics of diffuse axonal injury.

Fourier transform infrared (FTIR) imaging and microspectroscopy have been extensively applied in the identification and investigation of both healthy and diseased tissues. FTIR imaging can be used to determine the biodistribution of several molecules of interest (carbohydrates, lipids, proteins) for tissue analysis, without the need for prior staining of these tissues. Molecular structure data, such as protein secondary structure and collagen triple helix exhibits, can also be obtained from the same analysis. Thus, several histopathological lesions, for example diffuse axonal injury, can be identified from FTIR analyzed tissue images, the latter which can allow for more accurate discrimination between healthy tissues and pathological lesions.

The goal of the study was to assess whether Fourier transform infrared spectrometry (FTIR) micro-spectroscopy could produce distinct spectral information on biochemical characteristics of diffuse axonal injury (DAI) and to set them as molecular markers to diagnose atypical DAI.

Method: DAI was produced by rotational acceleration in rats and rabbits. Paraffin-embedded brain tissues from rats with head trauma were studied by hematoxylin and eosin staining, immunohistochemistry (please specify the staining), silver staining, and FTIR micro-spectroscopy. The characteristics of DAI were analyzed morphologically and molecularly. Biochemical parameters of DAI in rabbits' brain tissues were also conducted by using a chemical FTIR mapping.

Results: The most relevant bands identified were the amide A, B, I, and, II showing crucial spectral differences between apparent normal region and DAI region, including the peak position blue shift and the increased intensity of DAI. Comparing to single spectral band, the I1650/I1550 ratio was increased and rationally used as a molecular marker for diagnosing DAI. These novel preliminary findings supported further exploration of FTIR molecular profiling in clinical or forensic study, and were in accordance with histopathology.

In rabbits study, the N–H stretch (3290 cm^{-1}) of amide A, the CH_3 symmetric stretch of mainly proteins (2873cm^{-1}), fibrocollagenous tissues (1638 cm^{-1}), nucleic acids and phospholipids C-O stretch represented by PO_2^- symmetric stretch (1081 cm^{-1})were tested. All of the above represent changes of proteins, collagens, nucleic acids and phosphonolipid. Red, green, and their gradient color of the Infrared spectra (FTIR-mapping) represented the IR absorptive intensity of the tested microstructure. Red indicated strong

absorption and thus means a greater quantity of material is present at this peak; Green means a weak absorption, indicating of little quantity of material at the peak. The infrared spectra of the above four vibration peaks were different even if the infrared spectrum was consistent with the result of HE staining. Hence, each vibration peak represented a different chemical structure. With the help of different peaks of the infrared spectra, the extent a certain chemical substance that is involved in the pathological change can be explored, to reveal the pathophysiological process. The results of this study showed that N-H stretching (3290 cm^{-1}) of amide A, CH_3 symmetric stretch of mainly proteins (2873 cm^{-1}), and nucleic acids and phospholipids C-O stretch represented by PO_2^- symmetric stretch (1081 cm^{-1}), all widely participated in the diffuse axonal injury. The red region is mostly consistent with diffuse axonal injury lesion. The approaches described in this manuscript significantly enhance the rate and quality of spectroscopic analyses of tissue specimens, allowing realization of the statistical sampling and further numerical analysis to explore associations between molecular chemical changes and pathologic information. This imaging method also provides accurate information about the exact distribution of each component in the composite material, which is crucial for understanding its performance when in contact with pathologic processes.

In summary, it is proposed that FTIR be used as a new tool integrating both molecular and histopathological assessments to investigate the degree of biochemical and pathological characteristics of DAI diffuse axonal injury.

Fourier Transform Infrared (FTIR) Micro-Spectrosco, Histopathology, Diffuse Axonal Injury

G55 Multislice Computed Tomography in Two Fatal Stab Wound Cases With Knife *In Situ*

Antonio Nieddu, MD, Department of Forensic Pathology, University of Sassari,, Sassari, ITALY; Stefano D Errico, MD, PhD, Department of Forensic Pathology, University of Foggia, viale degli Aviatori, Foggia, 71100, ITALY; Francesco Meloni, MD, Department of Radiology, ASLNU3, Nuoro, ITALY; and Gabriela Perilli, MD, and Cristoforo Pomara, MD, PhD, Department of Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY*

The goal of this presentation is to present two fatal cases with multiple sharp injuries in which MSCT was performed before autopsy. The relevance of imaging contribute in forensic analysis in the assessment of penetrating injuries and sharp trauma casualties facilitating autopsy planning and increasing the overall detection frequency of traumatic findings is underlined and surprising images collected with knife in situ makes the case peculiar

This presentation will impact the forensic science community by demonstrating the relevance of MSCT as a valuable tool in detecting lethal stab and incised wounds and their course through the body and the hereby injured structures. Postmortem imaging does not replace autopsy, but rather aims at providing additional information for a more carefully planning of autopsy (virtuous autopsy). The autopsy can be improved upon but not replaced. Description of macroscopic features like margins, edges remain as indispensable for a correct framing of the death.

Fatal injuries due to sharp trauma are common in everyday forensic practice, be it in a homicidal, a suicidal, or in an accidental setting. The main common denominator of the injury-inflicting objects in sharp trauma is that they can pierce and slice the human body and thus cause internal damage. Death due to this harming of the body's integrity is manifold; exsanguination by injury of blood vessels is the most frequently encountered form. In the assessment of sharp trauma, issues such as the wound morphology, which may help to determine the type of weapon involved, the number, and location of the injuries, the wound channel, the injuries inflicted to the soft tissues and the skeleton and viscera in order to undertake a reasonable incident reconstruction. Traditional forensic autoptic approach provided by dissecting layer by layer has been generally integrated involving X-ray to detect gross injuries of bones or to detect foreign bodies but it reduces a three-dimensional corpse to a two-dimensional image, thus complicating reconstructive attempts. With the invention of spiral computer tomographs, two-dimensional reconstructions of radiological images in every possible plane or even three-dimensional reconstructions are possible. These multislice computed tomographs (MSCT), which have become everyday clinical standard, have been implemented in forensic pathology with promising results also in the assessment of sharp injuries. Two fatal cases with multiple sharp injuries are presented; MSCT was performed before autopsy in both.

Case 1: A 50-year-old man went to the local military police reporting to have killed his wife after a quarrel and that the cadaver was outside in the car. The cadaver of a 52-year-old woman was found sitting normally in the front passenger side of the car, wearing clothes. A knife handle came out from the left thorax in the precordial area. The prosecuter was immediately alerted and a crime scene investigation was performed by forensic pathology crew. Bloody stains were collected from the car. The knife had a plastic handle with a pointed 16.5 cm long single edge blade 74 gr in weight. MSCT scan was performed before autopsy. A complete postmortem examination was performed two days after death. Multiple stab wounds were recorded in the neck (four), in the precordial area (one) where the knife was found, in the left thorax (one), and in the abdomen (five). Defense wounds of palm of hands were also recorded. Gross examination of the head was unremarkable except for a mild cerebral edema. Neck wounds went deep into the muscle layers except for two in which cartilage of trachea and body of the 7th cervical vertebra were interested. The wound in the precordial area went deep into the pericardium and the anterior wall of the right ventricle stopping in correspondence of the left atria where a small laceration of the wall was observed. Abdominal injuries included hepatic lacerations and wounds to the anterior and posterior wall of the stomach. Histological examination with H&E stain revealed mild cerebral edema and acute emphysema was also recorded at microscopic examination of lungs. Samples of heart wounds were collected revealing typical aspect of cutting edge lesions. Intraparenchimal hepatic hemorrhages were also observed. Vessels were generally poor of blood.

Case 2: A 44-year-old man affected from psychiatric disorder attempted suicide by means of multiple stab wounds inflicted to the thorax and abdomen and incised wounds to the flexor surface of wrists, bilaterally. He was found unconscious by rescuers and immediately taken to the local hospital; resuscitation maneuvers were unsuccessful. At external examination multiple stab wounds to thorax (seven) and abdomen (seven) were recorded. In the precordial area the handle of the knife was sticking out and left *in situ*. Multiple superficial cuts observed in the flexor surface of the wrists, bilaterally were interpreted as hesitation marks. An incised wound through the muscular layer of the left arm was also detected lacerating radial artery. MSCT was performed before autopsy in order to study the channel of injuries in the thoracic and abdominal cavities. The corpse was placed in the supine position on the CT-table for the non-contrast CT. Non-contrast CT was performed with the knife *in situ*. Two- and three-dimensional (2D and 3D) reconstructions were calculated and assessed by both, a radiologist and a forensic pathologist experienced in postmortem imaging. The non-contrast postmortem CT of the thorax displayed position of the knife through the sternum and surprising images were collected. There was a small gas collection in the subcutaneous fat, at the level of the entry wound. The blade of the knife passed through the sternum. The knife was plastic handle with a pointed 9.8cm long single edge blade 65gr in weight. Autopsy was performed the day after death. Mild hemorrhagic infiltration of subcutaneous fat was observed in correspondence of the thoracic and abdominal wounds; thoracic wall examination was unremarkable except for sternum. No blood was collected in the thoracic and abdominal cavities. Pericardium was also unremarkable. Heart was normal in size and volume, with conical shape, as well as lungs except for a mild edema, with white foam on the main bronchi. Abdominal viscera examination was unremarkable. A complete laceration of left radial artery was recorded. A complete histopathological study with H&E stain was performed. Toxicological examination was negative for substances of abuse. Hemorragic shock from laceration of the left radial artery was indicated as the cause of death.

Experience with sharp injuries demonstrate the relevance of MSCT as a valuable tool in detecting lethal stab and incised wounds and their course

through the body and the hereby injured structures. Postmortem imaging does not replace autopsy, but rather aims at providing additional information for a more carefully planning of autopsy (virtuous autopsy). The autopsy can be improved upon but not replaced. Description of macroscopic features like margins, edges still remain as indispensable for a correct framing of the death.

Sharp Injuries, MSCT, Autopsy

G56 A New Tool for Coding and Interpreting Injuries in Fatal Airplane Crashes

Yves Schuliar, MD, PhD, IRCGN, 1 Boulevard, Theophile Sueur, Rosny Sous Bois, 93 110, FRANCE; Emmanuel Lagarde, PhD, ISPED - Inserm U897, Injury Prevention and Control, 146, Rue Léo-Saignat - Case 11, Bordeaux, 33000, FRANCE; Stéphane Chapenoire, MD, PhD, CTGN, IRCGN 1 Boulevard T Sueur, Rosny Sous Bois, 93110, FRANCE; and Alain Miras, MD, PhD, ISPED - Inserm U897, Injury Prevention and Control, 146, Rue Léo-Saignat - Case 11, Bordeaux, 33000, FRANCE*

After attending this presentation, attendees will understand the importance for forensic pathologists, investigators, and safety experts to have at their disposal the tools to collect and interpret injuries in case of an aircraft accident. The presented tool will be used in a real case to illustrate its possibilities.

This presentation will impact the forensic science community by proposing a new coding system and software to record, code, and analyze injuries sustained in aircraft crashes.

Unfortunately, every year in the world, more than 500 passengers die in air disasters involving commercial airplanes. There are numerous questions to be answered following an aircraft accident: What caused the accident? Who was involved? What were the causes of deaths or mechanisms of injuries? What can be done to prevent it?

In such cases, forensic pathologists are facing pivotal challenges, first to identify the victims but also to perform injury analysis in order to reconstruct the sequence of events and to estimate human-machine interactions. Crash reconstruction is generally obtained using data from the flight recorder but these are often supplemented by physical evidence coming from the site of impact especially the damage of the different parts of the airplane but also from documented injuries pattern linked to position of the victims in the airplane. Detailed records of injuries when many victims are involved are; however, sometimes overlooked with the priority being placed on identification procedures. This proved to be unfortunate, in particular when flight recorders could not be recovered, but also to issue recommendation in the area of injury prevention.

The objectives of this presentation are to describe a new tool to facilitate this work. A coding system has been derived from the AIS (Abbreviated Injury Score), which was developed from a nomenclature dedicated to research and statistics for trauma epidemiology. Numerous modifications and additions were necessary as the AIS system was developed to predict survival from injury severity while the goal is to code lesions that can be observed on corpses. Severity scores were replaced by scores corresponding to the amount of energy that caused the trauma (ECT).

In a second step, a software was developed to compute summary variables that will be further related to the position (assigned seat) of each of the victims in the airplane. Three types of variables are available:

- Variables representing the number, potentially weighted, of injuries coming from a group defined by the user (for instance, number of lesions of the pelvis).
- Variables representing a maximum ECT score among a group of injuries defined by the user (for instance, maximum ECT score for injuries of the upper limbs).
- Variables representing a sum, potentially weighted, of the ECT scores of a group of lesions defined by the user (for instance the sum of the ECT scores for all the coded lesions of the head).

When relevant, each score can take into account the laterality of a lesion.

A real case will illustrate the use of the coding system and software and the interest to collect and to interpret the pattern of injuries as a consequence of the circumstances of the air crash.

Air Crash, Injury, Coding

G57 Jay Dix Memorial Bonus Day

Michael A. Graham, MD, Saint Louis University School of Medicine, Division of Forensic Pathology, 3556 Caroline, Room C-305, St. Louis, MO 63104; Randy L. Hanzlick, MD*, Fulton County Medical Examiner Center, 430 Pryor Street, SW, Atlanta, GA 30312; Joseph A. Prahlow, MD*, South Bend Medical Foundation, 530 North Lafayette Boulevard, South Bend, IN 46601; Joyce L. DeJong, DO*, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; and Jonathan A. Hayes, MD*, Office of the Chief Medical Examiner New York City, 520 1st Avenue, New York, NY 10016*

After attending this presentation, attendees will learn how and why deaths temporally related to custody; related to sports and recreational activities; related to the environment; and, related to substance abuse occur. Attendees will learn a systematic approach to investigate these types of deaths. Attendees will learn about rare causes of death and how to evaluate difficult cases.

This presentation will impact the forensic science community by providing a comprehensive review of what causes and contributes to deaths involving custody, the environment, substance abuse, sports and recreation, and rare and difficult to evaluate entities. Attendees' knowledge in these areas will be expanded and focused and attendees will better be able to systematically evaluate these types of deaths when encountered in the attendees' daily practices.

A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual series of lectures is intended to provide the non-forensic pathologist forensic scientist a comprehensive basic review of selected topics in forensic pathology in order to increase familiarity and understanding and enhance inter-discipline communication.

This year's lecturers will discuss deaths related to custody, the environment, sports and recreation, less common drugs of abuse and rare and difficult entities.

Although there are myriad diseases and injuries that can cause sudden unexpected deaths, most of these are familiar to experienced death investigators and fall into familiar scenarios. However, there are a number of rare entities that cause death and a number of entities that rarely cause death. If these entities are not properly recognized and assessed, deaths in which they are involved may be erroneously certified. In other deaths, a variety of factors may lead to difficulty in case assessment and/or certification. This lecture will comprehensively and systematically delineate and discuss rare entities leading to death, deaths due to entities that rarely cause death and "hard cases."

There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are related to the environment. To understand and appropriately assess these deaths, the normal relationship between a person and the environment must be considered. In addition, physiologic changes that occur in response to changes in the environment must be recognized. Diseases, injuries and/or drugs (therapeutic and recreational) and alcohol can play significant roles in the interaction between a person and the environment. This lecture will comprehensively review human and environmental factors that potentially affect a person's ability to survive under a variety of environmental conditions. What constitutes "hostile" environmental conditions, how humans attempt to adapt to changes in the environment and what prevents successful adaptation to changing environmental conditions will be discussed. There will be discussion of how humans get into hostile environments, how they attempt to adapt to these conditions and what factors prevent adaptation and/or escape from inhospitable environments. Deaths caused or contributed to by cold, heat, altitude, drowning, animals and lightning will be among the topics discussed.

There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to participating in and, occasionally, while being a spectator at sporting or other recreational activities. Understanding these deaths requires understanding of the physical requirements to perform particular activities, susceptibility of particular diseases to stresses associated with particular activities, effects of various chemical and/or biological agents that may be taken to enhance performance and physical injuries associated with particular recreational activities. This lecture will provide a comprehensive review of these issues in the context of investigating deaths that occur in relation to sports/recreational events. Understanding factors that are involved in deaths occurring in these circumstances also helps in instituting appropriate safety measures to protect participants and spectators.

There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to custody. The custody process can be divided into several stages—pre-custody, pre-incarceration and incarceration. Particular diseases and injuries tend to occur and/or become manifest during each of these stages. This lecture will systematically review what diseases and injuries cause/contribute to death in the custody process, how they affect physiology and anatomy, when they are typically operative and how they are manifest. Recognizing what occurs during the various stages of custody allows a systematic approach to assessing deaths that occur during the custody process. This lecture will review the conceptual and practical aspects of understanding and investigating custody-related deaths.

The last three decades have seen an impressive expansion in the range of drugs available for abuse. The psychedelic revolution of the 60's spilled over into the 70's and 80's with the advent of "designer drugs" like Ecstasy (MDMA), joined in the 90's and 00's by the increased abuse of psychoactive drugs like ketamine and GHB, typically in nightclub and rave settings. A second pattern of expanded drug use involves increase in consumption in rural areas poorly served by the traditional distribution network for cocaine and heroin. The heartland of America has seen explosive growth in the use of methamphetamine, whether prescribed, homegrown or cartel-distributed, and in diversion and abuse of prescription medication. These other substances are commonly used in characteristic scenarios and have somewhat stereotypical death scenarios. Recognition of the patterns of abuse of these agents helps in assessing the role, if any, of these agents in particular deaths. This lecture will provide a comprehensive review of both increasingly and infrequently encountered agents in the context of investigating deaths.

Jay Dix, Death Investigation, Forensic Pathology

G58 Explosion Scene in Sri Lanka

Pradeep Rohan Ruwanpura, MD, Legal Medicine Unit, 4th Floor, Kingston Mall, 12, Ocean Boulevard, Kingston, JAMAICA, WEST INDIES*

After attending this presentation attednees will gain knowledge about specific injury patterns pertinent to suicide bomber related explosion scenes. It further studies two different types of suicidal bomb explosions compared to other circumstances and touches on the clinical aspects of victim management.

This presentation will impact the forensic science community by highlighting extend of damage and complexness of investigations when close target explosion attacks are made by using relatively smaller quantity of explosive substance in a form of a "body bomb."

In our days, explosives manufacturing has found rapid advancement and available in mass scales to become a weapon of choice in many parts of the world for military, commercial, criminal, and organized terror activities due the ease in handling, storage, and transportation; need in lesser quantity to cause devastating effects; simplicity of detonating mechanisms, etc. Injuries due to high explosive devices were often seen in Sri Lanka during past two decades, especially during the period from 1995 to 1997 and from 2004 to 2008 due to escalations of civil conflict. The suicide bomber became a hallmark of the Srilankan explosion scene. Two categories of suicide bombers have been observed: "body bomb" which may be described as a person with high explosive device attached to his body in different forms of attire including that of a pregnant woman; and, "Carried bomb" using other movable device, explosive effects of which had distinguishably reflected in the overall injury pattern.

There have been at least 125 attacks on civilian and military targets since 1986. The incidents have predominantly taken place in the capital city and autopsies on most of the cases were performed at the Office of the Judicial Medical Officer in Colombo. The findings of autopsy examinations, scene examination, and information gathered from the police sources and evidence given in the subsequent Court proceedings have been used for this study. The number of victims was excluded from the study due to unavailability of details of autopsy examinations conducted at different places. The present study is mostly emphasized on qualitative comparison of injury patterns with six principal types of explosive injuries described in the literature.

Analysis of injury patterns observed in the suicide bombers and the victims of these incidents revealed characteristic features of medico-legal and scientific importance. The following classification of explosive injuries is found to be more applicable to the local explosive scene, especially in the cases of individual suicidal bomb attacks: (a) a suicide bomber; (b) combined effect injuries including total disruption; (c) blast wave injuries; (d) burns; (e) injuries due to flying missiles; and, (f) circumstantial effects. The absence of shrapnel wounds, severe disruption of the trunk, and extensive burns of the transected body margin and presence of a cyanide capsule made a suicide bomber clearly distinguishable from other victims. The injury pattern of the victims was modified by the effects of the surroundings and the distance from the centre of explosion.

The recognition of the above injury patterns and their bodily effects found to be important in crime-scene investigations, subsequent legal proceedings, and organization of preventive measures. The effects of the modern vehicles with impact resistant desings on the gravity of injuries have also been considered.

Explosion Injuries, Suicide Bomber, Injury Pattern

G59 Stab Wounds and Drowning - A Fatal Combination

Alfredo E. Walker, MBBS, The Ottawa Hospital, Department of Anatomical Pathology, 501 Smyth Road, Ottawa, ON K1H 8L6, CANADA*

After attending this presentation, attendees will: (1) be able to state the percentage of cases in which more than one modality of fatal injury is used to kill; (2) recall the percentage of cases of homicide by stabbing; (3) recall the number of cases of homicide by drowning; (4) be able to quote the literature on the number of reported cases of death by drowning after infliction of stab wounds; (5) appreciate a case of homicidal drowning after the infliction of stab wounds of the chest; (6) review the pathological features of classical drowning; and, (7) review the utility of comparative diatom analysis as an ancillary investigation in cases of drowning and determine its appropriateness as an ancillary investigation.

This presentation will impact the forensic science community by showing how the use of more than one modality of fatal injury in homicides sometimes occurs. It is rare in forensic practice to have death from drowning following multiple stab wounds of the body, especially with penetrating stab wounds of the chest. An interesting case of homicide is presented in which death by drowning in an environmental watercourse occurs after an attack with a knife in which multiple penetrating stab wounds of the chest are sustained. This case is presented due to its rarity and to revisit the utility of the comparative diatom analysis as an appropriate and available ancillary investigation in cases of suspected drowning.

The use of more than one modality of fatal injury in homicides sometimes occurs. It is rare in forensic practice to have a death from drowning following multiple stab wounds of the body, especially with penetrating stab wounds of the chest.

An interesting case of homicide is presented in which death by drowning in an environmental water course occurred after an attack with a knife in which multiple penetrating stab wounds of the chest are sustained. This case is presented due to its rarity of presentation and to revisit the utility of comparative diatom analysis (Diatom Test) as an appropriate and available ancillary investigation in cases of suspected drowning.

A 17-year-old single mother was missing for two days. Her body was recovered from a canal in a fully clothed state with multiple stab and incised wounds. Investigations revealed that she was lured to the secluded area via text messages and phone calls sent by both her present boyfriend and ex-boyfriend. External examination at postmortem identified multiple stab wounds with four penetrating stab wounds of the chest and multiple defensive stab and incised wounds of the upper limbs. Internal examination revealed pale, hyperinflated lungs that overlapped in the anterior midline with no evidence of collapse from haemo/pneumothorax. There was stab wound injury of the lung and a small volume of residual blood within the right pleural cavity. The cause of death was given as Drowning with Multiple Stab and Incised Wounds. It was evident that the decedent was alive on entry into the water. Comparative Diatom Analysis provided ancillary support for drowning.

Drowning is not necessarily the cause of death when a body is recovered from water. The possible scenarios are:

Death before immersion in water

- natural disease
- injury

Death while in water

- natural disease
- injury
- drowning
- death from effects of immersion other than drowning

The autopsy diagnosis of drowning is a major problem in forensic medicine as the pathological proof is often difficult or impossible to obtain, especially when there is a delay in recovery of the corpse. The diagnosis of drowning can often be easily established in a fresh corpse that has been recovered early. The task becomes more difficult when putrefaction sets in and the signs become obscured!

Modell (1981) defined drowning as *"suffocation by immersion, especially in water."* This is the classic and most widely used definition. The World Congress on Drowning (2002) defined drowning as *"the process of experiencing respiratory impairment from submersion or immersion in a liquid."*

The pathological diagnosis of drowning can be made through identification of the following signs:

- Champignon d'mousse
- Froth in the tracheobronchial tree
- Emphysema aquosum - heavy, waterlogged and hyperinflated lungs – (600-700 g each) that fill the chest cavity, exhibit rib indentations (visible and palpable grooves), overlap/meet in the midline such that they obscure the bare area of heart and obliterate the anterior mediastinum. They are pale and crepitant and do not collapse when placed on the dissection board.

10 - 20% of undoubted drownings are "dry lung" cases with no excess weight (Copeland 1985)*

- Paltauf's hemorrhages
- Pleural effusions
- Water in the stomach*
- Middle ear hemorrhage*
- Low spleen weight*

* Too inconsistent to be of diagnostic use

Diatoms – Diatoms are microscopic algae that that live in water and range in size from 2µm to 1mm with most being 40-80mm. The smaller species of the order of 2-5mm can easily penetrate tissues. There are about 15 000 species which are almost equally divided between fresh water and brackish/seawater. They are covered by a heat and acid resistant silicaceous exoskeleton (frustule) which are physical properties which are taken advantage of in their laboratory extraction. Diatoms can be demonstrated as a microscopic finding in the tissues in drowning.

Diatom Test – The basis of the diatom test is premised on the aspiration of water into the lungs on entry of a living person into water during drowning such that such that the contained diatoms also enter the lungs. The aspirated diatoms then penetrate the alveolar walls, enter the pulmonary venous circulation and then the systemic circulation such that they are transported and deposited with distant organs and tissues such as the brain, kidney, liver, and bone marrow. Passive entry of diatoms into the lungs can occur in deceased bodies which inadvertently end up in water, through wave action. As there would not have been a functional circulation at the time of entry of these bodies into water, the diatom species of concern will not be present in the distal organs.

The diatom test was first applied by Revenstorf 1904 as an ancillary investigation in possible drowning deaths. It involved the identification and comparison of recovered diatom species to assist in the confirmation of drowning and possibly identify site of drowning. The validity of the test is strongly debated in the medical literature since diatoms can be demonstrated in non-drowning deaths.

The presence of diatoms in non-drowned bodies has been associated with ingestion of seafood, inhalation from the environment and laboratory contamination of glassware and reagents. Despite these, some believe that the diatom test is still the most reliable "drowning test" to date.

Hendey's criteria (1973) set out two (2) criteria for accepting a positive result from a diatom test as evidence of drowning in that:

i. *The species of diatoms recovered from pathological specimens are **all** present in the sample from the site of drowning.*
ii. *species are present in the same order of dominance for the admissible size range and in approximately in the same proportions*

Samples for Comparative Diatom Analysis/Sample preparation – Diatoms must be extracted from the body of water in which the corpse was recovered and compared with those extracted from the tissues. As such, the following samples are needed:

- Water sample from place of recovery of body (at least 500ml)
- Fresh tissues retrieved from the body in a sterile manner
  - lung (one lobe)
  - liver (150g)
  - whole kidney (100-150g)
  - long bone (femoral) marrow

To prevent cross contamination, it is necessary to take each sample *in-situ* with a change gloves and use of sterile instruments and blades when procuring each tissue sample. No co-mingling of the tissues must occur.

The laboratory preparation of the specimens entail:

1. Diatom extraction from tissues

- Acid digestion (HNO_3) *or*
- Water maceration *or*
- Incineration (most useful with fatty tissue eg. bone marrow)

2. Microscopic examination of the residue

3. Comparison of diatom species – The diagnosis of drowning can be made with reasonable degree of certainty from correlation of:

- History/Circumstances of the Death
- Gross lung findings
- Microscopic lung findings
- Diatom examination
- Other ancillary investigations

The Diatom Test should be used as an indicative aid and NOT as legal proof of drowning.

Drowning, Stab Wounds, Comparative Diatom Analysis

G60 Female Suicides by Firearm From 1990 - 2010 in Montgomery County, Ohio

Robert L. Hunkeler III, MFS, and Kent E. Harshbarger, MD, JD, Montgomery County Coroner's Office, 361 West 3rd Street, Dayton, OH 45402*

After attending this presentation, attendees will understand trends relative to firearm suicides by females over a 20-year timeframe in Montgomery County Ohio, an area encompassing 460 square miles with a population over 535,000.

This presentation will impact the forensic science community by examining female suicides by firearm and identifying any trends relative to age, sex, race, firearm type, wound location and alternate methods of suicide. This data can be used to compare to other studies to determine any geographical trends related to firearm suicides by females.

Suicide continues to be a very sensitive topic and significantly impacts families and the community at large. Firearm deaths have become commonplace in today's society and usually are seen in homicides, followed by suicides and accidental deaths. Although firearms are a predominate mode in male suicide, it has had a lower representation in female suicide. Montgomery County Coroner's Office began seeing higher numbers of female suicides by firearms and a study was conducted in order to determine the significance of these numbers and if they translate to an increase in rate for female suicides over time. In addition, Montgomery County Coroner's Office began seeing females in higher age categories selecting firearms as the mode for suicide; therefore, the study addressed age as well, in an effort to determine rate and if there was statistical significance to the findings. A total of 30 of the 87 cases involve females age 55 and over. Another interesting aspect is wound location, with Montgomery County Coroner's Office seeing a higher number of cases involving gunshot wounds to the head, versus historically seen wound locations of the chest and abdomen.

It is imperative for coroners and medical examiners to understand identified trends in order to determine fluctuations within their jurisdictions. It is vital for communities to understand trends associated with suicides. By identifying trends for our serviced communities, various services can be provided, or actions can be taken in order to design suicide prevention programs in an effort to prevent additional deaths. An example of this can be seen in Ohio where a number of pain management clinics have been shut down in the southern part of the state due to the amount of pain medication being distributed, resulting in overdose and death. By taking action, it will be interesting to see if the affected counties see a downward trend in overdose deaths.

This presentation will discuss the analysis of 87 female suicides by firearms over a 20-year period in Montgomery County Ohio. Analysis will include age, sex, race, firearm type, and wound location and determine if these factors are statistically unique for females as compared to male suicides by firearm for the same period of time. In addition, other methods of female suicide will also be compared to determine if there is statistical significance relative to female suicide by gunshot in the 324 female suicides from 1990 - 2010. Rates per 100,000 will be calculated for each year on each method for the population of Montgomery County, which has declined from 573,809 in 1990 to 535,153 in 2010.

Suicide, Firearm, Gunshot Wound

G61 Suicide and Profession

Ricardo P. Nachman, MD, The National Center of Forensic Medicine, 67 Ben Zvi Road, PO Box 8495, Tel Aviv, 61085, ISRAEL*

After attending this presentation, attendees will be aware of why it is of paramount importance to know the profession or skills of the victim before performing the autopsy.

This presentation will impact the forensic science community by serving to understand how the profession, knowledge, and or skills of the victim should influence the decision of what is the best way to commit suicide in a simple, rapid, intelligent, and effective way.

Methods of suicides most common used and examined at the National Center of Forensic Medicine in Israel for the last several years were by hanging, jumping, shooting, stabbing, and cutting. To choose the appropriate way to commit suicide, is probably a very complicated issue, and depends on many factors that certainly, the profession and skills of the victim are an important parameter to take into consideration.

In general, the people know the location of the heart or neck's great vessels, so those are usually the places of choice for cutting or stabbing. In most cases, the victim doesn't have the appropriate anatomy knowledge which tells him where to cut for achieving the most "effective" place to harm himself and usually they doesn't know how much pressure to apply in order to create the most effective lethal damage.

This lack of knowledge guides the typical victims to select the most inappropriate places for cutting which leads to produce several superficial and parallel cuttings (*hesitation wounds)*. Such wounds indicate repeated attempts of self-inflicted damage before to build-up of sufficient courage for the final deep gash that injures major blood vessels or expose the trachea or larynx to die. Those lesions not always appear near the deeper fatal injury.

In these cases not being able to achieve their goal by this method, they usually finish their life by hanging or jumping or choosing another way to die. Death may have been due to a cause other than exsanguination.

In self-inflicted incised wounds of the extremities, right-handed individuals usually cut the left wrist or forearm, typically found on the flexor surface and radial aspect of the forearm. Groins are not such a common place.

The story can take different angle when the victim has anatomy knowledge such as painter (artist), hunter or a physician when chosen the cutting method. In these cases, they know where to cut, at which depth, and may be they know how much pressure to apply on the skin. In such cases one can asked if hesitation marks must appear. The answer is: probably not.

This presentation will show an unusual case of a convict physician, who committed suicide on jail by cutting his own groin vessels.

For the first time, as far as the records at the The National Center of Forensic Medicine tells, the body of a person who committed a suicidal act by cutting the main blood vessels in the groin, with only a few hesitation wounds, was brought in for autopsy. A similar case like this has not been previously described in the forensic literature to the best of our knowledge.

Undoubtedly, the victim had a background of anatomical knowledge, and unquestionably this point helped him to select the proper area of his body to do a lethal damage.

In this case there are some interesting questions to ask:

1. It looks that in this case the appearing of hesitation marks are not a result of lack of knowledge of the amount of pressure to apply. Maybe it was the result of not enough courage to execute the act?
2. Even though the victim had knowledge in Anatomy; one of the groins' damaged wasn't effective enough to cause death. Why?
3. Why the victims choose the groin vessels as a target of damage instead of neck vessels?
4. Did the victim weigh another alternative which is more common option to commit suicide in jail like hanging?

Obviously, it is impossible to give answers to these questions today.

Suicide, Profession, Hesitation Marks

G62 An Unusual Homicide-Suicide Modality in an Elderly Couple

Margherita Neri, MD, PhD, Natascha Pascale, MD, Sara Vita, MD, and Irene Riezzo, MD, PhD, Department of Forensic Pathology, University of Foggia, Osp D'Avanzo, Viale degli Aviatori, 1, Foggia, 71100, ITALY*

The goal of this presentation is to present a case of homicide-suicide in an elderly couple, characterized by an unusual complex suicide achieved by three different tools: a knife, a razor blade, and a claw hammer.

This presentation will impact the forensic science community by presenting the case of a homicide-suicide in an old couple, where the murderer garroted his wife with an elastic band, and then he tried to kill himself first hitting his head with a claw hammer and then cutting his neck and arms with a razor blade, and stabbing the chest and neck with a knife. Moreover claw hammer self-inflicted lesions on the scalp are very rare, in particular in association of knife and razor blade and in a case of homicide-suicide.

Complex suicide is very rarely described in literature; in this case it was used three different kind of tools: a knife, a razor blade and in particular a claw hammer.

Homicide-suicide (HS) is defined as that lethal event in which an individual kills another and subsequently commits suicide within one week. The unusual injuring tool and the relevant injuries which are produced the suicide were studied and analyzed to approach the case of dyadic death. The most important question for the forensic pathologist is to distinguish between a real homicide-suicide and a double murder.

On June 2, 2011 at 1:00 p.m., a woman called the police and said that she found her old parents dead. The police and the forensic pathologist went to the crime scene and found the body of a 72-year-old Caucasian woman inside of the bedroom of her own house. The woman lived in the house with her husband. The corpse was lying supine on the bed; she was fully and tidily dressed. She had an elastic band wrapped around her neck; this band was a length of 240cm, width of 11cm. The thanatological data recorded at 4.00 p.m., showed early rigor mortis, hypostasis that was totally blanched with fingers pressure, but congruous with the position, the rectal temperature was 35°C and ambient temperature was 25°C. Inside the bathroom, on the floor, was lying the body of a 78-year-old Caucasian man, his corpse appeared extensively blood-stained with a surrounding blood stain. Close to the left arm of the man, on the floor, was a knife, it was extensively blood-stained and it was length of 31cm, blade length of 19cm, blade maximum width 2.2cm. Close to the left foot, was a razor blade also blood-stained, with a length of 4cm, width 1cm and a hammer with double prong also smeared of blood. The thanatological data recorded, at 4:30 p.m., the body showed early rigor mortis, and hypostasis that was in part blanched with fingers pressure, but congruous with the position, the rectal temperature was 34.5°C and ambient temperature was 25°C. The Prosecutor arranged the autopsy on the bodies because it was necessary to clear up the circumstances of the death and distinguish between homicide-suicide and double homicide. A complete autopsy was performed 24-hours after death on both bodies. At the external examination, the old man showed peculiar lesions of the head: multiple couple of linear lacerations of the scalp including tissue bridges because of the gap between the two claws, although some of the injuries caused marks of the skull. The damage was probably inflicted with a claw hammer. Moreover, it was present multiple slashed wounds on the neck, both forearms and chest; in particular on the neck three stab wounds: two superficial on the left side and one deeper than others on the right side. Section of the neck revealed hemorrhages in the subcutaneous tissues and at the right stub wound sternocleidomastoid muscle and the right jugular vein showed a deep tear. The other organs did not showed specific alterations except for an intense anemia. The toxicological analysis was negative and the cause of death was a hemorrhagic shock.

The woman showed, at the external examination, a remarkable cyanosis of the face, lips and nails; skin petechial hemorrhages in frontal and periorbital region and mucosal petechiae on oral vestibule and both conjunctivas were also detected. The face was covered with various bruises and superficial skin tears. On the neck a horizontal mild blue bruise areas was present with nails marks. Section of the neck revealed hemorrhages in the subcutaneous tissues and in both sternocleidomastoid muscles and thyroid muscles. Esophagus, larynx, and trachea were unremarkable. Subpericardial and subpleural petechiae were detected. The other organs did not showed specific alterations except for an intense vascular congestion. Skin sections for histological examination were removed at the neck in long strips perpendicular to bruises. Sample of muscle tissue were also taken at the neck. The histological examination showed mild hemorrhages in the cutaneous and subcutaneous tissues, and in the muscles. The stratum corneum of the epidermidis was detached and the dermis was split from the epidermis. An immunohistochemical study was performed to evidence the vitality of the skin injury. The toxicological analysis was negative. According to the examination of neck bruises, autopsy findings and histological data, the mechanisms of death consisted with an asphyxia. Death was attributed to an external neck compression; the tool that caused the death was perfectly compatible with the elastic band found on near the body.

Homicide-Suicide, Claw Hammer, Self-Inflicted Injury

G63 Eventual Suicide by Self-Inflicted Intracardiac Needle on the Eleventh Attempt

Benedetta Guidi, MD, Via santa dorotea 1, pescia, Pistoia, 51017, ITALY; and Monica Pedretti, MD, Stefania Fornaro, MD, and Marco Di Paolo, MD, Via roma 55, Pisa, 56100, ITALY*

After attending this presentation, attendees will be aware of the fatal complications due to intracardiac self-inserted needles.

This presentation will impact the forensic science community by illustrating a type of injury that is known but rare, showing how prompt surgical removal of the foreign body could be life-saving, preventing the complications related to the sharp nature of needles.

The migration into heart chambers can cause cardiac tamponade, infection, peripheral embolism, valve dysfunction, pneumothorax, and death.

Cardiac injuries produced by sharp penetrating foreign bodies are not uncommon. Bullets, acupuncture needles, fragments of Kirshner wires, and sewing needles represent the object usually inserted. Rarely the heart lesions result from an auto-aggressive behavior in patients with an underlying mental disorder or with opioids abuse. When injury is self-inflicted it's usually an expression of personality disorders, schizophrenia, major depression, mania, and gender identity disorders and can be associated with certain medical diseases or represents a suicide attempt. The major symptoms are chest pain and dyspnea, although patients may be asymptomatic.

Long-term survival with needles and other foreign bodies in the heart has been described in numerous cases. Furthermore there are reports of incidental findings on autopsy of needles embedded in the heart. Though immediate death is uncommon, the overall mortality exceeds 50%.

It is believed that needles should not be removed if the patient is asymptomatic, a conservative approach is also recommended for old wounds: with time most foreign bodies become securely encysted and do no damage. Instead, in the case of early diagnosis needle injury to the heart should be treated surgically, regardless of the presence of symptoms to reduce further myocardial damage and excluding complications including death.

A case is presented in which a young male prisoner who died due to cardiac tamponade after multiple self-inserted intracardiac needles.

The male prisoner was a psychiatric patient admitted to the Emergency Service because of sharp chest pain. The patient didn't disclose any suicidal behavior. However, clinical history was characterized by previous introduction of foreign objects in his chest left *in situ*. The man was oriented, his vital signs were stable, but his heartbeat rate was high. Electrocardiography disclosed no abnormality. Myocardial necrosis enzymes were slightly increased. PA- X-ray of the chest confirmed the presence of multiple intrathoracic and intracardiac metallic string-shaped objects.

The diagnosis was acute coronary syndrome. Nitrates and antiplatelets were administered and the man was immediately moved to the cardiology

unit. Because of a worsening of the cardiorespiratory functions, and the suspicion of a pulmonary embolism, a scintigraphy was requested but not performed because of the urgency of the situation. In the Coronary Intensive Care Unit, the patient had a cardiopulmonary arrest that, despite several resuscitation attempts lead to death after 13 hours after admission.

During forensic examination, acupuncture signs were detected at the precordial region. The autopsy showed chronic constrictive pericarditis, cardiac tamponade, and copious partially coagulated blood in the left hemothorax.

A needle, 11cm in length, was found penetrating the pericardium with about 3cm of its length infixed in the left ventricle of the heart. Another 10 metallic objects were found embedded in the thorax surrounded by a thin fibrous lamina: one at the base of the left costal arch on the midclavicular line and under the subcutaneous fat, one at the peritoneal level inside a fibrous mass near the greater curvature of the stomach, one inside the omentum, five at the precordial level out of the sternal plastron, one in the second intercostal space and one in the third. Accessory tests were non-contributory.

This case is out of the ordinary for the forensic scientist because of the injury pattern found at autopsy, it also involves clinicians of the Emergency Department and cardiac surgeons who have to make an accurate assessment of psychiatric patients with penetrating foreign body for a proper management to reduce myocardial injury and avoid complications.

Intracardial Needle, Suicide, Autopsy

G64 "One-Punch" Fatalities

Jan E. Leestma, MD, 1440 North Kingsbury Street, Suite 210, Chicago, IL 60642; and Andreas Buettner, PhD, Institut Rechtsmedizin, University of Rostock, St. Georg Strasse 108, Rostock, 18055, GERMANY*

The goal of this presentation is to show how special forensic and pathological issues associated with brief physical altercations result in fatalities. The cases presented and relevant published material will review typical circumstances, procedures for case analysis hopefully leading to proper forensic interpretations. Those attending should expand their knowledge base for immediate application to the forensic exercise at their own facilities.

This presentation will impact the forensic science community by highlighting that though "One Punch" fatalities are not especially common, they can pose significant forensic challenges and challenges for the justice system. Proper case analysis and interpretations can materially affect proper adjudication of these often sensational and notorious cases.

A relatively uncommon occurrence that often attracts attention of the media involves a physical altercation, usually between intoxicated young men in which sometimes a particularly forceful blow with a fist by one of them will result in the rapid death of another. The blow scenarios may involve a fist impact to the face, head or jaw, or neck, and sometimes to the chest. Other scenarios involve some other form of single impact. Following the blow-impact the stricken individual may immediately fall backward, often striking the head on a hard surface, with immediate unconsciousness. If the victim does not fall backward striking the head, there may be a period of confusion or stupor, then followed by unconsciousness. The victim is usually transported to hospital but may die en route or shortly after admission. Autopsy findings may range from major basilar and/or other skull fractures with or without epidural or subdural hemorrhages, or major subarachnoid hemorrhage with or without skull fracture or epidural or subdural hematoma. Tearing or avulsion of circle of Willis arteries, carotid, or vertebral-basilar arteries may also be found with or without dissections and/or thromboses in the absence of skull fracture. There is a significant literature on traumatic injuries to intracranial arteries by Krauland (*Verletzungen der intrakraniellen Schlagadern,* Springer-Verlag, Berlin, 1982), but being in the German Language may have escaped the attention of those with no knowledge of this language. The 31 cases of Krauland and other contributions will be reviewed and compared with cases of our own. There are significant technical problems associated with the pathological examination in these types of cases which will be reviewed with recommendations on how to avoid or minimize them.

Traumatic Subarachnoid Hemorrhage, Fatal Head Injury, Arterial Injury

G65 Homicidal Deaths in the Republic of Ireland Through the Work of the Office of the State Pathologist

Khalid Jaber, MD, Firebrigade Training Centre, Malahide Road, Marino, Dublin 3, IRELAND*

After attending this presentation, attendees will gain information on the prevalence and incidence of homicidal deaths in the Republic of Ireland, as seen through the workload of the Office of the State Pathologist.

The presentations will impact the forensic science community by presenting, possibly for the first time, internationally, the figures and characteristics of homicidal deaths reported in the Republic of Ireland for one complete decade (2001 to 2011). The office of the state pathologist is an administrative branch of the Department of Justice in Ireland and is responsible for the forensic pathology investigation of all these deaths. This presentation will attempt to provide an overview of the breakdown of the types of homicidal deaths and their respective demographical and forensically- pertinent features.

Homicide is defined literally the killing of the human being. Ireland, the Island of the saints and scholars is not totally immune to this regrettable human tendency. The archival system of the Office of the State Pathologist in the Republic of Ireland (covering the Island of Ireland except the six counties in the province of Ulster, known as Northern Ireland) has been searched between 2001 and 2011 for all reported and investigated homicidal deaths. The population of the Irish republic is just over 4.0 million inhabitants. This office is part of and works within the guidelines and rules set and approved by the Department of Justice and Law Reform.

This chosen period covers a socioeconomic time when the economic cycle and individual disposable income in the republic literally oscillated between one extreme of a boom position (known as the Celtic tiger era, 2000 to 2007) to literally the juxtaposed position of widespread bust period with significant and recession (the bursting of property market bubble, 2008 to present).

Homicidal deaths account for 30% to 40% of the office's case workload. The rest of the cases dealt with are, also, regarded by the Garda Siochana (police force) as suspicious deaths. The office handles a wide variety of homicidal deaths. The data collected briefly reveal that fatalities due to firearm - related, sharp force trauma, and/or blunt force trauma each accounts for one third of the total figures.

Increasing number of firearm related - deaths, involving handguns, rifles, and shotguns have been identified during this period. The increase within this period is attributed to a noticeable rise and conspicuousness of the activity of multiple and rival criminal gangs engaged in illegal activities. Following the Good Friday Accord between the republic of Ireland and United Kingdom over the state and future of Northern Ireland, some dissident paramilitary groups have increased their involvement in different criminal activities, bringing them into either direct turf struggle with the established criminal gangs or enhanced co-operation in criminality. Despite the perception and to some extent the evidence pointing to the presence of large varieties of firearms in the country (mostly smuggled) there appears a noticeable absence, during this study period, of military - style assault rifle related injuries.

Blunt force trauma is still a major cause of concern, despite its relative ratio decline, compared to what it used to account for in the past. The data confirms the international findings that major urban population centres are relatively more violent than urban communities.

Stabbing and incisional wounds which are still encountered reasonably regularly are discussed in terms of their relative impact into the homicidal death scene.

The data presented also includes homicide by motor vehicle accidents (hit and run, dangerous driving leading to deaths) but not other types of road traffic accidents fatalities, as these are not handled by this office. Drugs, especially ethyl alcohol, constitute an important part in the Irish homicidal death scene, especially non - firearm related. Alcohol still is a major health concern in the overall mortality figures in Ireland in general.

Despite the recent concerns voiced nationally over the activities of paedophilic priests, and the traditionally high relative birth rate when compared to the rest of the European Union countries, it appears that the incidence of fatal child abuse and fatal non-accidental infant and child traumata are noticeably relatively very low.

Men were more likely to be victims of homicide or serious assault than women in Ireland, like the rest of the European Union. Like many other countries, women were more likely than men to be victims of in intimate partner homicidal death and homicide-suicide deaths. The latter are encountered relatively infrequently occasionally.

At midpoint of this study period there were 58 victims of homicide in Ireland in 2005. Of these, 49 were men. Almost half of male victims were aged between 21 and 30 years of age. One third of female victims of homicide were aged between 21 and 30 years of age.

Homicidal, Death, Ireland

G66 Elemental Analysis of Gunshot Residue to Differentiate Bullet Type and Firing Distance

Christine E. Hay, BS, 329 Michigan State University, Department of Chemistry, East Lansing, MI 48824; Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824; and Brian C. Hunter, MD, 630 South Saginaw Street, Flint, MI 48502*

After attending this presentation, attendees will be familiar with the elemental analysis of gunshot residue (GSR) using inductively coupled plasma mass spectrometry (ICP-MS).

This work will impact the forensic science community by demonstrating how elemental analysis can be used to identify GSR in various stages of decomposition.

Porcine tissue was shot with jacketed and non-jacketed ammunition at two different firing distances. Samples were collected throughout decomposition and analyzed by ICP-MS to determine element composition of the GSR. Element concentrations were statistically assessed to investigate differentiation of bullet type and firing distance based on chemical concentration of the GSR.

In the fresh state, bullet entrance holes and a characteristic GSR pattern may be readily visible, enabling identification of a gunshot wound. However, due to chemical and biological processes occurring during decomposition, as well as larval activity, the entrance hole and GSR patterns can be obliterated. Thus, the natural decomposition of a gunshot victim in an outdoor setting can hinder the identification of a bullet entrance wound. The ability to detect GSR on corpses that have undergone advanced stages of decomposition would aid pathologists and medical examiners in cause of death determination, while the ability to identify the bullet type would aid law enforcement in narrowing down the suspect pool.

Differentiation of bullet type based on elemental composition of GSR has been demonstrated previously in our laboratory. Porcine tissue was shot with jacketed and non-jacketed ammunition and tissue samples were analyzed by ICP-MS for elements characteristic of GSR (antimony, barium, and lead), as well as elements characteristic of bullet type (copper, iron, and zinc). However, in these previous studies, the jacketed and non-jacketed ammunition contained different smokeless powders, all wounds were shot with a firing distance of 5cm, and only moderate decomposition was investigated.

The objectives of this research were to further investigate differentiation of bullet type based on chemical composition of GSR, as well as to investigate differentiation of firing distance based on GSR composition. Samples were collected throughout full decomposition, to determine if differentiation according to bullet type and firing distance was still possible.

In this study, control (unshot) samples were collected from each of four euthanized pigs. Two pigs were then shot eight times each with jacketed ammunition using a .357 Dan Wesson revolver (blued steel barrel, 1.5 inch in length); one was shot using a firing distance of 5 cm, while the second was shot using a firing distance of 10cm. The remaining two pigs were shot in a similar manner, except using non-jacketed ammunition. All ammunition cartridges were hand loaded with the same smokeless powder to ensure no elemental variation was due to differences in composition of the powder. One tissue sample was collected from each pig immediately after GSR deposition. The pigs were then allowed to decompose naturally and the remaining wounds were collected throughout the decomposition process.

The control samples and tissue samples containing GSR were microwave-digested in nitric acid and then analyzed by ICP-MS. Full mass scans were initially used to identify those elements present at significantly higher concentration in the shot tissue compared to the control tissue, for both bullet types. Once identified, the instrument was calibrated for the elements of interest and the tissue samples were analyzed using selected ion monitoring for those elements. Element concentrations in the fresh tissue were statistically assessed to differentiate tissue shot with jacketed versus non-jacketed bullets, as well as to differentiate tissue shot with a 5 cm firing distance versus a 10cm firing distance. Then, element concentrations were compared for samples collected throughout decomposition, assessing the persistence of GSR and the ability to continue differentiating bullet type and firing distance.

Gunshot Residue, Bullet Type, Firing Distance

G67 The Presence of Hyoid Bone Fractures in Self-Inflicted Gunshot Wounds to the Submental Region of the Neck

Alice J. Briones, DO, Philip J. Berran, JD, MD, Edward L. Mazuchowski, MD, PhD, and Howard T. Harcke, MD, Armed Forces Medical Examiner System, 116 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will understand how hyoid bone fractures may occur in association with self-inflicted gunshot wounds to the neck and head and how postmortem Computed Tomography (CT) can facilitate the identification of hyoid bone fractures in gunshot wounds to the submental region of the neck.

This presentation will impact the forensic science community by providing data demonstrating the presence of hyoid bone fractures in self-inflicted gunshot wounds to the submental region of the neck, a scenario not previously considered as a significant cause of hyoid bone fractures.

Hypothesis: Although within the forensic science community fractures of the hyoid bone are commonly considered to be seen in cases of manual strangulation, hyoid bone fractures can occur in association with self-inflicted gunshot wounds of the head and neck.

Methods: A retrospective review of Armed Forces Medical Examiner System cases 2005-2010 revealed 400 cases of self-inflicted gunshot wounds. The final autopsy reports were reviewed to identify the circumstances of death, the weapon used, entry and exit wounds, and the description of the hyoid bone.

Results: Of the 400 self-inflicted gunshot wounds, 55 were to the submental region of the neck. Of these 55 cases, eight had hyoid bone fractures. When the specific type weapon used was evaluated within the total number of gunshot wounds to the submental region (55); hyoid bone fractures were identified in: one of the five shotgun cases, six of the 35 rifle cases, one of the 10 handgun cases, and zero of the five cases with unknown weapons.

In the eight cases of hyoid bone fracture, postmortem CT was available in five cases and showed hyoid bone fractures in all three. Since this series was reviewed, two additional self-inflicted submental gunshot wound cases

were autopsied at our facility. Both cases demonstrated a fracture of the hyoid bone on CT which was confirmed at gross dissection.

Conclusions: Hyoid bone fractures occur with self-inflicted gunshot wounds of the neck and head involving a variety of weapons to include shotguns, rifles and handguns. Forensic pathologists should recognize that hyoid bone fractures may exist in this type of case and postmortem CT is capable of identifying these fractures. The presence of hyoid bone fractures in the setting of gunshot wounds of the neck and head does not necessarily indicate manual strangulation.

Self-inflicted GSW, Hyoid Bone Fracture, Postmortem CT

G68 Fatal Suicidal Gunshot Wound to the Head With Lack of Immediate Incapacitation

Pauline Saint-Martin, MD, Bruno Aesch, MD, and Christophe Destrieux, MD, PhD, Service de Medecine Legale, Hopital Trousseau, CHRU Tours, Tours, 37000, FRANCE; and Thierry Lefrancq, MD, Le Vauban, BP 549, 16 rue Clerget, Nevers, 58009, FRANCE*

After attending this presentation, attendees will learn special wound ballistics of the head, and general mechanisms of incapacitation that make sustained capability to act possible in rare cases of gunshot wounds to the head.

This presentation will impact the forensic science community by showing how questions concerning the possibility of physical activity following a given gunshot wound are often raised in court and can be of major importance in reconstruction of a crime and in differentiation between homicide and suicide.

Introduction: A case of physical activity following a suicidal gunshot to the head including perforation of the right frontal lobe from a 9mm is reported. The woman was able to walk a distance of 18m before dying. A review of the literature showed that the potential for physical activity following penetrating gunshot wounds to the head is related to general principles of wound ballistics and mechanisms of incapacitation.

Case report: a 45-year-old woman was found dead in a wooded area. The body was lying on the ground near a car and the face was covered by maggots. A suicide note was found inside the car. The decedent was known to suffer from severe depression and was last seen alive the day before by her estranged husband. The investigators first thought that the victim had died from fatal intoxication, as several empty blisters of alprazolam were found nearby. However, secondarily a 9mm carbine was found 18m distant from the body. At autopsy an entrance wound was located at the right temple. A circular depressed fracture of the right temporal bone was noted. There was an acute subdural hematoma of the right cerebral hemisphere. Several pellets were removed from the surface of the brain. Neuropathology showed traumatic injuries of the right frontal lobe. As the frontal brain does not include areas immediately essential to acting or consciousness, it was concluded that physical activity was possible in this case and that this woman had been able to walk a short distance before dying. Toxicology analysis was not requested by investigators. Death was ruled a suicide.

Discussion: Penetrating gunshots to the head are presumed to cause immediate incapacitation by subsequent disturbance of cerebral functions. In the literature, incapacitation has been defined as "a physiologically based inability to perform complex and longer lasting movements independent of consciousness or intention." However, not every severe or even fatal gunshot wound causes immediate incapacitation. Physical activity is possible if the trajectory is restricted to the frontal brain or one temporal lobe only and if a projectile of low wounding potential has been used for the gunshot. In our case, neuropathology showed that no central nervous area essential for physical activity was wounded directly, and the woman's capability to walk following the gunshot wound was of major importance in differentiation between homicide and suicide.

Forensic Pathology, Gunshot Wound, Incapacitation

G69 Sudden Unexpected Death Caused Probably to Eagle's Syndrome: A Case Report

Renaud Clement, MD, 1 rue gaston Veil, Nantes, 44093, FRANCE*

After attending this presentation, attendees will understand the profound implication of vagal reflex in relation to blow inside the neck by ossification of stylohyoid ligament.

This presentation will impact the forensic science community by highlighting the possible existence of higher number of deaths attributed to reflex cardiac arrest.

Case Report: An autopsy was performed to a man who was found dead in his car. The initial investigations determined that this young man without health problem went to his job at 5:00 a.m. He was making backing up his car in a parking lot and suddenly died. The policemen remarked that the back wheels crossed the abutments of parking protection. External examination of the body showed that this man was 175cm in height and weighed 73kg. There was no wound at the inspection. Internal inspection revealed bilateral bony hard vertical structures. The length of each ossified stylohyoïd ligaments were 5 cm on left and 3cm on right. The carotid vessels were normal without any injury, especially at the fork area. The macroscopic examination of the organs was normal and unremarkable. There were absence of congestion, cyanosis, and petechiae. Toxicological examinations did not reveal any recent or old consumption of toxic substances. Microscopic organ investigations were normal. The elongated stylohyoid ligaments were ossified with the presence of cartilage, bone, and bone marrow. Based on the necropsy findings, the cause of the death was suggested to be a cardiac arrest caused by the vasovagal reflex. This research reviews the embryology of styloïd chains and the anatomy of the styloïd process - the stylohyoid ligament and the lesser cornu of the hyoid bone form the stylohyoid apparatus. The ossified stylohyoid ligament is known as Eagle's syndrome which is an uncommon sequel of elongation of the stylohyoid process. It is an aggregate of symptoms that includes foreign body sensation, recurrent throat pain, dysphagia, facial pain, and vertiginous. The diagnosis is made by radiography. One part of subtypes is the stylo-carotid artery syndrome. The frequency of elongated stylohyoid process is estimated approximately 4% of the population. The term of calcified is erroneous, ossification is considered more precise because hyperplasia of the styloid process is exhibited by histology. Not as abvious, the ligament could be ossified and form a solid structure. The ossified stylohyoid ligament may press upon the adjacent structures in the neck such as the carotid sinus complex. The reaction could be a vagus nerve mediated reflex cardiac inhibition. The mechanism of cardiac arrest resulting of pressure on the carotid neural complex will be discussed. The referenced causes of reflex cardiac arrest such as manual strangulation, hanging, and blows to the throat or neck will also be reviewed.

Forensic, Eagle, Reflex Cardiac Arrest

G70 Harness Hang Syndrome and a Death While Rappelling

Christopher Swalwell, MD, San Diego County Medical Examiner's Office, 5570 Overland Avenue, Suite 101, San Diego, CA 92123; and J. Marc Beverly, MPAS, University of New Mexico, 1128 University Boulevard NE, Albuquerque, NM 87131*

The goal of this presentation is to review the nature and effects of suspension by a harness and to discuss a death that occurred under such conditions. Attendees should gain a better appreciation of the potential hazards of prolonged harness suspension. The goal is to inspire others to do further research on the topic.

This presentation will impact the forensic science community by introducing the unusual topic of harness hang, also known as suspension stress or suspension trauma. The impact of the presentation will be a better

understanding of the possible mechanisms and nature of deaths occurring under the condition of harness suspension. This experience may be helpful in future investigations of similar cases.

Rock climbing is a popular outdoor activity that may involve suspending oneself within a harness while climbing or descending. Harnesses as a component of a personal fall protection system are used in other recreational and industrial activities. The hazards of falls are obvious, but less well known are the possible hazards of prolonged harness suspension. The harness hang syndrome, also known as suspension stress or suspension trauma, is the result of the physiological response to a motionless body being suspended in a vertical position for a period of time. It is believed that this can lead to cardiovascular alterations, loss of consciousness and even death. Although the medical and forensic literature has little on this subject, other types of suspension and asphyxial deaths are well-known. The most common type of suspension death, of course, is hanging. But other types of asphyxial deaths may involve suspended or trapped body positions such as traumatic or positional asphyxia. The death of a young male who was rappelling down a rock face in close proximity to a waterfall is presented.

This 24-year-old man was found suspended in his rock-climbing harness along the rock wall of Mildred Falls in the Cleveland National Forest on evening of February 11, 2011. A hiker had reported hearing cries for help, but had to hike a long distance to get cellphone reception. The time of the 911 call was 5:08 p.m. By the time rescuers responded to the scene the decedent was motionless and unresponsive. His body was described as arched backward with his chest and face towards the falls. His recovery from the scene was delayed due to darkness and environmental conditions. The next day, he was pulled up from the falls, confirmed dead, and transported to the Medical Examiner's Office. He was known to be an avid rock climber and his car was found parked at the trailhead to the falls. The decedent had left his house in the early afternoon and had told his roommate that he was going to make the descent at the falls. According to family, his medical history was unremarkable.

At autopsy he had multiple scrapes and contusions of the skin, but no evidence of internal trauma. At least some of the abrasions appeared to have occurred during the recovery. Other findings were suggestive of asphyxia including numerous periorbital and conjunctival petechiae. No internal neck, head, chest, or abdominal trauma was found**,** and no pre-existing natural disease was noted. No alcohol, basic medications, or common drugs of abuse were detected on toxicologic testing. There was no evidence of neck compression and no specific findings suggestive of drowning. It is believed the mechanism of death was a result of mechanical asphyxia and probable hypothermia.

If conscious, someone in the decedent's position would be expected to exert oneself in an effort to escape or regain control until the point of exhaustion, unconscious, or death. The exertion itself along with panic or other emotional factors may also play a role. In this case, the rock wall was wet and covered with vegetation so there was little chance of climbing back up or even getting a foothold in order to transfer body weight from the harness. Of course, one would be unable to escape being suspended if an injury or other preceding event had already caused unconsciousness. Other factors considered in this death case were the possible roles of drowning and hypothermia. As seen and inferred by the video the body was not constantly or consistently in the water and the autopsy did not show evidence of drowning. Therefore this mechanism is unlikely. However, hypothermia may well have been a factor.

The literature theorizes that suspension stress or harness hang syndrome is due to orthostatic hypotension along with other possible cardiovascular mechanisms; however, this has not been verified experimentally. It is believed the mechanism is probably respiratory, not cardiovascular, and that these types of deaths should be considered a form of mechanical asphyxial. This may be the result of direct compression on the chest or abdomen impeding the ability to breath (traumatic asphyxia) or a body position that interferes with the ability to maintain an open airway (positional asphyxia). The body compression may be from the harness or its attached ropes and straps and may be influenced by the body's position. The position may vary depending upon the state of consciousness, the type of harness and attachments and how they are positioned. It is uncertain how long one must be suspended in order to have adverse effects, and obviously the time frame could vary depending on the circumstances.

Until further research and analysis of similar deaths are undertaken, the nature, physiological effects and dangers of harness suspension are still largely unknown. However, one should be aware of the potential risks of prolonged harness suspension while unconscious or otherwise.

Harness Hang, Suspension, Rappelling

G71 Unusual Patricide: Case Report

Maria Carolina Romanelli, MD, University of Bari, Sezione di Medicina Legale, Piazza Giulio Cesare, 11, Bari, 70122, ITALY; Giancarlo Di Vella, MD, PhD, University of Bari, DIMIMP, Sezione di Medicina Legale, Policlinico, piazza G. Cesare, Bari, 70121, ITALY; and Roberto Catanesi, MD, University of Bari, Section of Forensic Psychiatry, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will have a better understanding of the classification of homicide called case of patricide.

This presentation will impact the forensic science community by stimulating discussion on whether or not mental illness should be considered a "trigger point" for offenders.

Parricide is defined as a homicide in which victims are parents and the killers are their children. "Patricide" is the definition given to the murder of father, while "matricide" refers to the murder of the mother. International literature reports that this crime is often associated with psychiatric morbidity and is usually committed by males. Patricide committed by sons is the most frequent form. In Italy, parricide is quite rare and it represents less than 3% of all murders (59% matricides and 41% patricides). The typical profile of the offender is a young adult male who is single and unemployed. The offender typically lives with victim (quite often an old and disabled person), and is suffering from mental illness with co-morbidity of alcohol or drug consumption and/or abuse. Usually he is not able to separate himself from his parents or to assume responsibilities. The homicide usually takes place at home at the end of an argument, and common tools found in the house are often used as weapons. A 73-year-old man was found dead at home, on the kitchen floor, after his son confessed the murder. He killed his father early in the morning, after yet another argument with him. He then called the police, and sat on the floor awaiting the officers, fully aware of his guilt. A pair of scissors and a cross-head screwdriver, both with traces of blood, and a wooden board were located close to the body. At crime scene, the victim was supine and showed multiple injury pattern. Clothes were raised upon the thorax and multiple thoracic-abdominal lesions were found together with bruises and abrasions of the head. The sternal area showed two larger stab wounds, while eleven penetrating cross-shaped puncture wounds affected precordial, epigastric, and mesogastric regions. Four other shallow, cross-shaped punctures of the skin surrounded these lesions. At autopsy, gross examination of organs showed visceral lesions with cardiac, hepatic, and intestinal involvement, widespread hemorrhagic infiltrates of cranial soft tissues, skull fractures (vault), and diffuse subarachnoid hemorrhages (SAH). Multiple and serial rib fractures were also found. The cause of death was related to traumatic shock due to blunt head trauma and multiple stab wounds. All autopsy data allowed drawing the following crime reconstruction: victim's head was initially hit with the wooden board and the man fell down, striking his head on the floor. Then the offender uncovered the anterior thorax and abdominal anatomical regions of his father and stabbed him with the pair of scissors and the screwdriver. Finally, he raised the victim's body, crushing the chest with his weight. The offender's criminal profile revealed a 45-year-old man, with elementary school education. At a young age, he became a construction worker at building sites in Northern Italy. The father, a construction worker too, was described as extremely strict with the son. The mother, a housewife, was characterized as a warm-hearted woman. The offender was very shy, the second of six children, and the only son. He did not have any recent romantic interests and he remembered only

one relationship with a woman in the past. No psychiatric disorders were in his medical records. He had a history of drug-addiction (intravenous heroin) and during the last years, he admitted to occasional use of cannabinoids and cocaine sniffing. However, the drug screen was negative when he was imprisoned. His mother had died a few months before, and due to an accident at work, the offender had lost his job. He was at home with his father every day. The mother's death broke the intra-family balance, and co-habitation caused relationships to deteriorate. The domestic context and the special violence of the crime induced the Court to impose a forensic psychiatric assessment of the offender that excluded factors of mental illness or psychiatric disorders at the time he killed the father. On these bases, the presented case is an unusual patricide that departs from those typically found in the literature.

Forensic Pathology, Patricide, Forensic Psychiatry

G72 Accidental Decapitation Due to Tamping Machine: A Case Report

Lucia Tattoli, PhD, Univerisity of Bari, Section of Legal Medicine, Bari, ITALY; Alessandro DellErba, Professor, Piazza G. Cesare, BARI, 70124, ITALY; Biagio Solarino, PhD, Sezione di Medicina Legale, Università degli Studi di Bari, P.zza Giulio Cesare, 11, Bari, 70125, ITALY; and Eloisa Maselli, MD, University of Bari, Section of Legal Medicine, P.zza Giulio Cesare, 11, Bari, 70122, ITALY*

The goal of this presentation is to report an uncommon case of accidental decapitation in a worker of a railway line.

This presentation will impact the forensic science community by enhancing worker knowledge of the risks associated to railway activities by showing an unusual incident of work related heheading by heavy machinery.

Decapitation is represented by separating the head from the body with cuts in the soft tissues of the neck and resection of the spine at the level of the last cervical vertebrae. Generally speaking it is referred to the act of intentional or accidental decapitation and it can be the result of an explosion, car or industrial accident, or other violent injury. Suicide by decapitation is unusual. Death by beheading is quickly fatal and it consists in the resection of the neck structures (vessels, nerves, cervical spine).

Presented here is a case of a 45-year-old man who worked on the railway line with other four colleagues, in close proximity to a ballast machine. A ballast tamper or tamping machine is a machine used to pack (or tamp) the track ballast under railway tracks to make the tracks more durable. For each rail there is a tamping unit attached to the main frame by means of vertical guide columns and a lifting/lowering hydraulic cylinder. The operations are controlled from the control cabin by an operator using three pedals, while the lining bogie holds the track in its lifted and slewed position. The Ballast Cleaning Machine (BCM) carries-out deep screening of ballast, which is an important maintenance activity to improve drainage and the resilience of the track. The cutter blades of the BCM dig out ballast from under and around the sleepers, and a conveyor belt transfers it to the on-board cleaning equipment where the ballast is passed over screens which remove fine debris. The clean screened ballast is returned to the track and the fine screened residue is ejected to one side, usually into a hopper wagon on an adjacent track. The machine goes into reverse and the blades rotate counter-clockwise.

The victim was located to the left of BCM, near the cutter blades, checking the correct progress of operations, while another worker was driving the machine the other two were together on the other side. All workers were dressed with safety equipment such as helmet, headset, and reflective vest. The victim was probably bent near the chain when he was slipped due to the instability of the ground, being hit on the helmet or on the jacket by the teeth the chain. The speed of the machine did not allow the victim to move away from the chain and he was transported to the right arm of the BCM, inside of which entered his head, but whose size (45 centimeters height and 40 centimeters wide) did not allow the passage of whole body.

At the autopsy time we found the head and the right forearm detached from the rest of the body. The longitudinal diameter of the head was 28.5 centimeters and the diameter of the laceration at the base of the neck was 15x10 cm. In the right parietal region there was a large lacerated and bruised wound the total length of 15cm and in the left fronto-temporal region there was another lacerated and contused wound with margins diastase that affects the entire skin thickness; also he had fracture of the left lateral eye socket. The laceration line passed through the high left lateral to the low right lateral and posterior part of the upper cervical region. Head and neck were covered with powdered material. The airway was severed at the trachea level. The laceration present in the cervical region had a longitudinal diameter of 21.5 centimeters and transverse diameter of 16 centimeters and through it passed heart and part of lungs, traction by trachea and neck vessels. Excoriated streaks and de-epithelialisation area were observed in whole body even if mainly in the dorsal region; these injuries were due to the action of sliding on the stones present in the binary. The helmet and the headset were broken.

No other similar cases are reported in literature.

Decapitation, Railway, Ballast Cleaning Machine

G73 Seasonal and Environment Effects on the PMI Estimation Using the Entomological Approach

Stefano Vanin, PhD, University of Huddersfield, Queensgate, Huddersfield, HD1 3DH, UNITED KINGDOM; Valentina Bugelli, MD, Sezione Dipartimentale di Medicina Legale, Università di Pisa, via Roma 55, Pisa, 56100, ITALY; Martina Focardi, MD, Sezione Dipartimentale di Medicina Legale Università degli studi di Firenze, Viale Morgagni 85, Firenze, 50134, ITALY; and Mirella Gherardi, MD, SC Medicina legale, USL Valle d'Aosta, via Chaligne, Aosta, 11100, ITALY*

After attending this presentation, attendees will receive novel information about the advantages of practical application of forensic entomology in different environmental conditions (indoors, outdoors, water) and in different seasons.

This presentation will impact the forensic science community by offering new data about the composition of the carrion breeding fauna particularly during the winter season and the effect of global warming on the entomofauna. This presentation will offer as well a statistical approach for the estimation of the season in which the death occurred. This topic is of particular importance in "old cases."

Forensic entomology is a branch of forensic science in which insects are used as evidence in legal investigations relating to humans or wildlife. The examination, identification, and analysis of insects associated with human remains, combined with the knowledge of insect biology, can provide a further level of detail in addition to medical and anthropological data in the reconstruction of events occurring close to the time of death. In particular, necrophagous insects are useful in studying Postmortem Interval (PMI), postmortem transfer, and presence of drugs or poisons.

Seasons, environment, concealment, and accessibility play an important role in the selection of the carrion breeding insects. It is worth mentioning that during the last 25 years global warming and globalization have modified the species distribution with important effects on the application of the entomological method for the PMI estimation (Turchetto and Vanin, 2010, in Amendt et al., Current Concepts in Forensic Entomology, Springer).

Twenty cases have been considered from an entomological point of view. The cases occurred, during the last two years, in Central Italy which is an important area for the understanding of the global warming effect on the entomofauna.

The bodies were discovered between February and November and the estimated minimum PMI ranged from few days to several weeks. Socially isolated people, drug or alcohol addicts, or old people living alone were involved in the majority of the cases considered. The causes of death included natural, homicide, suicide, smothering, and drug overdose. In four

cases the bodies were burned due to fire or electricity. In one case, the body was found in a saltish lagoon.

The insects have been recovered during the autopsy and, where possible, also during the body recovery following the standards and guidelines proposed by the European Association of Forensic Entomology (EAFE, Amend et al., 2006, Int J Legal Med 121: 90-104).

Statistical analysis of the results reveals a strong correlation between fauna composition and decomposition stage of the body, between the fauna composition and the season of the death (winter vs. summer), and between the fauna composition and the environment (outdoors vs. indoors). No statistical differences have been detected comparing the causes of death. In burned remains, insects of the first waves of colonization (Calliphoridae and Sarcophagidae) arrive without any delay compared with other cases, confirming observations and experiments carried out by Vanin and Cattaneo (Vanin et al., in prep).

Species belonging to Diptera (Trichoceridae, Psycodidae, Stratiomyidae, Phoridae, Muscidae, Fanniidae, Calliphoridae, and Sarcophagidae), Coleoptera (Cleridae, Staphylinidae and Silphidae) and Hymenoptera (Formicidae) were collected. The genera *Trichocera*, *Calliphora* and *Hermetia* showed a fall/winter phenology whereas *Lucilia* (particularly the species *L. sericata*), *Sarcophaga* and *Chrysomya* a summer phenology, with the later species present also during the fall.

The recovered data highlight that *Hermetia illucens* (Stratiomyidae) (species introduced in Europe during the last century) and *Chrysomya albiceps* (Calliphoridae) (reported only from the Southern regions till 1985) are now present in the whole Italian peninsula. In addition the data underline the important role of *Megaselia scalaris* (Phoridae) in the colonization of indoors bodies.

Postmortem injuries caused by arthropods have been reported in two cases. An indoors case shows the activity and the possibility to have postmortem injuries by ants also inside an house, whereas the body recovered from the saltish lagoon showed different lesions on the face and on the body performed by aquatic Isopods (Crustacea, Isopoda).

This work summarizes and statically analyzes information coming from different cases. The data, here presented, represent an important point of reference for the definition of the season of death, for the comparison between different environments. In addition our data confirm the spread of alloctonous species, particularly from the southern regions. This information is important in order to avoid mistakes in estimation of body transfer. Moreover, the significant attention to indoors cases is related with the observation that over 70% of the cases occur in this environment (Vanin et al., in prep).

Forensic Entomology, Global Warming, Statistical Analysis

G74 Decapitation: Unusual Feature of a Fatal Dog Attack

Benedetta Di Battista, MD, and Irene Riezzo, PhD, University of Foggia, Department of Forensic Pathology, Osp D'Avanzo, Viale degli Aviatori, 1, Foggia, 71100, ITALY; Valerio Jarussi, VMD, Via G. Imperiale 13/G,, FOGGIA, 71100, ITALY; Fabrizio Iarussi, DVM, Department of Public Health and Animal Husbandry, University of Bari, Bari, ITALY; Eugenia Carnevali, BS, Hospital of Terni, via T. di Joannuccio, snc, Terni, 05100, ITALY; Massimo Lancia, MD, Institute of Forensic Medicine, University of Perugia, Perugia, ITALY; Giulio Zizzo, MD, Department of Radiology, Ospedali Riuniti, Viale Pinto 1, FOGGIA, 71100, ITALY; and Margherita Neri, MD, PhD, University of Foggia, Department Forensic Pathology, Viale degli Aviatori 1, Foggia, 71100, ITALY*

After attending this presentation, attendees will understand the concerns in a case of a fatal Rottweiler dog attack on a 52-year-old man who was found dead on a farm where he worked.

This presentation will impact the forensic science community by showing how the evaluation of fatal dog attacks requires an integrated approach in association with veterinary pathologists and forensic geneticists, involving review of the circumstance of death, examination of the death scene, CT analysis and autopsy examination of the victim and the histological and immunohistochemical examination (IL-15, CD15 and tryptase).

The cases were all characterized by extensive and mutilative stripping of soft tissues from the upper limbs, face, and scalp, progressing to decapitation in the man. Investigators found the entire skull, completely skeletonized, of about 800 meters away from the decapitated body. A complete methodological forensic approach by means of autopsy, histological and immunohistochemical examinations and an integrated study in association with a veterinary doctor and forensic genetics is an important part of such investigations. It may provide information helping to establish the identity and ownership of the animal, along with trace evidence confirming that the dog was involved in the attack with ccomparison of the bitemarks on the victim and the dentition of suspected dog.

Deaths due to animal attacks are rare. Deaths caused by dog attacks appear to be growing as the population of both humans and dogs has increased. Many types of dogs have been involved in fatal attacks on humans, with at least 25 different breeds reported in 238 deaths in the United States over a 20-year period. The majority of cases (60%) have, however, involved pit bull-type dog, rottweiler, and german shepherds, most of whom were unrestrained on their owner' property. Diagnosis of a wound as a bitemark is generally not difficult considering the rather pathognomonic wound pattern of "a hole-and-a-tear" together with skin abrasions and claw marks. Any part of the body can be the site of a dog attack. An unusual concentration of severe injuries to the head and neck regions is typically reported in the literature. Bites to the forearms are also common as the limbs are generally raised in an attempt to protect the face. Dog attack deaths usually result from exsanguinations through opened body cavities and/or large vessels and/or asphyxia.

Case: A 52-year-old Caucasian man was found dead on the sidewalk in front of his home on the farm where he worked. A multidisciplinary forensic approach, including CT analysis, autopsy findings, histological and immunohistochemical examination, and bitemark analysis was performed. A complete autopsy was performed 48-hours after death. The external examination revealed the presence of multiple and coarse lacerations of the skin in the upper limbs and clusters of superficial, linear, parallel abrasion from a dog's claws were present in the skin adjacent to bitemarks. In the thorax, cluster of ribbon and parallel abrasions with the same trend were observed bilaterally. The most striking finding was represented by decapitation, characterized by a laceration of the circumference of neck exposed second thoracic vertebra, the trachea completely dissected, the vessels of the neck and the paravertebral muscles and shoulders, strong friction and hemorrhagic. The CT analysis of the skull demonstrated small scratches at the neurocranium made by the canine teeth and/or paws. There were no other injuries on the body. The internal examination revealed a hemorrhagic area around the neck vessels that appeared frayed. Histological study of tissue samples confirmed the vitality of the skin lesions. The immunohistochemical examination of the bitemark specimens revealed a positive reaction for antibodies anti CD15, IL-15 and tryptase. The death was attributed to decapitation and hemorrhage due to vascular disruption.

An integrated study with a veterinary doctor was performed by creating the dog's dental cast. Dental casts were superimposed on the victim's wound samples collected at autopsy and analyzed for compatibility with the patterns taken from the jaws of suspected dogs could be clearly adapted on the bitemarks. The results of this investigation allowed the confirmation that the bitemarks found on the corpse matched the cast of the dental arches of the suspected rottweiler. The genetic laboratory was able to match the human DNA profile from the samples (blood and fecal impaction containing hair of the man) the suspected dog. The human DNA profile found was identical to that of the victim. Genetic typing was performed with 19 canine microsatellites markers, co-amplified in a single multiplex PCR reaction with "Canine Genotypes Panel 1.1 (Finzymes Diagnostics, Finland). The search for genetic traces of the dog was performed on samples of skin and muscle of the victim.

Dog Attack, Decapitation, Bitemarks

G75 A Case of a Death Related to Underwater Propeller at a Desalination Plant During Illegal Scuba Fishing

Benedetta Di Battista, MD, Stefano Derrico, PhD, and Cristoforo Pomara, MD, PhD, University of Foggia, Department of Forensic Pathology, Viale degli Aviatori 1, Foggia, 71100, ITALY*

The goal of this presentation is to show how injuries by propeller, amputation, and death by drowning are rarely reported events in forensic literature. A complete methodological approach with complete autopsy and histological study must be required as forensic approach to these cases.

This presentation will impact the forensice science community by educating them on a complete autopsy and histological study of all organ and surfaces of mutilated skin to determine the phases of death are of impact for attendees.

A self-contained underwater breathing apparatus (SCUBA) is often used in diving; it is practiced both as a sport and for some commercial activities. Most developed countries have legislation ensuring the safety of divers, but despite this, deaths are still recorded, especially among amateurs. In Puglia, many amateurs scuba dive for fishing for shellfish, such as mussels and clams, as well as octopus and bluefish. The most frequent cause of death, associated with this activity is drowning. In Italy, drowning occurs at a lower incidence than in others countries but is a highly lethal phenomenon. In almost half of the 800 events per year, the person involved dies (387 cases in 2007) and in the remaining 55% of the cases, people are hospitalized (near-drowning cases). Of these, it is estimated that in 2010 almost 10% occurred during SCUBA fishing expeditions. In contrast, propeller injuries are rare events and are thus seldom reported in the international forensic literature. According to a previous report, the frequency of propeller accidents is greater than 1 in every 20 boating accidents, and the fatality rate in propeller accidents is 15–23%.

Most propeller injuries occur at water recreational facilities such as those equipped for water skiing, boat racing, and skin and scuba diving. Injuries by propeller are typically multiple, deep, parallel lacerations that can result in permanent scarring, substantial blood loss, traumatic or surgical amputation, or death. Research has not shown any previous reports of injuries or reported deaths related to propellers from a desalination plant. This case study presents a scuba diver's death that occurred during an illegal scuba fishing trip in the vicinity of a desalination plant. During a scuba diving fishing trip at around 6:30 a.m., three scuba divers were fishing about 3-4m deep and about 30m away from the beach. One of the divers decided to fish close to the plant, probably attracted to the enormous quantity of "big mussels" attached onto the surface of the underwater parts of the desalination pump. After a sudden and unexpected start of the pump, a few minutes later, the other fishermen noticed a large, bloody patch in the water and then the lifeless body of their friend. They dragged him by swimming to the beach and then alerted local authorities.

An underwater scene investigation was conducted by an engineering team, studying the mouth of the pump and the dynamic characteristic of rotating propeller blades. An autopsy was performed the day after the death.

The external examination of the body showed multiple amputations of arms and legs; a large bluish/red abrasion/contusion of the right thoracic wall extending to the superior part of the ipsilateral abdominal wall was also observed. Autopsy confirmed the complete sectioning of the right arm, the left forearm, and both ankles, and corresponding great vessels. A contusion of the thoracic soft tissue without any fractures was also noted. Examination of all other organs was unremarkable except for pulmonary and cerebral edema. Vessels were completely free of blood. Lungs were increased in volume and size, with few subpleural hemorrhagic spots. Mild cerebral edema with focal subcortical hemorrhagic spots and focal pulmonary edema associated with extended areas of atelectasia, acute emphysema and "ballonee" cells inside the alveolar spaces were observed at histological examination with standard H&E staining. Histological examination of the heart was unremarkable except for few foci of contraction band necrosis. Histological examination of the skin of the amputated surfaces revealed the presence of red cells on the derma.

In accordance with the data obtained, the dynamics of the fatal event were reconstructed and the cause of death was a result of drowning and massive hemorrhage due to propeller injuries.

Histological study of all organ and surfaces of mutilated skin to determine the phases of death (drowning and after mutilations of lifeless body?) must be required as forensic approach to similar cases.

The public implications of this event will be discussed especially in regards to criminal charges initiated against the owners of the desalination plant.

Amputation, Underwater Propeller, Scuba Fishing

G76 The Reconstruction of an Unusual Pedestrian Road Trauma Using Forensic Pathology and Forensic Veterinary Medicine

Isabella Aquila, MD, Magna Graecia University of Catanzaro, Institute of Forensic Medicine, Viale Europa, località Germaneto, Catanzaro, 88100, ITALY; Orlando Paciello, VD, PhD, Magna Graecia University of Catanzaro, Institute of Veterinary Medicine, Viale Europa, Località Germaneto, Catanzaro, 88100, ITALY; Paola A. Magni, MS, Università di Torino, F.E.LAB ASL TO1, Via Accademia Albertina 13, Torino, 10123, ITALY; Francesco Ausania, MD, and Ciro Di Nunzio, MFS, PhD*, Magna Graecia University of Catanzaro, Institute of Legal Medicine, Viale Europa, località Germaneto, Catanzaro, 88100, ITALY; Domenico Britti, PhD, Magna Graecia University of Catanzaro, Institute of Veterinary Medicine, Viale Europa, Località Germaneto, Catanzaro, other 88100, ITALY; Pietrantonio Ricci, MD, Università degli Studi Magna Grecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, 88100, ITALY; and Francesca Pepe, MD, Magna Graecia University of Catanzaro, Institute of Legal Medicine, Viale Europa, località Germaneto, Catanzaro, 88100, ITALY*

After this presentation, attendees will understand how cooperation between experts in pathology and veterinary medicine can solve a crime involving both humans and animals.

This presentation will impact the forensic science community by highlighting the fact that experts with knowledge of the anatomy of different animal species can contribute to solving a crime.

Traffic accidents have increased in the last decade. Pedestrians are most affected group among the victims of vehicle accidents. At autopsy, it is evident that the most common cause of pedestrian death is central nervous system injury, followed by skull base fractures, internal bleeding, lower limb hemorrhage, skull vault fractures, cervical spinal cord injuries, and airways compromise. The determination of fault can be assigned through the reconstruction of the dynamic of the road accident. The reconstruction of the accident is made through on-site investigation, a survey of the vehicle involved and victim examination.

A case study concerning a car accident where both humans and pets were involved is reported here. During spring 2011 an old man and his dog walking along the road were knocked down by a SUV. The driver stated that the man and his dog were walking in the middle of the road.

The investigation and the reconstruction of the crime scene were conducted by a team composed of a forensic pathologist and a forensic veterinarian.

During the investigation, the pedestrian and his dog were recovered on the brink of the road. It was determined that an autopsy should be conducted on the man and a necroscopy on the dog. In addition, a complete inspection of the SUV was conducted.

The results of the autopsy and necroscopy were compared gollowing the histological analysis. This information was also used to reconstruct the collision.

Both the man and his dog showed lower limbs fractures with features indicating a collision on the dorsal side of the body. Furtermore, the man and

his dog showed cervical spinal cord injuries because of traumatic neck bend. The comparison between the human and the animal fractures and the autopsy results excluded allegation that the man and his dog were in the middle of the road. In fact, the biomechanics of injuries was suggestive of a collision that the pedestrian and his dog were struck from behind causing the propulsion along the roadside. This finding was supported by the presence dog hairs and fibers of clothing belonging to the man on the right front bumper of the car.

This unusual case was solved through the collaboration between the investigation using forensic pathology and veterinary forensic medicine.

Forensic Sciences, Forensic Pathology, Forensic Veterinay

G77 Wounds Vitality Evaluation in Decomposed Corpse: The Application of Monoclonal Antibody Against Heamoglobin Alpha Chain

Luisa Andrello, and Petra R. Basso, University of Insubria, Viale borri, 57, Varese, 21100, ITALY; Luca Tajana, Ospedale di Circolo e Fondazione Macchi - Varese, Viale borri, 57, Varese, 21100, ITALY; Terenzio Congiu, University of Insubria, Via Monte Generoso, 2, Varese, 21100, ITALY; and Antonio M.M. Oscualti, University of Insubria, Viale Borri, 57, Varese, 21100, ITALY*

After attending this presentation, attendees will become familiar with this immuno-histochemical method for wound vitality evaluation. This presentation will also identify the difficulty of diagnosis of injury vitality in putrescent corpses.

This presentation will impact the forensic science community by demonstrating a method that allows for the assessment of whether wounds are antemortem or postmortem in decomposed bodies. This can benefit the forensic community by adding to the methodology available for the identification of wounds vitality in decomposed bodies, especially in murder.

Forensic pathologists usually evaluate injury vitality through the identification of red blood cells in wounded tissues. Hematoxylin and eosin stain is one of the most commonly used histology stains to do this evaluation. Unfortunally this microscopic technique is not reliable in decomposed bodies, because erythrocytes are often lysed and not recognizable.

Although a lot of researches have attempted to use histological and immuno-histochemical methods to analyze the vitality of lesions of soft tissues, there is still no conclusive tools to determined whether a wound is antemortem or postmortem in decomposed corpse.

The inability to recognize red blood cells in histological samples with hematoxylin and eosin stain does not exclude the possibility to identify red blood cells specific components. In particular hemoglobin chains seem to be one of the most resistant elements to putrescence.

The immuno-histochemical method was used in some cases in which corpses were decomposed and where it was really hard to understand which lesions were caused antemortem and which were postmortem.

In this case, a homicide presented problems regarding injury diagnosis, because there were no existing tests that allowed the confirmation of the diagnosis of vitality. Gross observation and light microscopy examination of the samples (H&E histological samples) seemed to indicate that only some wounds had characteristics of vitality. That was important to determine because all the wounds were potentially dealt either to kill or to try to dismember the corpse. Application of monoclonal antibody direct against Hemoglobin alpha chain allowed the detection of the remaining red blood cells in soft tissues near some of wounds and not in others. Therefore, it could be identified, with some certainty, which wounds were inflicted in the attempt to hide the corpse. These results agreed with the case's reconstruction made by the police.

In another homicide case, when a female corpse was found about three months after the young lady disappeared, the immuno-histochemical method was used to determine which wounds were caused intra-vitam during the struggle and which were made postmortem.

This method was also used in a third case of homicide, when a decomposed body was found in a wooded area, about four moths after the disappearance. In this case, it was important to understand which wounds was antemortem and which lesions were due to animal scavenging. The majority of the wounds took place in the neck and it was difficult to determine which were made by a blade and which by animal teeth, because of the decomposition of the skin. This method confirmed the hematoxylin and eosin light microscopy analysis and helped to determine which lesions were really meant to kill and which were not.

Preliminary data presented here suggests that this method will be of great use in determination of wound vitality, even greater number of samples will have to be observed to validate this method for forensic routinary use.

Wounds Vitality, Immuno-Histochemical, Decomposed Corpses

G78 Estimation of Postmortem Interval: Determination of Hypoxanthine in Vitreous Humor by Mass Spectrometry

Cristina Cordeiro, MSc, Instituto Nacional De Medicina Legal, Largo Da Se Nova, Coimbra, 3000-213, PORTUGAL; Elena Lendoiro, MD, Institute of Forensic Science, University of Santiago de Compostela, Calle San Francisco, Santiago de Compostela, 15782, SPAIN; Maria Sol Rodriguez-Calvo, PhD, University of Santiago de Commpostela, Department of Pathology and Forensic Science, Faculty of Medicine, Calle San Francisco, Santiago de Compostela, 15782, SPAIN; Manuel Lopez-Rivadulla, PhD, and José Ignácio Muñoz-Barús, PhD, Institute of Forensic Science, University of Santiago de Compostela, Calle San Francisco, Santiago de Compostela, 15782, SPAIN; and Duarte N. Vieira, PhD, MD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

After attending this presentation, attendees will understand the potential contribution of a new method for confirmation and quantification of hypoxanthine in vitreous humor for determining the postmortem interval.

This presentation will impact the forensic science community by showing this a method and how it can increase the accuracy to calculate the postmortem interval, creating new possibilities, especially if a combined study is done taking into account the weight and the temperatures of the body and the environment.

Currently there are a number of procedures for determining the postmortem interval (PMI). Numerous methods have been used, some pseudoscientific, others merely descriptive, many without practical value, and most of them without any corroborating mathematical support. Others suffer from poor reproducibility and consequent uncertainty of their results exacerbated by failure to carry out field tests. Those using a methodology based on body cooling rate, although accompanied by statistical support, include certain clearly subjective factors.

The best results derive from the biochemistry of the vitreous humor (VH) and are based on the simultaneous determination of potassium (K) and hypoxanthine (Hx), correlating the value of both substances with postmortem interval. New statistical approaches have led to more precise and robust methodological processes which have helped clarify the interpretation of results. However, the analytical methodology for the determination of hypoxanthine has remained unchanged and therefore subject to certain limitations of validity and quantification in particular.

Objective: The goal of this presentation was to develop and fully validate a new method for confirmation and quantification of hypoxanthine in vitreous humor, applying liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS)

Methods: Vitreous humor samples, take in fresh bodies, were subjected to solid-phase extraction. Chromatographic separation was performed using an (2.1x100mm, 3µM) analytical column, working in gradient mode, with acetonitrile and ammonium acetate 10mM (pH=4.5) as mobile phase. A tandem mass spectrometer was employed for the detection of hypoxanthine. Mass spectrometer worked in electrospray positive mode (ESI +) and MRM

mode, monitoring two precursor-product transitions: 137> 110, and 137> 119 for identification and quantification of hypoxanthine. For method validation, linearity, precision, accuracy, limit of detection and quantification, matrix effect, extraction efficiency, and process efficiency were studied. All the studied validated parameters were within the accepted criteria, and LOQ of hypoxanthine was 10µM.

Discussion: It is a well known fact that hypoxanthine alone cannot provide an estimate of the time of death with any more accuracy than the potassium. However, it is necessary to use different variables to lend precision to the estimates. Hypoxanthine is one of the variables validated as an estimator for postmortem interval. The improvement in the statistical and analytical methods must be used in estimation methodology, reducing the confidence interval and increasing the accuracy and thereby provide the forensic pathologist with an objective validated method for postmortem interval estimation. With this method new studies could be made, for example taking into account the weight and the temperatures of the body and the environment.

PMI, Hypoxanthine, LC-MS/MS

G79 Fire, Flies, and Wasps: PMI Estimation of Burned Remains

Cristina Cattaneo, PhD, MD, LABANOS Lab, Universta Degli Studi Di Milano, Milan, ITALY; and Stefano Vanin, PhD, University of Huddersfield, Queensgate, Huddersfield, HD1 3DH, UNITED KINGDOM*

After attending this presentation, attendees will have novel information about the advantages of the practical applications of Forensic Entomology (FE) on burnt remains. In this particular condition FE could be the only method for PMI estimation.

This presentation will impact the forensic science community by validating the entomological approach in the PMI estimation on burnt bodies. The two reported cases, based on experiments, statistically confirm the applicability of the entomological approach based on the fly developmental rate for PMI estimation.

Different methods can be used in order to destroy a body or make its identification impossible: mutilation, burning, burying, acid dissolution, and concealment into concrete blocks. Burying and burning are perhaps the most common. Cases of burnt bodies found in different locations such as open fields, cars, and indoors have been reported regulary in literature. In burnt bodies, arthropod specimens may be the only tool useful in the estimation of the minimum time of death (mPMI). In fact, burning prevents the use of the classical thanato-chronological techniques (e.g., body temperature, livor, rigor, algor mortis, [K+]) for mPMI estimation.

This work deals with PMI estimation of two cases of burned bodies found during the summer of 2009, in Northern Italy, in the region around Milano. The two cases show several common characters, and in both cases the PMI estimation was (and could only be) performed using an entomological approach. This was possible thanks to data collected during experiments carried out during the previous years, in the same region (Vanin, Cattaneo, in prep). Insects were collected both from the crime scene and during the autopsy following standards and guidelines proposed by the European Association of Forensic Entomology (Amend et al., 2007).

Late June 2009, the burned body of a man was found along a river in a suburban area. The body was lying on the ground in a mostly skeletonized stage, with some areas of putrefied skin still surviving on forearms, lower limbs, and head which appeared dry due to heat and air exposure. The torso and hip regions had been completely burnt and presented as charred osseous remains. The Diptera samples were composed by larvae (maggots), pupae and puparia of three species *Lucilia sericata, Phormia regina* (Calliphoridae) and *Stearibia nigriceps* (Piophilidae). Several puparia of the blowflies were parasitized by the wasp *Nasonia vitripennis*. Among the Coleoptera, larvae and adults of *Dermestes frishii* (Dermestidae) were sampled, whereas all the other coleopters (Cleridae, Histeridae, Silphidae, Staphylinidae) were collected only at the adult stage. The entomological evidence allowed for estimation of a mPMI between 24 and 31 days. This value was obtained adding the time of development of the host, *Phormia regina*, and the time of development of the parasitoid, *Nasonia vitripennis*.

In July 2009, the body of a woman was found in the garden of an abandoned house in a village. The body, almost completely skeletonized, with some signs of burning to the extremities of arms and legs, was lying on the ground in a supine position and was covered by a plastic sheet. The Diptera samples were composed by larvae (maggots), pupae and puparia of three species *Lucilia sericata* (Calliphoridae), *Hydrotea capensis* (Muscidae), and *Fannia canicularis* (Fanniidae). Several puparia of the blowfly *L. sericata* and one of the muscid *H. capensis* showed the typical holes of a parasitoid infestation. The parasitoid presence was confirmed by the emergence in the rearing chamber of several *Nasonia vitripennis* adults.

Coleopteran species were collected both at the adult and larval stages. In particular, several larvae and adults of the dermestid *Dermestes frishii*, *Necrobia rufipes,* and *N. violacea* were collected. Histeridae, Staphilinidae, Nitidulidae, and Tenebrionidae were collected only at the adult stage. The entomological evidence allowed for an estimation of a mPMI between 57 and 63 days. This value was obtained adding the time of development of the host, *H. capensis*, and the time of development of the parasitoids, *Nasonia vitripennis*. This estimation was confirmed by the developmental rate of the beetle *Dermestes frishii.*

These two cases demonstrate, in agreement with previous experiments (Vanin, Cattaneo in prep), that in burned remains the first waves of insect colonization (Calliphoridae, Muscidae, Sarcophagidae) are the same as in the case of "fresh" bodies. This supports the application of the entomological approach, based on the developmental rate, for PMI estimation. In contrast the composition of the community cannot be used due to the occurrence at the same time of insects belonging to different "colonization waves."

It is worth mentioning that the presence of the parassitoid *Nasonia vitripennis* offers additional information for PMI estimation.

PMI, Burned Remains, Forensic Entomology

G80 The Use of Forensic Messenger RNA (mRNA) Analysis to Determine Stain Age

Jo-Ann C. Connolly, BSc, University of Huddersfield, Queensgate, Huddersfield, HD1 3DH, UNITED KINGDOM*

After attending this presentation, attendees will understand the principles of forensic mRNA analysis and learn how it may be used as a method to determine the age of biological stains found at crime scenes.

This presentation will impact the forensic science community by proposing a novel method for determining the age of biological stains. The proposed method could prove crucial for forensic casework and could run parallel to the predominant DNA analysis method. Where DNA analysis is used to identify a suspect, mRNA analysis could be used to determine the age of biological stains, that in turn could place the suspect at the scene of a crime at a specific time.

RNA has been presumed to be very unstable, as one of its features is that it degrades rapidly as it is broken down by ribonucleases. In previous literature however; it has been shown that RNA may be extracted from biological stains up to 16-years-old. For stain age determination, it has been suggested that using a decay rate ratio, derived from two endogenous controls differentially expressed within the body fluid stain, should eliminate the effect of any external decomposition factors. This should then be expressed as a linear change in mRNA expression over time.

The majority of previous research concentrates on determining the age of bloodstains. In this study, blood and saliva stains were used. The goal of the study was to try to determine the age of these biological stains by isolating mRNA and quantifying the expression of housekeeping genes 18s, GAPDH, and ACTB also known as β-Actin. This study aims to demonstrate proof of principle and explore any limitations to a decay rate ratio, to see if there is any correlation between the age of a stain and the amount of genetic material present.

Blood and saliva samples have been collected on a regular basis over the past two years. Bloodstains were prepared using the finger prick method and depositing blood on to a sterile filter paper. Saliva stains were prepared by swabbing the inside of the cheek with a buccal swab. All samples were taken from healthy individuals. The samples were stored at room temperature and protected from sunlight. Both blood and saliva samples were extracted using Qiagen RNeasy Mini Kit with the appropriate modifications for each body fluid. The extracted samples then underwent RNA quantitation, DNase digestion, and reverse transcription using M-MLV reverse transcriptase and random hexamers. The resulting complimentary DNA (cDNA) was then quantified using absolute quantitation on a 7500 Fast Real-Time PCR System, using pre-designed Taqman Gene Expression Assays for human housekeeping genes 18s, GAPDH, and ACTB (β-Actin). Only two housekeeping genes were run together at one time, this was to compare the differences between all three, for example the decay rate ratio between 18s and GAPDH as well as 18s with ACTB and then GAPDH with ACTB. The two values from quantifying the two housekeeping genes were then expressed as a ratio. The proof of principle would be demonstrated by a linear downward expression of the two genes over time.

The results from initial experiments show that mRNA can be extracted from stains up to two years old. Further experiments are being carried out to obtain enough data to determine the proof of principle.

Future work will involve optimising the protocols and identifying the shortest stain age per body fluid as well as exploring the use of more housekeeping genes. With bloodstains being the current focus in most of the literature, experiments will be carried out to determine the expression levels of human housekeeping genes in semen to see if it is possible to identify the time of deposition. Identifying the time a semen stain was deposited in a sexual offence case could prove to be vital when trying to convict or exonerate an individual.

mRNA, Stain Age Determination, Housekeeping Genes

G81 Death Due to an Acute Cocaine Intoxication and a Man With a Precedent Violent and Aggressive Behavior: Is it an Excited Delirium?

Gabriela Perilli, MD, Carmela Fiore, MD, Santina Cantatore, MLT, Margherita Neri, MD, PhD, and Irene Riezzo, PhD, University of Foggia, Department of Forensic Pathology, Osp D'Avanzo, Viale degli Aviatori, 1, Foggia, 71100, ITALY*

The goal of this presentation is to show an unusual fatal case of cocaine related death in a long-term abuser with symptoms of excited delirium. Postmortem findings with a complete histological, immunohystochemical, and proteomics study (Western blotting) on brain and heart and toxicological analysis of cocaine distribution in fluids and tissues are discussed.

This presentation will impact the forensic science community by describing the importance of a careful crime scene investigation, toxicological, and histological examinations in every drug-related death in order to clarify the exact mechanism of the death.

Excited delirium is a state of mental and physiological hyperarousal commonly associated with the use of cocaine. The actual pathophysiology of patients who have been previously identified with signs and symptoms of excited delirium syndrome is complex and poorly understood. Patients suffering from excited delirium can be extremely hostile and violent. The fundamental manifestations are delirium with evidence of psychomotor and physiologic excitation. There are several different potential underlying associations or causes, including stimulant drug abuse especially cocaine. The literature shows a high risk of developing psychosis in psychotropic substance abusers; psychotic symptoms, and experience of paranoia and suspiciousness are reported during the use of cocaine.

Case Report: April 24, 2011, at 11.00 a.m., a woman called the police and said that she found her husband dead at his home. A crime scene investigation was performed by forensic pathologist and police, who found the body of a 34-year-old Caucasian man in the kitchen. The man lived alone after a quarrel with his wife. The corpse was lying supine on the floor, wearing blood stained clothes. Close to the head, the floor was covered in blood. On the floor near the corpse, the following was found: a plastic handle length of 11.5cm; broken knife blade total length of 18.7cm; scissors with the blades length of 8.5cm; a bloodstained pillow; a spoon smeared with white powder; and, broken glasses. In the bedroom, next to the bed, a surgical patch and gauze were found. The entire house was in disarray, the furniture was upturned and broken. The man was known for his cocaine use as well as for his violent and aggressive behavior. The wife told to police about previous episodes of mental and physiological hyperarousal, anxiety, exaggerated startle responses, psychomotor agitation, destruction of inanimate objects, insomnia, and fatigue.

A complete autopsy was performed 48-hours after death. Multislice computed tomography (MSCT) was performed prior to autopsy. External examination recorded multiple superficial and parallel incised wounds to the neck and the flexor surface of left arm and were interpreted as hesitation marks. Abrasions, contusions, and lacerations were noted on the head and face and on both hands. Extensive loss of bilateral ala, destructive lesions of nasal septum, and hard palate perforation were observed. Section of the neck revealed thin hemorrhages in the subcutaneous tissues and muscles; but neck blood vessels were intact. Internal examination revealed cerebral edema, the brain weighed 1,522g, measured 18.5x16.5x7.8cm; the heart weighed 380 g, measured 12.5x11.5x5.5cm. The coronary arteries, the myocardium and the valvular apparatus were normal. Into the esophagus surgical gauze was found. An ectopic formation of pharyngeal tissue was showed. The other organs did not showed specific alterations except for an intense vascular congestion.

Routine histological investigations, applying hematoxylin and eosin staining, were performed on all organs samples. Brain samples presented subarachnoid and perivascular hemorrhages, vasogenic edema; lungs showed a massive pulmonary edema. Myocardium presented foci of fragmentation of entire myocells in anomalous cross bands formed by segments of hypercontracted sarcomeres and myofibrillar rhexis, pach-fibrosis, loss of the usual parallel alignment of myocardial cells, with a star-like disposition, defined as disarray. Between the disarrayed myocytes an increased interstitial matrix and a myofibrous hyperplasia of arterioles was observed. Liver showed a microvescicular liver steatosis. The ectopic neoformation of pharyngeal tissue was constituted by skin, fat and hair. The examination of other organs was unremarkable except for generalized hemostasis. To characterize and identify excited delirium "markers," an immunohistochemical study was confirmed using the Western Blotting analysis, performed on brain and heart tissue using the principal markers of programmed cellular death, apoptosis (NF-κB, bcl-2, bid, Smac/Diablo, TNF-α, Tunel assay), alteration of dopaminergic trasmission (antibody anti - Tryptophan hydroxylase), Heat Shock Proteins, and β_1 - β_2 cardiac receptors.

Cocaine was detected in the subject's urine through immunoenzymatic screening. Toxicological analysis by solid–liquid extraction and gas chromatography/mass spectrometry (GC/MS) analysis, was carried out to identify and quantify the individual substances present in the biological fluids and organs. Cocaine concentration was as follows: blood 23.76mcg/mL/g, liver 332.95mcg/mL/g, urine 230.42mcg/mL/g, and kidney 49.38mcg/mL/g. Ecgoine methyl ester concentration was: blood 12.56mcg/mL/g, liver 18.37mcg/mL/g, urine 154.82mcg/mL/g, and kidney 4.82mcg/mL/g. Benzoylecgoin concentration was: blood 6.57mcg/mL/g, liver 58.34mcg/mL/g, urine 737.27mcg/mL/g, and kidney 3.28mcg/mL/g. Examination of nasal swabs was performed and it was positive for cocaine. No other drugs or alcohol were detected.

According to the crime scene data, autopsy, histological and toxicological findings, death was attributed to an acute cocaine intoxication in a subject with symptoms of exited delirium.

Cocaine Abusers, Oxidative Stress, Excited Delirium

G82 Homicide by Strangulation With Postmortem Dismemberment of the Victim: Looking for Injuring Tool

Sabina Di Donato, MD, PhD, Ospedale San Carlo - U.O. Medicina Legale, Via Bovio n. 81, Canosa di Puglia (BT), 70053, ITALY; Irene Riezzo, PhD, University of Foggia, Department of Forensic Pathology, Osp D'Avanzo, Viale degli Aviatori, 1, Foggia, 71100, ITALY; Giuseppe Guglielmi, PhD MD, University of Foggia, Department of Radiology, viale Pinto 1, Foggia, 71100, ITALY; Fabrizio Monaci, MS, University of Siena, Department of Environmental Sciences "G. Sarfatti", Via P.A. Mattioli, Siena, 53100, ITALY; Federica Cruciato, PE, University ot Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY; Mariantonietta Di Stefano, BS, University of Foggia, Viale Pinto 1, Foggia, 71100, ITALY; and Margherita Neri, MD, PhD, University of Foggia, Department Forensic Pathology, Viale degli Aviatori 1, Foggia, 71100, ITALY*

The goal of this presentation is to provide insight into various aspects of this type of postmortem injury due to desmemberment, including new diagnostic means, which may help the forensic community with the identification of injuring tool.

This presentation will impact the forensic science community by increasing awreness of the importance of completing extensive examinations and tests to establish the type of the lesions and their vitality, the cause of death, the effect of drugs on the victim, the characteristics of the possible injuring tool. Many morphological and technical details concerning the victim, the used instruments for killing, and dismembering are presented.

Criminal dismemberment or mutilation, with regard to all legal autopsies, has an average frequency of 1:500. The classification of the different types of postmortem dismemberment/mutilation includes defensive, offensive dismemberment of bodies and necrophilous dismemberment. But also intravital decapitation or mutilation (e.g., transection during accidents) may occur. Victims may be of all ages, but primarily between 20 and 60 years old and generally are female. Apart from an unfavorable personal life situation at the time of the offense, essential predisposing factors were: poor integration in society and family; occupational problems; drug abuse; and, mental diseases. As the interactions between these factors differ in every single case and may be combined with other factors, the analysis of such homicides should always be based on the assessment of the individual case. Apart from rare cases of necrophilia, the victim of dismemberment is always a victim of homicide. Perpetrators are most commonly person close to, or at least acquainted with the victim, between 30 and 40 years of age. The psychiatric expertises often classify the perpetrators as "normal," infrequently as abnormal or even as psychotic. Dismemberment is performed at the site of homicide, generally in the place inhabited by the victim, the perpetrator or shared by both.

In cases of postmortem dismemberment, the main forensic task, apart from the identification and assignment of body parts to one or several individuals, is the determination of the cause of death and the identification of the injuring tool. Notably in cases of offensive postmortem dismemberment, the findings on the victim may be of special importance which also provide investigators with objective means to reconstruct the course of events and get to the killer.

Case Report: A man who was walking along a road of the suburbs was alarmed by the foul odor coming from a garbage bag and a rucksack along the road. When the plastic was cut human lower limbs were revealed among the decomposition. The alerted detectives found three other body parts wrapped in layers of plastic bags, also contained in two buckets, not far from the first discovery site. The head was intact, allowing classical identification, in accordance with other external findings (tattoos, scars, lesion of the left foot, etc.). The victim was identified as a 49-year-old woman, who was a known drug addict, affected by HCV infection. She had been seen alive two days prior wearing a dark shirt and black pants, and limping with a bandage on the left foot. The investigation inside the woman's home was unremarkable. The victim's former boyfriend was suspected of the murder.

The medical examiner performed an autopsy and opened the garbage bag revealing five dismemebered body parts: head-chest, upper limbs from the shoulder down, and lower limbs from the buttocks down were cut off using a sharp object. The whole body, as well as the inner organs were very well preserved. Maggots were present on the hairs.

Multi-slice-3D-CT on the five body parts indicated the use of a sharp tool, especially on the basis of the witness marks produced on bone, typically found on the kerf wall or floor. A horizontal ligature mark encircling the neck was clearly visible, it was consistent with a rope. There were multiple petechiae in the skin. The autopsy showed also deep hematomas of the scalp, the rachis severed al L5 intervertebral disk level, and a necrotic ulcer at the left heel. The long bones displayed an extreme degree of splintering and bending breakage. Histological investigation revealed cerebral edema, acute emphysema, alveolar hemorrhages and edema, contraction band necrosis to the heart, hepatic cirrhosis and steatosis, dermoepidermal detachment, flattening of the epidermal layers, and massive hemorrhages in the cutaneous and subcutaneous tissues of the neck. No hemorrhages were visible in the cutis samples from limbs and chest cuts. Also the spinal cord and the cartilage of the intervertebral disk at L5 level didn't show erythrocytes. Immunohistochemical studies (Fibronectin, α1- antichimotripsin, antitriptase, CD 31, and collagen type IV) performed on the cutis specimens collected from the neck lesion, chest and limb cuts confirmed the vitality only of the neck lesion. Toxicological analyses were positive for morphine, methadone, and EDDP. DNA typing by PCR amplification established that tall remains belonged to the same woman. Inductively coupled plasma atomic emission spectroscopy (ICP-AES), an analytical technique used for the detection of trace metals, was performed on the cutis and cartilage specimens to determine characteristics of the sharp tool used to dismember. The death was classified as a homicide by ligature strangulation with postmortem dismemberment. Dismemberment and bone breakage was accomplished by cutting, blunt force, and, in the case of long bones, manual bending.

Dismemberment, Ligature Strangulation, ICP-AES

G83 Severe Hemorrhagic Pancreatitis in Forensic Autopsies: Report of Four Unequivocal Cases and Two Equivocal Cases

Wendy M. Gunther, MD, and Babatunde L. Stokes, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046*

After attending this presentation, attendees will recognize factors from history, autopsy, and histology which may assist in identifying severe or hemorrhagic pancreatitis as a cause of death in forensic cases.

This presentation will impact the forensic science community providing case presentations showing how severe pancreatitis may be identified as a cause of death in forensic autopsies; differentiating unequivocal hemorrhagic pancreatitis from postmortem autolysis; and, providing consideration for difficult cases in which equivocal pancreatitis is a "red herring" which is not substantiated as the cause of death.

Pancreatitis is a natural disease which varies in severity from mild to fatal. Severe hemorrhagic pancreatitis may present at forensic autopsy, where it may represent the cause of death. Pancreatitis may be related to gallstones, to the abuse of alcohol, and to some prescription drugs. With this, toxicology is important in fully examining a death from pancreatitis. Pancreatitis may also represent a confounding or "red herring" contributor to death; it may also be suspected when it is not present.

A series of four forensic cases of fatal hemorrhagic pancreatitis from the Tidewater experience illustrates these findings, contrasted with cases which show how suspected pancreatitis (whether present or not) may present pitfalls to the medical examiner when assigning the cause of death.

Acute pancreatitis can arise from a variety of etiologic factors, but in most cases the specific cause is unknown. In some instances chronic

alcoholism or toxicity from some other agent, such as glucocorticoids, thiazide diuretics, or acetaminophen, can bring on an acute attack of pancreatitis. In about half the patients a mechanical obstruction of the biliary tract is present, usually because of gallstones in the bile ducts. Viral infections also can cause an acute inflammation of the pancreas. Acute hemorrhagic pancreatitis is an acute inflammation of the pancreas accompanied by purulent peritoneal fluid, the formation of necrotic areas on the surface of the pancreas and in the omentum, and, frequently, also accompanied by hemorrhages into the substance of the gland. Some of the postmortem findings are discussed and potential pitfalls in diagnosing acute hemorrhagic pancreatitis on postmortem examination.

Case 1: EL, a 32-year-old male with a history of hypertension and chronic alcohol use complained of recent onset abdominal pain associated with nausea and vomiting was found unresponsive in bed. He was pronounced dead in the emergency department. Medications included hydrocodone, cetirizine, sildenafil citrate, and metroprolol. Internal examination revealed red discoloration and hemorrhage into an enlarged and partially necrotic pancreas, distended pancreatic duct with inspissated material, 200cc of purulent peritoneal fluid, hepatomegaly (4,000g), and cardiomegaly (438g). Histology revealed extensive acute inflammation with patchy necrosis superimposed on diffuse fibrosis, inspissated material in the ducts, and peripancreatic fat necrosis. The liver showed marked steatosis. The cause of death was due to hemorrhagic pancreatitis due to acute and chronic alcohol use

Case 2: EW, a 42-year-old male with history of chronic alcohol and recurrent chronic abdominal pain unrelieved by over the counter stomache relief medications became incoherent before having a witnessed collapse. He died in the emergency department. On internal examination, the pancreas has multifocal areas of hemorrhage, partially necrotic, a pseudocyst in the head, inspissated material in the ducts, and peripancreatic fat necrosis and saponification. There is 200cc of purulent peritoneal fluid, marked fatty change of the liver, and mild splenomegaly (184g). Histology reveals extensive mixed inflammation, necrosis, pseudocyst, severe fibrosis (especially in the tail), and hemorrhage of the pancreas. The liver shows marked steatosis and regenerating nodules with severe chronic inflammation. The cause of death is hemorrhagic pancreatitis due to chronic alcoholism.

Case 3: SF, a 66-year-old female with a history of chronic alcohol use and gallstones was hospitalized for a subdural hematoma associated with an unwitnessed fall. She died approximately two months later while in a rehabilitation center. On internal examination, the head and body of the pancreas were firm with inspissated material in the main duct and the tail of the pancreas contained an abscess surrounded by necrosis. There was also six liters of ascites, severe jaundice, cardiomegaly (500mg), splenomegaly (327g), gallstones, and a fatty liver. Histology showed broad tract of fibrosis in the pancreas with amorphous cellular material in the ducts and advanced necrosis with saponification. The cause of death was attributed to multi-organ failure due to acute pancreatitis.

Case 4: MC, a 55-year-old male with a history of gastroesophageal reflux disease, hyperlipidemia, and hypertension complains of abdominal pain for a day associated with vomiting and diarrhea before being found dead on the living room floor in his home by his mother. Medications include fenofibrate. Internal examination shows severe hemorrhage into the pancreas with focal areas of necrosis, moderate amount of retroperitoneal hemorrhage, 400cc of serosanguinous fluid in peritoneal cavity, 100c of serosanguinous fluid in the right pleural cavity, and peripancreatic necrosis. Histology reveals diffuse fibrosis of the pancreas with multifocal areas of hemorrhage. Toxicology is currently pending. The cause of death was attributed to hemorrhagic pancreatitis. (however, this is a recent case that hasn't been officially signed out yet).

Case 5: LW, a 33-year-old female with a history of pancreatitis, hypertension, gout, foot pain treated with tramadol and recent shortness of breath was found unresponsive at home and died in the emergency department despite resuscitation. Her medications included tramadol, temazepam, and zolpidem. On internal examination, the pancreas was unremarkable but there was hepatosplenomegaly (1854 and 217g), cardiomegaly (495g), pulmonary edema (1579g combined weight), small left lower lobe pulmonary embolus, and a deep vein thrombosis in the right lower extremity. Histology showed a small focus of bronchopneumonia. When toxicology showed elevated levels of hydrocodone (0.07mg/L) and tramadol (5.2mg.L), death was attributed to the combined respiratory depressive effects of the two drugs.

Case 6: PC, a 49-year-old institutionalized woman with a history of mental retardation, recurrent renal stones, and gastric ulcer complained for two days of abdominal pain. Her medications included valproic acid for seizure disorder. She was treated with morphine and found unresponsive in a chair hours later. On internal examination, the tail of the pancreas showed sharply demarcated patchy areas of hemorrhage, and histology revealed diffuse fibrosis of pancreas with patchy areas of necrosis and hemorrhage. When toxicology showed elevated levels of morphine (0.2mg/L) and thioridazine (0.9mg/L), death was deemed due to overdose, although abdominal pain was probably due to acute pancreatitis, which is a recognized complication of valproic acid administration.

In these six cases, hemorrhagic to purulent fluid was always present in the lesser sac when hemorrhagic pancreatitis was the unequivocal cause of death. It was not identified when pancreatitis was either absent, or not the primary cause of death. Other findings common to fatal cases included extensive neutrophilic inflammation, and extension into peripancreatic fat. The absence of these findings suggests prudence in waiting for the toxicology results to determine the cause of death.

Hemorrhagic Pancreatitis, Forensic Pathology, Cause of Death

G84 DNA Persistence in Soft Tissues

Sarah Ellingham, BSc, and William Goodwin, PhD, School of Forensic Medicine and Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will become familiar with the relationship between Accumulated Degree Days (ADD) and DNA degradation and will have developed an understanding of how this relationship can be used in order to estimate the time frame during which it is still possible to amplify a complete DNA profile in temperate climates.

This presentation will impact the forensic science community by delivering results from a controlled decomposition experiment on animal muscle tissue providing a stimulus for the refinement of the guidelines for soft tissue collections in Disaster Victim Identification (DVI) cases, as well as discussing the feasibility of using DNA degradation as an alternative means of assessing the postmortem interval (PMI) of decomposing remains.

DNA plays a vital role in the process of disaster victim identification; DNA analysis can provide the identification of an individual, aid the re-association of remains which are fragmented, and be of assistance in on-going legal or medical investigations. In many cases, the collections of samples for DNA based victim identification needs to be part of the first response plan. Depending on the condition of the body, Interpol has given recommendations on which samples are best to extract for DNA typing. Blood and buccal swabs are the preferred source for DNA from non-decomposed cadavers; however, where neither blood nor buccal cells are available other samples need to be collected. The Interpol recommended sample for decomposing remains is compact bone, whereas the use of muscle tissue is only proposed in cases of non-decomposed, mutilated remains. However, what is regarded as the onset of decomposition is not further specified. While it is undisputed that DNA in bone and teeth experiences greater protection against degrading environmental influences and hence exhibits superior preservation to DNA in soft tissues, the processing of hard tissues for DNA analysis can be quite labor intensive and time consuming. Depending on the rate of DNA degradation in soft tissues, it could be possible to utilize muscle tissue for DNA based identification in DVI cases for a longer time postmortem, which could significantly increase the sample throughput and speed up the identification process.

The decomposition of tissues is a process dependent on accumulated temperature rather than time itself. Accumulated Degree Days (ADD), the

cumulative total of daily average temperatures, are successfully being used as a quantitative measure to estimate the PMI in the fields of forensic entomology and anthropology. Recent research has also suggested ADD to be a measure of predicting DNA degradation in soft tissues.

The present study monitored DNA degradation in muscle tissue of common rabbits (*Oryctolagus cuniculus*) and domestic pigs (*Sus scrofa*). This research was conducted at the Taphonomic Research in Anthropology Centre for Experimental Studies (TRACES) in the Northwest of England. A total of 120 tissue samples were cut into pieces weighing 5g and placed into open 50ml plastic tubes. They were suspended on a mesh plateau about 3cm from the bottom of the tube into which a hole was drilled. This allowed rain water to drain, preventing the samples from becoming submerged. Thirty samples of each species were left open to insect access and 30 were covered by a mesh preventing insect activity, accounting for four different experimental groups. Tissue samples were collected in triplicates per experimental group roughly every 50 ADD and frozen immediately after collection in order to stop any enzymatic or bacterial DNA degrading activities. DNA extractions were carried out using a standard blood and tissue Kit, according to the manufacturer's protocol. The extracted DNA was then visualized on a 1.5% (w/v) agarose gel and quantified fluometrically using a dsDNA assay kit. The samples were genetically profiled using a species specific PCR multiplex (4-plex) which simultaneously amplifies genomic DNA amplicons of 70 bp, 194 bp, 305 bp and 384 bp.

Results show that the total amount of extractable DNA of all samples decreases from death to around 200 ADD (this interval broadly equates to two weeks in a temperate environment, e.g., 14-15°C) and then exhibits a continuous increase. This can be accounted for by an increase in foreign bacterial DNA which coincides with the tissue samples losing their physical structure and integrity. There is no statistically significant difference between the different species ($p=0.33$) or samples to which insect access was enabled and those to which it was not ($p=0.93$).

Partial profiles can be obtained up to 200 ADD, which correlates with the minimum amount of extractable tissue DNA present. Increasing amounts of foreign DNA outcompete the tissue-specific DNA after this point. Studies at the University of Central Lancashire show that full profiles can be obtained up to 173 ADD for individual tissue samples.

The initial results of this study indicate that, depending on the climate, a full DNA profile can still be obtained from muscle tissue after several days. These results suggest, that the current guidelines for soft tissue sampling in DVI cases are very conservative, and the time for victims to be identified could potentially be significantly reduced by expanding the postmortem interval in which to sample muscle tissues.

DNA Persistence, Accumulated Degree Days (ADD), Disaster Victim Identification (DVI)

G85 Association of Chronic Methamphetamine Use and Idiopathic Pulmonary Arterial Hypertension

Lindsey Harle, MD, Amy Martin, MD, and John Carver, MD, JD, City and County of Denver, 660 Bannock Street, Denver, CO 80204; and James W. Wahe, MD, 5570 East Lehigh Avenue, Denver, CO 80237-1053*

After attending this presentation, attendees will gain insight into the prevalence of pulmonary hypertensive changes in a metropolitan methamphetamine/amphetamine user population, and learn the implications of this finding on cause and manner of death determination.

This presentation will impact the forensic science community by evaluating the association between methamphetamine/amphetamine use and the development of idiopathic pulmonary hypertension (IPAH) in the forensic setting and increases awareness of this potential relationship in the forensic community. Identification of increased rates of IPAH among methamphetamine users would provide the forensic community with further insight into a potential mechanism of death in this population, especially in autopsies showing minimal cardiac and cerebral pathology, very low methamphetamine levels in the blood, or in cases with only anecdotal evidence of methamphetamine use and no other identifiable cause of death. Additionally, identification of IPAH in decedents with no known risk factors might suggest the need for additional toxicological studies to include evaluation for exposure to amphetamines/methamphetamines or other stimulants. In the clinical setting, knowledge of the increased risk for IPAH among methamphetamine users would alert physicians to consider this disorder as well as to screen for amphetamine/methamphetamine use in IPAH patients with no identifiable risk factors.

Increased rates of amphetamine use are reported among IPAH patients with no other risk factors. Indeed, one study found that patients with pulmonary hypertension and no recognizable risk factors were 10 times more likely to have a history of stimulant use than patients with known risk factors. Methamphetamine was the most commonly used substance among IPAH patients in this study. Case reports of IPAH in association with illicit stimulant use, including methamphetamine and cocaine, have recently been published. Additionally, there are some reports in the literature suggesting a link between fatalities associated with stimulant use and IPAH. To date there is minimal data linking the development of IPAH to chronic methamphetamine use and even less published on the gross and histologic findings of pulmonary arterial hypertension at autopsy.

The pathologic effects of chronic methamphetamine use are incompletely understood. Given the similarities between cocaine and amphetamines in mechanism of action, it is plausible that methamphetamine and cocaine users would develop similar cardiopulmonary sequelae. There are many reports describing the cardiac and cerebral effects of methamphetamine. In contrast, there is limited discussion in the literature on pulmonary pathology in chronic methamphetamine users. Most reports have highlighted the association of methamphetamine with acute pulmonary edema and/or development of pneumonia; very few studies have specifically evaluated for histologic changes of IPAH in methamphetamine fatalities. There are, however, multiple reports of pulmonary hypertension in association with prescription amphetamine use, and methamphetamine likely produces some of the same adverse effects as prescription amphetamines.

The case records of Office of the Medical Examiner, City and County of Denver identified 166 deaths where methamphetamine was detected and 10 deaths with amphetamine alone detected on toxicological screen. The gross and histologic findings of these cases will be evaluated retrospectively to determine if evidence of IPAH is present. Correlation with the cause and manner of death, toxicological analysis, and where possible the length of use and route of administration of methamphetamine and/or amphetamine use will be discussed. Where available, medical records will also be reviewed for evidence of a prior history of pulmonary disease, specifically IPAH. The proposed mechanisms for the development of arterial changes in the lungs will be discussed.

Methamphetamine, Pulmonary, Hypertension

G86 Crossing Through the Borderland — Fatalities Due to Attempted Illegal Crossings Between the Mexico and United States Border Along the Rio Grande River in Southwest Texas 2007-2011

Corinne E. Stern, DO, Webb County Medical Examiner's Office, PO Box 2353, Laredo, TX 78044-2353*

After attending the presentation, attendees will be able to: (1) recognize the hazards faced by illegal immigrants while attempting to cross the border; (2) become familiar with federal laws regarding immigration and the scope and role of the United States Border Patrol; and, (3) recognize the most common causes and manners of deaths in those immigrants who die while illegally crossing.

This presentation will impact the forensic science community by shedding a light on the extent of the problem of illegal crossers in regard to identification, public health issues and the financial burden placed upon the counties in which they cross.

Thousands of immigrants from Central and South America, as well as Cuba, China, and other countries, attempt to illegally cross the Texas-Mexico border every year. Many are successful. Many are apprehended. A significant number die—succumbing to drowning, heat stroke, trauma, and natural death. Due to the vast amount of ranchland along the southwestern border of Texas, many succumb to the effects of the environment as they walk for days in extreme environmental conditions without adequate food, water, or other supplies.

During a five-year period from January 2007 through December of 2009, the Webb County Medical Examiner's Office has examined the remains of over two hundred illegal crossers. Although the most common cause of death in the earlier years was drowning, the majority of deaths that are seen now are due to heatstroke and dehydration. Other causes seen include rattle snake envenomation, blunt force injuries (pedestrians and motor vehicle drivers and passengers), and natural deaths due to heart disease.

Not all illegal crossers who die are sent for autopsy. The Webb County Medical Examiner's Office services seven additional counties that are under the jurisdiction of Justices of the Peace. Because of the cost associated with sending these individuals for autopsy, many are identified based on rudimentary means and returned to their families or buried at the counties' expense in pauper graves. Although Texas law mandates that all unidentified deaths have DNA submitted for analysis, compliance with this law is low in the smaller rural counties.

All unidentified crossers that are sent for autopsy are radiographed, photographed, and autopsied, including dental charting. Information is entered into the National Missing and Unidentified Persons System (NamUs) and samples for DNA analysis are sent to the University of North Texas Health Science Center. Skeletal remains are sent for complete anthropological analysis by a forensic anthropologist.

Open communication with the Mexican Consulate's offices as well as the other consulate offices is imperative. During this period, the office has experienced between a 65% to 75% identification rate. Identified Mexican nationals are returned home at the expense of the Mexican government. Others do not fare as well as the funds are not available to assist the families. Both unidentified crossers, as well as those identified but unclaimed, are buried in a pauper's grave at the expense of the respective county. If a decedent is identified at a later date through DNA analysis, the decedent can be disinterred at the family's expense.

New and pending legislation, especially with health care reform, may change the numbers of crossers that are attempting to illegally gain entry into the United States. In the meantime, educating this population on the dangers associated with illegal crossing must continue and use all means in attempting to identify them so that they may be returned home must be used.

Border, Illegal, Crosser

G87 Retinal and Optic Nerve Sheath Hemorrhages Associated With Non-Traumatic Subarachnoid Hemorrhage: Two Cases of Terson Syndrome in Young Children

Kristen M. Thomas, MD, Miami Dade Medical Examiner's Office, 1851 NW 10th Avenue, Maimi, FL 33136; and Kenneth D. Hutchins, MD, and Mark J. Shuman, MD, Miami Dade County, Medical Examiner Department, #1 on Bob Hope Road, Miami, FL 33136*

After attending this presentation, attendees will learn to recognize Terson syndrome and understand the direct relationship between rapidly increased intracranial pressure and ocular and optic nerve sheath hemorrhages.

This presentation will impact the forensic science community by demonstrating the direct relationship between rapidly increased intracranial pressure and intraocular and optic nerve sheath hemorrhages; and by reinforcing the need for thoroughness in investigation and postmortem medical examination of all sudden childhood deaths.

Ocular and optic nerve sheath hemorrhages in children are frequently attributed to inflicted traumatic brain injury; and when seen in conjunction with subarachnoid hemorrhage, are often mistakenly considered pathognomonic of Shaken Baby Syndrome. Two cases of nontraumatic subarachnoid hemorrhage with ocular and optic nerve sheath hemorrhage (Terson Syndrome), from Miami-Dade County are presented.

Case 1: A 2-year-old child was with his mother and her boyfriend when he complained of sudden ear pain and became hysterical. She was able to calm him and he fell asleep. When the mother returned to check on him, he was unresponsive. At autopsy diffuse subarachnoid hemorrhage, subdural hemorrhage and hematoma (75 grams) of the brain and spinal cord, and optic nerve sheath and retinal hemorrhages were identified. The cause of death was certified as Shaken Baby Syndrome with the manner recorded as a homicide. Subsequent investigation and review of the autopsy material revealed an intracerebellar hemorrhage with numerous, irregular blood vessels consistent with a ruptured ateriovenous malformation; and the death certificate was amended.

Case 2: An 8-month-old child whose parents observed her to be weak and lethargic with increased crying and loss of appetite for approximately two days. She was seen by her primary care physician, diagnosed with a stomach virus and sent home with instructions for supportive care. Her parents became concerned when she did not improve, and she was taken to the hospital. A preliminary CT scan showed basilar subarachnoid hemorrhage with possible mass effect and a ventriculostomy was placed. Despite maximum support, she died later that evening. At autopsy a ruptured giant aneurysm of the posterior communicating artery with diffuse basilar subarachnoid, retinal, and optic nerve sheath hemorrhages was identified.

Initially described in the early 20th century, Terson Syndrome referred to vitreous hemorrhage associated with subarachnoid hemorrahge. Today, the definition includes any degree of intraocular hemorrhage associated with intracranial hemorrhage and rapid elevations intracranial pressure. Although the findings in both of these cases mimic those described in cases of inflicted traumatic brain injury, they illustrate the importance of first excluding a natural disease process and of thorough examination of the brain in all pediatric cases.

Terson Syndrome, Retinal Hemorrhages, Non-Traumatic

G88 Polymorphic Salivary Glycoproteins Recognized by the Carbohydrate-Binding Protein Peanut Agglutinin

Oluseyi Adewale Vanderpuye, PhD, Albany State University, Forensic Science, 504 College Drive, Room 118, Hartnett Building, Albany, GA; Samuel O. Oladimeji, PhD, Lagos State University, Department of Biochemistry, PMB 1001 LASU Ojo Lagos, NIGERIA; and Ansley A. Williams, BS, Robert D. Simmons, BS, and Lakerria Williams, Albany State University, Department of Criminal Justice & Forensic Science, 504 College Drive, Albany, GA 31705*

The goal of this presentation is to characterize inter-individual variation (polymorphisms) in a subset of salivary glycoproteins that bind to the galactose binding protein peanut agglutinin. This research was undertaken because there is: (a) lack of knowledge on buccal cell glycoproteins; and, (b) characterization of both buccal cell and salivary fluid glycoproteins will facilitate testing these proteins as biomarkers for pathological conditions and forensic applications such as indicators of exposure to toxins and identity testing through protein polymorphisms.

This presentation will impact the forensic science community by showing how lectins such as peanut agglutinin may be used to detect and

characterize salivary fluid and buccal cell glycoproteins. The identified glycoproteins may be further tested for applications as forensic and biomedical markers.

Methods used in this study included: (1) SDS gel electrophoresis and tests of Peanut agglutinin (PNA) binding to proteins electrophoretically transferred to nitrocellulose sheets (blotting); (2) treatment of samples with the enzyme neuraminidase which removes terminal sialic acid from oligosaccharides; (3) microtiter plate binding assays; and, (4) fluorescence microscopy of buccal cells by the use of fluorescent PNA.

An initial analysis was performed to determine the nature of salivary glycoproteins that might be recognized by the galactose-binding protein peanut agglutinin (PNA). Different samples of cell free salivary fluid were analyzed by electrophoresis and blotting with PNA. A protein of molecular mass around 150,000 Daltons bound to PNA in six out of eight salivary fluid samples. This approximately 150,000 Dalton protein had slightly different electrophoretic mobilities in the various samples, being close to 150,000 Daltons in two samples, greater than 150,000 Daltons in three samples and less than 150,000 Daltons in one sample. In the one sample, this approximately 150,000 Dalton protein consisted of two closely spaced bands. The staining intensity of this protein also varied among samples suggesting that different amounts of this protein bound to PNA in different saliva samples. No proteins in human serum bound to PNA. In additional analyses, 45 salivary fluid samples were analyzed for PNA reactivity and 39 of the 45 samples contained the 150,000 Dalton PNA-reactive protein, but six samples were negative. Twelve of the positive samples reacted very strongly with PNA compared to the others. Thus in a total of 53 salivary fluid samples, 84.9% (45) contained a 150,000 Dalton PNA-reactive protein and 15.1% (eight) did not under native conditions.

In another analysis, three matched pairs of buccal cell preparations and corresponding salivary fluid samples from the same donors were compared for PNA-binding proteins. Buccal cells and their corresponding salivary fluid fractions contained proteins of similar electrophoretic mobility that migrated at positions of molecular mass between 200,000 to 150,000. The buccal cell PNA-binding proteins were slower in mobility and of slightly larger molecular mass than the corresponding salivary fluid proteins.

PNA binds to terminal galactose residues on oligosaccharides that are attached to glycoproteins by O-glycosidic linkages. Galactose is sometimes terminated by sialic acid (neuraminic acid sugar residues) which prevent binding of PNA. To further examine the nature of the 150,000 Dalton salivary protein, the binding of PNA was tested with and without treatment of electrophoretically transferred (blotted) salivary proteins with a Clostridium perfringens enzyme neuraminidase which removes sialic acid from oligosaccharides. For untreated samples of salivary fluid, only three out of eight samples had 150,000 Dalton proteins that bound PNA and one of these bound very weakly. After treatment with neuraminidase, seven out of the same eight samples had 150,000 Dalton proteins that bound PNA and the staining of the three samples that were previously reactive with PNA was increased. For a serum sample that was also tested in this experiment, no binding of PNA was observed without neuraminidase treatment, but after neuraminidase treatment very high molecular bands became reactive with PNA.

These results indicated that a salivary fluid protein of approximately 150,000 Dalton varies in reactivity with PNA because individuals vary in how much terminal sialic acid is present on oligosaccharides that are attached to this protein.

An experiment was performed to determine if inter-polypeptide disulfide bonds were involved in the structure of the 150,000 Dalton PNA-binding salivary fluid protein. Four different salivary fluid samples were subjected to SDS gel electrophoresis under non-reducing and reducing conditions and electrophoretic transfers of the gels were analyzed for PNA binding. No shift in electrophoretic mobility was observed for the 150,000 Dalton protein in reducing conditions compared to non-reducing conditions.

The results indicated that this protein did not form inter-chain disulfide bonds with any polypeptide that was large enough to cause a significant shift in electrophoretic mobility. The results also suggested that the 150,000 Dalton PNA-reactive salivary fluid protein did not contain extensive intra-polypeptide bonds of a sort that would cause changes in electrophoretic mobility.

Two different samples of buccal cells were also analyzed by PNA binding after gel electrophoresis under both reducing and non-reducing conditions and electrophoretic transfer to nitrocellulose sheets. The PNA-reactive protein migrated as a very diffuse band whose mobility was the similar under both conditions. This result indicated that the PNA-reactive buccal cell protein did not form inter-chain disulfide bonds with any polypeptide sufficiently large to alter its electrophoretic mobility.

The presence and relative amounts of PNA-binding proteins in salivary fluid and buccal cell was also confirmed by microtiter plate binding assays which showed that PNA bound to both buccal cells and salivary fluid coated onto microtiter plate wells. PNA binding to salivary proteins produced higher absorbance readings than certain other lectins such as soy bean agglutinin and galanthus nivalis agglutinin which recognize different oligosaccharides than PNA. However other lectins such as artocarpus integrifolia bound in greater amounts than PNA to salivary proteins and produced higher absorbance readings. Fluorescence microscopy by the use of fluorescent PNA or streptavidin and biotinylated PNA confirmed that all buccal cells tested bound PNA to their surfaces.

From the results of this study, it was concluded that buccal cells and salivary fluid contain glycoproteins of molecular mass between 200,000 to 150,000 that vary in amount of terminal galactose and molecular mass among individuals. These proteins may be further examined for use as forensic and biomedical biomarkers.

Saliva, Glycoproteins, Biomarkers

G89 Use of Proteins to Obtain Measure of Identity in the Absence of Usable DNA

Glendon Parker, PhD, Utah Valley University, Mailstop 179, 800 West University Parkway, Orem, UT 84103*

After attending this presentation, attendees will have a greater appreciation of the potential use of proteins in developing random match probabilities. Attendees will also have greater insight into additional uses of proteomics in forensics.

This presentation will impact the forensic science community by exploring how DNA can be wonderful if it is present in the sample. In the absence of usable DNA, protein can be a potential source of genetic information. This presentation focuses on extracting genetic information from a protein sample after DNA has been degraded or is contaminated. This information can be used to develop random match probabilities.

The use of nuclear DNA to provide matches between a forensic sample and an individual has revolutionized forensic science. DNA matches may have less than a 1 in 10^{13} probability of occurring randomly in the population. Unfortunately DNA is chemically and physiologically labile. In certain contexts, such as in hair shafts, degraded forensic samples, or in contaminated samples such as rape kits, amplification of DNA and subsequent DNA-typing is difficult or not possible due absence of usable DNA. Protein however can theoretically substitute for DNA: the sequence of amino acids is a record of the template DNA and incorporates in the primary amino acid sequence non-synonymous single-nucleotide polymorphisms (SNPs). There are 185,000 non-synonymous SNPs in the human genome (an average of nine amino acid changes per protein). 65,000 of these SNPS have a calculated allelic frequency based on genomic sequencing of bio-geographic populations. Many of these single amino acid polymorphisms (SAPs) can also be detected through tandem mass spectrometry. For this study it is hypothsized that SAPs will be detected in hair protein samples and that enough will be detected to provide a basis for calculating random match probabilities. To test this hypothesis three hairs from one individual were ground and digested with 20µg trypsin overnight. Three aliquots of 0.5% of the sample were then applied to a LC/MS/MS (UHR-qTOF) mass spectrometry instrument. A total of 18,154 peptides were detected, 1,694 of which were unique and not redundant. This corresponded

to 285 proteins, 120 of which contained a total of 291 unique and non-redundant polymorphic peptides. In addition, data from the initial application was submitted to the Robust Accurate Identification (RAId) portal operated by the Yu group of the Computational Biology Branch at the National Institutes of Health (www.ncbi.nlm.nih.gov/CBBresearch/Yu). These algorithms are able to search for SAPs. A total of 361 polymorphic peptides were identified using this method. When the results from both searches were combined, polymorphic peptides with corresponding allelic dbSNP frequencies from the Utahn and Northern European populations were identified in 80 proteins. Using the product of all phenotypic frequencies the probability that one person would have that combination of markers was calculated at 5.5×10^{-5}, or one in 18,800. Using loci from 14 of these proteins the chance that one person would have that profile was calculated at 5.8×10^{-5} (or one in 17000). Both major and minor alleles were detected at 4 loci, two of which were identified using the RAId algorithm. These 14 loci provide a basis for developing random match probabilities using peptide information alone. Naturally use of these loci requires additional levels of scrutiny, such as comparison with synthetic peptide standards, confirmation of inferred SNPs using a SNP-chip, confirmation of the robustness of the analysis by repetition, and analysis with hair samples from additional individuals. Higher levels of discrimination are probable with the use of custom reference protein databases, which contain all known SAPs. The precise relationship between amount of hair and level of information, or sensitivity, also needs to be established. While not as genetically powerful as DNA-typing, protein-typing has the potential to significantly contribute to the probative information gained from protein forensic samples in the absence of usable DNA template. This methodology, developed for hair shaft protein, has the potential to be applied to all protein samples that are found in a forensic context.

Single Amino-Acid Polymorphism, Mass Spectrometry, Random Match Probability

G90 Inborn Errors of Metabolism Explain a Suspected SIDS Case

Marco Di Paolo, MD, via Roma 55, Pisa, ITALY; Stefania Bello, MD, Margherita Neri, MD, PhD, and Ruggero Parente, MD, Department of Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY; and Valentina Bugelli, MD, Sezione Dipartimentale di Medicina Legale, Università di Pisa, via Roma 55, Pisa, 56100, ITALY*

The goal of this presentation is to underline the difficulty of diagnosis of SIDS. According to San Diego SIDS diagnostic criteria, a clinical, anamnestic, circumstantial, and autoptic investigation must be performed. In most of cases death remains unjustified after the diagnostic procedures and SIDS is unresolved. This presentation concerns a case of resolved SIDS, in which the postmortem investigation led to diagnosis of dilated cardiomyopathy (DCM) with endocardial fibroelastosis, associated to tubular hypoplasia of the aorta and inborn errors of metabolism.

This presentation will impact the forensic science community by showing the difficulty to diagnose clinical silent cardiomyopathy in children younger than one year old, and so an accurate clinical, anamnestic, circumstantial and instrumental investigation can lead to a timely diagnosis of DCM in life.

A 10-month-old female infant was born full term (41+2 gestational week) at a weight of 3,800g. She had no neonatal complications. She was exclusively fed with formula and her mother had familiar history of Celiac disease. At 4-months-old, growth retardation and several generalized convulsive seizures, without fever, appeared. Laboratory investigation and electroencephalogram were unremarkable. When she was 10 months-old, the infant reported recurrent convulsive crisis (twice a night) and she was admitted into the hospital, where, on clinical examination, she appeared a very small infant (weight 6720g, length 70cm, CC 43cm). Electroencephalogram revealed paroxystic activity and decelerated rhythm on right occipital area. Laboratory blood values demonstrated reduced red cells count, respiratory acidosis (pH 7.333, pO2 37.1 mmHg), increased liver enzymes. Celiac disease HLA haplotypes examination was negative. Aminoacids dosage in blood revealed above all high citrulline levels. The ECG showed inverted T-waves in all derivations. In the following days the infant returned home to continue anticonvulsant therapy, but in the night she had recurrent convulsive crisis and she was admitted to the Emergency Department for blue lips, generalized hypotony, and cardiorespiratory arrest. Cardio-pulmonary resuscitation was unsuccessful and the infant was declared dead.

The external examination was unremarkable. The internal examination revealed heart increased in size (7.5x7.5x3.8cm) and weight (161g). The left ventricle showed a marked dilatation with an anterior wall thickness of 1.2cm, a lateral wall thickness of 1.4cm and an interventricular septum thickness of 1.2cm. At the transverse section the myocardium showed white areas, extended from atrio – ventricular plane to apex, with increased consistence. The right ventricular chamber was dilated with increased wall thickening. The left and right ventricular endocardium was shining and brightness. The descending aorta showed a short tract of tubular hypoplasia with vascular constriction to a minimum vascular diameter of 0.2cm, at 2.5cm from the left subclavian artery. Macroscopical examination of other organs was unremarkable, although liver showed hepatomegaly (size 15x9x4cm and weight 256g).

Histological examination of the heart revealed diffuse fibrosis mainly interstitial and with an undulating aspect, and fields with patchy fibrosis, rare foci of contraction band necrosis, disarray and disappearance of myofibrils with intramyocardial oedema resulting in empty sarcolemmal tube and with any type of reaction (colliquative myocytolisis grade 1) in the subendocardial layers. Left ventricular examination revealed a diffuse and considerable thickening of the endocardium resulting from proliferation of fibrous and elastic tissue representing a diffuse subendocardial fibroelastosis. Liver histological findings were suggestive of diffuse microvesicular steatosis. Non-identified metabolic disease was characterized by the following laboratory data: citrulline *38 mmoli/l (VN 9.50-33.61)*. The urinary acid dosage offered many alterations: methylmalonic acid *12 (VN < 7)*. The complete aminoacidogram presented: *taurine 202.763 (vn 38-127), aspartic acid 29.335 (vn 3-9), serine 185.407 (vn 92-181), cystine 5.645 ↓ (vn 25-62), ethanolamine 7.841 (vn 0-6)*. The urinary amino acid dosage presented: "*aspartic acid 41.524 (vn 3-10), glutamine 66.581 ↓ (vn 74-197), glycine 96.764 ↓ (vn 114-445), valine 5.770 ↓ (vn 6-19), cystathionine 0.141 (vn 0-0), leucine 3.564 ↓ (vn 4-16), fenylalanin 8.754 ↓ (vn 11-28), 1-metyl-histidine 17.889 (vn 0-0), histidine 69.135 ↓ (vn 92-278).*"

These data show the close correlation between cardiomyopathy and metabolic-genetic disease, supported by the presence of hepatomegaly and reduction in cranial diameters.

The dilated cardiomyopathy is a myocardial disorder characterized by dilated left ventricular (LV) chamber and systolic dysfunction that commonly results in congestive heart failure. DCM shows an incidence of 0.34 cases per 100,000 children and it represents the half of all the pediatric cardiomyopathies. Age younger than one year is the most common age at diagnosis of DCM. In the most severe cases, the affected children are clinically silent until they suddenly present signs and symptoms of heart failure (breathlessness at rest, orthopnoea, early onset fatigue, abdominal pain, pallor). DCM is prevalent with 66% in the first year of life and it is correlated with metabolic diseases in 9% of cases. The main characteristics of this pathology are: increasing of size and weight of the heart, expansion of cardiac cavities and fibrosis. Metabolic diseases cause many alterations that involve mainly the brain, the hearth and multiorgans deficit generically leading to hepatopathy, kidneys, ocular and cutaneous alterations.

In conclusion, the cause of death was a dilated cardiomyopathy associated with tubular hypoplasia of the first tract of descendant aorta in a small female infant affected by inborn errors of metabolism.

Dilated Cardiomyopathy, Inborn Errors of Metabolism, Sudden Infant Death Syndrome

G91 A Methodological Approach in Deep Venous Thrombosis Fatal Cases: Clinical Diagnosis, Therapy, Genetics, and a Histopathological Approach

Irene Riezzo, MD, PhD, University of Foggia, Department of Forensic Pathology, Ospedale "C. D'Avanzo", Viale degli Aviatori, 1, Foggia, 71100, ITALY; Dania De Carlo, MD, and Santina Cantatore, MLT, University of Foggia, Department of Forensic Pathology Viale degli Aviatori 1, Foggia, 71100, ITALY; Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, via de' Toni, 12, Genova, 16132, ITALY; Alessandro Bonsignore, MD, University of Genova, Via de Toni 12, Dept of Legal & Forensic Med, Genova, 16132, ITALY; and Margherita Neri, MD, PhD, University of Foggia, Department Forensic Pathology, Viale degli Aviatori 1, Foggia, 71100, ITALY*

After attending this presentation, attendees will see how clinical diagnosis of pulmonary embolism (PE) is notoriously inaccurate, with many cases either wrongly diagnosed (overdiagnosed) or missed (underdiagnosed), and autopsy is still considered as the diagnostic gold standard. The accuracy of antemortem diagnosis of pulmonary embolism is within the range of just 10–30%, so representing one of the most frequent missed diagnoses in sudden, unexpected death. Abnormalities within the gene loci encoding for natural anticoagulants (antithrombin, protein C, and protein S) and for fibrinogen have been shown to be rather uncommon risk factors for VTE. The goal of this study was to verify the systematic search for the most common genetic thrombophilias (Factor V Leiden (G1691A)) and FII ((G20210A) gene variants) and dating the thrombus.

This presentation will impact the forensic science community by showing how in a case of death from PE, autopsy dissection, documentation and studies concerning pulmonary emboli are relevant for the evaluation of such fatality. The criteria to determine the chronological changes in the venous sites of thrombosis are supported by many technologies and methodologies available to forensic scientists, but are unfortunately very rarely applied in daily judicial practice autopsy findings, histology and genetic studies are essential to analyze various thrombotic risk factors and etiologies; thus a reliable protocol is needed for their investigation. The review of polymorphisms associated with thrombotic disease has highlighted the considerable variability of clinical associations with the various polymorphisms. Histological age determination of thromboses is a valid aid to date the DVT phenomenon and the chronological changes of the thrombus, so the forensic pathologist can objectively determine the causal relationship between a previous trauma and the following fatal PTE episode.

Fourty-three fatal cases of pulmonary embolism as confirmed by postmortem examination are described. The selection was carried out on the basis of some criteria including completeness of patients' medical history diagnosis of certainty of the cause of death, identification of macroscopic thrombus, identification of the thrombotic site, availability of formalin-fixed paraffin-embedded tissues for genetic and histochronologic studies. In all these cases postmortem examination confirmed the diagnosis of PE. PE was recorded as the cause of death only when the necropsy stated that embolism was the main contributing cause of death and when emboli were identified either in the main pulmonary trunk or in the proximal right or left pulmonary arteries formed from the bifurcation of the main trunk. Emboli found in the distal pulmonary arteries after further division of the right and left pulmonary arteries were included too. In each case, five tissue samples were obtained from lungs; one piece from each lobe. Cross sections in each segmental pulmonary artery were prepared and microscopically examined. The dissection of the deep veins of the pelvis and legs was performed to search for the starting point of venous embolism. In the venous sites of thrombosis, the histological assessment was performed in conjunction with the surrounding vascular wall of uncut blood vessel with at least three to six different transverse incisions. Pathologic features were estimated using histological sections stained by hematoxylin–eosin, (H&E), trichromic stains (Masson, Azan, Mallory, PTAH, Van Gieson) and Von Kossa for calcium salts. Perl's stain for hemosiderin was used to confirm the presence of iron. Immunohistochemical investigation of thrombus and embolus samples was performed using polyclonal anti-fibrinogen antibodies, CD61, CD45, CD15, CD68. To investigate whether the FV Leiden and FII mutations increase the risk of fatal PE, we investigated their presence in pathology material. The spectrophotometric analysis of the quality and quantity of DNA which was extracted led us to choose the heart as the best specimen to be used as a reference sample. DNA was extracted from a total of 43 paraffin wax embedded tissue specimens of hearth. For DNA extraction "*Tissue and Hair Extraction Kit (for use with DNA IQ)*" protocol was used. The spectrophotometric analysis of DNA was performed. DNA samples were genotyped by real-time quantitative polymerase chain reaction for factor V Leiden and FII A20210 alleles.

As a whole, 41 patients (95.3%) had at least one risk factor. Pre-existing symptoms are described just before fatal embolism in 18 (41.9%) out 43 patients. In 18 out of 43 (41.9%) it was not possible to find the thrombotic site. In 24 out of the remaining 25 cases the involvement of the deep veins of one leg was shown; in one case the thrombus was localised in the inferior caval vein, 10 (41.7%) were iliac vein thromboses, seven (29.1%) femoral, two (8,3%) popliteal, three (12.6%) posterior-tibial, one (4.1%) anterior-tibial and one (4.1%) peroneal vein thromboses. In our cohort of patients, four (10%) out of 40 cases carried the 20210A prothrombin gene variant in heterozygosis. One (2.5%) out of 40 carried the Factor V Leiden (G1691A) gene variant in heterozygosis. Patients carrying these gene variants in homozygosis or carrying both were not present in our case-series.

This study strongly underlines the relevance of a complete methodological approach, integrating clinical data by means of autopsy findings and histological study. On the contrary, investigating common inherited thrombophilia is not warranted. This observation strengthens the concept that thrombophilia screening is indicated when VTE occurs in young subjects in absence of malignancy, major trauma or surgery.

Factor V Leiden, Fatal Venous Thromboembolism, Prothrombin

G92 Ehlers-Danlos Syndrome Type IV Revealed by Sudden and Unexpected Death: A Novel Point Mutation in the COL3A1 Gene

Stéphane Triau, MD, Centre Hospitalier Universitaire, Département de Pathologie Cellulaire et Tissulaire, CHU Angers, 4 rue Larrey, ANGERS, 49933 Angers Cedex 9, FRANCE; Arnaud Gaudin, MD, Centre Hospitalier Universitaire, Service de Médecine légale, 4 rue Larrey, 49933 ANGERS cedex 9, FRANCE; Xavier Jeunemaitre, PhD, and Lisa Golmard, MD, Laboratoire de Génétique Moléculaire, Hôpital Européen Georges Pompidou, 20 rue Leblanc, Paris, 75015, FRANCE; and Clotilde Rouge-Maillart, PhD, Centre Hospitalier Universitaire, Service de Médecine légale, 4 rue Larrey, Angers, 49933 cedex 9, FRANCE*

The goal of this presentation is to describe the case of a 25-year-old man who presented with sudden death, consecutive to acute and extensive arterial dissection. Postmortem genetic analysis revealed heterozygosity for a novel point mutation in the COL3A1 gene leading to a diagnosis of Elhers-Danlos syndrome type IV.

This presentation will impact the forensic science community by showing the importance of considering Ehlers-Danlos Syndrome (EDS) diagnosis when confronted with spontaneous arterial rupture and then of alerting the family members of this hereditary and potentially fatal condition. Many health professionals are not familiar with EDS type IV syndrome, which is sometimes mistaken for coagulation disorders, Silverman syndrome, or physical abuse in children. Vascular Ehlers-Danlos syndrome can also be confused with other types of EDS, Marfan syndrome or Loeys-Dietz syndrome in adulthood.

Ehlers-Danlos syndrome (EDS) is a heterogeneous group of connective tissue disorders characterized by tissue fragility, excessive skin extensibility and joint mobility. Its prevalence in the general population varies between

1/10,000 to 1/25,000, with no ethnic predisposition. Type IV, also known as the vascular type represents 5% to 10% of all EDS types. It is an autosomal dominant disorder resulting from mutations in the gene for type III procollagen (COL3A1). The clinical diagnosis is made on the basis of four clinical criteria: easy bruising, thin skin with visible veins, characteristic facial features (acrogeria), and rupture of arteries, uterus, or intestines.

A 25-year-old white male died at home after sudden collapse and dyspnea. He had neither medical history nor cardiovascular risk factors except for tobacco consumption. Family members reported an addiction to cannabis.

A complete postmortem examination was performed. This man was 180cm tall and thin, and presented with dysmorphic facies (elongated face and acrogeria), elongated upper limbs and prematurely aged skin of the extremities, without evidence of recent trauma. The autopsy showed a massive hemo-pericardium of 200ml and a hemothorax of 330ml complicating a complete thoracic aortic dissection involving both the ascending and the descending aorta (type I of De Bakey, type A of Stanford). The dissection originated from the ascending aorta and extended into the abdominal aorta. The distal end of the dissection was situated in the superior mesenteric artery. Furthermore, aneurysms of both renal arteries and the celiac trunk without dissection were noted, with recent thrombosis in the left renal artery and the celiac trunk. Histological examination showed a complete aortic dissection localized to the media, the false channel being filled out by blood without any sign of organization or inflammation. There was also fibro-muscular dysplasia of the renal arteries and celiac trunk with thickening of the media due to hyperplasia, along with irregular arrangement of the smooth-muscle fibre. The diagnosis of EDS syndrome type IV was suspected and genetically confirmed. Molecular analysis of blood samples revealed heterozygosity for a causative mutation in exon 40 of COL3A1 gene. In research, this mutation has not been reported before.

The Villefranche classification identifies six clinical types of EDS, among which EDS type IV accounts for about five to 10% of cases. Complications were rare in childhood. Twenty-five percent of the patients had a first complication by the age of 20 years, and more than 80% had at least one complication by the age of 40. The mean life expectancy is between 48 and 54 years, most deaths resulting from arterial dissection or rupture with uncontrolled bleeding. The types of complications are not associated with specific mutations. Because of the autosomal dominant nature of this condition, family members should be informed of this genetic condition and submitted to genetic testing if they wish to. Based on this information, a particular check-up can be done with respect to obstetric complications and safety in everyday activities. Novel therapeutic modalities are under development.

Sudden Death, Ehlers-Danlos Syndrome, Aortic Dissection

G93 Maternal Congenital Antithrombin-III Deficiency in an Intrauterine Fetal Death

Cristoforo Pomara, MD, PhD, Benedetta Di Battista, MD, and Ottavia Bartolo, MD, University of Foggia, Department of Forensic Pathology. Ospedale "Col D'Avanzo", Viale degli Aviatori 1, FOGGIA, 71100, ITALY; and Maurizio Margaglione, MD, PhD, Insitute of Medical Genetics. University of Foggia, Ospedali Riuniti, Viale Luigi Pinto 1, FOGGIA, FOGGIA 71100, ITALY*

The goal of this presentation is to show how fetal autopsy and a careful placental examination as well as a complete genetic study, on both mother and fetus in this case, play a substantial role not only in identifying the cause of death and in serving justice, but also as a means of helping clinical and forensic practice.

This presentation will impact the forensic science community by showing how fetal autopsies should be performed following recommended protocol and should include a careful placental examination and genetic analysis.

Thrombophilia is a multigenetic disorder caused by an inherited and acquired defect and has been described as a predisposition to thrombosis. There has been growing interest in thrombophilia and its connection to the pathogeneses of certain pregnancy complications (such as gestational losses) because of the prothrombotic state it creates. In normal pregnancy, thrombotic risk increases and has been characterized as an evolutionary advantage against severe blood loss after delivery and placenta separation. A recent hypothesis has suggested, however, that maternal thrombotic predisposition could interfere with the initial development of an adequate uteroplacental circulation and may result in the production of microthrombosis in the placental vessels. Massive perivillous fibrin deposition (MPFD) and the related lesion maternal floor infarction (MFI) are rare but serious causes of placental insufficiency, occurring in 0.03 e 0.5% of deliveries.

The presented case concerns about an intrauterine fetal death at 30-weeks gestation in a 24-year-old woman who was affected by congenital antithrombin-III deficiency, with previous family history of venous thrombosis and venous thromboembolism, and who was receiving anticoagulant prophylaxis during pregnancy. During her pregnancy, a reduction of physiological protein S and antithrombin were reported and the woman was subsequently treated pharmacologically by her gynecologist.

At 30-weeks gestation, the woman was admitted to the department of gynecology after noting a few days with no movement from her fetus. After a rapid clinical and echographic study showed a typical image of "Spalding" (overlap of the fetus's cranial bones), the woman was induced and then vaginally delivered the lifeless fetus.

A complete autopsy of the fetus was performed 48-hours after death. The external examination revealed the presence of maceration over up to 40% of the fetal surface. The autopsy excluded the occurrence of acute and significant abnormalities in all fetal organs.

A complete examination of the placenta (size: 16x15x4cm, weight: 560 grams) was performed after fixation in buffered formalin. Upon external examination, a series of voluminous, fluid-filled serous cysts were noted to be occupying a total area of 12x10x5cm. On coronal sections, the peripheral portion of the placenta showed multiple whitish-bluish, hard areas, 16x4cm wide. At the point of insertion of the umbilical cord, two cysts were observed, each 1.5x1.0cm in size.

The etiopathogenetic definition was outlined by histological examinations, which were preformed on placenta tissue samples using haematoxylin-eosin (H&E), Trichrome stain and Perl's, and revealed an intraluminal thrombosis of placental vessels with signs of villa ischemia and massive perivillous fibrin deposition (MPVFD).

The intrauterine fetal death was consequently attributed to acute respiratory failure (hypoxia fetal) by placental thrombosis secondary to maternal thrombophilia. A careful placental examination as well as a complete genetic study, on both mother and fetus in this case, therefore played an important role in identifying the possible cause of intrauterine fetal death. These practices remain important so that such data may help to advise parents who are considering whether or not to consent to a postmortem examination.

Intrauterine Death, Antithrombin-III Deficiency, Placental Examination

G94 The Coming "Omics" Revolution and Forensic Pathology

Victor W. Weedn, MD, Office of the Chief Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223*

After attending this presentation, attendees will gain an appreciation for the quickening of genomics, transcriptomics, proteomics, and metabolomics research that will likely revolutionize clinical medicine.

This presentation will impact the forensic science community by increasing recognition and raising awareness of why the "omics" revolution is closer than generally appreciated and what this may mean for forensic pathologists.

The medical community has been hearing about the importance of clinical genetic testing for some the last couple of decades, but the promised tsunami has not materialized. Nonetheless, advances have progressed. The convergence of cheaper technologies, the ability to data mine the information,

and the greater understandings that have been achieved set the stage for transformative or disruptive new approaches to medicine. Specifically, the intersection of the informatics, robotics, microfluidics, and mass spectrometry has enabled the creation of vast data sets from single laboratories that are permitting ever deeper comprehension of integrative biologic systems. The human genome project began in 1990 and was completed in 2003 at a projected cost of $3 Billion dollars. Today there are several commercial companies founded on the anticipation of whole genome sequencing for $1,000.00 and the Archon Genomics X $10M Prize has been recently offered for the first team to sequence 100 genomes in 10 days. Clinical efforts perhaps need only focus on the set of genes that comprise only a small part of the whole genome. Off the shelf gene chips can now analyze all 25,000 human genes. Clinical genetics laboratories are moving from single target assays to multiplex systems and high-throughput systems interpreted using massive parallel processing. In addition to DNA gene targets, the global expression of those genes thorough the messenger RNA in the transcriptome is now routinely tested and is more informative about what is going on in the cells because it is a measure of the gene regulation. Microarray chips have become cheaper, more ubiquitous and more consistent and robust. They are used in clinical labs now for leukemia classifications. The RNA is translated into proteins. The proteome is affected by post-translational processes, not seen in gene or expression arrays. Because proteins are present in higher concentrations, they offer some advantages to testing. Eventually, the proteins, as the work horses of the cell, result in metabolic functions which can be assessed through metabolomics methods. Through recognition of complex patterns, recognizable disease patterns emerge. Pathology, the study of disease, stands to be transformed by such interrogations. This has been recognized by the College of American Pathologists (CAP) and launched a multiyear campaign to transform the specialty and adapt to the new realities. The reintegration of clinical and anatomic pathology is a central concept of this effort. The CAP has created a Transformation Program Office which "facilitates, coordinates, and integrates Transformation-related activities across the College." As Osler famously stated "as goes pathology, goes medicine" and "personalized medicine" is a goal that is becoming possible and even, perhaps, affordable. Accordingly, pathology residents are increasingly being exposed to these newer diagnostic technologies. If the health of a live individual can be so thoroughly described through omics testing, then surely it will have an impact on the diagnostics of those who succumb to such maladies. Yet there has been little talk of such these in forensic pathology. Genetic channelopathy testing and pharmacogenomics have garnered some discussion. Should the possibility of a molecular autopsy be considered in our armamentarium? Could a blood sample distinguish between an MVA caused by an MI or an MI cause by a MVA? Should we continue to cling to a procedure perfected in the 18th century as the main diagnostic tool?

Omics, Transformation, Genomics

G95 Microbial Analysis of Bitemarks by Sequence Comparison of Streptococcal DNA

Darnell M. Kennedy, BS, University of Otago, School of Dentistry, Room 3.72, PO Box 647, Dunedin, 9016, NEW ZEALAND; Geoffrey R. Tompkins, PhD, and Jules A. Kieser, DSc, University of Otago, Sir John Walsh Research Institute, Faculty of Dentistry, PO Box 647, Dunedin, 9054, NEW ZEALAND; Jo-Ann L. Stanton, PhD, University of Otago, Department of Anatomy and Structural Biology, PO Box 913, Dunedin, 9054, NEW ZEALAND; Jose M. Garcia, PhD, University of Otago, Department of Preventive and Social Medicine, PO Box 913, Dunedin, 9054, NEW ZEALAND; and Chris Mason, BSc, and Christy Rand, MSc, University of Otago, Department of Anatomy and Structural Biology, PO Box 913, Dunedin, 9054, NEW ZEALAND*

After attending this presentation, attendees will have an appreciation of an alternative, objective approach to bitemark analysis.

This presentation will impact the forensic science community by demonstrating the feasibility of linking a suspect to a crime by comparing the streptococcal DNA derived from the teeth with that from a bitemark.

Human bitemark analysis can be a vital component in the investigation of violent offenses, providing crucial physical and biological evidence in criminal prosecutions. Variability in mechanical properties related to anatomical location, ageing and ethnicity of the skin undermine morphometric bitemarkanalysis. While the recovery of human DNA from bitemarks may provide extremely compelling evidence, the presence of enzymes, especially deoxyribonuclease I, in saliva compromise the recovery of exposed DNA.

The scientific rigor applied to the establishment of nuclear DNA analysis has highlighted the deficiencies in evidence underpinning other forensic disciplines, including bitemark analysis. Such inconsistencies now challenge the value and objectivity of morphometric bitemark evidence. Consequently, investigation in our laboratory persued an alternative method of analysis, based on bacterial genotyping.

More than 700 bacterial taxa have been detected in the human oral cavity. The predominating species are of the genus *Streptococcus* and comprise the principal bacteria colonising the surface of the teeth. Streptococci exhibit extensive genetic diversity, which provides the premise for research aimed at exploring the forensic value of matching teeth to bitemarks by bacterial genotying. Streptococcal profiles may be distinctive among individuals to the degree that genotypic comparisons of isolates from bitemarks and teeth can provide a correct match with a high level of confidence.[1,2]

The current research extends this approach by applying high-throughput sequencing to obtain streptococcal DNA sequences amplified directly from bitemarks and teeth. Comparison of the sequences from the two sample types was used to establish the probability of matching a bitemark to the teeth responsible.

With ethical committee approval, ten participants consented to producing self-inflicted bitemarks on the bicep region to transfer bacteria from the teeth to the skin, in a benign fashion. The area of skin to be bitten was swabbed immediately prior to the generation of the bite. The bite and anterior teeth of each participant were swabbed three hours following the generation of the bite. Skin, bite and teeth samples from each participant were processed to extract the bacterial DNA. This provided the template for PCR using streptococcal-specific primers for three different regions of genomic DNA, to evaluate which region offered maximal discrimination between participant samples. The PCR products were elucidated using high-throughput sequencing technology (GS FLX, Roche) and the sequences from each bitemark were compared to those generated from each of the ten teeth samples. Statistical modeling, using the proportions of overlapping identical sequences (i.e., those detected in both sample types), indicated the predictive power of each region of DNA to correctly match a bitemark to the teeth responsible.

The highest proportion of overlapping sequences occurred between a bite and the teeth responsible in seven, eight and nine out of ten combinations for the three respective DNA regions. No DNA fragments were generated from the unbitten skin samples indicating that all amplified products had originated from the teeth and not the skin.

Statistical modeling to assess the predictive value of each of the three DNA regions revealed that while two were capable of correctly matching a bitemark to the teeth responsible with 92% and 96% accuracy, the third achieved 99% accuracy.

In conclusion, these findings indicate a very high likelihood of matching bacterial DNA amplified directly from a bitemark with bacterial DNA from the teeth responsible, constituting an objective method for analyzing bitemarks in situations where the perpetrator's DNA cannot be recovered.

Bitemark, Bacterial DNA, Streptococcus

G96 Fatal Diabetic Ketoacidosis and Antipsychotic Medication

Susan F. Ely, MD, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY 10016; Amber R. Neitzel, BS, 3842 East Branham Lane, Phoenix, AZ 85042; and James R. Gill, MD, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will understand the relationship between antipsychotic medications and the development of diabetes mellitus, diabetic ketoacidosis (DKA), and hyperosmolar syndrome.

This presentation will impact the forensic science community by demonstrating the relationship between antipsychotic medication administration and diabetes, and identifying those decedents most at risk. This understanding may affect the way that these deaths are certified, not only in terms of cause, but also manner, depending on the jurisdiction.

Schizophrenic and bipolar patients have been found to have an increased predisposition to the development of type 2 diabetes mellitus, independent of psychotropic medication administration, and after adjusting for other known risk factors. Within this susceptible population, however, poor glucose control, exacerbation of pre-existent diabetes mellitus, and new onset diabetes also have been widely described in association with the administration of certain antipsychotic medications, primarily second generation (atypical) antipsychotics, but, to a lesser degree, chlorpromazine, a low-potency first generation (typical) antipsychotic. This association has not usually been described with haloperidol, a high-potency first generation antipsychotic. The ushering in of these newer second generation (atypical) antipsychotic medications has rapidly rendered first generation antipsychotics all but obsolete due to the extreme efficacy of the former in treating psychotic symptoms, coupled with their greatly diminished negative motor and sexual side effects relative to the older medications. Their potential for sequelae of glucose dysregulation, however, has become a topic of much clinical literature review and analysis with recommendations for patient selection and monitoring. Theoretical mechanisms of dysregulation include insulin resistance, decreased insulin secretion, weight gain, hypertriglyceridemia, and elevated low-density lipoprotein cholesterol; however, a scientific consensus around mechanism has not been reached. While the atypical antipsychotics include quetiapine, clozapine, olanzapine, risperidone, aripiprazole, and ziprasidone, those that are thought to carry the highest risk for such metabolic side effects are clozapine, olanzapine, and quetiapine, with risperidone having the lowest.

In forensic practice, fatal diabetic ketoacidosis is the initial presentation of diabetes in some of these patients, who fall under the purview of the medical examiner due to their often precipitous and out-of-hospital deaths. This is the first large series describing such fatalities. Seventeen deaths were reported due to diabetic ketoacidosis in psychiatric patients treated with second generation antipsychotic medications.

Death certificates and toxicology data from January 2005 to December 2009 were searched for instances of diabetic ketoacidosis and hyperglycemia. The medical examiner records were reviewed which included the autopsy, toxicology, police, and medical examiner investigators' reports. Of all persons with DKA-related deaths (what is denominator/), 17 had a psychiatric history and were under current therapy with a second generation antipsychotic medication. The cause of death, contributing conditions, age, race, sex, co-morbidities, toxicology results, and BMI were extracted. Postmortem toxicologic analysis was performed on all decedents by the Forensic Toxicology Laboratory at the Office of Chief Medical Examiner. The decedents ranged in age from 32 to 57 years (average 48 years). There were fifteen men and two women. There were eleven Black, four Hispanic, and two White decedents. In all 17, the immediate cause of death was DKA. The psychiatric disorders included: ten schizophrenia, three bipolar/schizophrenia, two bipolar, and two major depression. The most frequent atypical antipsychotic medications were quetiapine and olanzapine (six each) followed by risperidone (three). Only one of the 17 had a medical history of diabetes. The decedent's BMI ranged from 20 to 60 (average 33). In 10 of these deaths, the use of the antipsychotic medication was recognized as the cause of death and the psychiatric disorder and/or medication were reflected in the cause and manner of death statements.

Diabetes, Antipsychotic Medications, Fatal

G97 Initial Studies Into Effects of Moderate Heat on Soft Tissue and Bone

Karl Harrison, PhD, Cranfield University, Defence Academy of the United Kingdom, Shrivenham, SN6 8LA, UNITED KINGDOM; and Brooke L. Webster, MSc, and Victoria Martin, MSc, Cranfield University, Shrivenham, SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will acquire valuable incite into the response of soft tissues, specifically brain tissue, to relatively low temperatures that may dominate in protected areas within modern compartment fires. They will observe that these soft tissues can be preserved through carbonization while still maintaining a degree of chemical structure therefore viable for use in further forensic analysis, e.g. tissue identification, PMI, etc. This research also describes the application of modern fire techniques being used in an archaeological setting.

This presentation will impact the forensic science community by providing proven information that brain tissue can maintain chemical structure after visual carbonization of the material has occurred, it is evident that these types of samples are viable for use in further forensic research into the reaction of postmortem human remains to a burning event. This method of preservation can also potentially impact future archaeological methods of analysis when dealing with burned human remains.

This study uses evidence from the archaeological record to initiate experimental observations of the behaviour of brain tissue when exposed to moderate temperatures that might be expected at a low level within a modern compartment fire. The site of Çatalhöyük in central Turkey preserves remains of an extensive Neolithic settlement that has been noted for the preservation of the remains of burnt buildings, beneath some of which have been found the graves of buried individuals.

In one such burnt structure on the site, five sets of remains have exhibited evidence of intense carbonization, caused by heating in a reduced atmosphere whilst the remains were buried. The remains of each individual showed varying levels of carbonisation to their skeletal structure along with revealing carbonised organic material within their crania that is thought to be charred yet preserved brain tissue. The assumption is that radiating heat from the burning of the overlying structure has caused these changes; however, the complete image of this burning event and the correlation between it and the condition of the remains is not yet fully understood.

The studies discussed here have attempted to model and recreate the burning event and its effects on the buried remains by using forensic fire investigation techniques to analyze the thermal characteristics of the building materials of the settlement and comment on the amount of fuel and duration of burning that the characteristics of thermal alteration might suggest. If it can be proved analytically that the carbonised organic material is brain tissue it could potentially be the oldest surviving human brain material yet identified, as well being one of the few subject to such a peculiar means of stabilization.

Studies conducted on skull fragments from the remains indicate the skull reached temperatures of less than, or equal to, 500°C and were exposed to this heat for an extended period of time. No existing research was found that considered the effects of such relatively low temperatures and it is generally assumed that brain tissue would not survive this, or any type, of burning event. Experimental burning of porcine brain material, coupled with

the use of micro-CT and FTIR analysis, were used to assess the capacity of brain tissue to carbonise at these temperatures over different durations of time and attempt to identify any remaining chemistry within the sample after this exposure.

The results of this work have not only succeeded in using the techniques of fire investigation to quantify the thermal energy required to create the necessary conditions to carbonise buried human remains, but in addition analysis of the preserved brain tissue has revealed preserved organic traces still present. This work not only demonstrates the adaptation of forensic techniques for archaeological applications, but also provides a valuable insight into the response of soft tissues to the relatively low temperatures that may dominate in protected areas within modern compartment fires.

Fire, Brain, Human Remains

G98 Age Estimation of Wounds Using the Proximity Ligand Assay

Linda Cedergren, and Maria Jepsen, Swedish National Board of Forensic Medicine, Retzius v. 5, 171 65, Stockholm, 171 65, SWEDEN; and Jenny Ronnlund, Kanar Alkass, BSc, and Henrik Druid, MD, PhD, Department of Forensic Medicine, Karolinska Institutet, Retzius v. 3, Stockholm, SE-171 77, SWEDEN*

After attending this presentation, attendees will learn how a novel immunohistochemical technique can improve the interpretation of histological samples from injuries.

This presentation will impact the forensic science community by showing how the proximity ligand assay has an advantage over other immunohistochemical methods by providing reactivity only when two marker proteins bind to each other, or are in close proximity, which may be an indication of a transient reaction after injury, not seen in uninjured tissue.

In the forensic pathology routine casework determining the time of infliction of wounds may be a critical issue. Conventional histological methods allow for a rough age estimation, but suffer from high imprecision. Platelet-selectin (P-sel) shows rapid dynamics in the early phase of an injury. Under normal conditions, it is stored in Weibel-Palade bodies in endothelial cells and in α-granules in platelets. After an injury, a degranulation occurs in these cells and P-Sel is transferred to the cell membrane; however, only for a short time, implying that membrane-bound P-Sel will disappear within hours after an injury. Deciding to take advantage of the possible co-localization of P-Sel and the Platelet Endothelial Cell adhesion molecule (PECAM-1), abundant in the cell membrane of both endothelial cells and platelets, by applying the proximity ligand assay (PLA) technique. This assay uniquely produces a reaction only when two secondary antibodies are physically very close. Further, von Willebrand factor (vWF) is also stored in the same granules as P-sel. This co-localization should therefore be expected to produce a PLA reaction under normal conditions. Degranulation due to vessel injury should reduce the positivity when these cells release P-Sel to the cell membrane and vWF to the circulation. Other combinations of antibodies, to factors involved in the coagulation and complement systems, as well as some early inflammatory markers were also investigated. The positivity of P-Sel - PECAM-1 showed a discrete time window. PSGL-1 is the natural ligand to P-Sel when exposed as a receptor in the membrane. P-Sel- PSGL-1 also showed a limited, and earlier, time window. A number of reactions in the coagulation cascade were futher examined. The reactivity of thrombin and fibrinogen showed a reactivity in the early phase of an injury, but the reactivity remained for a prolonged period. Antibodies against a number of other factors in the coagulation cascade were also examined, but the results were difficult to interpret. The methodology requires that each antibody shows a reasonable staining pattern in normal and injured tissue, and that their close co-localization occurs during a limited time period after an injury. Collagen III and Glycoprotein VI each showed a decent reactivity in normal tissue when applied separately, but still failed to produce a distinct reactivity in the early phase after injury when tested by the PLA technique. This may either be explained by a too large distance between the epitopes on each protein not allowing for the antibodies to produce a reaction. Alternatively, it might indicate that these factors do not interact, and that observation would then constitute a novel finding. The appearance of coagulation factor complexes of various kinds showed variable time patterns that need further studies. Having stated that, the reactivity of the different antibody combinations of the coagulation and complement systems consistently produced a negative reaction in uninjured samples, as well as in injuries of older age. It is believed that this methodology, using suitable combination of antibodies, will improve the age estimation of injuries, and conclude that the technique can be used by unexperienced users, since the all-or-none response that this method provides allows for an easy interpretation.

Wound Age Estimation, Immunohistochemistry, Postmortem

G99 Confined Space Asphyxia: An Unrecognized Hazard in a Plasma Fractionation Tank

Lisa A. Scheinin, MD, and Lakshmanan Sathyavagiswaran, MD, Los Angeles County Coroner's Office, 1104 North Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will understand how to recognize potential oxygen-deficient atmospheres in the workplace and the hazards they pose to rescuers as well as workers.

This presentation will impact the forensic science community by increasing awareness of potentially hazardous workplace situations that can lead to rapidly fatal deaths. This awareness, in turn, will allow for correct assessment of at-scene conditions by death investigators and aid the medical examiner in diagnosing the correct cause of death.

Confined spaces are often unrecognized as potentially lethal workplace hazards. Confined spaces are defined by the National Institute for Occupational Safety and Health (NIOSH) as spaces not designed for continuous occupancy by workers but large enough to allow persons to enter, and which have limited means of access; they also often have unfavorable natural ventilation. The Occupational Safety and Health Administration (OSHA) defines a "permit-required confined space" (permit space) as a confined space that has one or more of the following characteristics: contains or has the potential to contain a hazardous atmosphere; contains material that could engulf someone who enters; has inwardly converging walls or sloping floors that taper into a smaller area that could trap the entrant; or contains any other recognized safety or health hazard. Examples include tanks, tanker trucks, silos, pits, sewers, and underground vaults.

Confined spaces may not outwardly appear hazardous and may have been entered at other times without incident. They may contain flammable, toxic, or oxygen-deficient internal atmospheres. Oxygen-deficient atmospheres, i.e., those that contain less than 19.5% oxygen, can pose an immediate danger to life and should not be entered without NIOSH-approved self-contained or supplied-air breathing apparatus. In particular, atmospheres with less than 10% oxygen may cause extremely rapid loss of consciousness and death to those who enter them. Oxygen-deficient atmospheres can be caused by consumption of oxygen or its displacement by another gas.

The leading cause of death in cases involving confined spaces is asphyxia, usually from exposure to oxygen-deficient atmospheres. The victim often had not been properly trained and did not recognize or understand the hazards involved. More than half of workers who die in confined spaces were trying to rescue other workers.

A case history involving a worker at a pharmaceutical company who died inside a plasma fractionation tank after entering it inappropriately and without protective apparatus is presented. Two workers who attempted to rescue him were also injured, one severely. Death and injuries were felt to be due to an oxygen-deficient atmosphere of which the workers were most likely not aware. The case will serve as an illustration of the potential hazards of confined spaces to both workers and their rescuers. It will also assist forensic investigators and forensic pathologists in recognizing and correctly assessing such hazards during scene visits and death investigation.

Asphyxia, Oxygen-Deficient, Tanks

G100 Unknown Body Found in a Rug — Unraveling the Answers

Jeffrey Racette, MD, Allegheny County Medical Examiner's Office, 1530 1st Avenue North, Saskatoon, SK S7K 1Z3, CANADA; and Todd M. Luckasevic, DO, Baiyang Xu, MD, Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222*

After attending this presentation, attendees will understand challenges in death investigations to determine identity, cause of death, manner of death, time of death, and place of death require cooperation between a wide range of different disciplines.

This presentation will impact the forensic science community by showing how the importance of cooperation between different forensic disciplines can determine the questions surrounding a death investigation.

Introduction: Death investigation seeks to answer several important questions—who, what, where, when, and how death occurred. This process often requires the concerted efforts of a wide range of specialized individuals. The gravity is even more pronounced in those cases which are suspicious for criminal activity. Death investigation is not directly related to the legal outcome of these cases, but does provide evidence which is used by the court of law in their independent assessment of the guilt or innocence of accused individuals.

Case Presentation: An unidentified, largely decomposed body was discovered wrapped in a rug and partially concealed in a public park in Wilkinsburg, Pennsylvania in September 24, 2009. The circumstances of the discovery of the body, and the advanced state of decomposition with extensive insect activity significantly interfered with identification of the deceased; as well as determination of the time of death; the place that death actually occurred; and the cause and manner of death.

Discussion: The average person is unable to wrap themselves in a rug and tape the rug closed by themselves prior to their own death, suggesting that the deceased was placed in this position by additional person(s), who may or may not, have played a direct role in the death. At the very least, the actions of this additional person (or persons) led to the concealment of several points of interest within this investigation.

Identification of the cause of death could not be determined by autopsy, or toxological studies of the physical remains. No bony injuries where visible either grossly or by radiological scans of the remains.

The identity of the deceased was successfully ascertained and required the efforts of a range of individuals. A chance event spared identifying features from decomposition on the left hand and wrist including a portion of a tattoo and a single intact fingerprint. The deceased had finger print impressions on record. Additionally, the identity was corroborated by forensic anthropology, and forensic dentistry. The details were complicated by incomplete dental records, lack of documentation of a wrist tattoo and a delayed missing persons report.

The time of death was investigated by the work of a forensic entomologist based on evidence found on the body and at the scene. The individual was last documented to be alive in February of 2009, and a missing person report was issued on July 4, 2009.

The location of death (and the eventual determination of both the cause and manner of death) required police investigation and trace evidence comparison. A vehicle was obtained with carpet fibers in the box compartment. These fibers were definitively matched to the rug in which the deceased was discovered and led to the residence of the owner of the vehicle. The residence contained a similar carpet with a portion removed which also matched the rug in which the deceased was found. A bullet hole was found in the floor area corresponding to the missing area of carpet.

Conclusion: The final report on the death involved a 36-year-old Black female found wrapped in a rug was determined to be due to a perforating gunshot wound of the chest with a manner of homicide. The identity of deceased was discovered, the place of death and an approximation of the time of death were found. The police investigation and trace evidence matching provided the final cause and manner of death.

The police report information on the case involves two men who hired a female sex worker. They claimed she robbed them and they re-acquired her, where upon she was shot. The body remained in the home for an unspecified period of time before she was taken to the park.

Multiple resources and specialists were required for the successful resolution of this difficult case.

Homicide, Identification, Trace Materials

G101 Autopsy Findings in the Morbidly Obese

Johan A. Duflou, MMed, Department of Forensic Medicine, PO Box 90, Glebe, Sydney, New South Wales 2037, AUSTRALIA; and Julia Williams, BSc, and Kate Howson, BASc, University of Sydney, The Sydney Medical School, University of Sydney, Sydney, AUSTRALIA*

After attending this presentation, attendees will gain a more detailed understanding of the spectrum of pathological changes in persons with a body mass index greater than 35kg/m2 who have undergone medicolegal autopsy.

This presentation will impact the forensic science community by providing details of pathology and normality in a population of obese individuals who have died both of and with their disease.

Obesity is an increasingly prevalent problem in the United States, Australia and internationally. In both the U.Ss and Australia, in excess of 25% of the adult population are obese (body mass index, BMI, greater than 30kg/m^2). In all, in excess of 60% of adults are presently either overweight (BMI, between 25kg/m^2 and 30kg/m^2) or obese, and these levels have been increasing over the last decade. Obesity is linked to a wide range of chronic and acute disease, and previous studies have shown a strong association between obesity and premature death. However, these studies have almost invariably involved acceptance of clinical diagnoses on death certificates and in medical records, and are generally not based on confirmed autopsy observations. Autopsies are frequently not performed in cases of morbid obesity, with many reasons proffered, including a pre-existing assumption as to the cause of death, a general unwillingness to perform autopsies in such cases and a concern about the occupational safety and health of pathologists and mortuary personnel.

In this study, a cohort of 1,000 deaths reported for medicolegal examination in Sydney, Australia were retrospectively studied, in Class II (BMI 35 to 40kg/m^2) and Class III (BMI greater than 40kg/m^2) obese adult autopsy subjects. Full autopsies were performed in all cases, with histologic examination performed on representative tissues in all, and toxicology testing in relevant cases.

Of the 1,000 subjects, 59.2% were male, 40.8% were female, and the median age of the study population was 57 years (range 18 to 91 years). There was an inverse relationship between age at death and BMI. The median BMI in the study population was 38.74 and ranged from the minimum inclusion BMI of 35kg/m^2 up to 94.81kg/m^2.

The manner of death was natural in 80.1% of cases, and the most common cause of death was cardiovascular disease in 49.1% of all case, followed by pulmonary causes which accounted for 13.7% of all deaths. Neoplastic diseases were given as the cause of death in only 1.2% of cases. Homicide was the manner of death in 1.3% of cases and 4.4% were suicides. 14.2% of deaths were considered accidental. Positive toxicology was recorded in 46.9% of cases and drug toxicity was the direct cause of death in 8.8% of cases. Obesity was given as the direct cause of death in 2.4% of cases, with an additional 2.0% of subjects having obesity listed as an antecedent cause and 13.6% as a significant condition contributing to death. Cause of death was unascertained or undetermined by the autopsy pathologist in 3.0% of cases.

Obesity is known to have many serious effects on the cardiovascular system. Cardiac pathology in 88.8% of cases was identified, with significant coronary artery atherosclerosis the most common finding. Severe, potentially lethal coronary atherosclerosis was observed in 37.5% of cases. Paradoxically, and as reported previously, those cases with a BMI greater than 50 kg/m^2 were found to have less severe atherosclerosis than the less

severely obese. High rates of pathology were also identified in the respiratory system (87.7%) and in the liver (77.8%) with hepatic steatosis identified in two thirds. Renal pathology, predominantly nephrosclerosis and other forms of chronic renal disease, was observed in 60.5% of cases.

The autopsy investigation of cases of morbid obesity can provide important information to pathologists, law enforcement and public health authorities on the nature of this disease and events surrounding death. As probably expected, there is a high rate of lethal heart disease, and pathology of other major organ systems is very common, which together result in high rates of premature death. A detailed description and characterisation of the lethal form of this disease can only assist in designing effective death prevention strategies in a very common condition which is increasing in frequency. Finally, we note the low number of cases where obesity is given as a cause of death or a contributor to the death in this study – both pathologists and clinicians should be encouraged to include obesity in the cause of death formulation in those cases where appropriate.

Autopsy Pathology, Obesity, Sudden Death

G102 The Genetic Identification of United Kingdom Calliphoridae – A Multi-Gene SNaPshot® Approach to Species ID

Helen Godfrey, MSc, and Judith A. Smith, PhD, University of Central Lancashire, School of Forensic and Investigative Sciences, Preston, Lancashire PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will understand some of the problems associated with current identification methods and the advantages of molecular identifications. The sequencing results of a multi-gene approach and the development of a SNaPshot® multiplex for species identification will be presented.

This presentation will impact the forensic science community by providing a novel approach to Calliphoridae species ID. The developed SNaPshot® multiplex will provide a more time and cost effective way of analysing samples compared to the traditional Sanger sequencing. Multiple regions are analysed simultaneously, whilst the short amplicons make it suitable for degraded and comprised samples frequently found in forensic cases.

A dead body is an attractive habitat for many insect species but it is the members of the Blowfly family (*Calliphoridae*) that are usually the first to arrive, using the body as an oviposition site. The stage of larvae found on a body can be a useful indicator of time since death, but in order for species specific life cycle data to be applied, accurate species identification is critical. Damaged, unviable or immature specimens can be difficult to identify morphologically and recent work has focused on the genetic identification of Blowfly species.

The aim of this study is to assess the potential of various genetic regions to differentiate between United Kingdom Blowfly species of forensic importance. Nine genetic regions, including both nuclear (ITS2, 28s rRNA, CAD, Bicoid and Elongation factor 1 alpha) and mitochondrial DNA (Cytochrome oxidase I and II, cytochrome b and 16s rRNA), have been sequenced for six UK species commonly used in forensic investigations (*Calliphora vicina, Calliphora vomitoria, Lucilia sericata, Lucilia illustris, Lucilia caesar,* and *Photophormia terranovae*).

Existing sequences were downloaded from the sequence database and aligned. Primers were either previously published primers or manually designed based on the sequence alignments. Genomic DNA was extracted using a mini kit, from wild-caught specimens collected from nine locations throughout the United Kingdom.[1-3] PCR amplifications were performed as single plexes for each gene and purified before DNA sequencing. Sanger sequencing was conducted in-house using a cycle sequencing kit. Sequence reactions were ran on ABI 310 and 3500 genetic analysers and analysed using Sequence Analysis software v5.4 (Applied Biosystems).

Results show that while most regions are suitable for distinguishing between species, problems still exist when identifying closely related species such as *Lucilia illustris* and *Lucilia caesar*. Analysis revealed that the mitochondrial regions Cytochrome Oxidase I and II (COI and COII) and Cytochrome b are capable of distinguishing between all species examined. These regions exhibit higher levels of inter versus intra species variation making them ideal for species ID.

The nuclear markers appear more conserved, having levels of inter species variation. Each of the nuclear markers sequenced can only differentiate samples to the genus level, failing to distinguish between *Lucilia illustris* and *Lucilia caesar* at each marker (ITS2 – 400 bp, 28s rRNA – 2.2 Kb, CAD – 700 bp, Bicoid – 350 bp and Ef1α – 1 Kb).

As the rapid identification of species is advantageous in forensic investigations, a SNaPshot® approach to species ID was investigated. SNPs from the following regions were chosen to differentiate between the six UK species: 28s rRNA (4 SNPs), Ef1α (4 SNPs), COI (2 SNPs), COII (2 SNPs), Cytochrome b (2 SNPs) and 16s (1 SNP). Nuclear markers were included so that any possible hybridisation between species (with the exception of *Lucilia illustris* and *Lucilia caesar*) could be detected. This SNaPshot® multiplex gives a unique haplotype for each species. Each species can be differentiated based on between 4-12 SNPs.

G103 The Microbial Ecology of Carcass Decomposition Between Habitats and Through Time

M. Eric Benbow, PhD, and Andrew J. Lewis, BS, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; Jennifer Pechal, MS, Texas A&M University, TAMU 2475, College Station, TX 77843-2475; Tiffany Blair, BS, and Maureen Berg, University of Dayton, Department of Biology, Dayton, OH 45469-2320; Michael F. Diaz, California State University Monterey Bay, Division of Science and Environmental Policy, Seaside, CA 93955-8000; Jeffery K. Crippen, PhD, Southern Plains Agricultural Research Center, Agricultural Research Service, United States Department of Agriculture, College Station, TX 77845; and Aaron Tarone, PhD, Texas A&M University, Department of Entomology, College Station, TAMU 2475,TX 77843*

After attending this presentation, attendees will have a better understanding of the role of microbial ecology that drives the rate and biological dynamics of decomposing remains during different seasons and between years. Attendees will also be introduced to a growing knowledge foundation on how this information can be used to better understand and predict the stages of carcass decomposition, with direct application to estimates of a minimum postmortem interval (mPMI) using microbial communities. Attendees will learn how changes in the metabolic use of different carbon sources by the microbial community during decomposition succession can be utilized to estimate the stages of decomposition.

This presentation will impact the forensic science community by providing an introduction to the potential use microbial communities in crime scene investigations.

Microbial communities are fundamental to decomposition ecology of carrion and human remains. Studies in both aquatic and terrestrial systems have shown that microbial communities follow a pattern of succession by metabolizing and modifying resources in a way that makes them usable or unusable to other subsequent colonizing organisms. While there have been studies describing the succession and diversity of microbial communities involved in carrion decomposition, none have evaluated their potential use for making estimates of the mPMI in criminal investigations. In this study an economical method was employed for understanding changes in environmental microbial communities using Biolog EcoPlates™, microarray plates with 31 different carbon sources that are differentially used by microbial communities, providing a metabolic signature that acts as a surrogate for the functional diversity of the communities being evaluated. These profiles are often called microbial community level physiological profiles (MCLPPs) and can be calibrated with temperature and genomic sequencing to provide ecological data for predicting the duration of body decomposition.

The objectives of this study were to describe microbial community metabolic changes during decomposition (i.e., succession) in two different natural settings during multiple seasons and between years. The hypothesis was tested that MCLPPs from decomposing remains, the soil beneath and 1m away would change during decomposition as a function of microbial community succession, and that these changes would vary depending on season and year, but not with habitat for the carcass communities. It was predicted that successional changes in MCLPPs could be validated with the 454-pyrosequencing of the microbial communities.

Microbial samples were taken from carrion (swine) (N = 3–9), the soil underneath (treatment soil) and 1.0m away from each carcass (control soil). To understand microbial community structure differences on the carcass, swabs of the buccal, urogential and shoulder skin were evaluated, and MCLPPs were described using Biolog EcoPlates™. Three experiments were performed to test the above hypothesis: (1) seasonal decomposition of swine carcasses during 2009 in a rural forested lot (Habitat 1) in Ohio; (2) a decomposition experiment in July/August 2010 in a different rural forested lot (Habitat 2) about 25 km away from Habitat 1; and, (3) a repeated 2010 experiment in July/August 2011 to provide an assessment of annual variation in succession on swine carcasses. In the 2010 experiment, matched samples of each individual sample were taken and evaluated using the bacterial tagged encoded FLX amplicon pyrosequencing (bTEFAP) method with a pyrosequencing platform.

Using a tiered multivariate statistical analysis approach we found significant differences in the microbial communities both on the carcass and in the soil beneath and 1.0m away from carcasses, with significant differences in decomposition succession between seasons and habitats. There were not significant differences in MCLPPs among body regions or among replicate carcasses within a season, habitat or year, indicating consistency of MCLPPs among carcasses within the same habitat during the same time of year. However, within each season, habitat and year there were significantly different daily MCLPPs during decomposition that corresponded with established stages of decomposition described in the literature. Although more studies are needed to verify our findings, these results indicate that microbial metabolic profiles on carcasses have excellent potential for use in estimating stages of decomposition, and thus, time since death in localized habitat conditions and within specific timeframes. However, the data indicate that comparisons of metabolic profiles among locations or among seasons and years would be difficult or unrealistic. Validation and comparisons of MCLPPs with metagenomic sequencing is ongoing.

mPMI, Period of Insect Activity, Nocturnal Oviposition

G104 Blowfly Oviposition Dynamics on Liver Bait and Swine Carcasses Exposed at Dusk

Maureen Berg, BS, 300 College Park, University of Dayton, Science Center 211, Dayton, OH ; Andrew J. Lewis, BS, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; Megan Shoda, MS, University of Dayton, 300 College Park, Dayton, OH 45409; and Tiffany Blair, BS, and M. Eric Benbow, PhD, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320*

After attending this presentation, attendees will better understand nocturnal and diurnal oviposition (i.e., egg laying) behavior of blowflies, and the possible implications to estimates of the minimum postmortem interval (mPMI) and period of insect activity (PIA). Attendees will learn how environmental conditions affect blowfly oviposition dynamics, and how this can impact insect colonization throughout decomposition.

This presentation will impact the forensic science community a broader view of decomposition ecology, specifically insect colonization, and allow the attendees to evaluate how to refine methods of estimating the PIA, thus a more accurate minimum postmortem interval.

This presentation will allow attendees to better understand nocturnal and diurnal oviposition (i.e., egg laying) behavior of blowflies, and the possible implications to estimates of the minimum postmortem interval (mPMI) and period of insect activity (PIA). Attendees will learn how environmental conditions affect blowfly oviposition dynamics, and how this can impact insect colonization throughout decomposition. A broader view of decomposition ecology will be provided, specifically insect colonization, and allow the attendees to evaluate how to refine methods of estimating the PIA, thus a more accurate mPMI.

One aspect of forensic entomology concerns the use of arthropod evidence at crime scenes to estimate a mPMI based on the species that colonize and develop on the remains. The major assumption that blowflies do not oviposit at night can influence the length of the PIA and thus entomologically-based mPMI estimates. Previous field studies have indicated either an absence of nocturnal oviposition or highly reduced activity that may have been associated with artificial lighting. The objectives of this study were: (1) to test for nocturnal blowfly oviposition and evaluate the effects of different lighting conditions (i.e., artificial and natural) on oviposition using liver baits as a resource; and, (2) monitor oviposition on replicate swine carcasses exposed to the environment at dusk, in different habitats and temporally (i.e., three years).

In the first experiment (Liver Experiment), blowfly oviposition of liver baits was evaluated under experimental light treatments in wooded lot. We hypothesized that nocturnal oviposition would not occur, but initial diurnal oviposition would be correlated with abiotic conditions (i.e., temperature, humidity, precipitation). In a wooded habitat near Xenia, OH, from July-October, 2009, 35.0±2.0g pieces of beef liver bait (N=3/treatment) were placed under three artificial lighted conditions: high (6 lx), low (3 lx), and no light (0 lx). Different bait locations, 1m off the ground and on the ground, were also evaluated to understand the effect of height above ground on oviposition. Oviposition was monitored for 24 hours beginning with bait exposed two hours prior to sunset (determined by NOAA). At each time point, approximately 25% of collected eggs were reared for identification, while the remaining were weighed. A regression analysis for *Phormia regina* was developed to predict the number of egg/larvae from egg mass ($F=1775$, $df=43$, $p<0.0001$, $R^2= 0.97$). Temperature and humidity were monitored.

From all treatments and replicates only 90 eggs were collected within two hours of sunset and no oviposition was documented during the nighttime hours. There were statistically significant effects of light ($F=27.86$, $df=3$, $p<0.0001$) and height above ground ($F=15.8$, $df=2$, $p=0.0004$) on diurnal oviposition in August 2009. August was significantly the warmest month as statistically determined using one-way ANOVA, with a mean nighttime temperature of 20°C. There was less diurnal oviposition during the other months when average nocturnal temperatures ranged from 10-20°C, while average nighttime temperatures <10 °C were associated with no oviposition

the following day. Further, the greatest diurnal oviposition was associated with high artificial light and location (height-above-ground) treatment effects.

In the second experiment, replicate swine carcasses were exposed to the environment two hours before sunset and monitored for oviposition as in the liver experiment described above. During the summer of 2009 this was done in a small forested lot using six replicate carcasses, while in 2010 and 2011 identical trials were conducted in a different forested lot about 25km from the first location and using four and six carcasses, respectively.

Similar to the liver experiment, little to no nocturnal oviposition was documented on most carcasses in 2009, 2010 and 2011; however, there was notable exception with one carcass in 2009. On an evening with temperatures only between 15-20°C and rainfall, active oviposition was observed by one female *Lucilia* spp. approximately 0.5 hours before sunset under 0 lux conditions in the mouth of one out of the six carcasses. These are environmental conditions that are never expected to be associated with blowfly oviposition and could be important to estimates of PIA (and thus mPMI) in criminal investigations. Although it requires additional study, it is reported here that there is approximately a 17% chance that early nightfall oviposition can occur during rainfall under relatively mild temperatures during mid-summer in southwest Ohio. Diurnal oviposition in these trials was similar to the Liver Experiment. In 2009, 2010, and 2011, oviposition occurred no later than sunset and no earlier than two hours after sunrise. The average humidity, temperature, and lux that initial oviposition occurred during the three years was 71%, 25°C, and 30lx, respectively. This study demonstrates that early sunset/sunrise oviposition by blowflies varies greatly even within the same habitat, and the variability due to location, temperature, humidity, and light should be taken into consideration when making estimates of the PIA and mPMI using insect evidence.

Phormia Regina, Oviposition, Decomposition

G105 Invertebrate Species Diversity, Richness, and Evenness Indicate Delayed Colonization of Remains

Jennifer Pechal, MS, Texas A&M University, 2475 TAMU, College Station, Texas 77843-2475; M. Eric Benbow, PhD, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; Tawni L. Crippen, PhD, Southern Plains Agricultural Research Center, Agricultural Research Service, United States Department of Agriculture, College Station, TX 77845; and Aaron Tarone, PhD, and Jeffery K. Tomberlin, PhD, Texas A&M University, Department of Entomology, TAMU 2475, College Station, TX 77843-2475*

After attending this presentation, attendees will be able to comprehend the utilization of multivariate statistical approaches for analyzing adult insect data associated with decomposing carrion in order to predict a delay in colonization (i.e. pre-colonization interval); specifically, adult insect species richness associated with decomposing human remains can be used to determine the pre-colonization and post-colonization interval and thus provide a more accurate minimum postmortem interval (mPMI).

This presentation will impact the forensic science community by showing how insects are commonly used to estimate the period of insect activity (PIA), which may correspond to minimum postmortem interval. However, forensic entomologists currently are not able to offer a quantified pre-colonization interval estimate. Consequently, estimates based on succession or development more accurately represent the mPMI which could be much shorter than the actual postmortem interval.

Adult primary colonizers, specifically blowflies (Diptera: Calliphoridae), are rarely used by forensic entomologists to predict PIA because of a high level of variation and unpredictable nature of utilizing a resource. The adults are most commonly used to confirm species identifications of larval specimens. Blowfly larval length and weight are almost exclusively used to estimate the age of a larva which can be used to predict the amount of time since eggs were laid on a body. The PIA consists of two intervals: the pre-colonization and the post-colonization intervals. During the pre-colonization interval remains are made available in the environment, insects will detect and subsequently accept the remains. An oviposition event occurs which indicates the beginning of the post-colonization interval. Insect activity including insect succession during the post-colonization time interval has long been the cornerstone of forensic entomology. Current research focusing on the pre-colonization interval will better understand species interactions and mechanism controlling colonization of remains.

This study used passive insect-trapping methods to assess primary colonizer species diversity, richness, and evenness on three swine carcasses that initially had access to insects (ACC) and three swine carcasses that were excluded from insect access (EXC) for five days using insect exclusion cages. After five days, EXC carcasses were exposed to insects via removal of the exclusion cages. Insects were collected every 12 hours for both treatments of carcasses and then identified to the lowest taxonomic level. Ecological parameters including Simpsons index, Shannon-Weaver index, species richness and species evenness were analyzed with univariate and multivariate statistical approaches. Succession patterns of forensically important insect species were similar for ACC and EXC carcasses with *Phormia regina* being the initial and most abundant blowfly species followed by *Lucilia coerulivirdis* and *Cochliomyia macellaria*. Coleopterans from the families Staphylinidae, Trogidae, Histeridae and Dermestidae were the next wave of insects utilizing the carcasses. Despite similarities between succession patterns with each treatment, Student's t-tests indicated that ACC carcasses had significantly fewer insect taxa than EXC carcasses exposed on each day insects. A multivariate approach was taken to determine any insect community differences between the ACC and EXC carcasses. Nonparametric multidimensional scaling analysis coupled with multiple response permutation procedure indicated a significant difference between ACC and EXC carcasses ($p<0.0001$).

These data are important because of their implications in forensic entomology. Mainly, if a body is excluded from insect activity for five days and insect collections are made using standard entomological evidence collection protocols there is a possibility that the PIA will be underestimated by up to five days. However, the the limitations of these data as only a single time frame was used to exclude insect was understood. More studies are ongoing to determine if these results would be consistent for multiple days of insect exclusion, but at this time collections of adult insect communities present at a body are promising as an indication of whether or not there has been a delay in insect colonization of a body.

Decomposition Ecology, Entomology, Delayed Colonization

G106 Species Interactions Between Forensically Important Blowfly Species and the Invasive Hairy Maggot Blowfly (Diptera: Calliphoridae)

Erin J. Watson-Horzelski, PhD, Southeastern Louisiana University, Department of Biological Sciences, SLU Box 10736, Hammond, LA 70402; and James P. Geaghan, PhD, Louisiana State University, Department of Experimental Statistics, 161 Martin D. Woodin Hall, Baton Rouge, LA 70803*

After attending this presentation, attendees will become familiar with species interactions of native and invasive calliphorid species observed at decomposing animal and human remains.

This presentation will impact the forensic science community by demonstrating the importance of understanding biological and ecological aspects of forensically important blowfly species commonly collected at the crime scene.

Introduction: Native to tropical regions of Australia and the Orient, the hairy maggot blowfly, *Chrysomya rufifacies* (Macquart), was first reported in the New World in 1978 (Costa Rica) and then in the United States in 1980

(Texas). As an aggressive species, *Chrysomya rufifacies* has disrupted the natural balance of insect communities associated with corpses and carcasses in the continental United States. First-instar larvae are necrophagous, while second and third-instar *Ch. rufifacies* are facultatively cannibalistic and predaceous on other blowfly larvae.

The secondary screwworm fly, *Cochliomyia macellaria* (F.), is abundant throughout the New World and is often the first arrivers at human and animal remains. Due to overlapping niches, species interactions between *Ch. rufifacies* and *C. macellaria* not only affect their life histories but also impact forensically important predatory beetles. Prior to arrival of *Ch. rufifacies* in Louisiana in 1995, Tessmer and Meek (1996)[1] study seasonal abundances of adult Calliphoridae. They determined that >95% of the emerged adults in summer and fall 1992 were C. macellaria, as well as, approximately 52% of *C. macellaria* larvae migrated <0.9 m away from carcasses, and 65% moving in a SE/SW direction.

Material and Methods: Five experiments were conducted during summer and fall seasons in 2008-09 in a grassland habitat in Hammond, Louisianna. Each experiment included three fresh swine carcasses (55-70 kg), placed 30 m apart, with heads facing north. Two research phases per experiment: (1) carcass utilization by calliphorid larvae; and, (2) larval dispersion and adult emergence. Phase 1 sampling protocol: all carcasses manually sampled daily until majority of blowfly larvae migrated and/or pupated, with emphasis on species interactions within five regions of carcass (head, anterior portion, anterior limbs, posterior portion, and posterior limbs) and monitoring of resource quality per region (high, medium, low). Phase 2 sampling protocol: collection method designed to resemble Tessmer and Meek (1996). Nine emergence cages were constructed from PVC pipe and fiberglass screening: one center cage (1 x 1 x 0.6 m) placed directly over each carcass, eight cages (1 x 0.6 x 0.6 m) placed 60 cm away from center cage and each other. Emerged flies aspirated daily until no calliphorid adults were observed for two consecutive days. Temporal and spatial models were determined using logistic regression analyses (Proc Glimmix, SAS 9.1).

Results: Fifteen carcasses studied in 2008-09 were analyzed for spatial and temporal patterns of calliphorid larvae within five carcass regions (Phase 1). Seven species of blowfly larvae were collected until 10-15 d of decomposition, with majority of occurrences being *C. macellaria* and *Ch. rufifacies* larvae. Logistic regression models clearly demonstrated behavioral, spatial and temporal patterns observed in nature, including: delayed oviposition by *Ch. rufifacies*, relocation of *C. macellaria* to lower quality resources (limbs) to avoid predation, early migration of *C. macellaria* larvae away from carrion, and increased probability of *Ch. rufifacies* at all regions of carcass with favorable resources. All Type III tests were highly significant (Pr> F, P< 0.05) for time and carcass region, as well as, Tukey-Kramer pair-wise comparisons for species and region. Nine swine carcasses studied in 2009 were analyzed for spatial and temporal patterns of migrating post-feeding larvae (Phase 2). A total of 90,112 adults were aspirated between 11-19 d of decomposition: *C. macellaria*: 62,470 (69%), *Ch. rufifacies*: 27,568 (31), and *Lucilia sericata*: 74 (> 0.0008). Predicted adult emergence for *C. macellaria* and *Ch. rufifacies* peaked on days 13 and 16-17, respectively. All Type III tests were highly significant (Pr> F, P< 0.05) for time, cage position (north-south, east-west), and all interactions. Tukey-Kramer pair-wise comparisons were also significant for species and carcass region. Majority of *C. macellaria* were collected in the center cage (~ 89%), with less larvae migrating south and west. Whereas, *Ch. rufifacies* larvae migrated predominantly south and east.

Conclusions: In comparison to Tessmer and Meek (1996), a decrease in abundances of adult *C. macellaria* were documented. However, *C. macellaria* remained the predominant blowfly species collected in emergence cages (69%) despite the presence of Ch. rufifacies. In addition, the majority of *C. macellaria* larvae did not migrate a notable distance away to pupate as was hypothesized. Understanding species interactions of forensically important blowflies at a crime scene is of utmost importance for postmortem estimations.

Forensic Entomology, Blowfly Species Interactions, Hairy Maggot Blowfly

G107 Developing Genomic Tools for Forensically Important Flies to Improve Forensics

Aaron M. Tarone, PhD, Texas A&M University, Department of Entomology, College Station, TX 77843; Sing-Hoi Sze, PhD, Texas A&M University, Biochemistry and Biophysics, Texas A&M University, College Station, TX 77843; Joseph P. Dunham, BS, University of Southern California, Molecular and Computational Biology, Los Angeles, CA 90089; Brandi-Lee Carey, BS, University of Massey, Institute of Molecular BioSciences, Palmerston North, NC, NEW ZEALAND; Peter C. Chang, BS, University of Southern California, Molecular and Computational Biology, Los Angeles, CA; Fang Li, PhD, North Carolina State University, Department of Genetics, Raleigh, NC 27695; Courtney Fjeldsted, BS, University of Southern California, Molecular and Computational Biology, Los Angeles, CA 90089; Maxwell J. Scott, PhD, North Carolina State University, Department of Genetics, Raleigh, NC 27695; and Sergey V. Nuzhdin, PhD, University of Southern California, Molecular and Computational Biology, Los Angeles, CA 90089*

After attending this presentation, attendees will learn that developmental and quantitative genetics has an improving forensic entomology. Attendees will also gain an appreciation of how to develop genomic tools and implement genomic techniques to improve forensic entomology.

This presentation will impact the forensic science community by showing how recent technological advances have allowed non-model organism researchers to conduct genomic research which means that genomics can be used to improve problems in forensic entomology, which is dominated by non-model organisms. The data presented here represent the first set of genomic tools for a common forensically important blowfly species.

Recent research indicates that quantitative and functional genetic principles will be useful in improving the accuracy and precision of arthropod derived postmortem interval estimates. However, such endeavors require genomic tools, which are lacking in non-model species. Next-generation sequencing provides the necessary capabilities to develop genomic tools for blowflies and other forensically relevant species. For many species whole genome assembly is not feasible, but it is possible to assemble sequences that represent the transcriptome: the subset of the genome represented by transcribed genes. However, transcripts possess alternative splices, which must be accounted for in the assembly process (or ignored at the cost of losing information). The *de novo* assembly of the *Lucilia sericata* (Diptera: Calliphoridae) transcriptome is described here, outlining computational and molecular efforts to identify and confirm alternative splice, allelic, and gene expression information in a species important to forensic entomology.

An algorithm that enables the identification of alternative splices in assembled transcripts through the use of de bruijn networks was developed. This tool, ASplice, also identifies putative SNPs and reports library specific gene expression estimates (expressed as reads per million mapped reads per thousand bases of transcript; or RPKM). Before assembling blowfly data, *Drosophila melanogaster* data was assembled in this manner, revealing false positive and false negative rates for transcript and splice identification. The performance of ASplice was also compared to other algorithms, demonstrating the ability of the program to be conservative (unlikely to identify false positives) and/or less memory intensive than competing *de novo* assembly software packages.

After validation of the assembly methods, *Lucilia sericata* RNA derived from embryonic, larval, pupal, and adult samples was sequenced using a combination of Illumina and 454 sequencing. All developmental stages were sequenced using Illumina, producing >6 billion bases of raw useable sequence. In addition, reciprocal subtractive hybridizations were performed between larval and pupal samples in a manner that would enrich for transcripts that are differentially expressed between: (1) feeding and postfeeding third instars; and, (2) early and mid pupation. Samples derived from subtractive hybridizations and salivary gland RNA were sequenced using 454 sequencing, yielding tens of millions of bases of sequence data.

Results indicate that the authors have identified hundreds of transcripts (and isoforms) that are strong candidates for use in predicting blowfly developmental age in a manner that increases precision compared to traditional forensic entomology approaches. Many of these loci also have *Drosophila* homologs that are expressed in developmentally regulated patterns commensurate with expression patterns observed in *Lucilia*, while others are unique to the species. Thousands of putative SNPs and splices have been identified, which will be useful in quantitative and population genetic studies. Sanger sequencing has been used to confirm assembled sequences in seven genes, including several alternatively spliced sex determination genes. Results from the analysis of the transcriptome will be presented and the audience will be exposed to several lines of research that can be employed once genomic tools are available for forensically important species.

Postmortem Interval, Genomics, Gene Expression

G108 Improving Postmortem Interval (PMI) Estimations Through Curvilinear Development Modeling of the Blowfly *Lucilia Sericata* (Meigen)

Amanda Fujikawa, MS, 316 Biochemistry Hall, University of Nebraska-Lincoln, Lincoln, Nebraska 68583-0760; Leon G. Higley, PhD, University of Nebraska, 306A Biochemistry Hall, Lincoln, NE 68583-0760*

After attending this presentation, attendees will have a better understanding of the importance of forensic entomology in estimating postmortem interval (PMI) and the advantages of using curvilinear development data for postmortem interval calculations.

This presentation will impact the forensic science community by vastly improving on the current developmental data available for Lucilia sericata and increasing the accuracy of PMI estimations in human death investigations.

The blowfly *Lucilia sericata* is among that group of insects that can occur rapidly on decomposing animals. When found on a human body, the developing eggs, larvae, or pupae of *L. sericata* could be used as an index pointing to the initial time of death (postmortem interval or PMI). Estimating the PMI is crucial in most human death investigations, because time of death is needed for properly reconstructing events before and after death. To use the insects, like *L. sericata*, in estimating PMI we must be able to determine the insect age at the time of discovery and backtrack to time of oviposition. Consequently, understanding temperature-specific development rates is essential. Unfortunately, existing development models of forensically important insects are only linear approximations.

Here, experiments and findings for building a curvilinear developmental model for *L. sericata* are reported. Experimental considerations include diet, humidity, light cycle, temporal patterns of stage transitions, and temperature measures. Experiments were conducted over ten temperatures (10°C, 12.5°C, 15°C, 17.5°C, 20°C, 22.5°C, 25°C, 27.5°C, 30°C, and 32.5°C). Twenty eggs (collected immediately after oviposition) were placed on 25g (0.05lb) of beef liver that was on a 5cm^2 (2in^3) moist paper towel in an 88mL (3z) plastic cup. The cup was placed in a 9cm^3 (3.5in^3) plastic container that had 2.5cm (1in) of wood shavings in the bottom. A thermocouple was placed in the containers to monitor the internal temperatures. Measurements were taken at intervals calculated from accumulated degree hours (ADH). Each life stage had five measurement points: at the beginning, one-quarter mark, one-half mark, three-quarter mark, and the end. Each point was replicated four times, for a total of 20 measurements per life stage. During each measurement, the cups were pulled from the chamber and the stage of each maggot documented with a microscope using the posterior spiracle slits of each maggot (the number of slits corresponds to the life stage).

The *L. sericata* data illustrate the advantages of curvilinear models in describing development at environmental temperatures near the biological minima and maxima, and the practical significance of curvilinear models over linear approximations. Results here represent the first in a series of larger studies modeling development of key forensically important blowflies of North America.

Blowfly Development, Decomposition, Human Death Investigation

G109 Can Lucilia Sericata Change Gravesoil Microbial Community Structure?

Amy E. Maile, BS, Department of Entomology, 102 Entomology Hall, University of Nebraska-Lincoln, Lincoln, NE 68583-0816*

After attending this presentation, attendees will understand that there is potential in using fatty acids to characterize gravesoil microbial community with the ultimate goal of estimating postmortem interval (PMI). Attendees will also understand the effect of the blowfly Lucilia sericata on gravesoil microbial community structure.

This presentation will impact the forensic science community by the development of an additional method to determine extended PMI and increasing the understanding of cadaver decomposition. This knowledge can be used in conjunction with other methods to estimate PMI, such as forensic entomology.

Death investigations heavily rely on accurate estimations of PMI to assist in identification of victims and suspects as well as determining the validity of alibis. Currently, the most reliable method to estimate PMI at an outdoor death scene is forensic entomology. In cases where active blowfly larvae have already migrated away from the body, estimating PMI becomes difficult.

A controlled laboratory experiment was conducted to determine if the presence of the blowfly *Lucilia sericata* (Diptera: Calliphoridae) can affect the structure of the gravesoil microbial community. To do this Petri dishes were placed (150 mm x 25 mm) filled with 150 grams (g) of washed sea sand inoculated with 150 g of Pawnee clay loam soil in growth chambers. Soil was collected from Nine Mile Prairie, a natural tall-grass prairie ecosystem, which is located approximately nine miles northwest of Lincoln, Nebraska. Inoculated soil was calibrated to a water holding capacity of 55% and left to equilibrate for seven days in growth chambers.

A mouse carcass (killed with carbon dioxide) was then placed on its left side on the inoculated sand within 30 minutes of death. Fly eggs (10 per carcass) were counted and placed on the right eye of selected carcasses shortly after placement on soil and were monitored daily to prevent desiccation.

The temperature was kept at approximately 22°C during the experimental period and the water content of the inoculated sand was maintained at 55% every 3-4 days by adding distilled water. Carcass decomposition was monitored every 24 hours for 35 days using a decomposition scoring system. In addition, carcass mass loss was measured at 7, 14, 21, 28, and 35 days postmortem. A destructive harvest design was used to avoid the influence of carcass disturbance on the rate of decomposition. Following carcass harvest, inoculated sand was collected and analyzed for lipid phosphorus, fatty acid methyl esters, pH, and electrical conductivity. This experiment was replicated four times and controls (inoculated sand with no carcass) were used.

Results indicated that overall, carcass treatment had minimal effect on mass loss. There was no significant difference (P = 0.058) between the

treatments, however the overall percent of mass loss between treatments varied. Mass loss of carcasses on Petri dishes reached approximately 35% ± 3.38 of total body weight after 35 days, carcass on soil reached approximately 62% ± 5.80, and carcasses on soil with insects reached approximately 60% ± 5.44. A higher total body score was observed for carcasses on soil with insects than carcasses on soil, which were both higher in total body score than carcasses on Petri dishes. The highest possible total body score for all treatments was 21. Carcasses associated with insects had only their face consumed and therefore it was observed that the remainder of the body decomposed in a similar fashion to carcasses on soil not associated with insects. Lipid phosphorous analysis indicated that soil associated with carcasses had a much greater total microbial biomass than control soils. There was no significant difference between gravesoils regarding the presence or absence of insects for this analysis. Results from the analysis of fatty acid methyl esters will be presented.

Forensic Taphonomy, Extended Postmortem Interval, Ecology

G110 Hypostasis and Time Since Death: State of the Art and Proposal of an Operative Instrumental Protocol

Francesco Vinci, MD, Sabrina Leonardi, MD, Maricla Marrone, MD, Maria Carolina Romanelli, MD, Rossana Gianciotta, MD, Pasquale Beltempo, MS, and Alessio Veneziani, MD, Section of Legal Medicine, piazza Giulio Cesare, 11, Bari, 70124, ITALY*

After attending this presentation, attendees will understand that in evaluating time since death the study of parameters derived from the three abiotic signs (hypostasis, rigor mortis, and body cooling) is still the most commonly used in practice. This is due to its simplicity and rapid execution and because it allows immediate deductions to be made at the crime scene, thus rapidly orienting the investigations. However, some of these methods, especially the evaluation of hypostasis, are highly subjective, being largely based on the personal experience, skill and scientific knowledge of the operator. This makes standardization very difficult and the final result may not be entirely satisfactory in estimating the time of death, as compared to witness reports and circumstantial data, that are sometimes very accurate.

This presentation will impact the forensic science community and society. Infact, it is known that the lividity that occurs after death has certain qualitative and quantitative features, but although these findings can contribute to estimate the time of death, the evaluation is still subjective and other parameters are often more accurate. For this reason, a standard method for studying hypostasis to estimate the time of death is needed.

An extensive volume of "archeological" references, covering a period since 1700, in which hypostasis was underestimated as a medicolegal phenomenon will be analyzed. Initially, it was considered only to prevent misdiagnosis of death. Then various authors set chronological limits for the appearance of lividity. Since then, changes of hypostasis characteristics have always been used for a basic orientation in evaluating the postmortem interval. The main problem is that several external and internal factors, often difficult to recognize, can affect the evolution of the phenomenon, in relation to conditions that change the qualitative and quantitative status of blood. Only in the 1930s was the advisability of "testing" hypostasis "mobility" suggested, although it was never specified exactly how to perform these operations. The small evidence provided in this regard is evidently based on personal experience and it is therefore difficult to propose these "guidelines" in concrete cases to pathologists with little practice and experience.

A test of hypostasis as it is usually done in daily practice was performed. A map of the back of the body regions, where hypostasis appears if the body is in supine position, was made. A questionnaire was administered to 35 experts and residents training in forensic medicine. The results of these tests confirmed that no standardized method is used in daily practice, although the population sample consisted of coroners coming from the same school. Then, some internal, external, or subjective factors were considered (cause of death; ambient temperature; humidity; anatomical site to test; intensity and duration of the compression; assessment of color intensity), that can cause variations in hypostasis formation and evolution. These factors and their incidence in the evaluation are the basis of this experimental study, based on measurement of these same parameters using specific equipment (a colorimeter, a dynamometer, and a thermometer set also for moisture measurement) selected for its ease of use.

In conclusion, the results of this research are illustrated and discussed. They show that in time since death evaluations based on hypostasis, a more objective method is needed. It must be remembered that many factors may invalidate the most accurate analysis made using traditional parameters.

Hypostasis, Standardization, Time Since Death

G111 Frozen-Thawed vs. Freshly Killed: A Comparison of the Volatile Organic Compounds Detected From Decomposing Remains

Norma I. Caraballo, BSc, Florida International University, International Forensic Research Institute, Department of Chemistry & Biochemistry, 11200 Southwest 8th Street, CP 344, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institution, University Park, Miami, FL 33199*

After attending this presentation, attendees will have enhanced their understanding of the scent of death that is released during the decomposition process of a human cadaver analogue.

This presentation will impact the forensic science community by expanding upon the limited knowledge of volatile organic compounds (VOCs) that evolve from decomposing remains, as well as assessing the impacts that freezing and then thawing the remains may have on the VOCs generated.

The decomposition process, which starts soon after death (Vass 2001), has been studied under an array of conditions using a variety of animal models, such as pigs (Payne 1965), squirrels (Johnson 1975), rabbits (Johnson 1975), rats (Micozzi 1986) and humans (Mann et al. 1990). In the latter study, the effects of temperature on the decomposition process of human remains were investigated; it was found that when temperatures were cold or near freezing, the rate at which the cadavers decomposed reduced or ceased entirely. In the 1986 study conducted by Micozzi, the effects of temperature on the decomposition process were also evaluated. Within this study, the effects on rats that were frozen after being euthanized and then thawed versus those that were freshly killed were compared; it was determined that those rats that were frozen and then thawed decomposed from the "outside-in" while those that were freshly killed decomposed from the "inside-out."

Alive, the body consists of proteins, carbohydrates and lipids, and at death, these compounds breakdown into simpler molecules generating a putrid odor which has come to be known as the *scent of death*. Several research groups have evaluated the VOCs that are released during the decomposition process of human remains. Vass et al. (2004, 2008) conducted a two-part study: in part one, the authors discovered over 400 volatile organic compounds associated with the decomposition process of buried human remains and in part two, 30 compounds were selected as important markers in human burial decomposition and 19 out of those 30 compounds were identified in non-buried decomposing human remains. In a study conducted by Statheropoulos et al. (2005), volatile organic compounds that were released during the decomposition process of two cadavers were evaluated and over 80 compounds were detected. In another study conducted by Statheropoulos et al. (2007) over 30 decomposition-associated VOCs were detected. Hoffman et al. (2009) conducted a study evaluating the VOCs released from 14 separate tissue samples that were previously used as victim-recovery canine training aids; their study revealed over 30 volatile organic compounds. In a recent study performed by DeGreeff (2010), over 30

compounds were detected from human remains samples collected at a morgue and crematorium.

A method optimization study was performed, using a standard mixture of previously reported compounds for decomposing remains, to critically evaluate two different extraction techniques: Activated Charcoal Strip (ACS) and Solid-Phase Microextraction (SPME). In addition, different gas-chromatographic column chemistries were also explored to determine the best chromatographic stationary phase suitable for decomposition volatiles. The optimization study revealed that the use of SPME in combination with GC/MS equipped with a Sol-Gel Wax column provided the best response and selectivity for the target analytes. The optimized methods to evaluate the volatile organic compounds emanating from the decomposing remains of eight human cadaver analogues were utilized: four were frozen upon euthanizing then thawed prior to analysis and the remaining four were freshly killed. A variety of compounds were detected and included the following classes: aldehydes, ketones, carboxylic acids, and sulfur-containing compounds. A comparison between the human cadaver analogues that were frozen-thawed vs. freshly killed will highlight the similarities and differences between each set of specimens, as well as demonstrate the significant impact that freezing of the remains has on the VOCs detected.

Scent of Death, Decomposition, Volatile Organic Compounds (VOCs)

G112 Applications of Social Network Services in Medicolegal Death Investigation

Ryan Hookano, BS, Laura D. Knight, MD, and Ronald Brunelli, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210; and Robert Stoppacher, MD, 100 Elizabeth Blackwell Street, Syracuse, NY 13210*

After attending this presentation, attendees will have an understanding of how online social network services can provide valuable information relevant to medicolegal death investigation. This may include information leading to identification of unidentified remains, time of death determination, manner of death, and other relevant issues. Attendees will be aware of specific case examples in which social media has been helpful, and will understand some of the limitations and pitfalls associated with use of these sites for such information.

This presentation will impact the forensic science community by introducing the concept of using social network services to gather information crucial to medicolegal death investigation, and furthermore, will illustrate cases in which these media have already been useful.

With the increased popularity of social networking sites such as Facebook®, LinkedIn, Twitter, and Google®, a wealth of new resources are available to aid in medicolegal death investigation. Individuals are utilizing these social networking services (SNS) to share public information with the world and, in a sense, are creating a database of profiles that can be searched by anyone having an internet connection. While the information available does depend on the level of security the user has placed on his/her profile page(s), there are a large number of users who post publicly and have little or no security limitations on their information.

The medicolegal death investigator will immediately recognize the advantage of such a searchable public database. Information commonly available on user profiles includes photographs of the user (the owner of the profile page), past education and work history, and a list of friends and family. Pictures on a user's profile on such sites as Facebook®, MySpace, LinkedIn, and Google® can be used for preliminary identification purposes. Users may also have family members and significant others on their Facebook® "friends list," Twitter "followers," or Google "circles," which could aid in establishing the next of kin, and finding a way to contact them (via clicking on their profile, and sending a message). The "friends list" can also, of course, provide an idea as to the types of people with whom the decedent chose to socialize, which might be relevant in certain circumstances.

The actual content posted by the user may also be of interest. Suicide threats can be made via a Facebook® wall post, Twitter "tweet," or Google "share", just as they have been sent via text message on cell phones in the past. These "tweets" and "shares," updated activity lists on Facebook® profile pages, and even comments made by the user on other people's pages ("walls" in the case of Facebook®) can help in determining when a user was last at their computer (and/or, last known alive). All of these potential findings can aid in pinpointing a more precise time of death.

Furthermore, the comments left by the decedent user can give a sense of their state of mind, while the comments left by others on the decedent's "wall" or page can reveal aspects of the relationships the decedent had with others. Through the use of comments on profile pages, a user can hypothetically leave a public electronic suicide note while a murderer could also be found to make remarks on a victim's profile page, either before or after death.

There are limitations to the information gleaned from SNS. Some users may share their passwords with others, making it possible that the "user" is not the one updating their profiles or posting comments. Additionally, password-saving features in some computer programs may make it possible for another individual to post to a decedent's account by simply using the decedent's computer. Another issue is that information can be removed at any time by anyone who has access to the account. Furthermore, the "friends list" should be considered with caution, as it may consist of any range of constituents, from just a few closest friends and family for the most conservative of users, up to hundreds of acquaintances and strangers for other users with no concerns for privacy. Finally, it behooves one to remember that people are capable of lying over the internet just as they are of lying in person, and perhaps even more so because of the distancing and semi-anonymity.

This presentation will increase awareness of the usefulness of SNS to the medicolegal death investigator and/or forensic pathologist; describe specific applications to death investigation; and encourage attendees to consider how they might utilize the information available on these sites in their own investigations, while recognizing its limitations and potential pitfalls. Specific casework examples from the Onondaga County Medical Examiner's Office will be provided, with screen captures of relevant pages where available. The presentation will also cover what happens to a user's profile page after the user dies.

Social Network Services (SNS), Death Investigation, Facebook®

G113 Skeletal Trauma Observed in Exhumed Skeletons Compared With Trauma Recorded in the Corresponding Forensic Autopsy Reports

Maria D. Morcillo, MD, National Institute of Legal Medicine and Forensic Sciences, Cra. 7A No. 12-61. Piso 3., Bogota, COLOMBIA; Elia Lasso, MD, National Institute of Legal Medicine and Forensic Sciences, Cra. 24C #61-30, Manizales, COLOMBIA; and Silvia Lopez, MD, National Institute of Legal Medicine and Forensic Sciences, Cra. 7A No. 12-61, Bogota, COLOMBIA*

After attending this presentation, attendees will understand important recommendations for medical examiners when performing autopsies in violent death cases where bone structures are compromised. This information is important for the medical examiner and forensic anthropologist alike for the determination of the mechanisms and causal agents of injuries during autopsies and analysis of skeletonized bodies or skeletal remains.

This presentation will impact the forensic science community by demonstrating particularly to anthropologists and medical examiners the importance and the advantages of interdisciplinary, simultaneous and integrated casework in cases where hard tissues have been affected.

The purpose of this paper is to determine the consistency between the analysis of trauma obtained from exhumed skeletons and the findings described from the corresponding fresh body autopsy reports. One hundred and thirty seven skeletons from the modern skeletal collection curated by the

National Institute of Legal Medicine and Forensic Sciences (INMLCF) in Colombia were analyzed. The presence of traumatic injuries to bone was observed on 42 individuals. Of this sub-sample, all individuals died between 2005 and 2006 and there were thirty-three males and nine females, with an age range of 18-84 years old. The following features were documented: (1) compromised bone structure and location; (2) type of traumatic injury; (3) fracture characteristics; (4) possible lesion mechanism and causal agent; and, (5) number of gunshot wounds when applicable, including number of entrance and exit wounds. The review of the autopsy reports for these individuals included a search for description of these same five features.

The results of the analyses and the comparison of the information will be presented in terms of consistency between the findings described on autopsy reports and the findings of the examination of skeletonized remains, particularly in terms of the affected bone structure, type of fracture and its characteristics, mechanisms of the injury and causal agent, number of gunshot impacts, and number of entrance and exit wounds.

Regarding the exhumed cases examined, in 30 (71%) cases gunshot trauma was observed, sharp trauma in one (2%) case, blunt trauma in six (14%) cases and in five (11%) cases mechanism of trauma could not be determined with sufficient degree of certainty. The information obtained from the autopsy reports in these same cases stated that in 27 (64%) cases death was due to gunshot wounds, in three (7%) cases due to stab wounds, in 10 (24%) cases due to blunt force trauma and in two (5%) cases the cause of death was not determined and trauma to the skeleton was not described.

After comparing both groups of results, in 32 (76%) cases the information regarding mechanism of trauma was consistent with the information registered in the autopsy reports. However, in five (12%) cases, the information was not consistent and in five (12%) cases trauma was observed but the mechanism was not determined. Considering the number of impacts in gunshot cases and sharp trauma (30 in total), in 19 (63%) cases the number of impacts observed on the dry bones was not consistent with that recorded in autopsy reports. In eight (27%) cases the information of number of impacts is consistent with the information registered by the medical examiner in the autopsy report.

The accurate determination of traumatic bone injuries and the causal mechanism during the autopsy of fresh bodies or bodies with a large percentage of soft tissue remaining requires extensive dissection and good medical knowledge. On the other hand, when examining skeletonized remains, medical examiners and anthropologists must consider the physiopathology of aspects of trauma and anatomic relationships in order to make adequate interpretations of trauma, the number of impacts, and cause of death. The simultaneous and integrated participation of the anthropologist in the morgue, together with the medical examiner, is strongly recommended for cases where bony structures have been compromised.

Bone Trauma, Medico-Legal Autopsy, Forensic Anthropology

G114 Characteristics of Medical Examiner/ Coroner Offices Currently Accredited by the National Association of Medical Examiners

Mitchell L. Weinberg, MD, and Victor W. Weedn, MD, JD, Maryland State Office of the Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223; Seth H. Weinberg, BS, Johns Hopskins University Department of Biomedical Engineering, Traylor Building, 720 Rutland Avenue, Room 703, Baltimore, MD 21205; Steven C. Clark, PhD, 124 Elm Street, Big Rapids, MI 49307; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will become familiar with the characteristics of medical examiner and coroner (ME/C) offices that have attained Full or Provisional Accreditation by the National Association of Medical Examiners (NAME), such as budget, area and population served, staffing levels in key personnel positions, and the breakdown of specific types of cases.

This presentation will impact the forensic science community by providing an awareness of the profile characteristics of offices that are currently accredited by NAME.

Medicolegal death investigation in the United States is highly variable from state to state, and sometimes even within a single state. In 2004, the only comprehensive survey of the ME/C system in the United States was performed, and the Bureau of Justice found 16 states with a centralized statewide medical examiner, 14 states with a county coroner system, seven states with a county medical examiner system, and 13 states with a mixed coroner and medical examiner system.[1] At present there is no national oversight of medicolegal death investigation, with each state deciding on the minimum standards and criteria that must be attained. The National Association of Medical Examiners (NAME) has created inspection and accreditation standards that they believe should apply to all offices, large and small. The current NAME Inspection and Accreditation program was approved in 1997, although NAME has had inspection and accreditation programs for decades before that. As of July 21, 2011, there are 57 American offices/systems that are either fully or provisionally accredited (as well as one office in Singapore and one in Puerto Rico), and an additional nine offices/systems for whom inspection is in progress.[2]

Thus far, there has been no characterization of these offices/systems that have successfully attained accreditation. As part of the inspection and accreditation process, each office/system must fill out a detailed survey[3] In what ways are these offices similar and in what ways do they differ? By analyzing and presenting the data from these 58 accredited offices/systems (the office in Singapore has been excluded from the analysis) this presentation will help to partially answer those questions. Broadly, this presentation will look at jurisdictional, financial, and personnel characteristics of the NAME accredited offices. Basic operational issues such as the presence or absence of in-house toxicology and histology, an office's own dedicated medicolegal death investigators, and access to radiology, forensic odontologists, and forensic anthropologists will be presented. More specifically, we will present measures such as the average physical size of an accredited office, population served, total budget, funding per person served, and age of their facilities Other administrative questions to be addressed include the number of pathologists (including board-certified) and support personnel (such as autopsy assistants, investigators, toxicologists, administrators, and clerical support). This presentation will also look at total deaths in the jurisdiction, autopsies performed (including external examinations and partial autopsies), and breakdown of those autopsies by manner of death. For each of these measures, are the answers fairly uniform from one office/system to another, or is there a degree of variability between successful applicants? The data will be presented both statistically and visually via graphs, charts, and tables. Statistical analysis of the self-provided survey responses that each successfully accredited office/system submitted at the time of their inspection for accreditation will be provided. this study will provide computed data utilizing the provided survey responses, such as investigators per total reported deaths, investigators per scene attended, toxicology staff per autopsy, forensic pathologists per capita, and autopsies per pathologist full-time equivalent, and other measures about the staffing and financial resources available to these successfully accredited offices. Preliminary review of a subset of the data to include offices accredited since 2009 shows a mean population served of 1.8 million ± 2.1 million (range: 0.16 to 10.47 million). The mean annual budget is $4.1 million ± $4.9 million (range: $0.47 to $26.83 million). The mean budget per capita is $2.80 ± $1.88 (range: $0.47 to $10.22). The mean number of deaths investigated is 2179/year ± 2680 (range: 253 to 14,910). The mean number of autopsies performed 1051/year ± 973 (range: 76 to 3978). Mean number of pathologists (excluding residents) is 5 ± 6 (range: 0 to 26; median 3); the mean number of autopsies per pathologist is 215 ± 118 (range: 28 to 616; median 207). These early values varied widely and were not normally distributed, but rather were skewed by a few very large and a few very small offices. More detailed and complete analysis will be presented, including visual aids to facilitate appreciation for the full range of the data.

Considering the cost and effort of an accreditation application, this information could be extremely valuable to offices/systems preparing to

undergo inspection, or ones that are considering whether they ought to do so. Coroners, chief medical examiners, and the administrators will be well-served by the information to be presented.

Accreditation, National Association of Medical Examiners, Administration

G115 Literature Search for Journal Articles Authored by Board Certified Forensic Pathologists

Randy L. Hanzlick, MD, Fulton County Medical Examiner Center, 430 Pryor Street, SW, Atlanta, GA 30312; and Steven C. Clark, PhD, 124 Elm Street, Big Rapids, MI 49307*

After attending this presentation, attendees will understand the scope and type of peer-reviewed journal articles authored or co-authored by board certified forensic pathologists since the board certification was first offered in 1959.

The presentation will impact the forensic science community by providing a summary of the number and types of articles written by board certified forensic pathologists and by having available a readily searchable database of such articles written and published between 1959 and 2010.

Although typical on-line research resources such as Medline, PubMed, and other medical journal databases provide for easy searching of published articles by author or subject, it is much more difficult to search and retrieve articles written by specified types of authors. Further, a specified group of authors may publish articles that are not captured by a single key word or even large group of keywords.

In February 2010, a research grant form the AAFS Pathology/Biology Section to conduct a literature search was recieved. Shortly thereafter, an on-line survey was conducted of forensic pathologists that provided data which was extrapolated to suggest that the total number of journal articles authored or co-authored by the nearly 1,400 persons board certified in forensic pathology since 1959 could be estimated to fall between 10,000 and 20,000.

Using a master list of board certified forensic pathologist names, an initial search of Medline and PubMed disclosed more than 182,000 articles containing the last names and first initials of the authors. A search was constructed using author last name and all permutations of first name, first initial, middle name, and middle initial. It was apparent in reviewing these articles for subject matter that the large number of articles was due mainly to author names that included that same first initial but were different people. Attempts to narrow the list down by using keywords such as "forensic pathology" or MeSH headings had some impact on reducing the number of articles, but further study of board certified forensic pathologists with known numbers of articles showed that such filtering eliminated articles that should be included in the study results. Similarly, limiting the search to a relatively large group of selected journal titles also resulted in elimination of articles that should be included. A different approach was then taken to filter the number down by eliminating articles written 10 years or more before a person with a given last name and first initial was certified in forensic pathology, then eliminating articles that did not contain one or more of 238 key words in the title or abstract, then by eliminating articles that were not published in one of 645 selected journals with two or more published articles possibly published by a board certified forensic pathologists and having a journal title that seemed potentially relevant to forensic pathology subject matter. After these filters were applied, the group of remaining articles numbers 33,469. The titles and abstracts of these articles were reviewed manually and articles were eliminated if the subject matter did not involved forensic pathology-related issues. Ultimately, at the time this abstract was prepared, there were 27,052 articles remaining, although further review and filtering was still underway.

In short, this research project has been more complicated and time consuming than the authors had originally envisioned. Because many board certified forensic pathologists since 1959 have died, retired, or are no longer active in the field, and because there are nearly 1,400 such persons over time, it was not feasible to collect the curriculum vitae of individual forensic pathologists and combine their publication lists into a database.

Between August 2011 and the AAFS Annual Meeting in February 2012, it is anticipated that the target group of published articles will be further refined by manual review of publications. The plan is to categorize published articles into groups including Letters and Editorials, Case Reports, Case Series, Review Articles, Original Research, and others which do not fit into the preceding categories. A draft database will probably be made available for review by forensic pathologists to gauge how effective the search was in identifying appropriate articles, with an opportunity to add articles that were not located by our search procedures. The finalized database will be available on-line for review and searching by those who are interested. It is conceivable that yearly updates to the database could be made. Options will be explored to facilitate retrieval of such articles in the future, perhaps by suggesting that the board certification status of forensic pathologist authors be noted somehow in the published manuscript.

Forensic Pathology, Publications, Journals

G116 Standards of Practice in Forensic Pathology — Initial Outcomes From a Training Program for Medical Examiners and Coroners

Michelle P. Elieff, MD, Sparrow Health Systems, Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909; Joyce L. DeJong, DO*, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be informed about a novel NIJ-sponsored medicolegal death investigation training program aimed at educating medical examiners and coroners (ME/Cs) in nationally established best practices and standards in forensic pathology. Additionally, attendees will learn about further training resources for implementing policies and guidelines based on those standards in their offices.

This presentation will impact the forensic science community by alerting participants to the design of a NIJ sponsored regional training program intended to inform ME/Cs of current forensic pathology standards of practice and providing them with toolkits to translate the training into office-specific best practices and policies. Educating all ME/Cs in forensic autopsy practice standards is the first step in establishing national compliance with those standards. Adherence to standards of practice will create more uniformity and consistency across jurisdictions and improve the quality of death investigation. Dissemination of this training methodology has the potential to vastly improve the quality of ME/C services in the United States.

The National Association of Medical Examiners (NAME) defines best practices for forensic pathologists, medical examiners, and coroners in the United States through their forensic autopsy performance standards and voluntary inspection and accreditation program, along with incorporating guidelines established by NIJ. Qualifications for ME/C vary, but the majority of these decision makers have little or no forensic pathology experience and lack the essential instruction their roles demand. Many ME/Cs are unfamiliar with NAME practice standards, resulting in substantial discrepancies in the quality and consistency of forensic pathology across jurisdictions. Additionally, many offices have no jurisdiction-specific policies concerning scene investigation, selection of cases for autopsy, record keeping,

identification, or handling mass fatalities. The lack of awareness of and establishment of policies and practices negatively impacts criminal justice practice throughout the United States, as specifically noted in the National Academy of Sciences Report on forensic science.

In 2011, through a NIJ-sponsored grant, two training programs were developed in nationally established best practices and standards in death investigation for ME/C and death investigators. Feedback from the first session was used to augment the second training program. Topics included: standards in death investigation; standards in selecting cases falling under ME/C jurisdiction; investigative requirements; selection of cases for postmortem examinations; standards in forensic autopsies, autopsy reporting, documentation of significant postmortem examination findings; effective use of ancillary tests, forensic consultants, and support services during investigations and postmortem examinations; interpretation and the use of scientifically based opinions in death investigation; the unidentified body, and NamUs; mass fatality plans; scene and morgue safety; organ and tissue donation laws and organ procurement organizations; morgue operations; collection of evidence; chain of custody procedures; sexual assault and bitemark evidence; issues in toxicology, specimen collection, and interpretation of results; personnel and staffing of the ME/C office; laboratory requirements, reports, and record keeping; annual reports; computerized storage options; and accurate death certificate completion.

Beyond educating the trainees regarding best practices for forensic pathology, the training program provides participants with an extensive take-home *Toolkit* of materials, including modifiable generic policies and forms for implementation in their local jurisdictions. A website was developed that also contains the toolkit materials and other resources, as well as the opportunity to submit questions regarding policies to forensic pathologists from a NAME accredited office. Further, feedback on the needs and concerns of the trainees regarding their ability to put best practices into place, particularly given the very different problems and needs each ME/C office faces based on their location, the population size serviced, and available resources was used to improve the program. Finally, post-training changes in ME/C policies and practices with regard to incorporating NAME standards was explored and documented

Although recommendations to improve the ME/C system have been made in the past, to our knowledge, this is the first training program that gathered together key forensic pathology decision makers, trained them in best practices and standards for death investigation based on forensic pathology practice standards, and supported them (via website and peer-coaching) in effecting change and quality improvements. It also uniquely provides the ME/Cs with template policies, procedures, and forms, as a *Toolkit* to allow easy implementation of policies in line with forensic pathology practice standards.

Best Practices for ME/Cs, NAME Standards, Medical Examiner/ Coroner Offices Training

G117 Iatrogenic Death: A Review of Cases From 1990–2000 Investigated at the Department of Forensic Medicine, Vienna

Pia Paula, MD, Iris Pöttinger, MD, and Nicole Kordina, MD, Medical University of Vienna, Department of Forensic Medicine, Sensengasse 2, Vienna, 1090, AUSTRIA; Barbara Schneider, PhD, Medical University of Vienna, Department of Medical Statistics, Spitalgasse 23, Vienna, 1090, AUSTRIA; and Daniele U. Risser, MD, Medical University of Vienna, Department of Forensic Medicine, Sensengasse 2, Vienna, 1090, AUSTRIA*

After attending this presentation, attendees will have a increased awareness for the importance of adressing the problem of malpractice in order to relativize the hysteria propagated by the media.

This presentation will impact the forensic science community in terms of knowledge and awareness by adressing the problem of iatrogenic deaths.

Introduction: Regulations in Austria mandate, that every deceased person must undergo an external examination before burial, which is usually performed by general physicians. In the event that death occurs in a public hospital, the clinical pathologist must perform this examination. The objectives of this examination are to issue a death certificate. Furthermore, the Austrian Physicians Law stipulates that in any suspected case of a criminal offense, death or physical injury, a report has to be made to the police. In general, such cases of death are followed by a postmortem performed by a forensic pathologist.

Medical malpractice is a global problem which can have considerable financial and legal consequences for the community and personal consequences for those involved. Because of scarce country-specific data, media reports have been giving rise to somewhat of a public hysteria in Europe. Austria, a small country in central Europe with slightly over eight million inhabitants and its capital, Vienna, with about 1.6 million inhabitants, are deficient in providing statistical and epidemiological data concerning medical malpractice cases. Although relevant epidemiological and statistical data have not yet been determined, the media, especially in Vienna, persists in claiming that medical malpractice causing iatrogenic deaths occurs frequently.

Results: Due to the fact that there are no reliable data about medical malpractice and iatrogenic deaths in Austria, the data from a total of 7,211 autopsy reports filed between 1990 and 2000 at the Department of Forensic Medicine in Vienna have been retrospectively analyzed. In 2,074 cases, deceased individuals underwent medical treatment before death. Out of these 2,074 cases, only 55 deaths were relevant for this study. Thirty cases of surgical adverse events, 19 cases of negligence and six medication-related incidents could be found and were included in this analysis.

In those cases where court files could be obtained, the outcome was also included in this analysis. Out of a total of 40 cases from available court files, 36 cases were dropped, there were two acquittals and two convictions. In other words, in less than one in a hundred cases (2.75%) charges were pressed against the treating medical doctors.

Conclusively, the number of medical malpractice practices leading to iatrogenic deaths in Austria seems to be very low in comparison to other countries, where, during the same time period, 4.5 in a hundred cases (4.5%) were prosecuted. Although the figures claimed by the media do not appear to be legitimate and lack credibility since they are too high, the possibility that many cases go unnoticed in Austria, needs to be taken into consideration.

Iatrogenic Death, Medical Malpractice, Vienna

G118 Overview of Current Clinical Forensic Medical Practice in Beijing, China

Di Lu, MD, Institute of Evidence Law and Forensic Science, China University of Political Sicence and Law, 116 Lugu Road, Shijing Shan District, Beijing, 100040, PEOPLES REPUBLIC OF CHINA; Lin Chang, MD*, Key Laboratory of Evidence Science, China University of Political Science and Law, 116 Lugu Road, Shijing Shan District, Beijing, 100040, PEOPLES REPUBLIC OF CHINA; Xiaoming Wang, MD, Beijing Municipal Public Security Bureau, No.9, Dongdajie, Qianmen, Dongcheng District, Beijing, 100740, PEOPLES REPUBLIC OF CHINA; Baosheng Zhang, PhD, Institute of Evidence Law and Forenisc Science, China University of Political Science and Law, 25 West Tucheng Road, Haidian District, Beijing, 100088, PEOPLES REPUBLIC OF CHINA; Xiang Zhang, MD*, City of Baltimore, Office of the Chief Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223; and Ling Li, MD, State of Maryland, Office of the Chief Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223*

After attending this presentation, attendees will learn the basic structure and jurisdiction of clinical forensic medicine in China. In addition, the education, training, and qualification of clinical forensic physicians will also be presented.

This presentation will impact the forensic science community by providing participants with a deeper understanding of the role and scope of the specialty of clinical forensic medicine globally. This presentation will also demonstrate the interrelationship of the roles of clinical forensic medicine and forensic pathology.

Clinical forensic medicine refers to that subspecialty of forensic medicine that involves a wide range of activities at the interface of medicine and law. It generally involves the assessment and interpretation of the physical and mental conditions of living individuals. Clinical forensic medicine has become widely practiced in China in the last two decades.

A study was conducted on the current system of clinical forensic medical practice in Beijing, China. This study showed that there are 158 clinical forensic physicians certified by the Bureau of Justice in 14 offices in Beijing within five relatively independent agencies: private clinics, hospitals, government sponsored societies, department of forensic medicine in a university, and a forensic medical center. In addition, the police agency has its own clinical forensic physicians. The qualifications of clinical forensic physicians vary widely from agency to agency. The basic requirements for certifying as a clinical forensic physician are: (1) being a Chinese citizen with good moral standards, not having any felony convictions; and (2) having a bachelor's degree of medicine majoring in forensic medicine (BM Foren. Med) or Bachelor's degree in forensic sciences with on-the-job training in clinical forensic medicine for five years, or having a bachelor's degree of general medicine (BM) with working experiences in various clinical specialties and 240-hour special training in forensic medicine. In general, clinical forensic physicians do not deal with the deceased, and forensic pathologists do not deal with living individuals. However, in China, there are forensic pathologists who are involved in both the medico-legal death investigation and clinical aspect of the forensic medicine.

In 2010, a total of 38,759 cases were investigated by the clinical forensic physicians in the police agency and 16,107 cases were investigated by the clinical forensic physicians within the other 14 offices in Beijing. The services provided by the clinical forensic physicians mainly include: (1) documentation and interpretation of injuries due to physical assault, motor vehicle accident, and work; (2) examination of victims of sexual assault and the alleged perpetrators, (3) evaluation of the interaction of trauma and disease, (4) assessment of disability due to injuries, (5) investigation of personal damage due to medical malpractice, and, (6) examination of physical and mental status to determine the fitness to be interrogated by police or detained in police custody. Clinical forensic physicians also provide expert opinions/advice to court on the compensation of personal injuries in civil litigations. This presentation gives a general overview of current clinical medical practice in Beijing, China.

Clinical Foresnic Medicine, Injury Assessment, Civil Litigation

G119 The New INFOR (International Network for Forensic Research) Classification of Asphyxia: Towards an International Agreement

Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, AB T6H 5R8, CANADA; and Duarte N. Vieira, PhD, MD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

After attending this presentation, attendees will know about the new INFOR Classification of Asphyxia.

This presentation will impact the forensic science community by standardizing the classification of asphyxia.

Introduction: The classification of asphyxia and the definitions of subtypes are far from being uniform, varying widely from one textbook to another and from one paper to the next. Unfortunately, similar research designs can lead to totally different results depending on the definitions used. Closely comparable cases are called differently by equally competent forensic pathologists/medico-legal doctors.

In response, a unified system of classification was recently proposed. This standardized classification was pieced together by drawing mainstream definitions from a thorough review of forensic textbooks and literature. In the present study, an international consultation on this unified classification was undertaken in an attempt to achieve a global agreement on a standardized classification of asphyxia.

Material and Methods: A questionnaire was designed to evaluate which parts of the standardized classification and which definitions the international forensic community is ready to adopt and which parts need to be revised.

Results: Two hundred and three surveys were compiled: 110 from North America, 65 from Europe, 10 from form Asia, 5 from Oceania, four from Central and South America, four from Africa, and 5 from Middle-East.

There is a large majority in favor of adopting the overall standardized classification and the following definitions: suffocation (79%), confined spaces/entrapment/vitiated atmosphere (79%), strangulation (85%), hanging (84%), ligature strangulation (79%), positional asphyxia and traumatic asphyxia (74%), and drowning (78%).

The epiglottis as the anatomical landmark between smothering and choking is agreed with a small majority (57% worldwide, 75% in Europe, 80% in North-America).

There are two elements of the classification that will have to be further worked on. First, there is no consensus if the category of asphyxia labelled confined spaces/entrapment/vitiated atmosphere should be further subdivided (37% worldwide, 28% in Europe, 39% in North-America) or not (48% worldwide, 62% in Europe, 43% in North-America) (note: the sum of the % for yes and no do not ad to 100% because of a small % of abstentions). Second, it is not clear if a hanging accompanied by a fall from height should be part of the classification of asphyxia (46%) or not (47%). Third, it is not clear if mechanical asphyxia is a broad term encompassing several types of asphyxia caused by various mechanical means (33% worldwide, 58% in Europe, 11% in North-America) or is a term that designates asphyxia by restriction of the respiratory movements either by the position of the body or by external chest compression (60% worldwide, 31% in Europe, 84% in North-America).

Discussion: Mutual concessions are going to be necessary to achieve international agreement; but as a scientific community, we cannot continue to use different definitions and classifications depending on our geographical location or depending on our favourite textbook. As a scientific community, forensic pathologists and medicolegal doctors need to agree on a standardized classification of asphyxia. The practice of forensic pathology and legal medicine has been for a long time part art and part science. To grow as a scientific discipline, an effort has to be made to shift away from art and move toward a more scientific approach, and the standardization of classifications and definitions is an important step in that direction.

Asphyxia, Classification, Forensic

G120 When Hospitals Fail to Report Deaths in Medical Examiner Jurisdiction: What Are We Missing?

Dwayne A. Wolf, MD, PhD, Harris County Institute of Forensic Sciences, Joseph A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054; and Stacy A. Drake, MSN, MPH, RN, University of Texas Health Science Center at Houston, School of Nursing, Houston, TX 77030*

After attending this presentation, attendees will be able to identify categories of deaths that hospitals often fail to report to medical examiners/coroners (ME/C). Attendees will understand the impact that the lack of reporting may have on the legal and public health systems.

This presentation will impact the forensic science community by allowing death investigators to recognize which types of deaths are often not reported to the medicolegal death investigation system; understanding these categories will allow death investigators to develop targeted educational

outreach within community healthcare facilities in order to maximize reporting of appropriate deaths.

Although laws governing medicolegal death investigation vary among jurisdictions, reportable deaths generally include deaths of children, sudden and unexpected deaths, and deaths resulting from physical or chemical injury. However, some hospital deaths that should come within ME/C jurisdiction are not reported, either because of lack of knowledge on the part of healthcare providers, or in some instances because of religious or cultural beliefs and misconceptions about the consequences of reporting. When hospitals fail to report deaths to the ME/C, the cost is delayed law enforcement investigation, inaccurate death certification, and missed opportunities to collect evidence from decedents.

This study undertakes this prospective to ascertain the types of deaths that are not reported and to identify areas for targeted quality improvement efforts, e.g., education and development of guidelines. The study is a five-year longitudinal descriptive analysis of non-reported deaths that were in medical examiner jurisdiction. It is impossible to determine the total number of such deaths in any jurisdiction; however, we were able to identify 71 cases. The deaths were discovered after days to years' delay. The deaths were often discovered because of calls from family or lawyers regarding the death certificate, calls from funeral homes, from police, or from the bureau of vital statistics when a community physician completed the death certificate. Almost 60% were decedents over 60 years of age; not surprisingly, this category included those who died from injuries sustained in falls (e.g., hip fractures and subdural hematomas). In some cases, elements of neglect were also suspected. Smaller percentages of cases were identified in which cultural or religious factors may have influenced the medical facility's decision to not report. Unexpectedly, in 7% of the cases, the manner of death was ultimately either classified as homicide or classified as undetermined where homicide was suspected but investigative elements were lacking. The majority of the cases, 82% were accidents, and 11% were suicides. That none of these deaths were ultimately classified as natural may reflect relatively less cases in this category (i.e., that most natural deaths were appropriately reported), or may reflect a lack of means of identifying these cases. In 21% of these cases the death came to the attention of the medical examiner before the body was buried or otherwise disposed, and therefore direct examination was possible. If each of the 71 deaths had been reported in a timely fashion 44% would have been autopsied, while the other 56% would have been released following an external examination. Based on this experience, strategies are being developed to reduce the incidence of these failures, specifically by pursuing ongoing educational efforts in local hospitals to address reporting issues. A key finding is that healthcare providers require additional and more concrete guidelines for determining which deaths fall within ME/C jurisdiction.

Some interesting trends and surprising categories within the data set will be presented. Some case examples will illustrate these points. Quality improvement initiatives will be presented that can be implemented within any medicolegal death investigation system to reduce the incidence of jurisdictional lapses.

Hospital Deaths, Medicolegal Jurisdiction, Fail to Report

G121 Medical Problems and Medical Neglect in the Elderly

Lakshmanan Sathyavagiswaran, MD, and Christopher B. Rogers, MD, Los Angeles County, Medical Examiner's Office, 1104 N Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will understand problems encountered in nursing homes, a variety of medical problems found in the elderly, and risk factors for elder abuse.

This presentation will impact the forensic science community by increasing awareness of special circumstances often found in the elderly. It will raise awareness among forensic professionals of abuse of elderly individuals.

Approximately 1.5 million Americans or 6% of the population over 65 live in one of the 18,000 nursing homes in the United States. Seventy-two percent of the nursing home population is over the age of 75. By the year 2040 it is estimated that there will be 5.2 million nursing home residents, of whom 88% will be over 75. Currently 33% of nursing home residents expire there. The median length of stay of the elderly in the nursing homes is about 582 days and about 26% of the residents stay less than six months. Half of nursing home residents are demented and other half are incontinent.

Problems in nursing homes include malnutrition, falls, excessive drug use, decubiti, infection, and psychological problems including depression, dementia, late life paranoia, and behavioral problems. Iatrogenic disorders include inappropriate drug use and use of too high a dose of a drug or too many drugs. The prevalence of mental illness in nursing home patients is approximately 75%. Nearly 40% of residents have occult depression and may benefit from a low dose of antidepressant drug. Behavioral problems include passive and active aggression, verbal aggression, and manipulative behavior. About 1.5 million infections occurred annually in nursing homes and 27% of all hospitalizations in nursing home patients are due to infections. Influenza in nursing home settings has a case fatality rate of approximately 10%. It has been found that failure of the protective effect from influenza vaccination is probably related to impaired responses from poor nutritional status in nursing home residents. Similar questions also exist regarding the efficacy of pneumococcal vaccination in the frail elderly. Tuberculosis epidemics can occur in nursing homes.

Malnutrition has been found to be present in just under 60% of nursing home patients and weight loss is a major problem in the nursing home. Zinc deficiency has been important in the pathogenesis of decubiti, immune dysfunction and anorexia in the nursing home residents. Somatomedin is also low in this setting. Growth hormone deficiency is associated with increased adipose tissue and reductions in muscle mass, bone mass, renal blood flow, and liver drug metabolism. Dehydration is another major problem. There is decreased thirst perception with advancing age. Many nursing home patients live in a water desert. Hyponatremia mey be due to tube feedings, low salt diet, or syndrome of inappropriate antidiuretic hormone secretion. Elderly institutionalized patients, 10 – 25% will have a major fall each year. Usually the falls are associated with use of antidepressants, sedatives, hypnotics, vasodilators, osteoarthritis, and depression. The risk of falls is increased after a meal.

It is estimated that half a million elders living with younger family members are abused. Some old people become ill, demanding, less productive and more difficult to care for as they age. They become stubborn, quarrelsome, and untidy, refusing to eat and losing high order psychological defense mechanisms acquired during developmental phases. They may even become aggressive and combative, so they provoke aggression and punishment from the caretaker. With the demise of an extended family, many working children find it difficult to care for aged parents both physically and financially. In modern society such care is expensive and exhausting.

The temptation to punish an elder who acts like a mischievous child may be severe. It has been found that if a child has been abused, he may later become an abusive caretaker. New conflicts arise when aged parents move into a child's household leading to violence if they are not resolved. Differences in life style, values, and religious practices may be some of the unresolved family conflicts which may be reactivated. The caretaker becomes depressed, despairing at the hopelessness of the situation.

Neglect by paid caretakers arises because of poor pay of aides, poor working conditions, long working hours, and interference of red tape and paperwork with efficient care. Staff members may become depressed and pessimistic because they believe that their patients are dying and there is no hope of successful outcome no matter what the efforts. In for-profit nursing homes, there may be proprietary efforts to cut cost, and show better profit to management and stock holders. This may result in neglect, for example, by providing less food, poorer quality of food, fewer personnel, and less maintenance of facilities.

Many elderly patients don't complain because of fear of retaliation, including possible expulsion to homes that are worse or further away from families, physical abuse, or ignorance of their rights, and legal recourse.

They may become apathetic and feel defeated, depressed, and helpless. Impending death enhances these feelings. Case examples of medical neglect involving dehydration, severe fecal impaction, and vitamin deficiency will be presented.

Nursing Home, Elder Abuse, Geriatrics

G122 Pressure Sores In England: Comparing the Investigation of Two Cases

Stuart J. Hamilton, 9 Troon Close, Consett, Co Durham DH8 5XF, UNITED KINGDOM*

After attending this presentation, attendees will be better informed about how potential neglect cases are investigated in England and the interactions between coroners, pathologists and law enforcement in such cases, as well as the way British pathologists interpret pressure damage.

This presentation will impact the forensic science community by stimulating discussion over the responsibilities of carers for frail and vulnerable people and the differences in how the law views the development of pressure ulceration in different jurisdictions.

With the general increase in the number of elderly people in modern society, the care and support given to vulnerable and unwell older people is becoming an increasingly significant social issue. This is particularly true in the setting of care homes, where companies often receive large sums of money from both government agencies and private funds. The development of pressure ulceration in immobile individuals who are in a care setting will almost always lead to an investigation by various authorities, and communication between the various bodies may occasionally be limited.

In England, such cases fall under the legal jurisdiction of Her Majesty's Coroner who, because of the possibility of neglect, will usually instruct a pathologist to perform an autopsy. A subjective opinion will be formed as to whether the case is one where criminal charges may arise or not, and this will influence the extent and nature of the subsequent investigations, and different coroners may approach the cases in very different ways.

Here, are presented the very different investigations of two cases of vulnerable elderly people with significant pressure sores and some of the complexities arising from the distinction between "suspicious" and "non-suspicious" deaths are explored.

The first case is of an elderly female who was in poor health who lived in a residential home but who, like many similar patients, spent prolonged periods in different hospitals. After her ultimate death, concerns were expressed about the fact that she had developed pressure sores, but it became difficult to identify exactly when, and therefore where these had begun. The coronial investigation focused on who had been responsible for their development and where they had occurred, as well as whether they had contributed to the patient's ultimate demise.

The second case also concerns a frail elderly person, but in contrast she was being cared for by a relative and had not been seen outside the house in which she lived for a long time. She was taken to hospital by her daughter, but on her arrival the medical staff found her to be already deceased. An initial examination revealed very severe pressure damage (certainly the worst this pathologist has ever seen) and she was referred for autopsy. As the relative was the sole caregiver, she was interviewed by the police and an investigation into the possibility of this case representing one of gross negligent manslaughter was begun and the death treated as a suspicious one. The relative was found to be of sound mind, and her defense was that the deceased "didn't like hospitals" and that the carer preferred to treat the pressure sores by "natural means."

Pressure Sores, Elderly Patients, Neglect

G123 Extreme Shortness of Umbilical Cord Associated to Hematoma During Labor in Uncomplicated Pregnancy: A Fatal Case

Marco Di Paolo, MD, Via Roma 55, Pisa, ITALY; Laura Roas, MD, Via roma 55, Pisa, ITALY*

After attending this presentation, attendees will receive exhaustive information about an uncommon case of fatal hematoma at labor in a short umbilical cord fetus following an uncomplicated pregnancy. A complete forensic examination was performed by autopsy including histological examinations. The cause of death was established as acute asphyxia caused by acute traumatic vascular rupture of umbilical arteries as a consequence of the protracted cord traction during labor.

This presentation will impact the forensic science community by expanding awareness of with a fatal complication related to alterations of umbilical cord. In particular, the present case report will inform attendees about the risks associated with a short funiculus in an uncomplicated pregnancy and the significance of an accurate evaluation of umbilical cord morphology during the gestational period.

Case Presentation: A 26-year-old woman with an uncomplicated antenatal course, at 40 weeks of gestation + 2 days, was admitted to hospital for a scheduled induce labor. The contraction spontaneously started in the evening of the same day. The next day, at 2:00 a.m., the cervical dilation was 2cm and the fetal heartbeat resulted regular. At 3:20 a.m., the dilatation was 6cm and a significant deceleration of fetal heart tracing was recorded: at this point, the head of the fetus was fully engaged in the pelvis. On the bases of this risky circumstance, at 4:20 a.m. the dilation was complete. Oxytocin (10 IU, i.v. infusion) was administered and Kristeller procedure as well as episiotomy were performed. At 5:18 a.m., the woman delivered a dead female newborn (body weight: 3.610kg; body length: 55cm).

No significant findings at external examination of the fetus were found. The autopsy showed intense polyvisceral stasis. Funiculus disclosed a reduced length (27cm vs normal value of 35-80 m) and diameter (1cm vs normal value of 1.6cm); it showed the presence of multiple hematoma. Placenta, that was normally inserted, didn't reveal any significant alterations.

Histological examination of lung samples revealed the presence of fetal squames and debris in pulmonary vessels, acute emphysema, and pulmonary hemorrhages. The histopathological examination of the placenta didn't show anything of interest. Sections of umbilical cord demonstrated significant periarteriolar hemorrhage ascribable to the rupture of the umbilical vessels. The wall of arteries was characterized by manifest signs of traumatic dissection. Weigert's elastic stain and PAS were negative.

The cause of the death was indeed attributed to acute asphyxia dependent by the intrapartum traumatic rupture of arterial funiculus vessels. Strong traction of the short umbilical cord had a basic role in the pathogenesis of the fatal complication.

The present case report provides the evidence about the absence of alterations in the physiological development of the fetus as well as of complications for the pregnant in the antenatal period, despite the presence of a short umbilical cord. However, this morphological alteration resulted significantly involved in the newborn death, since the traction of short funiculus during the labor, caused the occurrence of a diffused hematoma through umbilical vessels tearing. These data suggest the opportunity of an accurate evaluation of the umbilical cord morphology during the gestational period using virtual reality system measurement also in pregnant without apparent complications.

Shortness and Hematoma of Umbilical Cord, Fetal Death, Autopsy

G124 Disseminated Varicella as a Cause of Sudden or Unexpected Death: A Case Report and Literature Review

Dawn B. Holmes, MD, Adrienne E. Segovia, MD, and James A. Filkins, MD, JD, PhD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612*

After attending this presentation, attendees will have a better awareness of the characteristics of disseminated varicella (chickenpox) infection as a rare cause of sudden or unexpected death.

This presentation will impact the forensic science community by presenting the autopsy findings and circumstances surrounding the death of a 28-year-old female who succumbed to disseminated varicella infection and by comparing her case with others reported in the literature.

Introduction: Varicella zoster virus (VZV) is an infection that commonly occurs in childhood and usually has a relatively benign course in immunocompetent individuals. Mortality from VZV infection in immunocompetent individuals is exceedingly rare. In immunocompromised individuals; however, VZV infection often produces severe manifestations, leading to significantly increased mortality.

Case Report: A 28-year-old African American female with a history of immune thrombocytopenic purpura and sarcoidosis presented to the emergency room with an acute onset of a diffuse vesicular rash throughout her body. Her medications included prednisone, and she reported a history of chickenpox as a child. She was subsequently diagnosed with chickenpox and was treated in the hospital with benadryl and calamine lotion for five days. No antiviral medications were administered. The night of her discharge, she complained of shortness of breath. The following morning she was found unresponsive in her bed at home. At autopsy, she was noted to have numerous macular and papular vesicular lesions in various stages throughout the body, predominantly involving the head/face, neck, torso, back, upper extremities, and proximal lower extremities. The lesions also involved the mucosa of the inner surfaces of the upper and lower lips. Several of the vesicular lesions were crusted. On opening the body, numerous erythematous vesicular lesions were noted on the surface of the lungs, liver, and the mucosal surface of the esophagus, trachea, and epiglottis. Multiple enlarged peribronchial, periaortic, and mesenteric lymph nodes were identified; the largest of these measured 3.0 cm in greatest dimensions, consistent with the patient's known history of sarcoidosis. Histologic investigation uncovered multinucleated giant cells in the enlarged lymph nodes with associated hyalinization. There were also patchy hyaline membranes in the lungs with hemosiderin-laden macrophages, scattered multinucleated giant cells, and pulmonary edema. Mucosal lesions revealed ulceration with marked chronic inflammation extending to the submucosal tissue. The Centers for Disease Control and Prevention confirmed via immunohistochemistry the presence of VZV in various tissues. Toxocologic analyses were negative for ethanol, opiates, and cocaine.

Discussion: Mortality from VZV infection is exceedingly rare. The annual varicella death rate in the United States is 0.4 deaths per million. Previous cases of disseminated varicella mortality have involved unvaccinated individuals who had a primary VZV exposure. These individuals were usually immunocompromised to various degrees, although mortality has been reported in otherwise healthy individuals. Consistent with the majority of the cases reported in the literature, this case report involves an immunocompromised subject; interestingly, however, this was not a case of primary VZV exposure.

Reported VZV complications include pneumonia, disseminated intravascular coagulation, septicemia, encephalitis, acute respiratory distress syndrome, nephritis, myocarditis, and myelopathy. VZV pneumonia is the most common complication with the highest mortality, seen in immunocompromised individuals. Case reports in the literature typically describe an insidious onset of pneumonia with dyspnea, usually developing 1-6 days following the appearance of a vesicular rash. A similar course of events was present this case report.

This case is reported to demonstrate the clinical course and autopsy findings of disseminated varicella infection. Although an extremely rare entity, it remains a cause of sudden or unexpected death that one may encounter in a forensic setting.

Varicella, Chickenpox, Disseminated

G125 Lethal Short Falls Can be Accidental Injuries

M.G.F. Gilliland, MD, and Karen L. Kelly, MD, East Carolina University, Brody School of Medicine, Forensic Pathology Division, Department of Lab Medical Pathology, Greenville, NC 27834*

After attending this presentation, attendees will learn that accidental lethal short fall child injuries can be identified and learn the investigative efforts necessary to reach such conclusions.

This presentation will impact the forensic science community by showing how accidental lethal injuries in children will provide reliable scientific knowledge to allow practitioners to competently certify cause and manner of death in children thus preventing inaccurate diagnoses and incarceration of innocent parents.

Background: For many years child advocates have regarded short falls as unbelievable explanations for injuries in young children. They relied on the common experience of parents and caregivers as well as literature describing survivability of short falls (Helfer 1977, Chadwick 1991, Williams 1991, Lyons 1993) to identify lethal injuries with a short fall history as non-accidental.

Report of a series of death investigations (Reiber 1993) identified accidental mechanisms in two of nineteen deaths with history of short falls. Fourteen others were considered homicides and three were undetermined. A contrasting report (Plunkett 2001) used the Consumer Products Safety database described 18 deaths from accidental injuries but having limited description of injury and investigations. The latter report has been thought-provoking but less reliable. Individual case reports continue to provide anecdotal evidence of the existence of lethal accidental short falls.

Methods: Two institutions' experiences were reviewed and identified three cases of child deaths attributed to accidental short falls. First was a recent case from the Eastern Regional Medical Examiner's Office where a 10-month-old male was reported to have fallen backwards at day care onto a concrete floor on the 17th of February but seemed unhurt. He began vomiting on February 22 and was taken to a local medical center, treated for flu and released. He continued to vomit and was taken March 1 and again on March 2, treated and released each time. The child was less active and slept most of March 4th. Put on the kitchen floor to play, he fell forward and hit his head. He was unresponsive when his mother picked him up. Rushed to the hospital, he was found to have a large subdural hemorrhage, retinal hemorrhages, and brain edema. He progressed to brain death on March 6th. The impending death was referred as a non-accidental injury death. Autopsy revealed a healing skull fracture consistent with the history of injury 17 days earlier. Organization was seen in the subdural membrane. Review of medical records confirmed the parents' description of the sequence of events and supported the conclusion of accidental injury.

The other two cases were taken from the prospective study of 169 child death investigations in Dallas, Texas. One was a 40-month-old female who had an unwitnessed fall from concrete stairs to a conglomerate-surfaced apartment complex patio. After a brief lucid interval, sleeping for two hours, and vomiting she was recognized to be unresponsive; medical attention was unsuccessful. Autopsy revealed a large subdural hemorrhage, brain edema, and retinal hemorrhages. Patterned injuries on her forehead and elbows were consistent with the patio. The second child was a 12-month-old male with a witnessed fall from his standing height on a washing machine to a tile-over-concrete floor. He seemed uninjured for approximately a day but fell from the bed to the floor the next day and was taken to hospital poorly responsive the following day. The child advocate team gave an affidavit describing the injuries as probably due to a fall. The child had bilateral subdural hemorrhage, brain edema, and bilateral posterior retinal hemorrhages.

Subsequent autopsy and investigations confirmed the subdural hemorrhage duration and accidental nature of the mechanism of injury.

Conclusion: Three accidental lethal short falls were found in review of medical examiner deaths at two institutions. Thorough law enforcement and autopsy investigation led to correct certification of these deaths, two of which were initially regarded as suspicious.

Infant/Child Death Evaluation, Short Falls, Accidental Injuries in Children

G126 Challenges in Evaluating Cause and Manner of Death in Palliative and End-of-Life Care Patients

Elizabeth A. Laposata, MD, and Cristina M. Padilla, MS, Biomedical Forensic Sciences, Boston University School of Medicine, 72 East Concord Street, Boston, MA 02116*

After attending this presentation attendees will be educated on the ethical, legal, and medical issues in suspicious deaths of terminally ill patients and provide the forensic pathologist guidelines for complete review and interpretation of evidence.

This presentation will impact the forensic science community by providing guidelines for the forensic pathologist to investigate cases of suspicious deaths of terminally ill patients.

Medicolegal death investigations of death in the end-of-life and palliative care setting are challenging and will become more numerous as the population ages. More than 90% of the 500,000 deaths in critical care units in 2007 were preceded by withdrawing or withholding life support treatments. Further, in 2008 more than 40% of all decedents in the United States received hospice care. And increasingly, end-of-life care is provided in non-institutional settings.

The forensic pathologist who is called upon to investigate such deaths must have the ability to differentiate compassionate care from malpractice and even murder in these complex cases. Further, competent and comprehensive death investigation may also be a cornerstone for assessing of quality of care in end-of-life care setting where such traditional indicators of quality of health care as death and recovery rates are not appropriate.

The intentions of clinicians who manage end-of-life-care are often scrutinized because of the role they play in shifting care from curative to palliative measures. Frustration or misperception fueled by powerlessness on the part of even a single family member or ancillary health care provider can give rise to allegation of euthanasia or murder. Moreover, hospice providers point out that families often believe that the death of their loved one was premature.

No comprehensive methodology exists to guide the forensic pathologist in evaluating suspicious deaths of terminal patients. On reviewing the standard practices in the palliative care community and examining controversial cases in the literature of physicians accused of euthanasia, we propose a set of guidelines to assist the forensic pathologist in answering the question: What information should be studied in order to derive a complete evaluation and interpretation of the evidence available?

Determining cause of death in these patients is difficult since the death may occur from the disease process, a complication of the disease process, a withdrawal of life-sustaining therapies, the medications administered, or any combination thereof. One difficulty in enforcing adherence to proper end-of-life-care policy and standards is having the data necessary to establish the intent or motivation of the healthcare provider (i.e. intent to kill, to shorten the dying process, to relieve pain, etc.). This is a multi-layered and complex task. It involves a careful review of medical records, autopsy findings, toxicology results and witness accounts. The medical records establish the foundation and context for the investigation. The autopsy provides information about the physical manifestations of the disease and eliminates other potential causes. Postmortem toxicology must be interpreted with caution because of potential drug interactions, drug tolerance and disease-altered drug clearance unique to each case. Inappropriately low levels of pain medication should raise the question of drug diversion by caretakers or family. Witness accounts given by family and friends who followed the care of the decedent can help determine whether the standard of care was met. The forensic pathologist must understand the symptom manifestations and pathophysiology of the dying process. Rarely does a single piece of evidence reveal the intent of the healthcare provider.

Understanding the bioethical aspects involved in treatment, such as the rule of double-effect, and using clear definitions of terms such as terminal sedation, active euthanasia, passive euthanasia and physician assisted suicide are essential are essential for proper determination of manner of death.

The goal of this study, is that the forensic pathologist will have the knowledge and structured format to investigate deaths in the end-of -life care setting. A competent death investigation will protect the vulnerable, dying patient population; protect practicing physicians from the distress of false accusation; and prevent terminal health care being used as a cover for euthanasia.

Palliative Care, Terminal Sedation, End-of-Life Care

G127 Using ß-Amyloid Precursor Protein Staining to Study Patterns of Axonal Injury in Young Children With Hypoxic Ischemic Encephalopathy

Mary E.S. Case, MD, St. Louis University School of Medicine, 6039 Helen Avenue, St. Louis, MO 63134; and Stephanie S. Burton, MD, Saint Louis City Medical Examiner Office, 1300 Clark Avenue, St. Louis, MO 63103-2718*

After attending this presentation, attendees will be able to appreciate whether the pattern of axonal injury in abusive head trauma in young children is caused by hypoxia or trauma.

This presentation will impact the forensic science community by presenting the findings in a group of infants and young children with hypoxic ischemic encephalopathy from causes other than abusive head trauma (AHT) using beta amyloid precursor protein (BAPP) immunohistochemistry reactivity. The study will detail the pattern/patterns of axonal injury caused by pure hypoxic/ischemic insults in young children. The hypothesis is that infants and young children with AHT have overlapping patterns of traumatic (tDAI) and hypoxic/ischemic axonal injury (VAI) and that these two patterns need to be able to be distinguished to determine whether traumatic axonal injury exists in the AHT group. In known fatal human cases of tDAI, the gross brains demonstrate numerous streak and punctuate hemorrhages in association with the axonal damage. These small hemorrhages are not seen in young children with tDAI. It has been questioned whether the vessels of young children do not tear because they are very elastic. Another possibility is that there is vascular injury without disruption of the vessels and that vascular damage causes failure to perfuse leading to hypoxia.

BAPP immunohistochemical reactivity is a very sensitive method of detecting axonal injury. Young children with AHT have been studied in several series to determine whether tDAI or VAI occurs in these children. Many of these children obviously have VAI as they have suffered respiratory arrest or distress early on in their course. Some of these children have evidence of both types of axonal injury present. Typically, tDAI produces a pattern of scattered small groups of axons reactive for BAPP in hemispheric white matter, corpus callosum, internal capsule, and brainstem. VAI appears to produce a pattern of reactive axons described as broad geographic areas often related to vessels. One possibility is that although young children with AHT frequently show the VAI pattern of damage, the more subtle pattern of tDAI is being obscured under the more pervasive damage caused by the VAI. Another possibility is that the pattern of VAI in young children with AHT is changed by the damage to small blood vessels and differs from VAI seen in non-AHT cases.

The first cases of intrauterine causes of hypoxic ischemic encephalopathy studied have demonstrated no or very minimal VAI BAPP

reactivity. These cases have survived several days with severe hypoxia which may have also existed for some period intrauterine. All cases demonstrate typical ischemic changes on H & E staining.

Because the axonal injury in cases of AHT may be present in a mixed pattern, it is important to study a non head injured group to discern true VAI patterns. An issue of great interest in AHT in children is the timing of the injury. If tDAI is the basis of AHT in young children, certain predictions can be made about the timing of the injury. Because tDAI is a type of immediate impact injury, the injury or disruption of the axonal processes occurs at the moment of injury and not subsequently as a result of hypoxia or increasing intracranial pressure. Damage of axonal processes at the level of the thalamus and deep gray matter has been demonstrated in experimental primate models of DAI as well as in the CT examination of brains of known human cases of tDAI to be lesions which produce immediate onset of unconsciousness.

Abusive Head Trauma, Axonal Injury, Hypoxic Encephalopathy

G128 Correlation of Antemortem and Postmortem Retinal Hemorrhages in Children

Kathryn H. Haden-Pinneri, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will gain information about retinal hemorrhages with regards to length of survival, cardiopulmonary resuscitation, level of intracranial pressure, coagulation parameters and presence of trauma.

This presentation will impact the forensic science community by providing a better understanding of the evolution of retinal hemorrhages in the pediatric population.

Retinal hemorrhages have been recognized as an important indicator of abusive head trauma for many decades. The ability to document the presence of intraocular injuries has greatly improved through the use of wide-field digital retinal imaging. Accurately describing the number, location, and morphology of retinal hemorrhages in children is extremely important for diagnostic as well as legal purposes.

Peripheral retinal hemorrhages are often asymptomatic and may be discovered incidentally during an ophthalmologic examination. Many systemic and ocular disorders are known to be associated with a mild nonspecific hemorrhagic retinopathy, such as hypertension, blood cell disorders (i.e., leukemia, anemia, idiopathic thrombocytopenia), sepsis, vasculitis, cerebral aneurysms, vitamin deficiencies (thiamine, vitamin C), retinal infections, increased intracranial pressure, prematurity and alterations in sodium, oxygen and glutaric acid levels. Also included in the differential for a few posterior pole retinal hemorrhages is abusive trauma. In most of these situations; however, the historical, systemic, or ocular findings allow for the correct diagnosis.

Birth related retinal hemorrhages have also been well documented in the literature, with an occurrence rate ranging from 3 to 50 percent. Vacuum-assisted vaginal delivery is a known risk factor for birth related retinal hemorrhages while delivery by cesarean section has a low rate of retinal hemorrhages. It is important to realize; however, that infants delivered by cesarean section may have failed prior vaginal delivery attempts. The retinal hemorrhages associated with birth may occur in all retinal zones, similar to that seen in suspected abusive head trauma. Over 90 percent of birth related intraretinal hemorrhages resolve within two weeks and none were detectable after four weeks in one study. Researcher and clinicians tend to agree that extensive confluent retinal hemorrhages identified in a child over the age of one month are not birth related.

Proper identification and description of retinal hemorrhages is crucial for developing an appropriate differential diagnosis. Traditionally, the gold standard for retinal examinations required the use of an indirect ophthalmoscope through neurologically or pharmacologically dilated pupils. Images could be taken through the ophthalmoscope; however, many times the hemorrhages seen by the ophthalmologist were crudely drawn in the patients chart. Wide-field digital retinal imaging with a RetCam is being increasingly utilized over the indirect ophthalmoscope, particularly in pediatric patients. Images can be stored as part of the electronic medical record and therefore are available for evaluation at later dates.

Different techniques have been employed at the time of autopsy to visualize and document retinal hemorrhages. The "gold standard" and most commonly employed procedure is removal of the eyes and adjacent periorbital tissues. The eyes are subsequently fixed in formalin for a minimum of two weeks, sectioned into superior, inferior and middle segments, photographed and embedded into paraffin blocks which are made into glass slides. This process allows for the distribution, location and number of retinal hemorrhages to be assessed. Additionally, hemosiderin deposition, an indicator of prior hemorrhage, into the retina, around the optic nerve or in the periorbital tissues can be assessed. Postmortem monocular indirect ophthalmoscopy has been used by some as an inexpensive adjunct to enucleation; however it can be a challenging technique to master and is not widely used.

A large part of the problem in determining the significance of retinal hemorrhages is that their pathophysiology is not well understood. Several hypotheses exist; including raised intraocular venous pressure due to a sudden rise in intracranial and central venous pressures, hypoxia, single blunt impact, and increased intrathoracic pressure. Vitreoretinal traction due to cycles of rapid acceleration and deceleration is thought to be the causative process by some researchers.

In this presentation, antemortem documentation of retinal imaging (photographs and/or chart diagrams) will be compared to the postmortem retinal findings of children whose deaths fell under the jurisdiction of the Harris County Institute of Forensic Sciences from 2005 - 2011. Only cases with both antemortem and postmortem data will be analyzed. Progression or non-progression of hemorrhages will be described with regards to age, survival period, cardiopulmonary resuscitation attempts, intracranial pressure (when available), presence or absence of intracranial trauma, presence or absence of extracranial trauma, optic nerve sheath hemorrhage, coagulation parameters and cause of death. As intracranial pressure increases and patients become coagulopathic, it seems logical that the number of hemorrhages would increase; however this type of correlation in a large medical examiner's office has not been reported in the literature.

Ophthalmologists are often consulted to examine the retinas of children who present to the hospital with evidence of trauma and/or hypoxic encephalopathy. The time frame for the examination varies – depending on the degree of suspicion for abuse by the treating physician. Should these results indicate progression of retinal hemorrhages with increasing time and intracranial pressure, clinicians may opt for a "sooner-rather-than-later" approach to ophthalmologic examinations in order to properly interpret the results.

Retinal Hemorrhages, Pediatrics, RetCam Images

G129 Spontaneous Non-Traumatic Subarachnoid Hemorrhage With Retinal and Optic Nerve Sheath Hemorrhages Associated With Segmental Cerebrovascular Fibromuscular Dysplasia

Patrick E. Lantz, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; and Vivian M. Hathuc, DO, Wake Forest Baptist Medical Center, Medical Center Boulevard, Winston Salem, NC 27157*

After attending this presentation, attendees will learn that retinal hemorrhages and optic nerve sheath hemorrhages can occur in young children who have a spontaneous non-traumatic subarachnoid hemorrhage.

This presentation will impact the forensic science community by emphasizing the need for routine postmortem ocular examinations in young children dying suddenly and unexpectedly.

Spontaneous non-traumatic subarachnoid hemorrhage (SAH) in children is usually attributed to arteriovenous malformations, aneurysms, neoplasm, infection, leukemia, hemophilia, or sickle cell disease. Aneurysms may arise with conditions such as polycystic kidney disease, Ehlers-Danlos syndrome, fibromuscular dysplasia (FMD) and other conditions. A case of a child with bilateral retinal hemorrhages (RHs) and optic nerve sheath hemorrhages (ONSHs) associated with a spontaneous SAH arising from a ruptured right vertebral artery aneurysm due to segmental FMD is reported.

A previously healthy 4-year-old boy had a witnessed collapse at his daycare facility. Paramedics found the child in asystole at the scene where he was intubated and received cardiopulmonary resuscitation along with epinephrine and atropine. By the time he reached the medical center he was in sinus tachycardia and had no neurological response. His cranial cranial computed tomography revealed diffuse subarachnoid hemorrhage with marked cerebral edema causing cisternal effacement and downward displacement of the cerebellar tonsils. No parenchymal lesion was visible to account for the hemorrhage. Due to the grim prognosis, organ procurement was contacted and viable organs were recovered for transplantation after declaration of clinical brain death.

No clinical fundal examination was recorded in the medical record; however, postmortem monocular indirect ophthalmoscopy revealed bilateral RHs over the posterior poles. His autopsy revealed diffuse cerebral and spinal cord subarachnoid hemorrhage due to a ruptured right vertebral artery aneurysm arising within segmental fibromuscular dysplasia. Additionally, there was intraventricular hemorrhage, cerebral edema with cerebellar tonsillar herniation and hypoxic ischemic brain injury, pituitary necrosis and patchy acute spinal cord infarcts. He had bilateral optic nerve sheath hemorrhages, most pronounced in the optic nerve-globe junction. The bilateral ONSHs were located not just in the subarachnoid space but were also subdural and intra-dural with extension in the adjacent periorbital soft tissue. Blood extended along the pial septa into the interior of the left optic nerve. The left globe contained multiple RHs involving the nerve fiber layer with focal pre-retinal extension. No FMD was in the globes or orbital soft tissues.

Vitreous bleeding associated with SAH was first described by Moritz Litten in 1881; however, the association of vitreous hemorrhage concurrent with intracranial bleeding has been attributed to Albert Terson and later broadened by some authors to include any intra-ocular hemorrhage. It was initially believed that blood from a SAH could track along the optic nerve sheath and penetrate the lamina cribosa to appear in the vitreous space, but this theory has been refuted because a connection has not been demonstrated on electron microscopy. Another theory suggests that rapid increase in intracranial pressure transmitted through the optic nerve sheath and impairs venous drainage to the cavernous sinus, resulting in venous congestion and rupture of retinal vessels.

A noninflammatory, nonatherosclerotic disorder, FMD is characterized by abnormal cell growth in the walls of medium and large arteries leading to stenosis. The etiology is not clear but believed to relate to hormonal and mechanical factors. It is familial in about 10% of cases and affects the renal arteries about 60-75% of the time. The extra-cranial cerebrovascular arteries are involved in 30-60% of cases.

Extra-renal FMD can cause critical stenosis, aneurysm formation and rupture or cerebral thromboembolism.

Many authors consider that RHs in young children are uncommon in the absence of abusive head trauma. This case highlights the lack of clinical fundal examinations in young children when abuse is not suspected and the importance of routine postmortem ocular examinations in young children who die suddenly and unexpectedly. Although the brain and spinal cord had only subarachnoid hemorrhage, the presence of subdural hemorrhage in the optic nerve sheaths suggests that a sudden rise in intra-cranial pressure preceded the ONSHs and RHs.

Forensic Science, Retinal Hemorrhage, Non-Traumatic Subarachnoid Hemorrhage

G130 Complicated Suicide Versus Autoeroticism? A Case Involving Multiple Drugs and a Porta-Potty

Evan M. Dickerson, BA, 6275 North Meridian Street, Indianapolis, IN 46260; Prentiss Jones, PhD, South Bend Medical Foundation, 530 North Lafayette Boulevard, South Bend, IN 46601; Dennis Wilkins, and Janis Regnier, Portage Police Department, 2693 Irving Street #P, Portage, IN 46368; and Joseph A. Prahlow, MD, South Bend Medical Foundation, 530 North Lafayette Boulevard, South Bend, IN 46601*

After attending this presentation, attendees will appreciate a bizarre circumstance of suicide that initially masks itself as a homicide. Moreover, attendees will learn to recognize alternative behavioral practices associated with paraphilias and transvestism that may be present at the scene of a death.

This presentation will impact the forensic science community by presenting a unique and bizarre case of a suicide in a Porta-potty. The necessity of thorough investigation including autopsy is emphasized whenever scene investigation suggests the possibility of homicide. Careful correlation of autopsy findings and death scene investigation are essential in determining how a death may have occurred. Moreover, toxicology findings can provide abundant evidence regarding not only the cause of death but also the manner of death. In the current case, the extremely high level of tramadol in combination with amphetamine provides a tremendous amount of evidence for suicidal overdose.

Suicides can mimic homicide until further investigation and pathology are reviewed. In this report, a unique case of suicide by drug overdose with possible contributing factors of positional asphyxia, hyperthermia, and exposure to the chemical contents of a "porta-potty" is described.

A 36-year-old male was found dead in the waste receptacle of a porta-potty in a park on a late afternoon of a hot August day. Police were notified of an abandoned vehicle in the parking lot adjacent to a local park. The interior and exterior of the vehicle were covered with hand-drawn graphic images and writings alluding to the male genitalia and homosexual acts. The vehicle contained several articles of clothing and an open gym bag. The bag contained personal lubricant amongst other items. The driver's seat contained several tubes of lipstick that matched the color of writing on the car. The decedent was found in the tank of the portable toilet at the edge of the parking lot. The decedent's leather jacket, vehicle keys, and additional tubes of lipstick were found inside the porta-potty.

Scene investigation revealed an obese man lying in the fetal position within the tank of a porta-potty. The decedent was noted to be shirtless, wearing only women's stockings. To allow for further investigation and autopsy, the body was extricated from the basin of the toilet by cutting the top portion of the tank off.

At autopsy, the approximately 100kg decedent was noted to have early signs of decomposition, including skin discoloration, slippage, and bloating. He was wearing women's makeup, a pair of nylon leggings, and a left nylon sock. The body exhibited blue debris and had a chemical smell. The flanks, back, and arms showed confluent linear abrasions. Multiple apparent chemical burns overlapped the abrasions. The lesions were dry, thickened, and firm.

On internal examination, the abdominal organs showed signs of decompositional change but few other abnormalities. The stomach contained approximately 150ml of brown, viscous fluid which contained at least three capsules exuding a viscous material. A battery-operated vibrating device was present within the rectum.

Urine, serum, bile, and vitreous fluid samples were submitted for toxicological testing. The urine drug screen was positive for amphetamine, tramadol, methylphenidate, nicotine, cotinine, and caffeine. Serum drug testing revealed the presence of ethanol (50mg/dL), formic acid (45mg/L), tramadol (140mg/L), O-desmethyltramadol, methylphenidate, ritalinic acid, and-amphetamine (13.5mg/L).

Subsequent police investigation failed to reveal any evidence that suggested someone other than the decedent was involved in this death.

Family members denied knowledge of homosexual tendencies, as well as suicidal ideation. Nevertheless, DNA analysis was run on several samples collected from the obtained lipstick, swabs of the porta-potty, and body swabs; the results proved to match the DNA of the decedent.

Based on the autopsy findings, as well as the historical and investigative information surrounding the case, the cause of death was listed as the combined toxic effects of formaldehyde, amphetamine, and tramadol with possible contributing factors of positional asphyxia and hyperthermia. The manner of death was ruled "suicide."

Cases of suicides can mimic homicide upon initial investigation.[1] Nevertheless, the unique presentation of this case is of importance. An exhaustive literature/media search was unable to obtain a similar case. Cases of individuals getting trapped in the basins of chemical toilets have been reported in the media, but none resulted in fatality. [2,3] Provided with the immediate evidence, homicide must be suspected. Furthermore, it is possible to conceive that a "hate-crime" against an individual who practices alternative sexual lifestyles occurred.

The results of police investigation, autopsy, and toxicology indicated otherwise. The pattern of the flank and other abrasions was isolated to the area of central obesity, indicating a methodic approach to minimize injury when entering the relatively small opening within the toilet seat. No other evidence of trauma was present at autopsy. Ultimately, the habitus of the man would likely have prevented an assailant from forcing the body through the opening without excessive trauma being incurred (or the assailant simply giving-up because of the difficult task at-hand).

It is important to note the bizarre circumstances surrounding the decedent's death. Paraphilias are occasionally described in the forensic literature and may be evident at scenes of suicide.[4] Although the family reported no known history of cross-dressing, it is likely that the decedent had a history of partaking in practices of transvestitism, as he was found with an anal vibrator while wearing women's clothing and make-up, indicating a level of sexual arousal associated with the act.

The primary component of many chemical toilets, including the one in this case, is formaldehyde.[5] At autopsy, firm, chemical burns were noted over several parts of the body. The skin hardening was essentially due to the fixing of the tissue. The primary metabolite of formaldehyde, formic acid, provides an additional mechanism of injury in cases of formaldehyde exposure. Upon absorption into the blood, formaldehyde is rapidly metabolized to formic acid. Normal formic acid levels range between 0 to 12mg/L. The decedent's formic acid level was 45mg/L, well above the normal range, indicating systemic absorption of formaldehyde had occurred.

Fatal outcomes attributed solely to amphetamine have been observed in a wide range of blood amphetamine concentrations. In a review of 17 fatalities attributed solely to amphetamine, the peripheral blood concentration ranged from 1.1 to 7.4mg/L.[6] Therefore, the high concentration of amphetamine (13.5mg/L) reported herein is remarkable.

Tramadol is a synthetic analog of codeine that possesses opiate-like properties; however, tramadol is not derived from an opiate. Although fatal intoxication with tramadol is rare, several cases have been previously reported.[7,8] The highest reported blood tramadol level for cases of Tramadol intoxication alone was reported to be 15.1mg/L.[7] In a separate case of multiple drug intoxication, the highest reported blood tramadol level was 38.3mg/L,[9] at least 100 times the therapeutic range of 0.1 to 0.3mg/L.[7,10,11] The decedent reported in this case had a tramadol level of 140mg/L, which is approximately 470 times the therapeutic range. In no other case could such a level of tramadol be found in the literature.

With no anatomic explanation for death but a sufficient toxicological explanation, it would be reasonable to rule this death as simply being due to the combined toxic effects of the several drugs and toxins identified. However, because of the unique body position and the history of an extremely hot outdoor environmental temperature, positional asphyxia and hyperthermia are potential contributing factors in this death.

In a "complex suicide," more than one mechanism is applied resulting in death.[12] The case presented exhibits multiple factors contributing to the decedent's suicide; however, the secondary insult resulting from the constraints of the toilet basin, heat, and chemical contents of the toilet were possibly unintentional mechanisms contributing to death. Therefore, the suicide more likely represents a "complicated suicide" – the initial insult resulting in suicide (the substances ingested) allows for a secondary insult that was not originally planned as part of the suicide.[12]

The current case is of interest to the forensic community for a variety of reasons. The case emphasizes the importance for forensic investigators and police to be aware of unorthodox practices and paraphilias. The bizarre practices of the decedent in this case produced a scene that suggested the possibility of a homicide. Whenever scene investigation suggests the possibility of a homicide, it is imperative that a thorough investigation be performed, including the performance of an autopsy. Careful correlation of autopsy findings and death scene investigation are essential in determining how a death may have occurred. Accurate toxicology findings can provide abundant evidence regarding not only the cause of death but also the manner of death. In the current case, the extremely high level of tramadol in combination with amphetamine provides a tremendous amount of evidence for suicidal overdose.

Suicide, Tramadol, Porta-Potty

G131 Anaphylaxis After the Injection of Buprenorphine

Cassie Boggs, MD, Mary G. Ripple, MD, Zabiullah Ali, MD, Melissa A. Brassell, MD, Barry S. Levine, PhD, and Rebecca A. Jufer, PhD, City of Baltimore, Office of Chief Medical Examiner, 900 West Baltimore Street, Baltimore, MD 21223; Suzanne Doyon, MD, Maryland Poison Control Center, 20 North Pine Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will become aware of the possibility of an anaphylactic reaction due to the intravenous use of buprenorphine, and attendees should consider analysis for tryptase in cases of its misuse.

This presentation will impact the forensic science community by increasing the awareness of the possibility of an anaphylactic reaction following the injection of abused prescription medications.

Buprenorphine is a partial opioid agonist that was developed for pain management in the 1970s and in 2002 became available for opioid substitution therapy (OST) in the United States. The formulations designed for OST are sublingual and include Subutex®, a tablet that contains only buprenorphine, and Suboxone®, a formulation of buprenorphine and naloxone in a 4:1 ratio designed to reduce the diversion and misuse of buprenorphine by causing withdrawal symptoms when administered intravenously. Despite the addition of naloxone to buprenorphine formulations, the drug is still diverted and misused. Buprenorphine is relatively safe when used appropriately, however multiple deaths have been reported due to buprenorphine use and misuse both with and without concomitant use of other drugs. In several of the cases reported, the levels of buprenorphine were not considered to be toxic; however, in many of these cases, since there was no other identifiable cause of death, buprenorphine toxicity was still listed as the cause of death. Two cases of anaphylaxis in decedents who had injected buprenorphine formulations just prior to death and suggest that anaphylaxis should be considered in individuals who misuse buprenorphine via intravenous administration regardless of the postmortem buprenorphine concentration are presented.

In 2009 and 2010, autopsies were performed on two individuals who were witnessed to die suddenly after the injection of buprenorphine. Initial thoughts were that the deaths were due to buprenorphine intoxication, however toxicologic analysis showed elevated tryptase. The first case was a 29-year-old woman with a history of asthma, drug abuse, and an allergic reaction in the past. Investigation showed that she and her boyfriend had bought 20 tablets of alleged 0.2mg buprenorphine via the internet from a Philippine based pharmacy. They soaked the tablets in water, filtered them and prepared two syringes each with a 1mg dose. After purging the air from the syringe, she injected the solution and was witnessed to immediately gasp for air and collapse. Her boyfriend administered two puffs of her albuterol inhaler without benefit. She received multiple doses of naloxone and epinephrine from EMS and in the ER. Analysis of the contents of the syringes revealed no buprenorphine. Autopsy showed hyperinflated lungs with mucous plugging of the airways, peribronchial smooth muscle hypertrophy and eosinophilic infiltration. Postmortem toxicology screen was positive for naloxone (22 ng/mL) and elevated serum tryptase concentration of 179ng/mL. The cause of death was Anaphylactic reaction complicating asthma and the manner was Accident. The second case was a 30-year-old woman who was three months postpartum with a history of heroin abuse. Investigation showed that her boyfriend witnessed her complain of not feeling well after injecting herself with Suboxone® from a 8mg/2mg strip that she had purchased on the street. She then went to her bedroom was found to be unresponsive five minutes later. Autopsy showed rare polarizable foreign material in the pulmonary macrophages, scattered multinucleated giant cells in the lungs and focal interstitial hemorrhage and edema of the larynx; however, no mast cells were identified. Postmortem toxicology screen was positive for buprenorphine (17ng/mL), norbuprenorphine (7.6ng/mL), and naloxone (96ng/mL). Postmortem serum tryptase concentration was elevated at >200.0ng/mL. The cause of death was Anaphylactic reaction due to intravascular injection of Suboxone®, and the manner was accident.

Anaphylaxis is an acute immunologic systemic reaction an allergen via IgE receptor activation on mast cells and basophils with the release of inflammatory mediators including histamine, tryptase, prostaglandins, and leukotrienes. Anaphylactic reactions can be elicited by many substances; therefore it is possible that any constituent in either formulation abused in these cases elicited the anaphylactic reactions. The postmortem diagnosis of anaphylaxis depends upon a complete investigative history with focus on the details of the reaction and the event surrounding it as there is individual variation in symptomatology. Investigation should include questions on how the decedent reacted immediately prior to death, how the person has reacted before from exposure to the substance, and a complete medical history including history of asthma or allergies. Autopsy should include gross and microscopic evaluation of the airway and toxicologic analysis for serum for tryptase. Postmortem tryptase concentration has generally been considered elevated when greater than 10ng/ml. It has also been reported that postmortem tryptase can be elevated in the absence of anaphylaxis but usually not to the degree seen in these cases.

Given the increasing use of buprenorphine in opioid replacement therapy and the recent increase in the quantities of diverted buprenorphine being seized by law enforcement, the possibility of an anaphylactic death should be considered when the drug is misused. Serum tryptase concentration should be assessed prior to assigning the cause of death as buprenorphine intoxication in these types of cases. Elevation of tryptase is particularly useful in confirming the diagnosis of anaphylaxis triggered by injection of a medication or agent that is not normally used intravenously.

Anaphylaxis, Buprenorphine, Injection

G132 Increasing Efficiency in the Autopsy Suite: Rapid Drug Screening on Pericardial Fluid

Jeffrey P. Walterscheid, PhD, Harris County Medical Examiner's Office, Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; and Pramod Gumpeni, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand usage of pericardial fluid for toxicology testing, and how to increase efficiency in the autopsy suite by utilizing rapid drug screens.

This presentation will impact the forensic science community by increasing efficiency during autopsies, reducing unnecessary laboratory work, and showing other offices how to reduce costs while maintaining high quality forensic work.

Suspected illegal and prescription drug abuse compose a large subset of autopsies that are performed. However, there are also many cases in which the death can be attributed to a natural cause, if drug abuse can be eliminated as contributing factor. In order to reduce the amount of toxicology work to be done by the laboratory, the medical examiners employ rapid urine testing at the time of autopsy in such cases. The TLC based test gives qualitative results for presence or absence of amphetamine, methamphetamine, cocaine, and PCP, the four most common illegal drugs associated with sudden death. If no drugs are detected, a cause and manner can sometimes be assigned at the end of the autopsy, expediting closure for the family. However, many of these cases yield toxicology laboratory work anyway, due to the lack of urine or unsuitable samples of urine in the body.

Several bodily fluids are available at autopsy. There is no doubt that fluid specimens are much more convenient to be handled for drug and chemical analyses than solid tissue specimens. The qualitative usefulness of urine and bile for analysis of drugs is well known, but there is little information on the usefulness of pericardial fluid in spite of usually sufficient amounts available at autopsy. Pericardial fluid is an ultra-filtrate similar to urine. Many of the substances that are detected qualitatively in urine are also detectable in pericardial fluid. By utilizing the same TLC based assay that is originally designed for rapid urine drug testing, 59 cases at the office were evaluated simultaneously via quick pericardial fluid testing, quick urine testing, and normal toxicology assays on routine toxicology specimens (routine toxicology assays include HPLC, gas chromatography, mass spectrometry and combinations thereof). Of the 59 cases, four were homicides, 15 were accidents, 10 were suicides, and 30 were classified as naturals. No decedents under the age of 12 were included, nor were cases in which urine or pericardial fluid was not present for testing.

The results of the quick toxicology tests were photographed and evaluated, and then compared to the final toxicology results. The sensitivity and specificity of the quick urine screen was 100% and 73%, and for the quick pericardial screen was 95% and 84%, respectively.

By utilizing pericardial fluid as a substitute for when urine is not available for rapid drug screening at the autopsy table, excess laboratory work can be eliminated, as well as expediting issuing of a cause and manner

of death. This has a has a three-fold effect of lowering laboratory costs, decreasing death certificate turnaround time, and also allows for families and loved ones to reach closure sooner. Further research includes expanding the pericardial drug screen from illicit stimulants to include major prescription drugs of abuse (i.e., – opiates, benzodiazepines, etc.).

Pericardial Fluid, Drug Screening, Efficiency

G133 Two Unique Cases of Volatile Substance Abuse Death: Huffing Halogenated Hydrocarbons With Plastic Bag Over Head

Saranjit Kaur, MS, Dennis J. Chute, MD, and Kari B. Reiber, MD, Office of the Medical Examiner, Dutchess County Department of Health, 387 Main Street, Poughkeepsie, NY 12601*

The goal of this presentation is to elucidate the mechanism by which two individuals died from inhalation of a halogenated hydrocarbon, assisted by securing a plastic bag around their necks.

This presentation will impact the forensic science community by better understanding of the mechanism of death in volatile substance abuse cases.

The inhalation of volatile substances for their intoxicating effect, an act popularly referred to as "huffing," is a relatively new form of recreational drug abuse in the United States. These volatile substances are commonly found in consumer aerosol sprays, such as keyboard cleaners and air fresheners. Easy access and low costs make these products particularly attractive to adolescents.[1] Presented in this study are two unique cases in which individuals died from inhaling an aerosol spray (containing halogenated hydrocarbons) within the confines of a plastic bag secured around the neck. The plastic bag serves to potentiate the intoxicating effects of the aerosol, by increasing the concentration of chemicals in the user's breathing space. Given the presence of the plastic bags, the cause of death in both cases was certified as asphyxiation by placement of plastic bag over the head while huffing. In both cases, the volatile substances of abuse were halogenated hydrocarbons: difluoroethane and chloroethane. The purpose of this study is to investigate the mechanism(s) of death, i.e. determine its toxic effect. There are a number of possible mechanisms that may have contributed to death in these cases: anoxia, aspiration, vagal inhibition, respiratory depression, suffocation after loss of consciousness, and cardiac arrhythmia (due to sensitization of the myocardium by the chemical agent and/or from carbon dioxide in the user's environment).[2] In addition, volatile substance abuse puts the user at risk for "sudden sniffing death syndrome," a fatal cardiac arrhythmia caused directly by the sensitization of the myocardium to endogenous epinephrine. This later mechanism is supported by animal experiments which show that numerous halogenated hydrocarbons are capable of inducing cardiac arrhythmias. In the forensic setting, the postmortem diagnosis of a cardiac arrhythmia is often a diagnosis of exclusion due to the lack of pathognomonic changes within the heart.[3] Arrhythmias are reported in the literature as being the most likely cause of death in volatile substance abuse cases, but this is usually speculation and cannot be proven without more specific postmortem evidence of cardiac arrhythmia.[4] In the two huffing cases another significant variable was the placement of plastic bags secured over the head. It is proposed that hypoxia also plays a role in the abuser's death possibly by contributing to a fatal cardiac arrhythmia. Hypoxia has direct effects on the cardiovascular system and may heighten the cardiac response to epinephrine. For example, animal experiments suggest that cardiac sensitization is amplified by both volatile substances and the presence of hypoxia. It may be that the combination of a volatile halogenated inhalant, elevated epinephrine blood levels and hypoxia has the most cardiotoxic effect.[2] These two cases seem to demonstrate this triad of causation; alternatively, depression of central nervous system function and subsequent asphyxiation by plastic bag remains another possible explanation. Further studies are required for a more exact diagnosis.

G134 The Short-Term Effect of a Prescription Drug Monitoring Program on Prescription Drug Overdose Deaths Investigated at the Minnesota Regional Medical Examiner's Office

Marie Barbesier, MD, CHU la Timone, Service de Médecine Légale, 264, rue Saint Pierre, Marseille, 13385, FRANCE; Susan J. Roe, MD, Minnesota Regional Medical Examiners Office, Regina Medical Center, 1175 Nininger Road, Hastings, MN 55033; Shannon M. Mackey-Bojack, MD, John Nasseff Heart Hospital, Cardiovascular Registry, 333 North Smith Avenue, Room 4625, Saint Paul, MN 55102; and Lindsey C. Thomas, MD, and Emily Duncanson, MD, Minnesota Regional Medical Examiners Office, 1175 Nininger Road, Hastings, MN 55033*

After attending this presentation, attendees will be made aware of the impact of the Prescription Drug Monitoring Program of Minnesota (PDMP) on the drug overdose deaths investigated at the Minnesota Regional Medical Examiner's Office.

This presentation will impact the forensic science community by attendees' participation in a discussion of the epidemic of drug overdose deaths observed in the United States and the evaluation of the Prescription Drug Monitoring Program, a possible solution to this phenomenon.

The increase of drug overdose fatalities in the United States is a major public health concern. This phenomenon was related to an increase in the number of prescriptions and use of opioid medications. In January 2010, the State of Minnesota adopted an operational PDMP similarly to 34 other states in the United States. The PDMP was initiated in an attempt to improve the control of the opioid prescriptions and subsequently to reduce drug overdose deaths. This studies goal is to evaluate the short-term impact of the Minnesota's PDMP on prescription drug overdose deaths investigated at MRMEO from 2006 to 2010.

This observational and retrospective study was using data from MRMEO. The study population was all residents of MRMEO counties who died of prescription drugs from 2006 to 2010. The death certificates, scene investigation, autopsy and toxicology reports of 154 prescription drug overdose deaths were systematically reviewed.

The mean age of the decedents was 43.3 years (10-73 years) and 51% were female. The manners of death were in 48.7% of the cases undetermined, in 33% an accident and in 17.6% a suicide. The number of mixed drug cases was similar to the number of cases with a single drug. Opioid analgesics were the most prevalent drugs, leading with 132 deaths (85.7%). Psychotherapeutic drugs were involved in 69 deaths (44.8%). Two third of the deaths (67.5%) were due to a drug prescribed to the decedent. There were more psychotherapeutic drugs prescribed to the decedent than opioid analgesic drugs (75.4% and 64.4%, respectively). Prevalence of diversion was higher in male decedent cases (70.6%) and in younger decedent cases (mean age 36 years). Of all 154 cases, 34 (22.1%) had an association with alcohol. Methadone and oxycodone were the two most common opioid analgesics identified. Fentanyl was responsible for the highest percentage of single drug deaths in this study (14 (58.3%) of 24 deaths). Methadone and morphine were the two most frequently diverted drugs. Indeed, these two drugs were prescribed to the decedents in less than

half of the cases (49% and 44.5%, respectively). The benzodiazepines detected in 51 cases (33.1%) were mainly found in association with the other classes of drugs (94.1%). Over the first four years studied, prescription drug fatalities increased annually. In the fifth year of the study (2010), the PDMP was implemented in Minnesota, and we observed a trend of a decrease in the number of the prescription drug overdose cases, opioid analgesic overdose cases, and prescribed opioid analgesic overdose fatalities.

In conclusion, it was observed as a short-term effect a decrease in the number of drug overdose deaths investigated at MRMEO. Therefore, this result confirmed our initial hypothesis that PDMP in Minnesota is effective in prevention among our study populations, as the majority of drugs involved in overdose deaths investigated at MRMEO were prescribed to the decedents. However, the trend has to be confirmed by analyzing the data from MRMEO in the coming years, possibly in conjunction with other jurisdictions with different population demographics.

Prescription Drug Overdose, Prescription Drug Monitoring Program, Minnesota

H1 Effect of Obesity on the Accuracy of Age-at-Death Indicators of the Pelvis

Daniel J. Wescott, PhD, Forensic Anthropology Center at Texas State University, Texas State University, Department of Anthropology, 601 University Drive, San Marcos, TX 78666; and Jessica Drew, MA, Busan, KOREA*

After attending this presentation, attendees will learn how obesity, measured using the body mass index, affects the accuracy of skeletal age-at-death estimations based on the pubic symphysis and auricular surface.

This presentation will impact the forensic anthropology community by demonstrating that caution should be used when estimating age in obese individuals using the auricular surface, and that age-at-death estimations based on the pubic symphysis are preferred for obese individuals.

Age-progressive stages or macromorphological changes of the auricular surface of the ilium and symphyseal face of the pubic bone are commonly examined by forensic anthropologists to estimate adult age-at-death from skeletal remains. However, individual rates of progression through these stages can vary considerably depending on life history events such as diet, disease, physical activity, and body mass. Since the sacroiliac and pubic symphysis are weight-bearing joints, it is likely that the rate of progression through age-related stages is influenced by body mass, especially obesity. To date, no study has examined the effects of body mass on the progression of age-related morphological changes in the pubic symphysis or auricular surface. Since 1990, adult obesity rates have been dramatically increasing. As the number of obese individuals increase, so will the representation of obesity in forensic cases. Therefore, it is vital that forensic anthropologists know whether obesity affects the rate of progression through the different age stages in the pubic symphysis and auricular surface. This study investigates if obesity affects the age-related progression of morphology in the auricular surfaces and pubic symphyseal faces, and how these modifications affect the accuracy and precision of age-at-death estimates. In addition, sexual dimorphism in age-related changes was examined. It is hypothesized that obesity causes acceleration in degenerative age-related changes in these two anatomical regions, especially the auricular surface, and therefore, the inaccuracy of age-at-death estimations will be greater in obese individuals compared to those with a clinically normal body weight for stature.

The hip bones of 245 adults (23-90 years of age) of known age, sex, stature, and body weight from the William M. Bass Donated Collection were used in the study. Specimens with gross pathological anomalies of the pelvis or lower limb were not used. BMI was calculated for each individual by dividing recorded body weight in kilograms by stature in meters squared. Age-related stages were scored on the hip bones of 119 adults of clinically normal body mass (BMI between 19 and 25) and 126 obese (BMI $\geq$ 30) adults using the Suchey-Brooks method for the pubic symphysis and the Buckberry-Chamberlain method for the auricular surface. In some analyses the obese sample was subdivided into obese (BMI 30 to 39) and morbidly obese (BMI $\geq$ 40). In addition to the overall progression through the age-related stages, specific traits (transverse organization, surface texture, microporosity, macroporosity, and apical lipping) were scored for each auricular surface to reveal which of these features, if any, are affected by obesity. The accuracy of each method was calculated by subtracting the actual age from the mean and median age of the stage for the pubic symphysis and auricular surface, respectively. The correlation between actual age and the estimated age was calculated for both obese and normal body massed individuals using Pearson's correlation coefficient. Bias was calculated to determine the under- and over-aging results for the different age groups of each population, while inaccuracy is the average absolute error of age without reference to under- or under- age prediction.

As expected, the degree of bias and inaccuracy generally increases with age using both methods regardless of BMI. However, young adult obese individuals exhibit greater inaccuracy in age-at-death estimations using the auricular surface, but not the pubic symphysis compared to individuals with a normal BMI. This is probably due to the greater weight-bearing function of the sacroiliac joint and postural changes during locomotion in obese individuals. In addition, age was estimated with less precision in obese individuals compared to clinically normal weight individuals for both methods. Obese males show greater inaccuracy than obese females. There was also a greater tendency to over-age morbidly obese compared to obese individuals. Morbidly obese individuals also exhibited greater inaccuracy than either clinically normal or obese BMI individuals. The specific characteristics all follow the same general pattern of onset regardless of BMI.

This study helps to elucidate how obesity affects the rate of age-related skeletal change of the human pelvis. The results indicate that the pubic symphysis method is preferred when estimating age in obese individuals, especially males. However, the results also indicate that forensic anthropologists should use caution when assessing age-at-death from the skeletons of obese individuals using either auricular surface or pubic symphysis methods.

Obesity, Age-at-Death, Auricular Surface

H2 A Test of the Mann Maxillary Suture Aging Method

Nicole D. Siegel, DVM, Department of Applied Forensic Science, Mercyhurst College, 501 East 38th Street, Erie, PA 16546; and Nicholas V. Passalacqua, MS, 1559 Mount Vernon, East Lansing, MI 48823*

The goal of this presentation is to inform attendees about a test of the Mann et al. (1987; 1991) maxillary suture aging method performed on the Hamann-Todd Collection.[1,2]

This presentation will impact the forensic science community by demonstrating the accuracy of the Mann maxillary suture aging method on a large sample of known remains.

Accurate estimation of age-at-death from the human skeleton can be especially difficult in cases of fragmentary or incomplete remains. When presented with an isolated cranium, estimating the age-at-death is often limited to dental development, cranial, or maxillary suture closure. A previous test of the Mann method by Gruspier and Mullen found the variation in age was too great for recommendation of widespread usage in forensic cases, while another test suggested the method was useful when combined with other age indicators.[3,4] However, Gruspier and Mullen's sample was limited to White males predominantly over 40 years old, and the Ginter sample was heavily biased towards individuals above 60 years of age.[3,4] The goal of this project is to test the Mann method on a large, diverse sample, and to present a recommendation for forensic applications.

The present sample consists of 200 male and female individuals of European and African American ancestry from the Hamann-Todd Collection, with ages ranging from 10-82 years. Efforts were made to avoid any individuals expressing bony pathologies of the cranium as well as to create a balanced sample.[5] This large and diverse sample will allow for investigations into possible differences between sex and ancestry. Following Overbury et al, the side with greater fusion was scored as present when confronted by asymmetrical palatal fusion. Palatal suture closure was

scored using the criteria described in Mann et al. and Meindl and Lovejoy for cranial suture closure in order to readily compare the two scoring systems and determine if one system performed better than the other for estimating age from palatal suture closure.[2,6]

Preliminary results of this study support those findings of Gruspier and Mullen, although the findings of Ginter are not disputed.[3,4] Other than the reliably early fusion of the incisive palatine suture and the delayed or minimal fusion of the anterior median palatine suture into adulthood, too much variation exists in the fusion of the other sutures to recommend widespread use of Mann et al. in forensic contexts.[2] That does not mean the method has no value, as it is best used in conjunction with other methods in a supporting role. In addition, the Miendl and Lovejoy and Mann scoring methods each resulted in Spearman's correlations of r=0.377 and r=0.380 with age (in years), respectively.[6,1] While the Mann method has a larger correlation to age than Miendl and Lovejoy, this may not be significant in terms of scoring palatal fusion.[1,6]

Based on results of this study, the Mann method is most useful in separating younger from older individuals. Smith and Tondury, and more recently Kroman and Thomspon, demonstrated that cranial suture closure appears to be more closely related to individual brain and connective tissue (dura) development and somatic dysfunction than advancing chronological age.[7,8] In light of this finding, it is unclear if maxillary suture closure will follow this trend.

H3 Comparison of Vulture Scavenging Rates at the Texas State Forensic Anthropology Research Facility Versus Off-Site, Non-Forensic Locations

Lauren R. Pharr, MA, Department of Geography & Anthropology, Louisiana State University, 227 Howe-Russell Geoscience Co., Baton Rouge, LA 70803*

After attending this presentation, attendees will gain an enhanced understanding of vulture scavenging occurring at the Texas State Forensic Anthropology Research Facility (FARF), and the impacts vulture scavenging may have on future forensic investigations involving decomposition rates obtained at this site.

This presentation will impact the forensic science community by presenting an overview of vulture scavenging at FARF in comparison to vulture scavenging at off-site, non-forensic locations. Furthermore, the results from this study illustrate the need to incorporate avian scavengers into models pertaining to scavenger succession to help insure an accurate interpretation of taphonomic events during forensic anthropology investigations.

FARF is an outdoor laboratory dedicated to studying the rates of human decomposition and has an abundance of turkey vultures and black vultures residing nearby. Both vulture species are obligate scavengers and common visitors to the FARF site, thereby providing an excellent opportunity to study how soon after death vultures will arrive to feed on either carrion or a human cadaver. However, vultures are intelligent birds capable of recalling their prior successful scavenging locations, which raises the question, "Have the vultures residing near FARF learned that this site provides a reliable source of food, and if so, are the vulture scavenging rates at FARF the same as scavenging rates at off-site, non forensic locations?"

Substituting pigs for human models, two series of decomposition trials were conducted at FARF and in surrounding locations on the Freeman Ranch, which is a 4,204 acre working cattle ranch, to determine at what point during the postmortem interval vultures will arrive to scavenge and if these arrival times are the same at FARF in comparison to off-site locations.[1] Trial one began on July 01, 2011 and Trial two began two weeks later. Each trial involved three fetal pigs weighing between 1.38kg and 2.06kg and three separate field placement sites. The first pig was placed at FARF, the second pig was placed at an off-site ranch location that remained constant during both trials, and the third pig was placed in an off-site location that differed between trials. The sites shared similar vegetation and geographical features, but all sites were at least 1.5km apart. The three pigs used during Trial one were placed at their corresponding sites on same day, and all pigs were left to decompose without the protection of a cage. Trial two involved identical methods, with the only difference being the start date. Furthermore, each site was equipped with a motion activated infrared wild life camera and a weather station programmed to record climatic variables using one-minute sampling intervals. The cameras and the weather stations were in operation 24-hours a day throughout the duration of the study.

Results indicate that vultures are the primary scavengers at FARF and surrounding Freeman Ranch locations. Vultures arrived at five of the six pigs during the first 17 hours following pig placement, and at two of the pigs, a Crested caracara (Mexican Eagle) fed alongside turkey vultures and black vultures. A canine living on the ranch property scavenged the sole pig not scavenged by vultures. The failure of vultures to scavenge this pig is attributed to the pig's placement occurring late in the day and close to the time that vultures were preparing to return to their roosts. The canine took the pig in the middle of the night approximately eight hours following field placement.

For each of the five pigs scavenged by vultures, the vultures arrived, skeletonized the pig, and departed the site in less than three hours. This rapid scavenging reduces the probability that forensic investigators will observe vultures feeding at a crime scene, but systematic field searches conducted during this research revealed that the presence of down feathers in the surrounding vegetation and an intact vertebral column can be reliable indicators of recent vulture scavenging. Lastly, no differences were detected between the vultures' arrival times and scavenging behavior at FARF compared to the off-site locations, indicating that vultures are currently not impeding on the applicability of uncaged decomposition rates obtained at this facility.

Vulture Scavenging, Postmortem Interval, Taphonomy

H4 Validation of Two Age Estimation Methods Based on the First and Fourth Ribs in the Colombian Population

Susana Restrepo, BA, National Institute of Legal Medicine and Forensic, Carrera 23 # 53d- 56, Barranquilla, COLOMBIA; and Juliana Lopez, BA, Prosecutor General's Office, Carrera 19 # 24- 61, Bucaramanga, COLOMBIA*

The goal of this presentation is to show the application of two aging methods, one with the first rib and one with the fourth rib in the Colombian population.

This presentation will impact the forensic science community by showing how the aging process of the first rib on the costal facet and the face of the tubercle, as well as the morphological changes of the costal facet of the fourth rib and the general aspects of each method and their application to Colombian populations.

This study was carried out with the skeletal collection curated by the National Institute of Legal Medicine and Forensic Sciences in Bogotá, Colombia. The collection consists of 135 adult individuals, both male and female, with ages ranging from 19 to 93 years at the time of death.

The method used for the first rib was developed by DiGangi et al.[1] In this method, the geometric features of the costal facet are observed together with the texture of the surface of the tubercle. Each one is assigned a score according to the tables developed for this method. Changes were observed and recorded, excluding structures that showed diseases, where the area of interest was concealed by remnants of dry soft tissue, were incomplete or deteriorated.

The Loth & Iscan method was used for the fourth rib.[2] This method observes the changes produced by the aging of the costal face; morphological changes of this area were recorded, taking into account the features present on the articular surface, the borders, the walls, the depth and shape of the pit, and the porosity and quality of the bone in general. Both studies took into account both the right and left ribs, regardless of sex.

Results indicate that current methodologies utilizing both the first rib and fourth rib capture age-related change more accurately in young and middle-aged adults. For the first rib, the correlation coefficient between the best point estimate and real age was 0.623 (*p-value* < 0.001). Not surprisingly, adults aged 60 years and older had the most amount of error associated with their age estimates. In the case of the first rib method, these individuals were most likely to fall outside of both the 50% and 95% posterior density regions and in the case of the fourth rib method, these individuals often fell outside of the mean and standard deviation. Overall, the first and fourth rib methods do appear to contribute to age estimates and should continue to be tested.

These efforts to validate the methods according to the characteristics of the Colombian population provide more scientific rigor to the forensic work in the country. This contributes to the standardization process in the research of the biological profile of modern populations. Additionally, estimates will be more precise and they will strengthen the practice of forensic anthropology in Colombia and its role in the resolution of criminal cases.

The most important aspect of these projects is that they provide support to the families of the victims of the Colombian armed conflict. They are part of the resolution of forensic cases and facilitate identification. Consequently, they contribute to the return of individuals to their families.

Age Estimation, First Rib, Fourth Rib

H5 Human Identification from CT and MRI Scans: Novel Approaches to an Old Problem

Caroline A. Dimmer, BA, and Michael W. Warren, PhD, C.A. Pound Human ID Laboratory, 2033 Mowry Road, Room G17, PO Box 103615, Gainesville, FL 32610*

After attending this presentation, attendees will learn about the various ways in which computerized tomography (CT) and magnetic resonance imaging (MRI) scans can be used for comparison with radiographs, scans and models of unknown decedents to establish personal identity.

This presentation will impact the forensic science community by demonstrating novel approaches to human identification based on CT and MRI medical records. These approaches allow multiple avenues for antemortem/postmortem radiographic comparison and address the issue of pattern recognition.

Prior to the advent and widespread use of computerized tomography (CT) and magnetic resonance imaging (MRI) techniques in clinical medicine, patients who had sustained traumatic injury to the head and face were evaluated using plain film radiography. Anthropologists used these skull series and various facial radiographic projections to compare with postmortem radiographs of unknown decedents to establish the decedent's personal identity using frontal sinuses, grooves for the middle meningeal arteries, the *sella turcica*, and other structures thought to be morphologically unique in each individual. Over the past decade, plain film radiology has been abandoned as a diagnostic tool for most head and face injuries. Instead, the more detailed and clinically useful CT and/or MRI are used. This shift in diagnostic radiology has resulted in a dearth of available plain film radiographs from which to identify putative decedents. Investigators are, instead, presenting CT and MRI studies to anthropologists, while anthropologists are generally limited to plain film technology for radiographic imaging of skeletal remains. CT and MRI scans may be available as a film series, digital imaging and communications in medicine (DICOM) images on a digital recording medium, or scan volume data.

An obvious solution is to perform a CT scan on the unidentified cranium, matching the transverse or axial images between the antemortem and postmortem scans. Volume scan data may be used to recreate, in three dimensions, a virtual model of the skull that provides further information, such as frontal sinus volumes, upon which identity may be established. However, this route towards identification is costly and dependent on the availability of CT and MRI scanners (which are usually running at capacity in clinical areas), and one must deal with the probability that the two scan formats may not be precisely aligned. Another solution is to use the antero-posterior and/or lateral "scout films," taken as part of the CT or MRI protocols, as a proxy for the antemortem "plain film" which can then be compared to postmortem images. However, scout films are small and generally become pixilated when expanded to a useable size.

More creative uses of CT and MRI scans are:

- Using axial scans of the head to capture the dental pattern of the putative decedent for comparison with a postmortem odontogram. The investigator may then use Adams et al. OdontoSearch 2.0 program to determine the relative frequency of the matching pattern, and then assign probative value of the match based on that information.[1]
- Using scan volume data to produce a three-dimensional model of the putative decedent's skull, this can be compared with the unknown specimen both metrically and via digital radiography. This method requires access to a three-dimensional model printer. Once the model is printed it can be radiographed. Comparison of this "antemortem" film with the radiographs of the unknown skull is only limited by the resolution of the printed models. In most cases; however, the model represents a faithful reproduction of most of the anatomical variants used by anthropologists to establish identity. Additionally, one may compare metrics obtained from the

model, the unidentified skull, and the population from which the individual is derived.

- Evaluating scans for idiosyncratic variation, pathology or trauma that might correspond with findings based on examination of an unknown skeleton.

This presentation will use case reports to explore the various ways in which CT scans may be used to establish personal identity in forensic contexts.

Forensic Anthropology, Human Identification, Radiographic Comparison

H6 Taphonomy of Infant and Child Sized Remains in Western North Carolina

Paul S. Martin, Western Carolina University, Department of Anthropology & Sociology, 101 McKee Building, Cullowhee, NC 28723; and Cheryl A. Johnston, PhD, Western Carolina University, Western Carolina Human ID Lab, Department of Anthropology & Sociology, 101 McKee Building, Cullowhee, NC 28723*

After attending this presentation, attendees will have a better understanding of the arrival sequence of scavengers, their impact on the decomposition, scattering, and recoverability of remains deposited both on the surface and buried in western North Carolina.

This presentation will impact the forensic science community by highlighting the impact avian and mammalian species have on the scavenging and scattering of infant and child sized remains placed within a wooded area of western North Carolina.

There have been limited studies of the scavenging and scattering of infant and child sized remains. This research focuses on the relationship that scavengers play in the decomposition process and the associated pseudotrauma that they can cause to remains, and examines the recoverability of scavenged remains. These data are of importance to personnel tasked with the search and recovery of such remains, as well as the pathologist and the physical anthropologist.

The first phase of this research was conducted from February to July, 2011. Six sets of pig remains weighing less than 10 pounds were placed in a wooded environment both on the surface and buried. Three areas were chosen to place remains. Each area contained a shallow burial and a surface deposit. In Area 1, the burial and surface deposits were both covered with small piles of brush. In Area 2, both sets of remains were wrapped in common shopping bags from the local market. In Area 3, the remains were deposited with no additional alteration. Motion activated game cameras were utilized to track scavenger activity and field visits were conducted to track changes in the remains.

The second phase was conducted from March to June, 2011 and involved the deposition of one 30 pound pig on the surface in a wooded environment. Multiple motion activated game cameras were utilized to track scavenger activity and field visits were conducted to track changes in the remains.

The two phases of this research project resulted in varying observations of animal behavior in response to the remains. In the first phase no buried set of remains was disturbed, whereas two sets of surface remains were completely removed from the area. The set of remains placed on the surface in a bag was finally fully scavenged but only after an extended period of time. In the second phase arrival and contribution of the scavengers was not as expected from previous studies. In particular, the role of canines seemed to be highly diminished in comparison to avian involvement with scavenging and scattering.

This research shows the relationship that scavengers in western North Carolina have to the destruction of infant and child sized remains. It is recommended that additional studies be conducted throughout the United States. By becoming more familiar with the results professionals involved with the search and recovery of infant and child sized remains will be better prepared to develop effective search strategies in cases where scavenging and scattering of remains have occurred.

Taphonomy, Scavenging, Forensic Archaeology

H7 I'd Give My Eye Teeth for Cementum Increment Analysis

Shirley Hsieh, MS, Western University of Health Sciences, College of Dental Medicine, 309 East 2nd, Pomona, CA 91766; Vicki Wedel, PhD, Western University of Health Sciences, Department of Anatomy, 309 East 2nd Street, Pomona, CA 91766; and Kenneth P. Hermsen, DDS, Creighton University, School of Dentistry, 2500 California Plaza, Omaha, NE 68178*

After attending this presentation, attendees will gain an understanding of how dental cementum is deposited and how it is used to determine age and season at death in humans. Specific to this talk will be a discussion of which tooth to choose for dental cementum increment analysis for season at death.

This presentation will impact the forensic science community by marking one step in preparing a new method for use throughout anthropological and odontological forensics.

Zooarchaeologists have long used dental cementum increment analysis to estimate the season at death in mammals, yet testing the validity of using this method to determine season at death in human teeth is very limited and still on-going.[1,2] Cementum is the tissue that binds the tooth to the periodontal ligament, and in the interest of teeth being retained throughout adulthood, cementum is deposited throughout the course of life. From seminal zooarchaeological pieces, it was learned that cementum is secreted in pairs of bands each year. Pilot work by Wedel demonstrated that the seasonal transitions of the outermost cementum band in humans change from translucent to opaque in teeth extracted in fall/winter (October - March), and from opaque to translucent in teeth extracted in spring/summer (April - September).[3] Counting these pairs of bands and adding that number to the age at which the tooth erupts derives an age at death estimate. This study focuses on distinguishing the outermost increment in transverse thin sections of the middle third of the root by using transmitted polarized light microscopy.

Wedel[3] took Lieberman[4] and Wittwer-Backofen[5] at their word, namely that "any tooth will work." However, neither paper demonstrated the veracity of this statement by supporting it with data; they simply used all four types of teeth (incisor, canine, premolar, molar). All adult teeth that are erupted and in occlusion do exhibit increments (Wedel)[3], but here is no consensus on which adult tooth derives the most repeatable and reliable results. Pinichi et al. tested the different types of teeth in predicting age and showed that premolars and third molars have the highest prediction efficiency.[6] Kagerer and Grupe's study supported the use of impacted third molars having very reliable precision in age determination.[7] On the other hand, they showed that premolars have one of the highest standards of deviation when cementum increment analysis was used to determine chronological age. Moreover, very few studies are testing the use of the outermost band of cementum to determine the season-at-death in humans. Recent studies using this method have focused on animals. Wall-Scheffler and Foley tested the use of dental cementum on first molars of sheep without justifying their research subject choice.[8]

This study seeks to test the hypothesis that the cementum bands transition from light to dark on multiple teeth from the same patient at the same time, and while examining 10 teeth from any one individual, determine whether one tooth type or another is most useful for determining season at death in humans. Two sample pools containing a total of 300 samples were included in the study. Sample pool #1 contains teeth donated by the patients from a school of dentistry. Ten individuals who each had 10 teeth extracted in the normal course of dental treatment were embedded,

sectioned, ground and polished, and examined under 10X magnification. Of these 100 teeth, 94 valid specimens resulted. The most precise results, where season observed matched actual season at extraction (our proxy for season-at-death) were obtained from the canines (eye teeth, cuspids). Sample pool #2 contains teeth donated by patients from a Santa Cruz doctor's office and are being evaluated at present. The data will be presented side by side.

H8 Validation of the Kindschuh et al. (2010) Method for Determining Sex from the Hyoid Body

Adam D. Emig, 1724 Grenada Boulevard, Knoxville, TN 37922; and Jonathan D. Bethard, MA, Boston University School of Medicine, Department of Anatomy and Neurobiology, 72 East Concord Street, Room L1004, Boston, MA 02118*

After attending this presentation, attendees will understand: (1) the sex estimation method presented by Kindschuh et al.; (2) the significance of analyzing comparable datasets for metric studies; and, (3) the importance of utilizing modern skeletal collections for forensic studies.

This presentation will impact the forensic science community by illustrating the importance of utilizing comparable datasets for metric studies of sex determination. In addition, this study demonstrates that the accuracy of the Kindschuh et al. method may be difficult to judge when subtle differences in data collection are utilized.[1]

The hyoid bone is widely used in forensic contexts as an indicator of neck trauma; however, other studies such as the work of Kindschuh et al. have suggested that the hyoid bone can be used to estimate sex.[1] In their study, 398 hyoid bones were utilized from the Terry Collection to generate six discriminant function equations with classification accuracies that ranged from 82% to 85%.

Two of the equations developed by Kindschuh et al. exclusively utilized unfused hyoid bodies to estimate sex and the current study was designed to test the accuracy of those discriminant functions.[1] This study made use of original data collected by Devlin on a large sample of unfused hyoid bodies drawn from the William F. McCormick Collection (n=1,033).[2] Both males and females of European and African ancestry were utilized and age-at-death of the sample ranged from 20-79 years. Two measurements of the hyoid body were employed: body height and body length. In both studies, Kindschuh et al. and Devlin define these measurements identically; therefore, data from the McCormick Collection were applied to the Kindschuh et al. formula.[1,2]

While the original study performed with a rate of 82% accuracy, a rate of only 40% was achieved here and in the majority of cases, males were classified as females. This discrepancy is explained by decreased means for both body length and body height between populations. For example, in the Terry European-American sample, mean body length was 25.11mm for males and 21.04mm for females while in the McCormick European-American sample, mean lengths were 20.89mm and 17.67mm, respectively. Mean body heights follow a similar decrease in size between samples. For example, mean body height for Terry European-American males was 12.25mm and 10.46 mmfor females, while in the McCormick sample mean heights were 11.04mm and 9.20mm, respectively. Overall, mean body length decreased by 17.01% in males and 16.01% in females and mean body height decreased by 9.88% in males and 12.04% in females.

While metric differences between the Terry Collection and contemporary samples like the McCormick Collection have been attributed to secular change in other studies, it is possible that the discrepancy observed here is due to variation in measurement technique.[3,4] Recent contributions have documented the importance of demonstrating low inter-observer error when multiple datasets are compared, though no studies have systematically compared techniques utilized for measuring the hyoid bone.[5,6] Additional data collection and direct comparison between the Terry and McCormick samples are necessary to elucidate a clear pattern.

Sex Estimation, Hyoid Body, Metric Measurement Techniques

H9 Pubic Aging Indicator Symmetry

Kevin Hufnagl, MA, University of Tennessee, 250 South Stadium Hall, Knoxville, TN 37996; and Donna McCarthy, PhD, 1502 Northshore Woods Drive, Knoxville, TN 37919*

After attending this presentation, attendees will understand that age estimation from the pubic symphysis is not as straightforward as it appears and that assumptions about the methods employed may not always hold true.

anthropologists should consider more carefully how they create age estimates from pubic symphyses. Forensic anthropologists routinely determine age estimates from established and commonly-used methods as part of the biological profile. However, whether age is estimated by a student anthropologist or seasoned professional, precision of the estimation may be affected by as minor a factor as which side of a bone is chosen for analysis. In forensic cases where only partial remains are recovered, this factor becomes even more significant in age estimation.

If aging indicators are truly linked to biological age then it is logical to presume that, barring gross pathological exceptions, the left side indicators should mirror the right side, and vice versa. In this study, the degree of symmetry between the right and left sides is measured on various age indicators of the pubic symphysis. One hundred seventy-six pairs of pubic symphyses from the William M. Bass Donated Collection housed at the University of Tennessee, Knoxville were scored according to the definitions of 35 different aging indicators compiled from eight aging methods. Both

component and phase methods were used. Five of the variables are newly created variables based on variations or alternative interpretations of variable definitions from the literature. The two sides were observed independently by the same observer to maintain consistency.

The data were analyzed using simple statistical calculations on the differences of the observations between the sides. Calculations included the range of the differences and the magnitude of the asymmetry. The percentage of observations that demonstrated a difference between sides was calculated, as well as the average magnitude of asymmetry for those observations scoring differently on the two sides.

There is significant difference between the right and left pubic symphysis. Generally, the differences between the two sides are no more than one stage removed from one another. Thus, an aging indicator having only three or four possible states would be highly unlikely to score a difference measure of three or even two between the two sides. Likewise, methods with a large number of different states can more easily achieve a greater magnitude of asymmetry. Therefore, the percentage of observations that exhibited a difference bilaterally is more meaningful than the magnitude of the difference. None of the 35 variables tested exhibited 100% concordance between the two sides, although a few were relatively close. Eleven of the 35 variables had more than 30% of the observations differ between sides, with a maximum range of 47%.

These data illustrate that anthropologists cannot assume the right pubic symphysis will be aged the same as the left. This factor should also be taken into account when establishing definitions for new aging indicators.

Aging, Pubic Symphysis, Symmetry

H10 Decomposition of Dismembered Pig Carcasses in Insect Repellent and Conventional Waste Disposal Bags

Kassra L. Scholl, BSc, and Tal Simmons, PhD, School of Forensic & Investigative Sciences, University of Central Lancashire, Preston, Lancashire PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will gain an understanding about how decomposition of heads, limbs, and torsos in separate, sealed plastic waste disposal bags proceeds; and, if insect activity and the decomposition process can differ between regular waste disposal bags and insect repellent waste disposal bags.

This presentation will impact the forensic science community by providing results from a controlled experiment in an area with very little previous research. This presentation will add to research being carried out in forensic taphonomy by broadening the understanding of how dismembered remains decompose in particular settings, enabling a better appreciation of these processes in human decomposition.

Dismemberment of remains to complicate identification and for ease of transportation may be encountered in homicide cases. Heads and limbs, especially hands, of victims are often found severed from the trunk and disposed of separately for this reason. Furthermore, perpetrators may strive to complicate forensic analysis of remains by trying to distort indicators that aid postmortem interval estimation. Since insects are commonly known to be of forensic importance, disposal of remains in insect repellent plastic bags could be an additional way to complicate a time-since-death estimate. It has been shown previously that wrapped remains pose a greater barrier for insects. Research conducted into the effects of various coverings on decomposition by Dautartas observed that insects seemed to appear at a later stage on wrapped remains compared to exposed remains.[1] Furthermore, an examination of Louisiana cases by Manhein showed that remains buried and covered in plastic exhibited a markedly delayed decomposition.[2] It is therefore assumed that the rate of decomposition is distorted in wrapped remains as a result of reduced or delayed insect activity as well as other factors. Previous research and case studies have also found that products such as insecticide, patchouli perfume, HCl, and gas can result in delayed insect activity, and therefore may have a masking effect on decomposition of cadavers, which possibly leads to an underestimation of the postmortem interval.[3,4]

In this experiment, 24 *Sus scrofa domestica* carcasses were used as research subjects. The experiment was conducted at the Taphonomic Research in Anthropology Centre for Experimental Study (TRACES), Northwest England. The 24 carcasses were dismembered into heads, limbs, and torsos and distributed separately into 72 waste disposal bags (36 insect repellent experimental and 36 regular control bags). The 72 bags were subdivided into four sets; three of which were opened alternatingly at intervals of approximately 50 Accumulated Degree Days (ADD) for data collection. The fourth set was held back to act as a disturbance control. A scoring scale based on the degree of surface area covered to quantify insect activity was developed for the purpose of this research, as well as a scale based on Heaton et al. for scoring decomposition stages of heads, limbs, and torsos in separate, sealed plastic bags.[5]

Insect activity was first observed at 98.5 ADD in both the experimental as well as the control group. Preliminary statistical testing found there to be no significant difference in insect activity over time between the experimental and control groups ($F_{1,250} = 2.165$; *p-value* = 0.143). Analysis of insect data did show a significant difference in insect activity over time between heads, limbs and torsos respectively ($F_{2,250} = 8.477$; *p-value* = 0.000). Trends for insect scores show that while torso bags have a continuously higher insect activity compared to limb bags they progress at the same rate, whereas heads show relatively little insect activity in the earlier stages, but then exhibit a markedly faster progression. Trends for decomposition scores of both the experimental and control groups indicate that torsos progress at the fastest rate, followed by heads and ultimately limbs with a distinctly slower rate. These observations support earlier findings that heads and limbs decompose at a slower rate than whole bodies, likely due to limited bacterial action caused by the absence of gastrointestinal organs and hence gastrointestinal bacteria, which drive most of the putrefaction process.[6,7]

In conclusion, this study provides evidence that insect repellent bags neither deter insect activity nor distort the decomposition of remains when compared to regular bags, and that decomposition rate and insect activity differs between different elements in separate bags. Furthermore, data gained from this research may be used to generate a formula for PMI calculation of heads, limbs, and torsos in separate, sealed plastic bags.

H11 An Evaluation of the Use of Modern Medical Imaging Techniques for the Determination of Biological Sex From Craniometric Measurements

Aisling M. Smyth, MSc, Cranfield University, 59 Barrington Road, Watchfield, Swindon, Wilts SN6 8TN, UNITED KINGDOM; Mark D. Viner, MSc, Inforce Foundation, Cranfield Forensic Institute Defence Academy of the United Kingdom, Shrivenham, SN6 8LA, UNITED KINGDOM; Gerald J. Conlogue, MHS, Quinnipiac University, Diagnostic Imaging Program, 275 Mount Carmel Avenue, Hamden, CT 06518; and Tania Blyth, MHS, Quinnipiac University, 275 Mount Carmel Avenue, N1-HSC, Hamden, CT 06518*

After attending this presentation, attendees will be aware of the range of imaging techniques that may be used as alternatives to direct physical craniometric measurements. They will understand the relative advantages and disadvantages and levels of accuracy of Computed Tomography (CT) Scanning and Computed Radiography (CR) and their suitability for deployment.

This presentation will impact the forensic science community by increasing awareness of alternative non-invasive methods of taking measurements from the cranium for the determination of biological sex in human subjects.

The acquisition of direct anthropological measurements from human remains can sometimes involve the removal of flesh. This practice raises many ethical, cultural, and religious issues, and, in the United Kingdom, is in conflict with the recommendations of the Clarke enquiry. The process is also time-consuming and involves the manual handling of biological material. Radiography has long been an alternative, non-invasive method for obtaining measurements from fleshed remains, but has traditionally been a very time-consuming process requiring correction for magnification. However, the advent of modern digital imaging techniques appears to offer more efficient methods of gathering anthropological data non-invasively. This paper will present the findings of a study that aimed to evaluate the viability of two modern imaging methods; Multi-Detector Computed Tomography (MDCT) Scanning and Computed Radiography (CR) for determining cranial measurements to aid human sex identification.

Twenty skulls from a museum collection were examined using both MDCT and CR and five standard measurements were taken from each skull using the image data from both techniques. These measurements were compared with direct physical measurements taken using callipers, mandibulometer, and osteometric board.

The results showed that measurements taken from CT scan images were as accurate as direct osteometric measurements, and measurements taken from CR images were affected by magnification proportional to the distance of the body part from the image receptor. The results from this study suggest that the effect of magnification on measurement data from digital radiography is significant enough to alter any resulting assessment of biological sex and should be corrected for. However, the process of examination and measurement from Computed Radiography is rapid and the technology is far more widely available to investigators than CT scanning and can be deployed easily in field situations. It is recommended that an accurate and reproducible magnification correction method for use at various object-to-film distances should be developed for CR technologies.

It is recommended that CT should be used as the method of choice for taking craniometric measurements from fleshed remains. However, where this is not possible digital radiography is an acceptable alternative, provided that the magnification can be accurately corrected for.

Craniometrics, Radiography, CT Scanning

H12 Cranial Sexual Dimorphism and Anthropological Standards: Preliminary Investigations in a Western Australian Population

Daniel Franklin, PhD, University of West Australia, Centre for Forensic Science, MBDP M420, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; Ambika Flavel, MSc, Algis Kuliukas, MSc, and Charles E. Oxnard, PhD, The University of Western Australia, Centre for Forensic Science, Crawley, 6009, AUSTRALIA; and Murray K. Marks, PhD, University of Tennessee, Department of Pathology, 1924 Alcoa Highway, Box 108, Knoxville, TN 37920*

After attending this presentation, attendees will gain awareness of: (1) the relationship between contemporary population specific standards and the expected accuracy of sex estimation in adults; and, (2) the value of 3D medical databases as potential sources of contemporary morphometric data for creating forensic anthropological standards.

This presentation will impact the forensic science community by quantifying population specific standards in forensic anthropology. Further, it will demonstrate how 3D medical databases provide abundant sources of contemporary research data that are complementary to traditional approaches based on direct examination of physical remains.

The formulation of a biological profile (osteobiography) is a crucial tool when unidentified skeletal remains are investigated. Accurate sex estimation ensures that the most appropriate and accurate statistics and standards for analyzing the remaining aspects of the biological profile are applied, e.g., sex-specific age, ancestry, and stature. Also, the most accurate biological profile is achieved using contemporary population-specific standards.

Australian forensic anthropology is constrained by a paucity of population specific standards as repositories of documented skeletons, traditionally the main source of population-specific data, do not exist. Today, if a morphometric approach is required for sex estimation, then a standard formulated from a non-Australian reference sample is the only option. The general effect of applying non-population standards creates an accuracy reduction in classification, the magnitude of which is proportionately related to the degree of dissimilarity (increasing biological distance) between the original reference sample and the individual to which those standards are being applied.

This research provides preliminary results of sexual dimorphism in Western Australian crania. The primary purpose is to formulate a series of morphometric standards for the estimation of sex and to demonstrate the effect on classification accuracy when non-population specific vs. population-specific standards are applied. The sample comprises cranial multi-slice computed tomography (MSCT) scans at a maximum thickness of one millimeter on 100 adult females (mean age of 36 years) and 100 adult males (mean age of 40.33 years). The 3D coordinates, using 3D volume rendering of 48 landmarks were acquired (by AF) using *OsiriX*® (v.3.9). A total of 55 linear measurements were calculated using *Morph Db* (an in-house developed database application). Measurements were analyzed using basic descriptive statistics and discriminant function analyzes using *SPSS 19.0*. The degree of correct sex classification in the Western Australian (WA) sample was also explored using the Giles and Elliot and Steyn and Iscan standards.[1,2]

Results reveal strong dimorphism in the WA population with bizygomatic breadth, mastoid height and maximum cranial length contributing significantly to sex discrimination. Maximum cross-validated classification accuracy using a step-wise analysis of five variables is 93% with a 4% sex bias. When classifying the WA sample using Giles and Elliot (Function #16 – American Caucasians) and Steyn and Iscan (Function #1 – South African Caucasians), sex was estimated correctly in 83% and 80% of cases respectively. However, the sex-bias is 31% and 36% respectively. Using the same variables required by the aforementioned foreign functions to formulate specific WA standards, results had an expected classification accuracy of 89% (sex bias 1%) for Giles and Elliot and 88% (sex bias 2%)

for Steyn and Iscan. While the overall sex classification accuracy is still relatively high, using foreign standards for the WA sample results in an unacceptably large bias. These non-Western Australian standards will thus frequently misclassify females. These results highlight the importance and necessity for developing population-specific standards for Western Australians.

Sex Estimation, Cranium, Western Australia

H13 Fetal Sexual Dimorphism of the Ilium: A 3D Geometric Morphometric Approach

Fatima-Zohra Mokrane, MS, Laboratoire d'Anthropobiologie AMIS, UMR 5288 CNRS, Université Paul Sabatier, 37 Allées Jules Guesde, 1 Avenue Professeur 31059 Toulouse Cedex 9, 31000, FRANCE; Fabrice Dedouit, PhD, Service de Médecine Légale, Hôpital de Rangueil, 1 Avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE; Stéphane Gellée, MS, Service de Radiologie, CHU Toulouse-Purpan, place, Toulouse, 31059, FRANCE; Hervé Rousseau, MD, PhD, Service de Radiologie Générale, Hôpital de Rangueil, 1 Avenue du Professeur Jean Poulhès,TSA 50032, Toulouse Cedex 9, 31059, FRANCE; Norbert Telmon, MD, PhD, Service Medico-Judiciare, CHU Rangueil, 1 Avenue Jean Poulhes, Toulouse, F-31054, FRANCE; and Daniel Rouge, MD, PhD, Service de Médecine Légale, CHU Toulouse-Rangueil, 1 Avenue Professeur Jean Poulhès, Toulouse, 31059, FRANCE*

After attending this presentation, attendees will be familiarized with the use of 3D geometric morphometric measurements for the study of sexual fetal dimorphism.

This presentation will impact the forensic science community by demonstrating feasibility of outline analysis for immature forms.

This study aims to look for a sexual fetal dimorphism, using 3D geometric morphometric measurements, by applying Elliptic Fourier analysis (EFA) based on the study of 93 European fetal iliac bones aged between 21 weeks and 40 weeks from amenorrhea (WA), recorded by multi-slice computed tomography (MSCT), and 3D reconstructions. This study demonstrates the feasibility of outline analysis, especially for immature forms; however, there was no sexual dimorphism established by this study.

The evidence of sexual dimorphism in human adults has been established and studied for decades. Therefore, the information for fetuses is not well known, with few studies and contradictory results. Ninety-three French fetal iliac bones aged between 21 weeks and 40 weeks from amenorrhea(WA), coming from the anatomic collection of Marseille Hospital, were recorded by multi-slice computed tomography (MSCT), and 3D reconstructions. The 3D geometric morphometric analysis was based on outline analysis. EFA was used because of the immature morphology and the difficulty of landmark positioning. Reconstructions allow shape descriptions for each harmonic. Principal Component analysis (PCA) was performed separately for each age group (cut off at 30 WA).

According to the literature, the collection was divided into two age groups, with a limit at 30 WA. Both groups are well balanced (sex ratio respectively about 0.86 and 0.94). The first ten Principal Components axes represent 96% of the global variability, with harmonics or with amplitudes study. To allow best choice about the most discriminant principal component axes, PCA axes were selected using the most important eigenvalues (PC1- PC2), then by Wilks' Lambda analysis, and finally by applying Jolliffe eigenvalue threshold of 0.7 on the most discriminant PC axes with Wilk's test. In order to describe the best methodology in the Elliptic Fourier outline analysis, PCA was applied on amplitudes and harmonic coefficients derived from the Fourier series.

The accuracy of the reconstructions increased with the number of harmonics. The simultaneous analysis of the step-by-step reconstructions and the harmonics ellipses demonstrates that harmonics presenting the greatest amplitudes (magnitudes) and greatest axis ratios have the greatest morphologic contributions, which can be related to anatomic features. The convergence between the reconstructed outlines and the original outline by the use of an increasing number of harmonics can be easily appreciated visually, and can be quantified by the fit index, which is the sum of the squared distances between the reconstructed points and the original outline. The major morphologic characteristics were mainly described by the first seven harmonics presenting the greatest amplitudes. Finer features were described by harmonics of higher order. The iliac crest was the first to be described in step by step reconstruction from the second harmonic. The ischial tuberosity appeared as a positive relief around the fourth harmonic and its asymmetry around the fifth. The greater sciatic notch is described by the fifth harmonic. Its real depth and its asymmetric aspect appeared with the seventh harmonic. A perfect description is acquired around the seventh. After the eighth harmonic, there are no visible significant differences between shapes described by each one.

The best graphical representations in terms of sexual dimorphism were different between the age groups. But, these representations were not so easy to interpret, because of the absence of clear discrimination between female and male groups, regardless of the PCA selected. The overlap between age groups was too large to allow a sexual discrimination.

For fetuses between 21 and 29 WA there was no clear discrimination between age groups, regardless of which method was used (PC1-PC2, PC1-PC21 and PC1-PC11). The study for oldest fetuses leads to the same findings: big overlap and no clear discrimination between sex groups.

While various pelvic indicators showed marked sexual dimorphism in adults, there are no comparable levels of dimorphism in subadults and especially in fetuses. Several studies tried to answer questions asked by anthropologists and forensic physicians. Even if a significant sexual dimorphism in 2D elliptical Fourier analysis of the iliac outline was revealed, it was not possible to localize the source of this dimorphism. Computer-assisted image analysis allowed an automatic quantification of the outlines shape. It presents many advantages like greater objectivity and reproducibility, greater rapidity, and facilitation of measurements traditionally impossible to determine directly. Unlike the adult hip bone, where landmarks are relatively simple to define, the fetal ilium is a smooth continuous form with few or no landmarks. These characteristics make a classic Procrustes analysis unreliable. Summary forms need another type of morphometric study, which overcomes reference points. For cases where landmarks are difficult to obtain, outline analysis is the preferred option for analyzing shape. Elliptic Fourier analysis (EFA) used in this study is Fourier series for closed outlines. EFA is a Fourier method that interpolates the outline to get a large number of points. Many shapes can be described by the amplitudes of only few first harmonics. This method has been tested extensively in the literature. It has its applications in many fields, like biology, paleobiology, palaeontology, zoology, and biological anthropology, with different methods such as harmonic coefficients or amplitudes. Data agree that there are no significant differences between Fourier analysis and analyzes using landmarks for simple shapes, or shapes with reproducible point references. This study is the first to apply outline analysis using Elliptic Fourier analysis on shapes derived from immature remains. 3D was used because of its better accuracy in outline description, with homogenous age and sex groups. Even if a description was possible for the different anatomic regions of the ilium by the step-by-step reconstructions, there was no difference between sex groups demonstrated by these methods on the population. The intraobserver variability has been tested and was less than 5%, highlighting good reproducibility of the outline delimitation.

The question of the fetal sexual dimorphism is quite difficult to resolve. In immature bones, the relationship with age and the difficulty to use reproductive homologous points are factors of limitation of the geometric morphometric studies like Procrustes or eigenshape analysis. Furthermore, the small size of age and sex group and the possible poorly

marked dimorphism need more investigation, with larger samples in order to assess the absence of a sexual dimorphism.

Outline Analysis, Sexual Dimorphism, Ilium

H14 Morphometric Comparison of Nasal Aperture Shapes Among Modern South Africans

Jennifer L. McDowell, BSc, University of Pretoria, Department of Anatomy, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; Ericka N. L'Abbe, PhD, University of Pretoria, Department of Anatomy, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; and Michael W. Kenyhercz, MS, 6327 Catawba Drive, Canfield, OH 44406*

After attending this presentation, attendees will learn of the variation in mid-facial characteristics of African, European and Colored South Africans and to understand the statistical framework used to describe similarities and/or differences within and among these groups.

This presentation will impact the forensic science community by contributing to the knowledge base of human variation within a modern South African population, in providing a more scientific evaluation of this variation, and in presenting a mathematical approach to the classification of ancestral groups.

With more than 49 million people of various social identities, languages and belief systems, South Africa is an ideal country to evaluate human variation and the statistical relationship between social identity and biological characteristics. Because patterns of variation within and between populations are shaped by culture, language, geography, and secular change; it is necessary to define the effect these parameters may have on the reliability and accuracy of the commonly used methods for estimating ancestry as well as sex, stature and age-at-death. With a large database of population groups, FORDISC 3 has addressed problems regarding osteometric differences among populations. Mid-face and nasal bone morphology has been shown to be the most accurate region of the cranium to sort population groups in North American (Hefner) and South African samples (L'Abbé et al.).[1,2]

The purpose of this study was to assess variation in nasal bone structure, interorbital breadth and nasal shape, among African, European and Colored South Africans using elliptical Fourier analysis (EFA), geometric morphometrics (GM) and traditional linear measures through discriminant function analysis (DFA). Colored refers to a heterogeneous group of people in South Africa who are defined socially and geographically (Adhikari).[3]

A total of 310 crania of African, European, and Colored South Africans (165 males; 145 females) from the Pretoria Bone, Raymond A. Dart and Kirsten skeletal research collections in South Africa were used. All crania were photographed in the Frankfort plane, at a distance of 46 cm, using an Olympus 305 digital camera. Standard landmarks, which include subspinale, inferior point of nasal borders, alare, nasale inferius, dacryon, nasal superius, nasion and glabella, along with three nasal arcs were digitized using a MicroScribe G2. Inter- and intra-observer error was evaluated.

Geometric Morphometric (GM) analyzes including Procrustes fit (generating Procrustes Coordinates) and Elliptical Fourier analysis (EFA) were used to obtain shape variables. These variables as well as linear measures were imported into FORDISC 3.1 for linear discriminant function analysis (DFA). Statistical significance was assessed within and between ancestral groups. Each group was tested for normality and each was proven to be normally distributed. Outliers were identified through boxplots.

For all linear measurements, statistically significant differences between the sexes were observed in each ancestral group. But, these size differences did not affect classification of these groups. Mahalanobis distance was used to test the statistical significance between each ancestral mean for all variables. DFA with linear measures demonstrated a statistical significance among all groups, except for blacks and Coloreds which were metrically indistinct (*p-value*=0.062). However when size was removed, nasal aperture shapes were statistically different between these two groups. For osteometric and shape analyzes of the nasal aperture, European and African South Africans as well as European and Colored South Africans were significantly different (*p-value* < 0.01). Inter- and intra-observer agreement was high (0.7 and 0.8, respectively).

The differences observed between these groups may be used as a tool for estimating ancestry, especially with separating European and other South African groups. Colored groups were more likely to misclassify as Africans than Europeans, which may reflect the heterogeneous nature of the group and the history of the country. In evaluating and defining the nasal aperture, shape does provide more ancestral information than size.

To approach the evaluation of ancestry from unknown skeletal remains, the relationship between social and biological race has to be examined, understood and continually evaluated on modern groups. Large databases are needed and an understanding of the cultural history of the population is crucial for the interpretation of these differences.

Ancestry Estimation, Geometric Morphometrics, Discriminant Function Analysis

H15 Estimation of the Postmortem Interval of Human Remains in a Subtropical Humid Environment Using Accumulated Degree-Days and Total Body Scoring

Steve A. Noser, BS, Box 2296, Huntsville, TX 77341; Ashleigh Gallaway, BS*, Montgomery County Sheriff's Office, 95 Wood Manor, The Woodlands, TX 77381; Kevin R. Derr, 16410 Locke Haven, Houston, TX 77059; Joe Trevino III, 2401 Montgomery Road, Apartment B 109, Huntsville, TX 77340; and Joan A. Bytheway, PhD, Sam Houston State University, Box 2296, Huntsville, TX 77341-2296*

After attending this presentation, attendees will understand the utilization of the total body score (TBS) and accumulated degree days (ADD) to quantitatively estimate the postmortem interval (PMI) in a subtropical, humid environment. This presentation will show the accuracy of the TBS-ADD method to estimate PMI from experimental field studies using human subjects of known date of death and recovery and known postmortem interval.

This presentation will impact the forensic science community by revealing the variability in decomposition scoring on four subjects in two environmentally different settings. The presentation will also impact the forensic science community by showing the accuracy of the TBS-ADD method for estimating PMI based on data from experimental field studies using a controlled sample of human cadavers of a known postmortem interval. It will also show that the method is region-specific and equations must be tailored to each particular environment.

Most forensic taphonomy studies involving postmortem interval data are derived from research conducted in temperate and arid climates and has been qualitative in nature. More limited research has been conducted in the cold weather climate of Edmonton, Alberta (Komar, Weitzel).[1,2] This postmortem interval data has been applied to interpret the rate of decomposition in climates in the US and abroad that are environmentally distinct.

Although qualitative studies have been very useful, there are more recent studies that utilize quantitative data (Megyesi, et al., Adlam and Simmons).[3,4] The Megyesi and colleagues' pilot study claims "80% of the observed variation in human decomposition could be accounted for by the combination of elapsed time and temperature as it is reflected in accumulated degree-days (ADD)" (Megyesi et al.), therefore a more accurate assessment of PMI can be obtained quantitatively.[3] However, Megyesi et al.'s study was based on assessment of PMI from case photos and not from a known sample.

The Southeast Texas Applied Forensic Science Facility (STAFS) at Sam Houston State University is a human decomposition facility located in a subtropical, humid climate zone similar to climates of Louisiana, Mississippi, Alabama, Georgia, most of Florida, South Carolina, and portions of North Carolina.

Human cadavers were used in experimental field studies using TBS during the human decomposition process and ADD to estimate postmortem interval in a subtropical, humid climate.

Four unclothed male subjects of similar weight and age were placed in the outdoor research facility in the summer of 2011. All individuals were placed in a supine position and cages made of a wood frame and galvanized mesh hardware cloth were placed over them. Two individuals were placed in direct sunlight and two were placed in a shaded area. Photographs of each body region were taken daily as well as gross observation descriptors of the human decomposition process. The descriptions previously established for the various stages of the human decomposition process in temperate (Bass) and arid climates (Galloway) were revised to coincide to the process seen in the subtropical, humid environment of southeast Texas.[5,6] Variability in decomposition scoring was also noted. Daily recording of temperatures were also recorded.

Initial results show that there are deviations from and similarities to the human decomposition process recorded for temperate, arid, and cold weather environments.

Human decomposition descriptions were adjusted to correspond to gross observations seen in the subtropical humid environment. For example, desiccation of tissue was moved to early decomposition. Also, as a result of desiccation throughout the body tissue, including the abdominal tissue, bloating is prolonged well into advanced decomposition and therefore the descriptors for advanced decomposition in determining TBS were adjusted.

Subjects placed in the sun reached bloat (TBS 9-11) approximately two to three days after placement, which corresponded to an ADD of 57-88 (C). Subjects placed in the shade reached bloat (TBS 9-11) approximately four to six days after placement, which corresponded to an ADD of 124-189 (C). Megyesi, et al. record bone exposure of the face occurring at a TBS between 14-26.[3] In the present study, no subjects with a TBS between 14-26 had bone exposure of the face.

With these and other distinct differences, the equation designed by Megyesi et al. was adjusted to align with the subtropical humid environment of southeast Texas.[3] This study confirms that the use of the TBS-ADD equation designed by Megyesi et al. to determine postmortem interval must be tailored to fit various types of environments.[3]

Postmortem Interval, Human Decomposition, Total Body Score

H16 Decomposition Pattern and Rate in Hanging Pigs

Tal Simmons, PhD, School of Forensic & Investigative Sciences, University of Central Lancashire, Preston, Lancashire PR1 2HE, UNITED KINGDOM; and Jeanne Lynch-Aird, BSc, The Old Forge, Burnt House Lane, Battisford, Suffolk IP14 2ND, UNITED KINGDOM*

After attending this presentation, attendees will understand the major differences in the decomposition patterns and rates between hanging pigs and those decomposing on the ground.

The presentation will impact the forensic science community by adding to the knowledge concerning decomposition in hanging bodies carried out under controlled conditions and by providing a scale analogous with Megyesi, et al. for scoring hanging bodies which, combined with accumulated degree days (ADD), will allow for the calculation of time-since-death.[1]

Establishing the postmortem interval (PMI) is an essential part of any death investigation. Critical to establishing PMI is an understanding of the process of decomposition. Using decomposition scoring and ADD, the PMI can be calculated for bodies. The scoring tables currently used have been prepared from bodies lying in contact with a surface. There is little data for the decomposition pattern in hanging bodies[2] and previously there has been no scale for scoring hanging bodies that compares with the total body score (TBS) scale introduced by Megyesi, et al. [1]

The findings of a decomposition study carried out under controlled conditions at TRACES (Taphonomic Research in Anthropology: Centre for Experimental Study), University of Central Lancashire, United Kingdom will be presented. Twenty freshly killed pigs (*Sus scrofa*) of the same age and weighing between 19.5kg and 57.0kg were used as human analogues. Ten pigs were hung by the neck using nylon rope attached to hooks hung from an A-frame of scaffolding poles. The animals were between 60 and 90cm distance apart with their hind feet approximately 100cm off the ground at the start of the experiment. To protect the pigs from vertebrate and avian scavengers, the A-frame was surrounded at the bottom with chicken wire to a height of 60cm above ground, and bird netting was stretched over the whole frame. A further ten control pigs were placed on the ground and covered with chicken wire cages to protect them from scavengers.

The pigs were observed and the pattern of decomposition recorded and photographed for head and neck, torso, and limbs at approximately 50 ADD intervals until 932 ADD (the end of the study period). Continuously recording data loggers, set to take temperature readings at six-hourly intervals, were used to measure the ambient and internal temperatures. Total Body Score (TBS) score was assigned to the control pigs at each visit using the existing Megyesi, et al. scale.[1] The hanging pigs were weighed at seven and eight day intervals throughout the experiment to compare the percentage body weight loss between the males and females.

As the TBS system was constructed using bodies in contact with the ground and not hanging, a new scale for hanging bodies analogous with Megyesi et al.'s was constructed using the observations and photographs from the study. This enabled the assigning of a Total Hanging Body Score (THBS) to each of the hanging pigs, and allowed a direct comparison to be made with the control pigs when looking at rates of decomposition as a function of ADD.

In the control animals the pattern of decomposition showed no differences between the sexes. For the hanging pigs; however, the post

bloat body shape was markedly different for males and females. Females retained an equally swollen rectangular shape throughout the length of the torso with an evenly swollen profile. Swelling in the males centered around the mid-torso being at its greatest width around the umbilicus and penis.

As decomposition progressed, the hanging males and females displayed differences in the expanded anal opening. Initially in both sexes the anus opened to a diameter of approximately 10cm. In the males the back of the scrotal sack subsequently "gave way" and merged with the perforated anus producing a large clear hole directly below the hanging pig from which the bones dropped. The females remained swollen for longer with a pouch of stretched skin forming below and to the front of the anal opening.

While there initially appeared to be differences in the rates of decomposition between the sexes in the hanging pigs these are not statistically significant.

The new scale for hanging bodies will be presented together with photographs of the differing decomposition patterns.

Hanging, Decomposition, Score

H17 An Evaluation of the Use of Modern Medical Imaging Techniques for the Estimation of Human Stature

Rachael Walls, MSc, Cranfield University, DEAS, Shrivenham, Wiltshire , UNITED KINGDOM; Mark D. Viner, MSc, Inforce Foundation, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham, SN6 8LA, UNITED KINGDOM; Gerald J. Conlogue, MHS, Quinnipiac University, Diagnostic Imaging Program, 275 Mount Carmel Avenue, Hamden, CT 06518; and Tania Blyth, MHS, Quinnipiac University, 275 Mount Carmel Avenue, N1-HSC, Hamden, CT 06518*

After attending this presentation, attendees will be aware of the range of imaging techniques that may be used as alternatives to direct physical measurement of skeletal elements. They will understand the relative advantages and disadvantages and levels of accuracy of computed tomography (CT) Scanning and Computed Radiography (CR) and their suitability for deployment.

This presentation will impact the forensic science community by increasing awareness of alternative non-invasive methods of measuring skeletal elements for the estimation of human stature.

The acquisition of direct anthropological measurements from human remains can sometimes involve the removal of flesh. This practice raises many ethical, cultural, and religious issues, and, in the United Kingdom, is in conflict with the recommendations of the Clarke enquiry. The process is also time-consuming and involves the manual handling of biological material. Radiography has long been an alternative, non-invasive method of obtaining measurements from fleshed remains, but has traditionally been a very time consuming process requiring correction for magnification. However, the advent of modern digital imaging techniques appears to offer more efficient methods of gathering anthropological data non-invasively.

This paper will present the findings of a study that aimed to evaluate the viability of two modern imaging methods; Multi-Detector Computed Tomography (MDCT) Scanning and Computed Radiography (CR) for the measurement of long bones to aid human identification.

Twenty hind pig legs were examined using both MDCT and CR and three measurements (length, breadth, and diameter) were taken from the femora, tibiae and fibulae of each leg. Following de-fleshing by dissection and maceration, each measurement was repeated using an osteometric board.

The results showed that measurements taken from CT scan images were as accurate as direct osteometric measurements, and measurements taken from CR images were affected by magnification proportional to the distance of the body part from the image receptor.

The results from this study suggest that the effect of magnification on measurement data from digital radiography is significant enough to alter any resulting stature estimates and should be corrected for. However, the process of examination and measurement from Computed Radiography is rapid and the technology is far more widely available to investigators than CT scanning and can be deployed easily in field situations. It is recommended that an accurate and reproducible magnification correction method for use at various object to film distances should be developed for CR technologies.

It is recommended that CT should be used as the method of choice for taking osteometric measurements from fleshed remains. However, where this is not possible digital radiography is an acceptable alternative, provided that the magnification can be accurately corrected for.

Stature Estimation, Radiography, CT Scanning

H18 Determination of Sex from 2nd to 4th Digit Ratios of the Hand

Christopher K. Barrett, PhD, Western Carolina University, Department of Anthropology and Sociology, 101 McKee Building, Cullowhee, NC 28723; and D. Troy Case, PhD, North Carolina State University, Department of Sociology and Anthropology, 230 1911, Campus Box 8107, Raleigh, NC 27695*

After attending this presentation, attendees will be familiar with the developmental basis for differences in 2nd and 4th digit ratios of the hand between males and females and the practical application of this knowledge to the determination of sex from skeletal remains.

This presentation will impact the forensic science community by demonstrating that, despite its initial promise, the 2nd to 4th digit ratio does not appear to be an accurate method for determining sex from hand bones. The results of this discriminant function analysis suggest that total length of the 2nd and 4th digits or a combination of phalanx lengths provide a more accurate means for determining sex.

The ratio between the length of the 2nd digit (index finger) and 4th digit (ring finger) is strongly influenced by fetal testosterone in utero and has been shown to vary significantly between males and females (Manning et al.; Manning).[1,2] In general, males are expected to exhibit a lower 2D:4D ratio (ring finger longer than index finger) while females exhibit a ratio closer to 1.00 (ring finger and index finger of identical length). Garn has shown that this ratio is fixed by the 14th gestational week, suggesting that 2D:4D may be appropriate as a factor to differentiate males and females using skeletal remains.[3]

For this study the utility of finger length, phalanx lengths, and 2D:4D ratios for discriminating between males and females in a population of 342 adult individuals (171 Females, 171 Males) from the Terry collection are tested. All individuals were classified as "White." Metacarpals and phalanges were measured using a mini-osteometric board from Paleo-Tech Concepts to the closest hundredth of a millimeter. Statistical tests were made using PASW Statistics (SPSS) version 18 for the Windows 7 operating system. Fingers missing bones were dropped from the analysis, as were outliers that failed a Grubb's Test. A D'Agostino-Pearson K^2 omnibus test was used to evaluate whether measurement distributions were normally distributed.

Significant differences existed between 2D:4D ratios of males and females for the right and left hands (One-Way ANOVA: right: F=8.767, p-*value*=0.003; left: F=18.424, p-*value*=0.000). Three Discriminant Functions were used to evaluate the ability of measures to differentiate

males and females. The sum of phalanx lengths for the 2nd and 4th digits yielded a correct classification rate of 81.2% for the right hand and 85.3% for the left hand. A step-wise discriminant function analysis of phalanx length was also conducted for right and left elements independently. Length of the distal 2nd phalanx and medial and distal 4th phalanges yielded a correct classification rate of 84.3% for the right hand. For the left hand the medial and distal 4th phalanges correctly classified 82.8% of individuals. Contrary to the initial expectations, 2D:4D ratio correctly classified only 58.1% of individuals for the right hand and only 58.8% for the left hand.

These results show that despite the ability of the finger bones to differentiate males and females with a reasonable degree of accuracy (> 80%), digit ratio, at least as measured from hard tissue, does not. This may be due to several factors. The racial category "White" used by the Terry collection may obscure important differences between sub-populations from the European continent. In addition, the historic nature of the Terry collection may mean that its individuals exhibit more "feminized" digit ratios (males and females differed by only about 1%) due to developmental, health, and nutritional dissimilarities with current populations. Further work is needed to determine if these conclusions are applicable to other population groups.

Sex Determination, Digit Ratios, Discriminant Function Analysis

H19 Sex Determination: A Study of Sexual Dimorphism in Complete and Fragmentary Cuneiform Bones

Amber Y. Schmuhl, BS, Middle Tennessee State University, 1301 East Main Street, Murfreesboro, TN 37132; and Hugh E. Berryman, PhD, Department of Sociology & Anthropology, Middle Tennessee State University, Box 89, Murfreesboro, TN 37132*

After attending this presentation, attendees will understand how to use the cuneiform bones to aid in the estimation of sex in unknown individuals.

This presentation will impact the forensic science community by showing new measurements which will aid in the identification of sex in fragmented remains.

Accurate sex estimation is a necessary step in the identification process and sexing techniques that can be applied to all bones is advantageous. Since the 1970's, metric sexing techniques have been applied to the talus and calcaneus more than any other tarsal bone. Steele was one of the first researchers to examine sexual dimorphism of the talus and calcaneus.[1]

Other researchers including Barrett et al, Bidmos and Asala, Bidmos and Dayal, Gualdi-Russo, Murphy, and Wilbur repeated Steele's research and confirmed that the talus and calcaneus are useful in determining sex with accuracies as high as 96%.[2-10] These researchers not only verify that the talus and calcaneus are sexually dimorphic, but that the accuracy rates are repeatable and the techniques can be applied to different populations from the past and the present. Other than the talus and calcaneus, little research has investigated the utility of other tarsal bones, particularly the smaller bones of the foot, for their potential in estimating sex. In addition, most of these studies require the tarsal bones to be in good condition and that most, if not all, of the bone is present. Kidd and Oxnard added the navicular and the cuboid to their study of the talus and calcaneus, but failed to include the three cuneiforms.[11] Sheena Harris, using The William M. Bass Skeletal Collection and a mini-osteometric board, measured the maximum length, width, and height of all seven tarsal bones.[12] However, her measurements required the bones to be complete.

The present study examined cuneiform bones from 100 adult individuals (50 male and 50 female) including both Blacks and Whites from the William M. Bass Skeletal Collection for their potential in sex determination. This study not only examines the typical "maximum" measurements from complete cuneiform bones, but also devises new measurements that divides the bone into smaller segments (e.g., measurements involving articular surfaces and tubercles). Using a digital sliding caliper, this study examines eight new measurements each from the medial cuneiform, the intermediate cuneiform, and the lateral cuneiform. Previous researchers (Wilbur; Barrett et al, Bidmos and Asala), have shown that there is no significant difference between the right and left foot and therefore, only tarsals from the left side are used in this study.[10,2-4]

To test the accuracy of the new measurements, the data in this study was analyzed by importing all measurements into FORDISC 3.0 (Ousley and Jantz) and applying discriminant function analysis.[13] The results were positive and showed that not only were Harris' maximum measurements repeatable, but including smaller dimensions of the bones can be equally useful in determining sex. When all measurements are taken into account, the medial cuneiform was shown to exhibit the most dimorphism of the three with an accuracy rate of 94.2%, followed by the lateral cuneiform at 86.7%, and then the intermediate cuneiform at 84.7%. While some accuracies of the measurements fell below 75.0% when taken individually, the accuracy rate raised above 75.0% if they were combined with at least one other measurement. Three measurements (one from the medial cuneiform and two from the intermediate cuneiform) were excluded due to the fact that they were not useful in sex determination. When these measurements were excluded, the overall accuracy for the intermediate cuneiform increased from 84.7% to 88.3% while the medial cuneiform's accuracy decreased by 0.1%. This study has shown that while the cuneiforms are smaller and more difficult to side than other bones, they can be equally useful in the determination of sex. In addition, the use of new measurements developed for this study allows incomplete or fragmentary cuneiform bones to be used to determine sex.

Sexual Dimorphism, Tarsals, Sex Determination

H20 Analysis of Recovery Korean War Remains

Shin Han Park, BA, Ministry of National Defense Agency of Killed In Action Recovery and Identification, 65 Hyeon Chung-Ro, Donggak-Dong, Donggak-Gu, Seoul, KOREA; and Yu Ryang Jang, Korea Ministry of National Defense, 65 Hyeonchung-Ro Donggak-Dong Donggak-Gu, Seoul, 156-080, KOREA*

After attending this presentation, attendees will learn how the Korean War, an international conflict that occurred between 1950 and 1953, has important implications for the development of forensic sciences in South Korea. It is estimated that approximately 137,000 Korean soldiers were killed during the Korean War. MAKRI takes a leading role in the identification of Korean soldiers. Here we present our preliminary results of the analysis of 2,470 Korean KIA remains recovered between 2009 and 2010 are presented.

This presentation will impact the forensic science community by combining all the above, the Korean War KIA were mostly 17 – 25 year olds and 160 – 170 cm tall. The "Asian" characteristic of shovel-shaped teeth, cranial ossicles, and linear enamel hypoplasia were the most observed non-metrical and pathological characteristics observed. The majority of observed trauma included gunshot and projectile wounds. Recovered Korean War remains sustained 60 years of taphonomic processes causing poor preservation, meaning that many of the specimens were unable to go through the forensic anthropological identification process. Eighteen cases (0.73%; n=2,470) were identified through material evidence, testimonies, and DNA. Approximately 3,000 KIA remains are stored since they are not identified due to a lack of personal (antemortem) information. Further international collaborative research is necessary to help expand and further elaborate on these initial findings.

Forensic science is a relatively new discipline in Korea that is currently being influenced by the more established research organizations found in the Western Europe and North America. In 2007, with government support, the Republic of Korea Ministry of National Defense (ROK MND) established the MND Agency for Killed in Action Recovery and Identification (MAKRI) research organization. MAKRI is a forensic sciences research organization whose main goal is the identification of recovered killed-in-action (KIA) Korean soldiers using standard theoretical and methodological research approaches in the international forensic sciences, particularly forensic anthropology.

Of the remains available, those in a good state of preservation were selected for creating a biological profile, including data on sex, age, stature, trauma, and non-metric traits. It was possible to estimate stature based on the long bones using 19.1% (471) of cases; 38.4% ranged between 160.1 – 165.0 cm and 38.2% ranged between 165.1 – 170.0cm. Age could be estimated in 44.6% of cases and the majority of ages ranged from 17- 25 years (86%). Sex could be accurately determined in 55.6 % of cases with 49.1% being male, and 50.8% containing masculine characteristics. Non-metric traits were documented from whole crania (15% of cases, 371 skulls). Ten percent had cranial suture ossicles, and 9.2% had a metopic suture. Approximately 10% of cases had intact teeth and 89.0% had shovel-shaped incisors. Enamel hypoplasia was highest in specimens with pathology (80%). Five percent of the subjects had observable trauma, of which 26.6% exhibited gunshot wounds and 72.4% projectile wounds. Approximately 63% of the gunshot wounds were observed in the cranium and 36.4 % were observed in the extremities.

MAKRI, Korean War, Recovery Remains

H21 Anthropology and the AAFS: A Significant Impact in Its First 40 Years

Michael Finnegan, PhD, Kansas State University Osteology Lab, 204 Waters Hall, Manhattan, KS 66506*

After attending this presentation, the attendees will understand the origin of the Physical Anthropology (PA) Section of the AAFS, its significant growth, and patterns of its demographic evolution. Attendees will also learn of the impact that the Section has had in the Academy's annual programs.

This presentation will impact the forensic science community by showing the significant growth of the field and the increase of forensic anthropologists available to pursue identification of primarily skeletal remains.

Excellent accounts of the origins of the Physical Anthropology Section are available in Snow, Ubelaker and Scammell and Rhine.[1-3] Origins generally reflect the state of osteological identification at the time. Of the original 14 members, there were 11 PhDs and 3 MAs; 11 males and 3 females; the East was most heavily represented, followed by the Rocky Mountain region. More importantly, they were bright, broad based but focused, moderately assertive, and enjoyed the fruits of research and the dissemination of knowledge. All but two were, or would work in, academics and all but two continued as productive members of the Section. The section experienced a rapid growth: at the end of its first decade it numbered 66; by 1992 it had climbed to 159; the following decade to 245; and currently there are 406 individuals spread over eight membership categories. It is believed that the Physical Anthropology Section has grown faster than any other section during the past 40 years. Based on the AAFS Membership Matrix presented at the Chicago meeting, the PA Section is currently composed of 45 Applicants, 80 Associate Members, 90 Fellows, 47 Members, 9 Retired Fellows, 1 Retired Member, 121 Student Affiliates, and 13 Trainee Affiliates for a total of 406 individuals. The sex ratio is 33% males and 67% females.

More importantly, the PA section has been a leader in the presentation of scientific papers. The Connective Tissue has chronicled the PA section relative to other AAFS sections seven times since 1994. The most recent Academy profile (Table 1) presents the data from the Chicago meeting in 2011 and is generally indicative of earlier years.

	N	PP	MM	R_1	PP_2	R_2	%MP	R/M
Criminalistics	2845	(207)	41.2	1	27.3	1	7.3	10
Path/Bio	935	(136)	13.5	2	17.9	2	14.5	5
General	847	(54)	12.3	3	7.1	4	6.4	11
Toxicology	526	(52)	7.6	4	6.9	5	9.9	9
Odontology	446	(50)	6.5	5	6.6	6	11.2	8
Phys. Anth	406	(102)	6.7	6	13.5	3	25.1	1
Qu. Doc	212	(27)	3.1	7	3.4	9	12.7	7
Jurisprudence	210	(47)	3.0	8	3.6	8	22.4	3
Engineering	174	(24)	2.4	9	3.2	10	13.8	6
Psychiatry	152	(36)	2.2	10	4.8	7	23.7	2
DMS	106	(21)	1.5	11	2.8	11	19.8	4
Total	6919	(758)	100.00					

Table 1. Summary statistics of interest to our section, 2011.
N = section size in rank order;
PP = number of papers presented by members of that section;
MM = percent of members within Academy;
R_1 = rank order of membership in the Academy;
PP_2 = percent of total presented papers from that section;
R_2 = rank order of percent of total papers from that section;
%MP = % of members presenting papers from each section;
R/M = rank order of members presenting papers by Academy section

For being 6th in size, the PA Section has shown to be the most productive in scholarly presentation at any of the recent Annual Meetings! To put this in perspective, the members of the Criminalistics Section presented 27.3% of all papers at the Chicago Meeting, but they comprise 41.2% of the Academy membership. The Pathology/Biology Section presented 17.9% of all papers at the Chicago Meeting and they comprise 13.5% of the Academy Membership; a rather balanced presentation production. The Physical Anthropology Section, presented 13.5% of the

papers presented at the Chicago Meeting while holding only 6.7% of the Academy membership. As in the past few years, the members of the Criminalistics Section presented a lower relative percentage of papers; the members of the Pathology/Biology Section presented papers commensurate with their size in the Academy, and members of the Physical Anthropology Section appear to be more industrious in presenting their scholarly work at the annual meetings. There are excellent reasons for this distribution of data: the criminalists have a large number of individuals doing the applied work and may have less time for research or case presentation, while the anthropologists, mostly university faculty and graduate students, are expected to have a commitment to research and the dissemination of knowledge which are necessary for professional promotion and salary increases. The Central Identification Laboratory also maintains a high level of research and scholarly activity despite a significant level of deployment for Search and Recovery missions and subsequent identifications.

Student, Trainee Affiliate, and Members have been very competitive in applying for and receiving considerable, significant grant monies from within the section, within the AAFS and external sources. As well, numerous student presenters have received the J. Lawrence Angel Award, and 28 members or colleagues have received the T. Dale Stewart Section Award, three members have been named as Distinguished Fellows, and one has been the recipient of the International Adelaide Award.

It will be very interesting to watch the continuing evolution of the Physical Anthropology Section over the next ten years. Changes that currently reside in the Anthropology Scientific Working Group and the Executive and Legislative branches of our government will provide continued excitement for both the near and long range future of the Academy's Physical Anthropology Section.

Section History, Growth, Impact on AAFS Program

H22 Further Femmes Fatales: Do Women Dominate Forensic Anthropology Professional Practice in the United States, Canada, and the United Kingdom?

Anna Williams, PhD, Cranfield University, Defense Academy of the United Kingdom, Shrivenham, Wiltshire SN6 8LA, UNITED KINGDOM; Joan E. Baker, PhD, Defense Prisoner of War/Missing Personnel Office, 2600 Defense Pentagon, Washington, DC 20301-2600; and John A. Williams, PhD, Western Carolina University, Department of Anthropology & Sociology, 101 McKee Hall, Cullowhee, NC 28723*

After attending this presentation, attendees will gain awareness of the phenomenon that women outnumber men in forensic anthropology professional practice. It is anticipated that many attendees will have seen last year's presentation on this trend in the United Kingdom, and therefore will obtain more in-depth appreciation into whether this trend is reflected in the United States and Canada. Attendees will be able to compare gender distribution, motivations, career pathways and career progression in North America versus the United Kingdom.

This presentation will impact the forensic science community by presenting additional research that extends the investigation into professional practice and competence, allowing an overview of the uneven gender distribution that exists today. The composition of the forensic anthropology community has implications for deployment opportunities around the world, career progression, and acceptance of the discipline by male-dominated institutions such as police and law enforcement agencies.

This research extends that presented at the 2011 AAFS conference (Williams),[1] which examined the fact that more consistently women than men enroll in forensic anthropology university courses in the United Kingdom. The present study aims to determine whether this trend in education is reflected in professional practice and membership of professional forensic anthropology-related associations in the United States, Canada, and the United Kingdom, and to elucidate reasons for this trend.

Gender distribution statistics for forensic anthropology professionals were gathered via two mechanisms. Member details from the main professional Forensic Anthropology associations in the United States, Canada, and the United Kingdom for the last decade were collated, including the Physical Anthropology Section of the AAFS, the Forensic Anthropology section of the International Association for Identification (IAI), the British Association of Forensic Anthropologists (BAFA) and others. Questionnaires were also circulated to Forensic Anthropologists employed at leading universities, forensic laboratories, museums, and professional institutions, in order to determine the gender distribution of professionals, and to record their motivations for entering the discipline, career ascent and pathways, and persistence in career.

Preliminary results suggest that greater numbers of women than ever before are applying for forensic anthropology professional positions and membership to professional associations. Female membership of the AAFS Physical Anthropology section has risen by 11% over the last 10 years. However, the apparent saturation of women at lower levels is not translated vertically, and the distribution of women in the higher echelons of the discipline has not yet reached equilibrium with men. The number of female Diplomates of the ABFA has risen to 35%, and has remained relatively constant over the last 10 years, a trend which is projected to continue, but this is not representative of the distribution of women throughout the educational system. This research aims to raise questions as well as answer them, and to determine why there is this saturation at lower levels, without equality of progression. Is it simply a matter of time? Are female forensic anthropologists reluctant to apply for more senior positions, or are men better at securing the more senior positions? Is the discipline still dominated by men from the early growth years of the discipline? Are the competency tests giving equal opportunity to both genders?

This research is the first trans-Atlantic study to examine the apparently global profusion of women in forensic anthropology, and to elucidate reasons for the lack of gender parity at all levels of the discipline. This has important implications for the future of professional practice, membership of professional organizations, and higher education in the discipline.

Forensic Anthropology, Professional Practice, Gender

H23 Forensic Anthropology Fellowship Training Model

Deborrah C. Pinto, PhD, 208 Hollyberry Trail, Toronto, ON M2H 2P4, CANADA; and Jennifer C. Love, PhD, Sharon M. Derrick, PhD, and Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will learn a model for a forensic anthropology fellowship training program and to discuss potential funding sources.

This presentation will impact the forensic science community by raising awareness of the insufficiency of the current on-the-job training model practiced in the field of forensic anthropology and the advantages of a formal training program modeled after the American College of Graduate Medical Education Forensic Pathology Fellowship Program.

Few opportunities for formal post-graduate training in forensic anthropology exist. Although doctoral programs in physical/forensic anthropology are well suited for teaching the fundamentals of the field, necessary analytical skills are best obtained through casework. Medical examiner offices with in-house Diplomat of the American Board of Forensic Anthropology (D-ABFA) should develop formal training programs for emerging forensic anthropologists that involve them in diverse casework.

The American College of Graduate Medical Education (ACGME) Forensic Pathology Fellowship Program provides an excellent training model for the field of forensic anthropology. The program is a minimum of 12 months and requires the fellow to perform 200 - 300 autopsies under the supervision of a practicing forensic pathologist. The program also encourages the fellow to participate in crime scene investigation and court proceedings. The fellow must keep a log of his experiences, including: autopsies, external examinations, crime scene visits, and opportunities to observe or provide court testimony. The program requires objective assessment of fellow competence by multiple evaluators and to provide each fellow with documented semiannual evaluation of performance with feedback. ACGME requires the faculty to include a board certified forensic pathologist.

The Harris County Institute of Forensic Sciences (HCIFS) Forensic Anthropology Division created a Forensic Anthropology Fellowship Program following the ACGME model. A recent doctoral graduate from a physical anthropology program was hired. The fellow was assigned a diverse caseload and was responsible for the processing, analyzing and report writing of each case. Each case was supervised by a forensic anthropologist and each report was co-signed by the fellow and supervising anthropologist. In addition to the casework, the fellow was required to conduct a research project and to present the findings at a national scientific meeting. The program was funded through the National Institution of Justice Paul Coverdell Forensic Science Improvement Grant Program. Funding was awarded for salary, including a standard benefit package, and registration fees and travel expenses for participation in the national scientific meeting. The salary rate was set following the National Institute of Health Salary Guidelines for Postdoctoral Scholars.

During the program, the HCIFS Forensic Anthropology Fellow completed nine biological profile analyzes, 83 trauma analyses, 23 scene recoveries, and 41 autopsy consultations. The fellow conducted research on the trauma pattern associated with the use of an automated cardiopulmonary resuscitation device and presented the results at the American Academy of Forensic Sciences Annual Scientific Meeting. The fellow also participated in pre-trial meetings with prosecutors and defense attorneys and observed court testimony presented by a forensic anthropologist and pathologist. She attended continuing education courses that included ethical training, advancements in decedent identification, pediatric trauma seminars and medicolegal death investigation. The fellow completed rotations in the investigation division and crime laboratory.

The current on-the-job training model used by the field of forensic anthropology should be replaced with a formal training model as described here. The American Board of Forensic Anthropology requires an applicant to have three years of experience after the receipt of a doctoral degree and to submit three case reports for review. With a formal training program, the three years of experience should be replaced with a year-long fellowship program. The proposed requirement ensures that the applicant is receiving training from a D-ABFA as opposed to possibly practicing without supervision until eligible for board certification.

Forensic Anthropology, Training, Fellowship Program

H24 Recent Activities of the Scientific Working Group for Forensic Anthropology (SWGANTH)

Thomas D. Holland, PhD, Department of Defense JPAC, Central ID Laboratory, 310 Worchester Avenue, Hickam AFB, HI 96853; and Angi M. Christensen, PhD, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will become familiar with the recent activities of the Scientific Working Group for Forensic Anthropology (SWGANTH).

This presentation will impact the forensic science community by raising awareness of the SWGANTH's work to establish, identify, and publish "Best Practices" within the forensic anthropology discipline.

In late 2007, the U.S. Department of Defense Central Identification Laboratory (DOD CIL) and the Federal Bureau of Investigation (FBI) Laboratory cosponsored the creation of the Scientific Working Group for Forensic Anthropology, or SWGANTH. With the formation, success, and continued effort of SWGANTH, Forensic Anthropology has demonstrated its dedication to the advancement of discipline practices, improving communication, and building consensus among forensic anthropology professionals and with forensic community partners.

SWGANTH's initial purposes were to identify best practice guidelines for the Forensic Anthropology discipline and to disseminate guidelines, studies, and other findings that may be of benefit to the forensic anthropological community. To achieve this goal, the group's 20-member Board, comprised of professionals representing a broad cross-section of expertise and jurisdictional involvement, created committees to address specific topics relevant to the practice of Forensic Anthropology. Each committee, populated by forensic anthropologists from the United States and around the world, is charged with researching, capturing, and distilling the current best practices for the topic addressed by that committee. In addition to the development of Bylaws and a Code of Ethics and Conduct, topic areas addressed by the SWGANTH to date include:

- [Individual] Qualifications
- [Forensic Anthropology] Laboratory Management and Quality Assurance
- Determination of Medicolegal Significance
- Sex Assessment
- Identifying and Describing Pathological Conditions, Lesions and Anomalies
- Facial Approximation
- Age Estimation
- Skeletal Sampling and Preparation
- Personal Identification
- Resolving Commingled Remains
- Stature Estimation
- Trauma Analysis
- Statistical Methods
- Ancestry Estimation
- Postmortem Interval
- Documentation, Reporting and Testifying
- Detection and Recovery

Most of these guidelines have already been approved and published, and the remaining committees are close to issuing their final recommendations. In addition, the SWGANTH recently created committees charged with developing a proficiency testing program for forensic anthropology laboratories, identifying basic components of forensic anthropology educational programs, identifying research needs in the field of forensic anthropology, and creating an audit checklist that will aid forensic anthropologists in evaluating their performance relative to the larger community. The SWGANTH has also arranged for these documents and recommendations to be translated into Spanish, French, Arabic, and Russian. These guidelines, recommendations, and other materials of interest are published on the publicly accessible website: *www.swganth.org*.

Several major developments that have occurred within the last year involve organizational changes to the structure and intent of the SWGANTH. First, the Board voted to expand the membership from 20 to

25 members. While logistical and administrative constraints argue for maintaining the Board's composition at or near 20 members, the group voted to add the International Committee of the Red Cross (ICRC) as a member of the SWGANTH, allowing the ICRC to participate as an organization and bring a broad international perspective to the group. Second, the group voted to enact term limits for Board members. Board members will now serve three-year terms beginning in 2011 and 2012. Third, the group voted to expand the purpose of SWGANTH to include the possibility of developing consensus Minimum Standards rather than being limited to identifying only Best Practices. Fourth, the group created a committee to examine the concept of Forensic Archaeology with an eye toward integrating this emerging sub-field into the larger Forensic Anthropology discipline.

Forensic Anthropology, SWGANTH, Best Practices

H25 Sexual Dimorphism in Crania and Humerus of Central Indian Population

Nasir M. Ahmad, MSc, and Ruma Purkait, PhD, Sagar University, Department of Anthropology, Dr. H.S. Gour Central University, Sagar, Madhya Pradesh 470003, INDIA*

After attending this presentation, attendees will understand new osteometric techniques devised for fragmentary bones for central Indian population for sexual dimorphism in crania and the humerus bone. Attendees will also gain knowledge regarding the parameters useful for sexual dimorphism in the fragmentary regions of crania and humeri.

This presentation will impact the forensic science community by devising measurements for fragmentary bones, which is the form bones generally arrive to forensic experts. India is a multi-ethnic country and area-specific equations should be applied. This is the first time that equations specific to the central Indian population are reported.

Each individual has a right to retain his or her identity, even after death. In cases of mass disaster or incidents of unnatural death where only skeletal remains of an individual are found, it is a tough task for the forensic anthropologist and the medicolegal personnel to complete identification. Therefore any data set or a statistical formula based on the particular population is vital to the investigator. One of the four main attributes of biological identity that a forensic anthropologist tries to establish is sex.

In India, skeletal remains are minimal, due to cultural practices related to disposal of dead bodies. The remains that require a medicolegal opinion are usually taken back either by relatives or by law enforcement personnel following the analysis. So the collections of known bones are very few. The remains used in this study are from the collection of the Department of Anatomy and Forensic Medicine of various medical colleges in central India. They belong to cases macerated in the medical college or cases whose identity has been established by experts. All the cases are from central India. The age and sex of skeletons are documented 173 (100 male and 73 female) crania and long bones included in the study were free of any orthopedic and pathological disorder.

All the measurements included in the study were taken following the methods prescribed by Martin and Saller (1957).[1] Few measurement are devised by the authors, keeping in mind the practical need where the forensic anthropologist is frequently confronted with fragmentary bones as compared to complete bones in criminal and disaster cases.

Sixteen cranial measurements and ten humeral measurements were taken. The data were subjected to discriminant function analysis with SPSS 16. The level of accuracy achieved for this population with a single variable ranged from 67.7% to 90.3% for the cranium and 77.5% to 98.4% for the humerus. The equations where applied on a test sample to check the efficacy of the parameters and gave nearly 90.0% and 95.0% sexing accuracy for the cranium and humerus, respectively.

The formulae generated from the present study can be used by the forensic anthropologist and the law enforcement agencies to diagnose sex of unknown bone of central Indian origin.

Forensic Anthropology, Osteometric Techniques, Mass Disaster

H26 Non-Metric Assessment of Ancestry through Cranial Macromorphoscopics: A Validation of the Hefner Method

Alexandra R. Klales, MS, 1133 Taylor Avenue, Apartment 7, Winnipeg, MB R3M 2K4, CANADA; and Michael W. Kenyhercz, MS, 6327 Catawba Drive, Canfield, OH 44406*

After attending this presentation, attendees will learn the reliability and the validity of the newly proposed Hefner (2009) method.

This presentation will impact the forensic science anthropology community by assessing the validity of this method for ancestry estimation in human crania and will allow attendees to evaluate the utility of the method when applied to forensic cases and assess the method's ability to meet the *Daubert* requirements.

Ancestry estimation is essential for the construction of biological profiles for unidentified individuals found in forensic contexts. The human skull has historically been considered the best indicator of ancestry and has been analyzed in a number of metric and non-metric studies. Arguably, metric assessment of population affinity is primarily done with FORDISC 3.0 (Ousley and Jantz); although, non-metric methods of ancestry estimation continue to be employed and taught, as they are the suggested methods presented in a number of introductory osteology and forensic anthropology textbooks (cf. Bass, Byers).[1-3] The benefits of non-metric methods are numerous including ease of use, no need for specialized equipment, and relatively quick data collection.

Hefner (2009) presented a new method of ancestry estimation by creating ordinal scores with descriptions and corresponding illustrations for a set of 11 macromorphoscopic traits commonly, or historically, applied to ancestry estimation in the crania. The frequency distribution of those traits was analyzed in four populations (African, American-Indian, European, and Asian). Ten of the eleven traits analyzed by Hefner were found to be significantly different between groups and, when analyzed within a statistical framework, can reliably predict ancestry with accuracy rates ranging from 84-93% depending on the method applied and variables used. Also in the original study, tests of observer error were found to be low, suggesting that this method can be accurately applied for ancestry estimation.

Since publication, the Hefner method has been applied and cited in a number of actual forensic cases and has been incorporated into Osteoware (Smithsonian Institution), a free program developed for data collection and storage. However, in order for the Hefner method to be reliably applied for the estimation of ancestry, independent tests of both the reliability and validity of the method must be conducted by alternative observers and in populations not previously studied for scientific rigor.

Two observers, with some previous familiarity with the Hefner method, scored a sample of 84 crania from the Hamann-Todd (HTH) Collection. Two ancestral groups were analyzed: American whites (20 female, 21 made) and American blacks (22 female, 21 male). All crania used in this study had no apparent pathological conditions and were complete enough to score at least 14 of the 16 traits (the 11 traits originally used by Hefner 2009 and five additional traits included in the Osteoware 2011 package).[4,5]

The data were analyzed through linear discriminant function to examine ancestral affiliations. The variables for each analysis were forward stepwise selected. Analysis of inter-observer error was also conducted using Cohen's Kappa (K). Initial results provided accuracy results considerably lower than those found by Hefner with correct cross validated, classifications of 52.4% for observer one and 54.8% for observer two.[4] The

Mahalanobis D^2 from WM and WF means were not significantly different, while the D^2 for BM and BF means were found to be significantly different in each of the observer's analyzes (*p-value* > 0.05). Intra-observer agreement was similarly lower than that found by Hefner.[4] Six of the traits had a moderate level of agreement (K=0.41–0.60), six traits showed a fair level of agreement (K=0.21–0.40), and four traits had only a slight level of agreement (K=0–0.20) based on Landis and Koch.[6]

Lower classification accuracies than those found by Hefner may be the result of less experience with the method and trait scores.[4] Additionally, some of the trait representations found in the HTH collection lacked corresponding descriptions and illustrations and were forced into the most similar score. Results from this study suggest that caution should be used when applying this method to samples other than the one with which it was created and suggest that this method may require extensive practical experience with the traits, scores and illustrations before being used for ancestry estimation.

Ancestry Estimation, Cranial Non-Metric Validation, Discriminant Function Analysis

H27 Using Metric Analysis to Investigate Ancestral Affinity of the Mandible

Beatrix Dudzik, MA, 3909 Briargate Avenue, Knoxville, TN 37919; and David Echeverry, BA, 2334 Jefferson Avenue, Knoxville, TN 37917*

After attending this presentation, attendees will gain an appreciation of the morphometric variation of the mandible of seven distinct geographic regions. Numerous studies have examined metric landmarks of the human skull to investigate geographic differences among human populations. However, most of the research has focused on the cranium, and far fewer studies have utilized the mandible to assess variation within human populations. Previous research has established that morphological differences of the mandible exist between sexes and ancestral groups. Berg (2006, 2011) has shown that discriminant function analysis of mandibular morphology is an accurate tool for classification of individuals (including sex and ancestry).[1,2] This study utilizes discriminant function analysis, and calculation of Mahalanobis distances to further assess morphological patterns in distinct populations.

This presentation will impact the physical anthropological and forensic community by identifying the morphological differences of the mandible in distinct populations. The purpose of this study is to test the hypothesis that metric analysis of the mandible can be used to interpret ancestral relationships and thus aid in the classification of unidentified individuals.

This paper assessed metric differences of the mandible between 1,259 modern individuals. The individuals represented seven geographic groups which consisted of United States blacks (n=151), United States whites (n=166), North Eastern Asia (n=434), Eastern Asia (n=151), Southeastern Asia (n=115), Latin America (n=129) and West Africa (n=113).

The sample consisted of a combination of individual measurements compiled from the University of Tennessee's forensic anthropological database and the Hanihara craniofacial data set. The combination of datasets has not been previously utilized to address the amount of mandibular morphological variation within differing geographic and ancestral modern human groups. The mandibular measurements utilized in this analysis consisted of seven measurements as defined by Martin (1928).[3] Bicondylar breadth (CDL), bigonial breadth (GOG), height of the mandibular symphysis (GNI), corpus mandibular width (TML), minimum anteroposterior width of the ramus (WRL), and maximum ramus height (XRL). As population differences and sexual dimorphism has been described by previous studies, discriminant function analyses were run on males and females separately to assess what is driving differences among population groups in regards to the combination of the effects of the mandibular measurements of CDL, GOG, GNI, TML, WRL, and XRL.

Results of the discriminant function analyses utilizing the measurements described on the male only sample indicated that the population groups were most clearly distinct in the combination of WRL, CDL, and TML, which accounted for 65.5 % of the variance observed, the combination of GNI, WRL and negatively correlated CDL (23.3%) and GNI (9.8 %).

Centroid plots from the discriminant function analysis of males only indicated that in regards to the first combination of measurements, the Northeast Asian sample exhibited the largest averages and were distinct from East Asian and Southeast Asians samples that plotted together in the middle of the axis. The North American blacks and West African samples plotted near each other below the Asian groups. The Latin American showed a large amount of variation but mostly plotted in the middle of the axis. The North American white sample exhibited the smallest averages and plotted at the negative end of the axis. The combination of GNI, WRL and negatively correlated CDL indicated a more linear relationship, with North American blacks and West Africans exhibiting the highest means and clustering together. The Asian samples plotted together with Latin American and North American whites, which exhibited the smallest average. Centroid plots from the discriminant function analysis of females only indicated the same patterns observed in the male analysis. Observation of Mahalanobis distances grouped the North American black and West African samples together with the North American white samples furthest from these groups. The Latin American and Asian samples grouped together and exhibited distances intermediate between the North American black and white groups.

Results of these analyses confirm conclusions of previous studies in that mandibular morphology can be used to infer ancestral affinity. This study shows that metric analysis of the mandible can be used to assess intracontinental variation as seen in comparison of Northeast and Southeast Asian samples, in addition to broad ancestral categories. Further studies are required to assess the degree in which morphological variability of the mandible is affected by environmental factors, and which traits (metric and non-metric) are most susceptible to plasticity.

Mandible, Metric, Variation

H28 Pubic Symphyseal Age Estimation from Three-Dimensional Reconstructions of Pelvic CT Scans of Live Individuals

Alexandra E. Wink, MS, 51 Elm Street, #1, Charlestown, MA 02129*

After attending this presentation, attendees will understand the growing role of computed tomography (CT) and digital imaging technology in forensic anthropology, specifically how these techniques are applied to age estimation of both living and deceased individuals.

This presentation will impact the forensic science community by demonstrating how three-dimensional CT (3D-CT) technology can aid in anthropological assessment of live individuals as well as remains that are not completely skeletonized, thus expanding the purview of forensic anthropology.

Age estimation is a critical component of the biological profile in forensic anthropology. The pubic symphysis has been widely studied and is thought to be a reliable indicator of skeletal age; however, traditional pubic symphyseal aging techniques rely on access to the bony pelvis, which is not always feasible. Such is the case with fleshed or partially-decomposed remains as well as living, undocumented individuals. In recent years, 3D-CT technology has been developed to visualize the skeleton digitally. These "digital osteology" techniques are employed by forensic anthropologists to establish aspects of the biological profile. Previous studies have been performed on 3D reconstructions of CT scans of dry pubic bones. The goal of this study is to test the applicability of 3D-CT pubic symphyseal aging to CT scans of living individuals performed using clinical parameters.

A sample of 44 patient abdominal-pelvic CT scans from the Boston Medical Center was analyzed retrospectively for age at the time of the scan. The scans were de-identified in compliance with IRB guidelines, and only the sex of the patient and age of the patient at the time of the scan were recorded. Representation of males and females was approximately equal, and the subjects' ages ranged from 19-89 years at the time of the scan. Three-dimensional images were created using the volume-rendering capabilities of OisriX software and analyzed for age using the Suchey-Brooks criteria for pubic symphyseal age estimation. The assigned Suchey-Brooks age ranges were compared to the age of the patient at the time of CT scan.[1,2] The images were analyzed randomly a second time to test for intra-observer reliability.

The features best visualized in the three-dimensional reconstructions were the symphyseal rim, the ossific nodule, and depression of the symphyseal face. The pubic symphyseal age estimates made based on the 3D images captured the true age of the subject 79.5% of the time, and intra-observer agreement was high (Krippendorff's alpha coefficient of 0.65). In cases in which the true age of the patient was not captured, the errors primarily concerned Suchey-Brooks phases III and IV. All misclassifications were underestimations (i.e. the actual age of the patient was higher than the assigned age range). Idiosyncratic variation in pubic symphyseal morphology could very well account for the majority of the error in this study.

The results of this study demonstrate that three-dimensional reconstructions of clinical CT scans of living individuals are useful for visualizing the pubic symphysis for forensic anthropological age determination. As radiological techniques and imaging software capabilities improve, digital osteology may be utilized even more frequently to assess age and other aspects of the biological profile in fleshed remains and in living individuals.

Digital Osteology, Pubic Symphysis, Age Estimation

H29 Reassessment of Cranial Trait Scores: Effects of Sex, Population, Age, and Body Size

Sabrina B. Sholts, PhD, University of California, Integrative Biology Department, 3060 Valley Life Science Building, Berkeley, CA 94720-3140; and Heather M. Garvin, MS, Johns Hopkins University, 1830 East Monument Street, Room 302, Baltimore, MD 21205*

After attending this presentation, attendees will understand the effects of sex, population, age, and body size on cranial trait scores, and how these effects are relevant to sex determination methods.

This presentation will impact the forensic science community by providing knowledge regarding the reliability of cranial sex traits, the factors influencing cranial trait scores, and suggestions regarding which of these factors should be considered during sex determination methods.

Forensic anthropologists continue to rely on morphological cranial traits as key variables in sex determination methods. Typically, forensic anthropologists score the morphological expression of the glabella/supraorbital ridge, orbital margins, mastoid process, mental eminence, and nuchal crest using ordinal scales, such as those presented in Buikstra and Ubelaker (1994).[1] While numerous studies evaluate the diagnostic significance of these trait scores, investigations of the factors influencing these trait morphologies remain much more limited. These factors can be vital when applying sex determination methods using these traits. Traits may be highly variable in their expressions or patterns between populations, which would support the need for population-specific standards of assessment. For example, some populations may display relatively more "masculine" or "feminine" traits, and would therefore be more likely to be misclassified by a set of universal standards. The reliability of specific cranial traits may also vary between populations with differing levels of sexual dimorphism. Furthermore, if age-at-death or body size is highly correlated with cranial trait scores, these factors should be taken into consideration during sex determination methods to obtain accurate results.

In order to address these problems, cranial trait scores and postcranial size measurements were obtained from males and females across six different samples: (1) Bass Donated Collection European-Americans; (2) Terry Collection European-Americans; (3) Terry Collection African-Americans; (4) Hamann-Todd Collection African-Americans; (5) Kulubnarti medieval Nubians; and, (6) Arikara Native-Americans. Data were obtained from at least 30 males and 30 females of each sample (total n = 498). Age-at-death and sex were known for the documented samples, and were estimated in the archaeological samples using traditional aging techniques and pelvic morphology. Pooled and sample-specific statistical analyzes were conducted to evaluate how cranial trait scores vary with each other, as well as with sex, population, age, and postcranial size.

Across- and within-sample analyzes revealed significant sex differences in all five cranial traits ($p\text{-value} < 0.05$). Discriminant Function Analysis (DFA) results revealed that glabella and the mastoid process were the best cranial trait sex indicators, whereas nuchal crest scores were the least reliable. Sample-specific correct DFA classification rates ranged between 86 and 94%. Kruskal-Wallis tests confirm significant sample differences in all cranial traits, including significant differences between Terry European-Americans and Bass European-Americans (e.g., $p\text{-value} < 0.01$ for nuchal crest, mastoid, and orbital margin differences in both sexes), and between Terry African-Americans and Hamann-Todd African-Americans (e.g., $p\text{-value} < 0.05$ for nuchal crest, orbital margin, and mental eminence differences in both sexes). These results suggest not only ancestral differences, but also more specific sub-population differences or possible secular trends. On average the Bass European-Americans exhibited greater (more "masculine") scores in all traits, except the mental eminence. However, no other consistent patterns in sample differences could be discerned. For example, a greater average score in one trait did not coincide with greater scores in other traits. Furthermore, samples of similar ancestries did not necessarily display similar trait scores. Jonchkeere-Terpste test results support an overall increase in trait scores

with femoral head diameter when males and females are pooled separately (*p-value* < 0.05 for all traits except mental eminence in males and orbital margin in females), but these relationships are mostly lost when samples are analyzed independently. Similarly, pooled sample results indicate a significant trend in nuchal and glabella scores with age (*p-value* = 0.000 for both traits in both sexes), but in many of the sample-specific analyzes these relationships do not reach statistical significance.

In summary, regardless of the sample, glabella and mastoid process were found to be the most reliable cranial sex indicators. Significant sample differences in trait expressions, even between samples of the same ancestral group, suggest that sample-specific standards would likely increase the accuracy of sex determination methods. When all samples were pooled, however, discriminant function analyzes were still capable of correctly sexing 86.5% of individuals, indicating that in the absence of sample-specific standards, a universal set of sex standards will still provide accurate results. Although the results of this study support a general increase in trait scores with body size and age, these relationships are weak ($r^2 < 0.14$) and not likely of significance during sex determination methods.

Sex Determination, Cranial Traits, Population Variation

H30 A Test of the Revised Auricular Surface Aging Method on a Modern European Population

Konstantinos Moraitis, PhD, University of Athens, Department of Forensic Medicine and Toxicology, School of Medicine, 75 M. Asias Street, Athens, 11527, GREECE; Constantine Eliopoulos, PhD, Liverpool John Moores University, School of Natural Sciences and Psychology, James Parsons Building, Byrom Street, Liverpool, L3 3AF, UNITED KINGDOM; Eleni Zorba, BSc, University of Athens, Department of Forensic Medicine and Toxicology, School of Medicine, 75 M. Asias Street, Athens, 11527, GREECE; and Sherry C. Fox, PhD, Wiener Laboratory, ASCSA, 54 Souidias Street, Athens, 10676, GREECE*

After attending this presentation, attendees will learn more about this revised aging method and see whether it is applicable on modern populations, as previous tests employed historical collections. The results of this test are more relevant to modern forensic practice.

The presentation will impact the forensic science community by helping current forensic practitioners decide whether this is a method that they should be using as a standard assessment technique for the examination of human skeletal remains. It may also prompt further testing on modern populations from other regions of the world.

Age estimation methods for human skeletal remains attracted considerable attention during the 1980s, with old techniques being revised and new ones being developed. The method for estimating age from the auricular surface of the ilium, as developed by Lovejoy and colleagues (1985), was recently revised by Buckberry and Chamberlain (2002). One of the reasons for this revision was to render the method easier to apply. Tests on historical populations were conducted for the revised method, with mixed results. The present study tests the Buckberry and Chamberlain method on the Athens Collection. This collection consists of documented skeletons of individuals who lived in the 20th Century. Sex, age, and ancestry information was derived from death certificates. A blind study of 120 remains was carried out by using the definitions outlined in the revised method. The auricular surfaces were scored in each individual component: transverse organization, texture of surface, microporosity, macroporosity, and apical changes. Statistical analysis was carried out using SPSS statistical software package.

An independent sample t-test was performed to test for significant differences between males and females for each composite score. It was found that there were no significant differences between ages for males and females (*p-value* > 0.05). In addition, Spearman's rank correlation statistics were applied to identify relationships between each individual component as well as the derived composite score and documented ages. In all cases there was statistically significant positive correlation between features and the composite score with documented age (*p-value* < 0.01 in most cases, except for macroporosity where *p-value* < 0.05). A positive correlation means that the higher score assigned to a particular trait expression, the more frequently it was associated with older age. The same is true for the composite score (higher composite score means older age). Surface texture showed the strongest correlation among the features followed by transverse organization. As was expected, the composite score also presented a very strong correlation with age (r_S=0.756, *p-value* < 0.01). Furthermore, partial correlation coefficients between features controlling for the effects of age were calculated. It was found that the partial correlations among the features are low and mostly non-significant, confirming that the features provide independent sources of information about age. A significant correlation was found only between transverse organization and surface texture, as well as surface texture and microporosity. Some of the results echoed those of Buckberry and Chamberlain. Finally, a Spearman correlation coefficient was calculated to test the correlation between documented and estimated age. It was found that there was a significant positive correlation between documented and estimated age (r_S=0.730, DF=118, *p-value* < 0.01).

The data generated from the present study suggest that the revised auricular surface method can be reliable for age estimation on a modern European population. There may be applications for the Buckberry and Chamberlain method in bioarchaeology as well.

Forensic Anthropology, Age Estimation, Auricular Surface

H31 Estimation of Body Mass from Measurements of the Calcaneus and Talus

Paul D. Emanovsky, PhD, Joint POW/MIA Accounting Command, Central Identification Laboratory, 310 Worchester Avenue, Hickam AFB, HI 96853*

The goal of this presentation is to introduce regression equations for the prediction of body mass from measurements of the calcaneus and talus.

This presentation will impact the forensic science community by presenting alternative skeletal elements for use in estimation of body mass, which typically relies on femoral head dimensions.

Estimation of body mass has been intermittently examined in the forensic anthropological context; however, body mass estimates are not a main component of the biological profile. In contexts outside the medicolegal field (e.g. paleoanthropological, bioarchaeological, ecological), estimation of "body size" from skeletal material is of interest. Allometric comparisons, for instance, are best made with reference to body mass.

The current study utilizes anthropometric data collected from white and black males and females from the Hamann-Todd Collection (HTH). The available anthropometric data (e.g., stature and weight) are combined with osteometric data from the foot in order to test proportionality and scaling consequences, as well as to generate predictive regression equations for body mass estimation. Measurement data for four variables, two from the calcaneus and two from the talus, were collected for a sample of 105 individuals (females: n=29; males: n=76) who exhibited clinically normal body mass indices (i.e., BMI=18.5 - 25.0). These four variables were entered into a Least Squares regression analysis using stepwise selection to choose the variable or combination of variables that best predict body mass. These elements both directly transmit the weight of the body during locomotion and are irregular bones comprised primarily of trabecular bone. This feature, as well as their functional relationship as articular joints, makes them ideal choices for estimation of body mass as they are not expected to vary in external dimensions with increasing or decreasing levels of activity, but are expected to correlate with overall size.

In a combined group analysis (n=105) forward stepwise selection identifies the maximum length of the calcaneus (body mass = (CALMAX

* 0.813) – 3.279; r =0.643; Adj. r^2 = 0.408; SEE = 5.81 kg) as well as the combination of CALMAX and the maximum length of the talus (body mass = (CALMAX * 0.534) + (TALMAXL * 0.438) - 7.142; r = .0670; Adj. r^2 =0 .438; SEE = 5.66 kg) as the most useful predictors of body mass. These equations predict body mass in kg, though the bony variables are in mm. Tests of efficacy on the Least Squares regression equations were conducted using a separate HTH sample for which maximum lengths of the calcaneus and talus were made available. These tests of efficacy were also limited to individuals who fell in the range of a normal BMI (n=38). Three measures were used to evaluate the performance of these predictive models – percent prediction errors (%PE= [(observed-predicted)/predicted] *100), accuracy (∑ |observed - predicted| / n) and bias (∑ observed - predicted / n).

Using the CALMAX only equation, results in %PE ranges from -27.12kg to 15.44kg (mean = -4.60kg , SD = 10.11kg), accuracy is 5.63kg, and bias is -2.89kg. While using the model that incorporates both CALMAX and TALMAXL, results in %PE ranges of -26.21kg to 16.84kg (mean = -4.27kg, SD = 9.93kg), accuracy is 5.34kg, and bias is -2.69kg. The elements of the foot are on par with or superior to, existing methods for estimating body mass and may be considered superior for theoretical and empirical reasons. Based on the merits of the regression equation statistics and tests of efficacy, body mass estimation may not be as farfetched a goal as previously perceived in the forensic context.

Body Mass, Linear Regression, Biological Profile

H32 Estimating Sex from the Human Skeleton: A Validation Study on Recent Scapular Methodologies with Emphasis on Population Diversity

Ian C. Bell, BA, 5681 Rhuland Street, Apartment 903, Halifax, NS B3H 4J6, CANADA*

After attending this presentation, attendees will have a better understanding of population diversity as it relates to recent methodologies established for estimating sex from the human scapula.

The presentation will impact the forensic science community by introducing and validating pervious methodologies established for estimating sex on different population groups.

The objectives of the study were to determine which methodologies by Dabbs and Moore-Jansen (2010) are more accurate and which are more reliable to the forensic investigator; to examine, through metric analysis, the sexual dimorphic traits of the human scapula; and to better understand the relationship between biological sex and population differences.[1]

One of the integral parts of developing the biological profile is the estimation of sex. Not only does it constitute a large part of the biological profile, but it provides for a better understanding of other elements of the profile. Methodologies for age-at-death and stature are generally sex specific and if there are no accurate methodologies to estimate sex, an entire individual may go unidentified. The human pelvis, skull and various long bones have been shown to be the best predictors of sex for an osteologist. Unfortunately, within a forensic and archaeological context, degradation of the skeletal material may render these bones unusable to the investigator. Therefore research to investigate new methods of estimating sex from other skeletal elements is crucial. Since 1887, the human scapula has shown potential for estimating sex through metric analysis.

In this study 298, contemporary white European individuals (168 males and 130 females) were used from two different skeletal collections: The William H. Bass Collection at the University of Tennessee, Knoxville and the Athens Bone Collection at the University of Athens, Greece. The methodologies follow those outlined in Dabbs and Moore-Jansen (2010) in which only left scapulae were used to measure six landmarks.[1] These six measurements were used in two previously established discriminate function equations to estimate sex of an individual (the "five-variable model" and "two-variable model"). Those measurements were: the maximum length of the spine, maximum height of the scapula, maximum breadth of the scapula, height of the glenoid prominence, lateral curvature, and the thickness of the lateral border.

Using a two sample t-test to compare the Greek population with the North American population, the results indicate that four out of the six measurements were statistically different for males and one measurement was statistically different for females (*p-value* ≤ 0.05). Similar results were found when two sample t-tests were used to compare each population group with the results of Dabbs and Moore-Jansen (2010).[1] This indicates that, with regard to these six measurements, the two population groups are statistically different. Inter- and intra-observer error was performed on both population groups. However, the overall accuracies for correctly identifying the sex of the individual from the "five-variable model" for both the Greek and North American populations were: 91.89% in males, 85.18% in females and 96.80% in males, 94.73% in females, respectively. The overall accuracies of the "two-variable model" for both the Greek and North American populations were: 85.13% in males, 87.03% in females and 94.68% in males, 82.89% in females, respectively. To test for statistical similarities of these accuracies a chi-squared test was performed. The results indicate that the "two-variable model" for estimating sex in males is statistically different between the Greek and North American population groups (*p-value* ≤ 0.05). This could be a consequence of age. The "two-variable model" uses the maximum height and breadth of the scapula. As male individuals age, the ventral curvature of the scapula increases and the maximum height of the scapula decreases, which could have a direct impact on the "two-variable model" (Dabbs).[2] Further research could be done to confirm those findings.

Results show that although there are statistical differences in scapular measurements between the two population groups there is still a high overall accuracy of the two methodologies presented by Dabbs and Moore-Jansen.[2]

H33 A New Method for Histological Age Estimation of the Femur

Christian Crowder, PhD, and Victoria M. Dominguez, MA, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will understand the current issues with histological age estimation and be introduced to a new method that uses the anterior midshaft of the femur. In addition, newly defined and tested histological variables will be presented and distributed.

This presentation will impact the forensic science community by providing a new method for histological age estimation. This will result in a higher quality of forensic practice and reduce errors in histological analysis.

Estimating adult age is problematic owing to biological variability in skeletal age indictors and their differential response to environmental factors over an individual's life. Furthermore, when standard age indicators (e.g., pubic symphyses and sternal rib ends) are absent or altered by post-depositional taphonomic factors, anthropologists often resort to less accurate methods such as cranial suture closure. In order to improve age estimates, the use of multiple age indicators and various modalities of assessment should be considered. Histological methods are based on the continuous turnover of primary cortical bone with secondary cortical bone, which has been argued to occur at a more predictable rate than other degenerative changes. Despite this, a histological approach is typically not employed owing in part to inherent methodological issues ranging from

subjective definitions to difficulty reproducing microscopic field sizes. This research evaluates histological age estimation using the anterior femur and explores the biological limitations of bone turnover as an age indicator. The study builds upon previous histological methods, recognizing their importance and impact to our current understanding of bone turnover as an age indicator.

The sample includes femur cross-sections of known age individuals from three histological collections. The sample consists of 206 individuals (102 males, 104 females) from the Ericksen collection and 14 individuals (8 males, 6 females) from the Kerley collection, and 16 (10 males, 6 females) from a modern forensic collection of known age individuals.[1,2] Prior to this study, research was performed to redefine and validate histological variables. The variable definitions are available to attendees as a supplemental document provided by the authors. The following variables were collected:

- Surface Area (Sa.Ar.) per mm^2
- Intact Secondary Osteons (N.On.):
- Fragmentary Secondary Osteons (N.Fg.On.)
- Intact Secondary Osteon Population Density (I-OPD) per mm^2
- Fragmentary Osteon Population Density (F-OPD) per mm^2
- Osteon Population Density (OPD): sum of I-OPD and F-OPD
- Mean Osteonal Cross-Sectional Area (On.Ar) per mm^2
- Mean Anterior Cortical Width (Ant.Ct.Wi.) per mm^2

Histomorphometric data were collected using a transmitted light microscope and a firewire digital camera. The topographic sampling method was modeled after Iwaniec and colleagues and Stout and Paine.[3,4] The method evaluates ten columns from the periosteal to the endosteal cortex located at the anterior femur midshaft. Using a Merz counting reticule at 200x magnification (field area = 0.2304 mm^2), 50% of the microscopic fields were evaluated in each column by alternating fields. This sampling strategy accounts for 95% of the remodeling variability within the anterior cross-section. Principles of stereology were followed, thus different magnifications or counting reticules may be employed to collect the histological variables. Osteon areas and cortical widths were calculated using imaging software.

Statistical analyzes were performed in SPSS 19 to examine the relationship between age and cortical bone histomorphometrics. Stepwise linear regression was used to develop the prediction equation and bootstrap methods were performed to assign measures of accuracy to sample estimates. Two variables (F-OPD and On.Ar.) required log transformation to meet normality requirements. Analysis of observer error was performed using Bland and Altman's procedure for testing the repeatability of methods.[5]

To examine the relationship between histomorphometrics and age, a general linear model was employed. Pearson correlations show moderate and strong relationships with age for all collected variables except I-OPD. Due to this finding it was determined that the constituent variables for OPD should remain separate in the regression model. A slight level of collinearity between predictor variables was recognized and influenced the selection of variables. A one-way ANOVA indicated that all variables, with the exclusion of I-OPD (p=0.296), demonstrate significant sex differences at the 0.05 level. Stepwise regression analysis of the male dataset produced a model using F-OPD [log] and I-OPD as predictors, while the female model selected F-OPD [log] and Ant.Ct.Wi. as predictors. The standard error of the estimate is 12.87 years and 10.49 years, respectively. In the event that sex cannot be determined, a general equation was developed using F-OPD [log] and I-OPD, providing a standard error of 11.98. Observer error results indicate the method passed repeatability standards as described by Bland and Altman.[5]

Current histological methods demonstrate significant issues that affect their reliability and accuracy. The method developed from this research demonstrates several advantages over previous methods. The method is based on validated variable definitions, accounts for 95% of the spatial variation in osteons within the anterior cortex, and is not restricted to a specific field size or magnification. The age-related biological significance observed in the histological variables demonstrates that age-related accumulation of intact and fragmented osteons is not equivalent. While the literature suggests combining I-OPD and F-OPD to reduce observer error, the results suggest that doing so may impact the ability to interpret age-related bone remodeling. Overall, the results of the study indicate that histological analysis of the anterior femur provides reliable age estimates. Considering the biological variation in both macroscopic and microscopic adult age indicators, the standard error in this study is similar to that of previous studies with large sample sizes. One of the most prevalent issues regarding adult age estimation is the inability to accurately age older adults. The described regression model is most accurate for individuals over 50 years of age. Bearing in mind that the elderly are a rapidly growing percentage of North American populations and that unidentified adults are a common occurrence in the forensic setting, this research will significantly increase the accuracy of estimating age for older adults.

H34 The Unique Biodiversity of Avian and Mammalian Carrion Scavengers in Southern Illinois and Their Effect on Decomposition Rate and Pattern

Megan K. Cleary, BA, D.C. Martin, MA, and Gretchen R. Dabbs, PhD, Southern Illinois University, Department of Anthropology, 1000 Faner Drive, MC 4502, Carbondale, IL 62901*

After attending this presentation, attendees will be aware of the unique biodiversity of the faunal assemblage in southern Illinois and how it affects the rate and pattern of soft tissue decomposition in the region. Those involved in human remains recovery and investigation will benefit greatly from the information and visuals presented.

This presentation will impact the forensic science community by highlighting the previously unknown differences between the faunal assemblages of southern Illinois and other regions housing forensic anthropology research facilities. Furthermore, this presentation will demonstrate how these unique assemblages can affect the rate and pattern of decomposition, further supporting arguments for multiple outdoor research facilities in various environments.

Scavengers can alter or destroy evidence pertinent to the cause and manner of death, destroy or scatter remains, and cause taphonomic effects that could potentially mimic trauma. Within specific microenvironments unique assemblages of mammalian and avian scavengers affect decomposition rates and patterns. Thus, it is imperative to study local fauna and the specific effects that they can have on both soft and hard tissues. Studies of scavenger behavior will aid in efforts to locate and recover dispersed remains, interpret the relative time the scavenging took place, and distinguish between faunal and other modifications on soft tissue and skeletal elements.

This study utilized a sample of 12 pigs (*Sus scrofa*) obtained from the Southern Illinois University-Carbondale (SIUC) Swine Center. Each pig

was humanely euthanized with a 15mm captive bolt gun (approved by the SIUC Institutional Animal Care and Use Committee) and all were scheduled to be euthanized due to illness or trauma. Once euthanized, the animals were immediately brought to the Complex for Forensic Anthropology Research for placement. Pig size ranged from approximately 1-64kg (nursery-15 weeks). Seven carcasses were buried (25-46cm). Five carcasses were placed on the surface in a mix of sun and shade (two frozen, three fresh). Subjects were placed at CFAR during two trials (October and December 2010) to assess seasonal differences. The five surface subjects were covered in 18-gauge wire mesh allowing scavengers access the subject from all angles, but preventing them from carrying off the entire carcass. Daily observations of the subjects were made by one of the authors and multiple measures of collection were used (Total Body Score, photographs, and written personal observations). Site-specific temperature data were recorded by iButton Link thermochrons (DS1921G). Motion-activated cameras were used to take still images and video of research subjects in the absence of the authors. All subjects were exposed for nine months before skeletal elements were cleaned and assessed for taphonomic damage.

Results show a multitude of scavengers feeding on the subjects beginning on the first day after placement for up to six months, with some evidence that feeding occurred even later. The most commonly observed species were the turkey vulture (*Cathartes aura*), Virginia opossum (*Didelphis virginiana*), and several species of rodent such as the eastern woodrat (*Neotoma floridana*). There is also moderate evidence of the common coyote (*Canis latrans)*, bobcat (*Linx rufus*), and white-tailed deer (*Odocoileus virginianus)* being involved in the scavenging process.

Each species affected the decomposition rate and pattern of the subjects differently. This is clearly visible in the time of scavenger onset. Rodents and the opossum were present early, while the turkey vulture appeared after and seemed to be present only on the warmer days of the colder months. While rodents would gnaw on several small areas of the carcass, turkey vultures would rip apart the limbs of the subjects and abscond roughly 10m away to imbibe the flesh from the bones. The opossum was seen entering into the body of the carcass through the anal cavity to remove visceral tissue. Though the surface subjects were scavenged sooner, in some cases six months sooner, all subjects exhibited evidence of scavenging. The rate of decomposition was most affected by the turkey vulture and opossum, both accelerating the decomposition process by removing large quantities of flesh, thus exposing more carcass surface area to environmental and entomological elements. After skeletal elements were cleaned, characteristic light scores with flat floors were witnessed most prominently from rodent scavengers, while deep furrows and punctures point to possible carnivore or vulture damage. The bones collected exclusively from the vulture scatter pattern exhibit deep punctures, furrows, and multiple fractures.

It is clear that the southern Illinois region displays a unique biodiversity of scavengers that could affect the rate and pattern of decomposition, and possibly hinder a criminal investigation or positive identification. Further research is needed in this area and is currently ongoing at CFAR.

Taphonomy, Scavenging, Forensic Anthropology

H35 The Development of Forensic Anthropological Standards in Western Australia

Daniel Franklin, PhD, University of West Australia, Centre for Forensic Science, MBDP M420, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; Ambika Flavel, MSc, Algis Kuliukas, MSc, Robin Hart, PhD, The University of Western Australia, Centre for Forensic Science, Crawley, WA 6009, AUSTRALIA; and Murray K. Marks, PhD, University of Tennessee, Department of Pathology, 1924 Alcoa Highway, Box 108, Knoxville, TN 37920*

The goal of this presentation is to increase awareness of the need to develop population-specific standards for identifying unknown human skeletal remains in Western Australia and calls attention to the importance of a statistically-valid foundation for those standards.

This presentation will impact the forensic science community by demonstrating that, in the absence of demographically-sound skeletal collections, medical scans and measurements on living individuals offer an appropriate and reliable source of contemporary population-specific data from which skeletal standards for the estimation of age, sex, and stature can be developed. The presentation will highlight the importance of quantifying not only the degree of error associated with forensic standards, but also the accuracy and precision of the raw data (measurements) from which they are derived.

In Western Australia, there is an absence of population-specific standards for the estimation of sex, age and stature from skeletal remains and the living. Therefore, we apply skeletal standards from non-Australian populations. These skeletal standards are an inaccurate representation of our modern regional society both geographically and often temporally. In a global era of terrorism, crime, and natural disasters, the need for precise Western Australian standards, and novel approaches to identify unknown remains, are greatly overdue. To this end, our purpose is to fortify the capabilities of forensic scientists in Western Australia through the development and implementation of a 'Human Identification Package' (HIP): a software tool designed to provide statistically quantified estimations of standard biological features commonly utilized in the creation of an osteobiography e.g., sex, age, and stature. And, as they become available, additional modules capable of complementary analyzes will be incorporated (e.g. identifying human versus non-human remains).

In the age of *Daubert* and other relevant decisions, the statistical quantification of error and uncertainty in forensic science is vital. As the acquisition of morphometric data from clinical computed tomographic (CT) scans is still a relatively novel approach, our first level of analyzes are designed to validate raw data to formulate forensic standards. The two primary goals in our validation study include: (1) assessing precision in acquiring bone CT measurements, e.g. extent to which repeated measures provide the same value; and, (2) evaluating the accuracy of bone CT measurements, or the extent to which measurements depart from their true value.

Six dry human skulls from the Centre for Forensic Science (CFS) teaching collection were subjected to clinical multislice computed tomographs (MSCT) at Royal Perth Hospital using a *Philips Brilliance 64 Scanner*® with 0.9 millimeter slice thickness. Following 3D volume rendering, 90 bilateral landmarks were designed and acquired using *OsiriX*® (v.3.9); a total of 33 linear measurements were then calculated using *Morph Db* (an in-house developed database application). The same linear measurements were also acquired from the six dry skulls using traditional anthropometric instruments (sliding and spreading calipers – *GPM*®). Each CT scan and its corresponding dry skull were digitized and/or measured a total of six times, with a minimum of one day between re-measurement. The significance of difference between CT and dry bone ('true value') measurements are quantified using ANOVA; intra-observer error (precision) is assessed using standard anthropological statistics (e.g., TEM; rTEM; R).

No significant differences between the CT data and dry bone measurements were found. Intra-observer error was within accepted standards (rTEM < 5%; low TEM and high R values) for all measurements indicating high measurement repeatability for both data acquisition methods. The most "imprecise" measurements were expectedly those with Type III landmarks – points that have at least one deficient coordinate, e.g., mastoid height. Those landmarks are more accurately located by feeling for the tip of a rounded bump or bottom of a concavity, which is not possible in CT data. Irrespective, we demonstrate that the raw data underlying our forensic standards are valid and can be reliably acquired in CT and dry skulls.

Osteobiography, Multislice CT, Measurement Error

H36 Multiplication Factor versus Regression Analysis in Stature Estimation from Hand and Foot Dimensions

Kewal Krishan, PhD, Panjab University, Department of Anthropology, Sector-14, Panjab University, Chandigrarh, 160 014, INDIA; Tanuj Kanchan, MD, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; and Abhilasha Sharma, MSc, Panjab University, Department of Anthropology, Sector-14, Chandigarh, Chandigarh 160 014, INDIA*

After attending this presentation, attendees will understand the usefulness of stature estimation methods in forensic examinations and will realize the variability in estimated stature and actual stature using multiplication factor and regression analysis methods as the literature on this aspect has been scanty.

This presentation will impact the forensic science community by confirming that stature estimation is more accurate and reliable with regression analysis method than that of multiplication factor method.

Estimation of stature is an important parameter in identification of human remains in forensic examinations. The objective of the present study is to compare the reliability and accuracy of stature estimation and to demonstrate the variability in estimated stature and actual stature using multiplication factor (MF) and regression analysis (RA) methods. The study is based on a sample of 246 subjects (123 males and 123 females) from North India aged between 17 to 20 years. Four anthropometric measurements; hand length, hand breadth, foot length and foot breadth taken on the left side in each subject were included in the study. Stature was measured using standard anthropometric techniques. Multiplication factors were calculated and linear regression models were derived for estimation of stature from hand and foot dimensions. Derived multiplication factors and regression formulae were applied to the hand and foot measurements in the study sample. The estimated stature from the multiplication factors and regression analysis was compared with the actual stature to find the error in estimated stature. Significant male-female differences were observed for stature, based on hand and foot measurements (p-value < 0.001). Significant sex differences were also observed for the MF derived in the study (p-value < 0.05) except for the MF derived for Hand Length that was almost similar in males and females (p-value $= 0.712$). Hand and foot measurements show a significant correlation with the stature in males and females (p-value < 0.001). Mean actual stature and stature derived from MF analysis and from regression analysis did not show any differences between them. However, it is evident that the range of stature estimated from MF analysis is broader and that from regression analysis is narrower than that of the actual stature. It is apparent that the MF analysis overestimates the maximum actual stature whereas the regression analysis underestimates it. The minimum actual stature is mostly underestimated in MF analysis and overestimated in regression analysis. However when error of estimate was calculated, it is observed that the minimum and maximum error in estimating stature in the study group is significantly larger in multiplication factor analysis than from the regression analysis. The study showed that the range of error in estimation of stature from the regression analysis method is less than the multiplication factor method; thus indicating that the regression analysis method is better than multiplication factor analysis in stature estimation.

Forensic Anthropology, Personal Identification, Methods of Stature Estimation

H37 The Forensic Anthropology Center at Texas State University

Sophia R. Mavroudas, MA, Daniel J. Wescott, PhD, Kate Spradley, PhD, Michelle D. Hamilton, PhD, and Kyra E. Stull, MS, Texas State University, 601 University Drive, ELA 232, San Marcos, TX 78666*

After attending this presentation, attendees will be familiar with the willed body donation program at the Forensic Anthropology Center at Texas State (FACTS).

This presentation will impact the forensic science community by highlighting the myriad research opportunities FACTS has to offer. FACTS aims to advance the field of forensic anthropology and other associated forensic science disciplines by creating a modern documented skeletal reference collection and providing access to both an osteological laboratory and outdoor human decomposition research facility for forensic scientists to conduct innovative interdisciplinary research in human identification studies.

The Forensic Anthropology Center at Texas State (FACTS) established a willed body donation program and an outdoor research facility in April 2008. Both the Forensic Anthropology Research Facility (FARF) and the Texas State Donated Skeletal Collection are available for research use by both national and international scholars. The mission of FACTS is to advance forensic science and anthropology through world-class education, research, and outreach. FACTS will: (1) provide the highest quality education and training for students and professional scientists in forensic anthropology; (2) provide training and certification for the medicolegal community; (3) assist national and international scholars from numerous forensic science disciplines in conducting quality scientific research that will benefit the medicolegal community; (4) facilitate interdisciplinary research and study, including providing state-of-the-art facilities and collections for research that advances forensic anthropology and other forensic sciences; (5) disseminate research in forensic anthropology through peer-reviewed conference proceedings and professional journals; (6) provide technical and scientific expertise and services to law enforcement, the medicolegal community, and the general public; and, (7) build local, national, and international partnerships with law enforcement agencies, laboratories, and research institutes to advance knowledge in forensic anthropology and other forensic sciences that deal with skeletal and decomposing bodies.

The Forensic Anthropology Research Facility is a large outdoor forensic decomposition facility, with 26 acres available for use on the Freeman Ranch. The decomposition facility provides opportunities for researchers to conduct studies that increase the understanding of variables affecting decomposition in climates similar to south central Texas. Longitudinal decomposition data for both human and non-human subjects are currently being collected. In addition, FARF is currently host to several national and international research projects covering the fields of anthropology, entomology, geography, molecular biology, and pathology. Accessibility to a weather station on the Freeman Ranch facilitates collection of weather and environmental data that assists researchers in outdoor studies. Approval for use of FARF requires submission of a research proposal and approval from the Director of FACTS.

The Texas State Donated Skeletal Collection is a growing modern skeletal collection consisting of permanently accessioned donated human remains from FARF research. Although a young center, FACTS has been quickly growing. Anatomical donations per year have risen from three donations in 2008 to 15 donations in 2010. As of July 2011, FACTS has already received 12 donors for the year. To date, there are 78 living donors on file that have willed their bodies to FACTS. The Texas State Donated Skeletal Collection currently has 37 accessioned donors, both males and females, ranging in age from 32-91 years, of African, European, and Hispanic ancestry available for research. Collaboration with other research institutions is an important aspect of FACTS; therefore FACTS has developed policies and data collection protocols that allow researchers to utilize the FACTS collection in conjunction with other similar research

facilities and standard osteological databases. The required paperwork for donation includes the basic biological profile, geohistory data, facial photographs, brief medical history, and life history. The data collected by FACTS prior to each donation are available to researchers and national databases. Approval for use of the Texas State Donated Skeletal Collection requires submission of a research proposal and approval from the Director of FACTS.

In addition to collaboration with other decomposition research facilities, FACTS also works with local law enforcement, FBI, and Texas Extension and Engineering Services (TEEX) offering educational lectures and workshops. The opening of a new multipurpose building located on Freeman Ranch will facilitate future workshops designed for the forensic education of graduate students and professionals.

The Forensic Anthropology Center at Texas State has immense research and outreach potential as a resource for the medicolegal and forensic science communities. It is important that researchers are aware of the resources available at FACTS and are encouraged to apply for use of the outdoor decomposition facility and/or the skeletal collection.

FACTS, Decomposition, Body Donation

H38 Histological Aging of Neurocranial Bone

Lindsay H. Trammell, PhD, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996-0720*

After attending this presentation, attendees will be introduced to the microstructure of several neurocranial bones and the utility of numerous features in formulating regression equations to estimate age-at-death.

This presentation will impact the forensic science community by expanding knowledge of bone histology to include neurocranial specimens as a solitary means of age estimation in biological profiles.

Successful skeletal age-at-death estimation employs a variety of traditional methods. One disadvantage is the necessity of near complete and proper preservation of target elements to reliably estimate age. Instances lacking traditional gross odonto-skeletal features force anthropologists to rely on bone or dental microscopy. Relevant histological research has focused on numerous bones, including the ribs, clavicles and mandible, but primarily the long bones. One limitation in some previous research is the insufficient attention to how biomechanical and metabolic factors affect the osteonal remodeling process in long bones and the accuracy of aging techniques. The influence of variation resulting from localized trauma, as well as the generalized effect of diet, disease, or excessive or minimal physical activity, is also important. [1-2]

Past histological research has focused on bones believed to be less vulnerable to environmental stressors.[3-4] This research examines the neurocranium, specifically the frontal, parietal, and temporal. Hypothetically, this region is less affected by biomechanical remodeling factors, given fewer muscle attachments, and has rarely been utilized in age-related histological research, with only Clarke and Cool performing histomorphometrics.[1,3] Their results indicate a low correlation of variables to age resulting from the irregular organization of features. However, these results may be due to a small sample size and a skewed older age distribution. Curtis focused on histomorphometrics of the frontal bone.[4] It was concluded that age-predictive equations should be controlled for sex when new variables were included. While promising, her large sample size is primarily reliable when estimating age on individuals over sixty years. Notwithstanding these issues, it is necessary to continue neurocranial histomorphometrics by expanding the younger to middle ages.

This research was performed at the University of Tennessee, Department of Anthropology's Mineralized Tissue Histology Laboratory, the Forensic Anthropology Laboratory at the University of Tennessee Medical Center, and the Pima County Office of the Medical Examiner in Tucson, Arizona. Sixty white male and female decedents of known age (20 through 82 years old), sex and ancestry from the University of Tennessee Medical Center were sampled during autopsy to remove three one-by-one centimeter specimens from the sectioned margin of the left frontal, parietal and temporal bones. Complete medical histories were available; so retrospectively, if outliers demonstrate differential bone remodeling or atrophy, they could be excluded from analyses.

A research light microscope and computer imaging software were used to examine slides at 40, 100, and 200 magnifications; a photographic series of the entirety of each thin section was captured using a mounted digital camera attachment. The following histological features were examined: external table thickness, the number of secondary osteons, secondary osteon area, secondary osteon perimeter, secondary osteon maximum and minimum diameters, secondary osteon diameter ratios, secondary osteon Haversian canal area, secondary osteon Haversian canal perimeter, secondary osteon Haversian canal maximum and minimum diameters, secondary osteon Haversian canal diameter ratios, number of secondary osteon fragments, and osteon population density.

Pearson's correlation coefficients identified which of the above-mentioned variables (measurements from the frontal, parietal, and temporal bones) proved significant to estimate age. Also, stepwise selection determined which independent measurements were predictors. The significance level required for entry into the model was $\alpha=0.15$; predictors with coefficients greater than a significance of $\alpha=0.05$ were dropped and the model rerun. Statistical results demonstrate that the ratio of secondary osteon maximum to minimum diameter is a significant predictor. Also, the frontal bone has a stronger correlation to age than does the parietal or temporal bones. The results indicate the utility of neurocranial histomorphology in formulating age-at-death estimation regression equations.

Histomorphology, Neurocranium, Age Estimation

H39 Sex Differences in Vertebral Centra Height From a Modern Autopsy Sample of Adolescents and Young Adults

A. Midori Albert, PhD, University of North Carolina Wilmington, Department of Anthropology, 601 South College Road, Wilmington, NC 28403-5907*

After attending this presentation, attendees will be introduced to preliminary findings of sex differences in vertebral centra height for purposes of better understanding normal human variability in this region of the skeleton.

This presentation will impact the forensic science community by showing the ways in which vertebral centra height was found to vary in females and males, which may lead to the future development of a sex determination method for use in human identification.

The goal of this study was to examine sex differences in the maximum height of vertebral centra in a sample collected at autopsy for purposes of exploring normal human variability. The sample comprised 42 sets of as many as all 12 thoracic (T1-T12) and the first two lumbar vertebral centra (L1-L2); there were 13 females and 29 males, ranging in age from 12 to 31 years. This was a pre-existing sample, whereby the vertebrae were originally collected for an age estimation study in 1992. For each

individual in the sample, a vertebral column "wedge" was cut at autopsy; longitudinal cuts were made on the lateral aspects of the centra with transverse cuts at T1 and L2 enabling a wedge to be removed intact. Once removed, vertebral column wedges were macerated, and each vertebra was labeled. Two researchers independently and blindly (i.e., sex and age were unknown) measured in millimeters the maximum height of each centra at midpoint using GPM sliding calipers, and data were analyzed grossly and statistically. It should be noted that in some cases, the superior portion of T1 and the inferior portion of L2 were cut midway across the centra due to soft tissue obscurity, resulting in the omission of some height measures for these vertebral centra. This was accounted for during data analysis.

Raw data observations revealed that more cranially-situated thoracic vertebral centra were shorter than caudally-situated thoracic and lumbar vertebral centra, an unsurprising finding which supports anecdotal evidence. When considering age, an *F*-Test Two Sample for Variances showed no significant difference in the age ranges between the female and male samples. Mean vertebral centra height values were calculated for each individual in the sample, and these mean values were correlated with known age. Pearson's correlations for age and mean vertebral centra height values showed no clear relationship ($r = -0.45$ for females, and $r = 0.44$ for males). Thus, the variation found in vertebral centra height was thought to be more related to sex rather than skeletal maturation or aging effects. Since stature was unknown, it remains possible that some differences attributed to sex could very well be a function of living height. Nonetheless, when exploring sex differences in centra height, ANOVA tests were highly statistically significant among all vertebral types (T1-L2).

Descriptive statistical results indicated that females and males had similar low and high centra height values: females had a low of 14mm (T1) and a high of 30mm (L1), and males had a low of 14mm (T1 and T2) and a high of 31mm (L2). Although these low and high height values were comparable, the mode in centra height for the different vertebrae showed variation between the sexes. For nearly each vertebra type, the male mode was consistently about 2mm higher than the female mode. Mean height values were calculated for each vertebral centra type (T1-L2) in the female and male sample; and observations of the raw data (i.e., comparing the means visually) showed that males were consistently higher than females for all vertebral types, although these differences were not statistically significant. Yet, when centra height for each vertebral type (T1-L2) for each individual in the female and male samples was compared, Student's t-test results indicated statistically significant (*p-value* < 0.05) sex differences in all vertebral types except T1, T12, L1, and L2. There was a possible small sample size effect on T1 inasmuch as only 17 out of 42 sets of vertebrae contained T1s that were not cut off superiorly at autopsy when the sample was collected.

For each vertebral centra type (T1-L2), the range of low to high centra height measures was calculated in the female and male samples. For example, the range in height for T1 in the female sample was 14-17mm and in the male sample it was 14-20mm. Next, the magnitude of the ranges was calculated for each vertebral centra type in the female and male samples. Thus, based on the example above, for T1 in the female sample the magnitude of the range was 3mm (14-17mm is a 3mm magnitude of difference) and in the male sample it was 6mm (14-20mm is a 6mm magnitude of difference). Results of a Student's t-test indicated a statistically significant sex difference in the magnitude of the ranges (*p-value* < 0.05). Gross observations of the raw data showed that the magnitudes of the ranges were wider for males when compared to females for all vertebral types except L1 and L2. This finding seemed to suggest that males exhibit greater variability in vertebral centra height than females, yet with some greater variability becoming apparent in L1 and L2 for females. Moreover, in females, the magnitude of the range of centra height increases from T1-L2 while in males it fluctuates, peaking at T7 and T8 and becoming slightly less than the females at L1 and L2. Findings from this preliminary investigation into sex differences in vertebral centra height provide some initial insight into normal human variability in this area of the skeleton. The goal of this study is that this study will stimulate further research to help explain the reasons for the sex differences in centra height as well as encourage additional studies of the relationship between vertebral centra height and overall stature as linked to sex.

Vertebrae, Sex Differences, Human Variation

H40 Using a Portable XRF to Detect the Transfer of Material from the Prior Use of a Saw in Cutting Bone

John A. Williams, PhD, Anthropology & Sociology, Western Carolina University, 101 McKee Hall, Cullowhee, NC 28723*

After attending this presentation, attendees will have a better understanding of how saw blades when used to cut bone can transfer evidence beyond typical saw class characteristics.

This presentation will impact the forensic science community by demonstrating that an XRF can be used to detect prior use of a saw in dismemberment.

The principle of transfer evidence is a fundamental tenet of forensic science. Within forensic anthropology the assessment of bone trauma often hinges on the transfer of tool or instrument characteristics to bone.

A protocol was designed to test whether a saw blade used to cut a copper pipe could transfer minute particles of copper when subsequently used to cut through bone. Copper was chosen to simplify the procedure by focusing on a single element and to reduce the likelihood of environmental transfer. Two saw blade classes were chosen: 18 teeth per inch raker set and 18 teeth per inch wavy set. Copper concentrations were measured using an Innov-X Systems handheld X-ray Fluorescence (XRF) unit. This XRF detects 23 elements between titanium and lead on the periodic table. The x-ray exposure is software driven, set by the manufacturer and was identical for each sample. A shielded test stand was used for testing ensuring that the distance from the XRF to the bone was the same for each sample. Each bone sample, control or test, received at a minimum of one XRF exposure session. Larger bones required multiple exposures to ensure that the complete surface had been exposed. This was performed for all cut surfaces. All non-human samples consisted of long bones of *Odocoileus virginianus*. Thirty-one uncut human and non-human bones formed one control set. These included contemporary and prehistoric elements. A second control of 25 non-human bones were saw cut using new blades without prior use. The test samples consisted of 31 non-human bones. Prior to each test cutting the saw blade was used to cut through a piece of 25mm copper tubing. Immediately after cutting the tubing each bone was completely cut through and then analyzed using the XRF. The saw blades, used and unused, were also tested for the presence of copper.

Among the non-cut controls no bone had a detectable copper level. The control cut group of 46 sample sessions from 25 bones yielded detectable copper in four samples in four bones (16.0%). Levels ranged from 62ppm to 129ppm, with an average level of 91ppm. The prior use test cuts consisted of 31 individual bones with 84 sample exposures. Copper was detected in 31 of the 84 sample sessions. This translates to 24 individual bones, or 77.4%. Copper levels ranged from 27ppm to 321ppm with an average of 100ppm. Detectable copper was present in each blade sample, used or unused. Levels were consistently high and ranged from 663ppm to 2,088ppm with an average level of 1,168ppm. A test of the average copper levels of the cut control and test cut groups, 91ppm and 100 ppm respectively, was not significant ($t = 0.2573$, *p-value* = 0.7896). However, in terms of absolute numbers the test cuts had a much higher total percentage of bones with detectable copper, 77.4% vs. 16.0%.

As no uncut bone had detectable copper the environmental transfer of copper can be ruled out as a possible source of copper presence. The transfer of copper from the prior use saw blades was confirmed microscopically. This demonstrates that copper was directly transferred from the copper tubing to the bone. It is assumed that the transfer of copper in the cut control samples was from the blade alloy. Therefore the true indication of prior use transfer cannot be ascertained using the XRF. While

copper was transferred from the saw blade to the bone during the cutting process the XRF cannot distinguish between the prior use transfer and incidental transfer from the saw blade itself. The latter scenario may have equal utility in using an XRF in assessing saw cuts in dismemberment.

XRF, Dismemberment, Transfer

H41 Pair-Matching of Human Skeletal Elements: Evaluation of Morphological Features for Visual Examination and Statistical Tables for Metric Assessment

Richard M. Thomas, PhD, Federal Bureau of Investigation Laboratory, Trace Evidence Unit, Room 3210, 2501 Investigation Parkway, Quantico, VA 22135; Douglas H. Ubelaker, PhD, Department of Anthropology, NMNH - MRC 112, Smithsonian Institution, Washington, DC 20560; and John E. Byrd, PhD, 95-033 Hokuiwa Street, #51, Mililani, HI 96853-5530*

The goal of this presentation is to provide attendees with a better understanding of both the visual and metric techniques of the process of pair-matching human skeletal elements.

This presentation will impact the forensic science community by presenting a description of which morphological features of individual skeletal elements are most useful for making a visual pair match and by presenting a new statistic (M) that can be used to metrically assess whether homologous bones are a possible pair match.

The process of matching paired skeletal elements (e.g., left and right femurs) is a technique used in forensic anthropology, paleodemography, and other osteological studies to determine if two homologous bones could have originated from a single individual. It is commonly used to resolve commingling issues from mass graves or disaster scenes, but can also be used in individual forensic cases where partial remains are found in different areas or at different times. When dealing with a closed population (e.g., aircraft accident), pair-matching is an easier task for the anthropologist than when dealing with an open population, when the anthropologist must decide whether the skeletal homologs can be matched to the reasonable exclusion of all other individuals.

There are two methods of pair-matching: visual pair-matching, a subjective technique which uses gross visual evaluation of similarities in bone morphology and taphonomy to match pairs; and osteometric sorting, a quantitative technique which allows statistical evaluation of size similarities between homologs to evaluate possible matches. This presentation covers both methods.

Visual pair-matching has been discussed as a reliable process; however, the details of how the exercise of visual pair-matching is done and what skeletal features are used have been seldom explored. The work presented here evaluates discrete morphological features of the major postcranial paired skeletal elements as described by White and Folkens (2005). Examination of morphological features included pairwise comparisons of 26 skeletons (which led to 231 comparisons for each feature) from the Robert J. Terry collection, housed at the Smithsonian Institution's National Museum of Natural History. Postcranial skeletal elements were examined, including the clavicle, scapula, os coxa, and all long bones. Cranial bones as well as smaller and less diagnostic bones (i.e., ribs, patellae, hand and foot bones) were excluded from this study. This effort provides anthropological investigators with a list of features that are the most consistent between the left and the right side, which can be used for the identification of matched pairs. Perhaps more importantly, it also provides a list of features that show variation between the left and the right side, which should not be used as means for the exclusion of possible pair matches.

This presentation will also address metric evaluation of possible pair-matches. Previous studies have produced statistical tests to resolve commingling, which can be used for pair-matching purposes, but also apply to osteometric sorting of other skeletal elements, and therefore are more laborious than necessary for use in matching single pairs. These techniques usually require multiple measurements for each bone, which may be impossible in the case of fragmentary remains. Data from a database of standard skeletal measurements (Byrd and Adams 2003) are used to produce a statistic (M), which is designed to capture the range of variability between the left and right elements within human individuals to aid in the metric assessment of possible pair matches. This presentation will include an introduction to reference data tables that show the maximum value, as well as the 90th and 95th percentiles of the M-statistic. These values are shown for 52 standard measurements for paired elements and are applicable to fragmented bones. These tables allow a simple metric test of the null hypothesis that homologous bones originated from the same individual.

Pair-Matching, Osteometric Sorting, Commingling

H42 A Bone to Pick: Obtaining Modern Human Skeletons for Education and Training

David O. Carter, PhD, University of Nebraska-Lincoln, Department of Entomology, 202 Entomology Hall, Lincoln, NE 68583-0816; Karl J. Reinhard, PhD, University of Nebraska-Lincoln, School of Natural Resources, 719 Hardin Hall, Lincoln, NE 68583-0987; Charlotte A. Wacker, MS, University of California, Davis School of Medicine, Body Donation Program, 4800 Broadway, Suite 100, Sacramento, CA 95820*

After attending this presentation, attendees will understand that some whole body donor programs associated with medical schools in the United States have the ability to prepare human skeletons for use in education and training at forensic science programs.

This presentation will impact the forensic science community by increasing awareness of resources available for obtaining and using modern human skeletons for education and training in forensic science and forensic anthropology. This presentation will also inform the forensic community that skeletonization services are beneficial to body donation programs because they allow for the use of donors that may otherwise be excluded. Some exclusionary factors include obesity, disease, and surgical history.

Thousands of people each year become donors to whole body donation programs throughout the United States. For example, the Body Donation Program at the University of California, Davis School of Medicine receives an average of 125 whole body donors per year. Whole body donors are primarily used to teach human anatomy to medical, undergraduate, and allied health students. To complement anatomy education, medical students are often given a "bone box" to learn human osteology. This holistic approach aims to provide students with a robust understanding of all the systems that comprise the human body. In contrast, education in forensic science and forensic anthropology is often limited by access to skeletal material. Many available skeletal collections do not contain modern human skeletons or many educational institutions simply do not have access to human skeletons. At best, students in these situations are limited to learn from casts of modern human bone.

Resources exist whereby forensic science and forensic anthropology programs can obtain access to modern human skeletons. Forensic science institutions interested in obtaining human skeletons for education can contact their local medical school and ask if they conduct skeletonization services. The process of preparing the skeletons is relatively straightforward. After a donor is selected for skeletonization the soft tissue is removed manually. Skeletons are then placed in a dermestid beetle colony to remove the remaining soft tissue. Oils and fats are then removed using acetone baths. The skeleton is placed in a water bath to clean out residual beetle artifacts and to remove traces of acetone. Lastly, skeletons are air dried at room temperature. Skeletons can be whitened at the request of the end user using hydrogen peroxide. For forensic applications, they are rarely bleached; exposure to the natural color of bone is beneficial.

At present, relatively few whole body donor programs are asked to conduct skeletonization services. For example, the University of California, Davis School of Medicine Body Donation Program has

prepared 12 skeletons since 2003. The relative lack of interest in skeletonization services may be due to the idea that many forensic science programs are not aware of the possibilities that exist for obtaining modern human skeletons. Questions regarding the ethical use of whole bodies for science may further reduce the use of human remains by forensic researchers.

Regardless, the lack of interest is certainly not due to the unavailability of human specimens. A more likely explanation is that forensic science programs are unaware of where to request skeletonization services. Furthermore, skeletonization services can benefit body donation programs because they allow a use for donors that may be otherwise unsuitable for medical research or medical education. Medical research and medical education typically require specific characteristics such as average height/weight, no previous surgery, or a narrow age range. In contrast, forensic science education and training benefits from skeletal variation because it accurately represents the skeletal material discovered at crime scenes.

To conclude, the acquisition of skeletons from whole body programs has several benefits. For the forensic science and forensic anthropology programs it provides opportunities to educate and train using modern human skeletons that accurately represent what practitioners will encounter at a crime scene. Skeletonization services are beneficial to whole body donor programs because they allow for the use of donors that are potentially unsuitable for medical research and medical education.

Anthropology, Body Donation, Skeletonization

H43 Detecting Submerged Remains: The Application of Side-Scan Sonar to Forensic Contexts

John J. Schultz, PhD, and Carrie A. Healy, BS*, University of Central Florida, Department of Anthropology, 4000 Central Florida Boulevard, Philips Hall, Room 309, Orlando, FL 32816; Kenneth G. Parker, Orange County Sheriff's Office, Marine Unit, 2500 West Colonial Drive, Orlando, FL 32804; and Bim Lowers, BS, Orange County Sheriff's Office, Marine Unit, 2500 West Colonial Drive, Orlando, FL 32804*

After attending this presentation, attendees will understand the application of side-scan sonar to forensic contexts, and specifically how this technology is used to detect submerged human remains. Successful case studies will be presented so that attendees will be introduced to both the advantages and the limitations of utilizing side-scan sonar to detect submerged bodies.

This presentation will impact the forensic science community by providing a better understanding of the application of side-scan sonar to the search for submerged bodies and associated evidence.

Forensic anthropologists and archaeologists frequently work with law enforcement to search for and recover bodies and associated evidence. At the same time, they are continually involved in improving various search methods, particularly with the use of geophysical tools for grave and buried evidence detection. The challenges of forensic searches can be even more confounded when dealing with submerged bodies. While traditional search methods involve multiple divers, side-scan sonar is increasingly replacing divers for the initial search. Side-scan sonar has been an important search tool for locating sunken ships, downed airplanes, and associated debris. Recently, improvements in the resolution of side-scan sonar have enabled the detection of smaller targets such as submerged bodies and evidence. As a result, more law enforcement agencies have acquired and incorporated side-scan sonar into their search and recovery protocols; therefore, forensic anthropologists should be familiar with this remote sensing technique and be involved with the recovery of submerged remains, particularly with mass disasters such as plane crashes resulting in body fragmentation. The goal of this paper is to discuss the methodology of side-scan sonar while emphasizing how this technology can be utilized to detect submerged human remains by drawing from forensic case examples.

Side-scan sonar consists of a towfish, containing the transducer, connected by a cable to a monitor with an attached differential global positioning system (GPS) unit. The operation of the sonar involves a boat dragging the towfish, which emits repetitive pulses into the water. The returning echoes are received by the towfish, which are converted into a digitized signal to discern features on the bottom surface. The sonar operator uses the differential GPS to plot the path of the sonar and ensure that the entire search area is covered. Once a feature is detected, a surface float is used to mark the location so that divers can then investigate. The experience of the sonar operator is paramount when interpreting the sonar data. Targets, such as submerged bodies, are recognized by the combination of the shape and shadow formation, with confirmation of the approximate target size. Additionally, the operator must distinguish between features and aspects of the terrain that reduce visibility, such as thick vegetation, irregular bottom surfaces, and debris. There are numerous advantages for using this technology for water searches. These include decreasing the time involved in searches, reducing the number of divers as well as the risk to the divers, and increasing the area searched. Additionally, since the submerged remains are located quicker than traditional methods, the taphonomic effects to the body are decreased.

Side-scan sonar has been used by the Orange County Sheriff's Office Marine Unit since 2007 to search for submerged remains resulting from homicides, plane crashes, car crashes, boat accidents, and accidental drownings. Two successful submerged human remains cases are highlighted to demonstrate the value of this technology for locating submerged bodies. The first case involved a boating accident that resulted in a drowning. Witness statements reported a specific location of the victim, but the victim was located once the search area was expanded. Since the search continued after dark, this case illustrates the utility of side-scan sonar for night-time searches. This case provides an example of ideal conditions resulting in clearly discernable features. The second case discussed involved a jet-ski accident. In this case, the witness accounts provided an accurate location for the search, but the terrain of the lake bed produced additional challenges and highlighted the importance of operator experience. Additionally, this case demonstrated the difficulty involved with data interpretation when the terrain is irregular. Both of these cases illustrate the application of side-scan sonar for forensic contexts and demonstrate the advantages and limitations of this technology when searching for submerged human remains.

Submerged Bodies, Forensic Geophysical Searches, Side-Scan Sonar

H44 The Contribution of the Artificial Radiocarbon Dating Method in Determining the Medicolegal Relevance in Skeletonized Human Remains Cases: Experiences in Chile

Macarena Arias, BS, and Ximena Leiva, BS, Servicio Médico Legal de Chile, Avenida La Paz 1012, Santiago, CHILE*

After attending this presentation, attendees will appreciate the significant value of radiocarbon analysis in forensic cases.

This presentation will impact the forensic science community by showing how time-since-death of skeletonized remains obtained using radiocarbon analysis, can help establish their medicolegal relevance.

The estimation of time-since-death (TSD) of skeletal remains is one of the most important tasks in the forensic field; by defining the age of a skeleton, forensic anthropologists can determine the medicolegal relevance of the finding. Moreover, regarding the particular history of Chile, this determination provides evidence for the probable link between some remains and some of the victims of the military dictatorship (1973-1990) who are still missing.

This presentation discusses the experience of the Unidad Especial de Identificación Forense, of the Servicio Médico Legal of Chile, in relation to the estimation of this parameter using the Modern Radiocarbon Method

(post-bomb). This method is based on the dramatic increase in the concentration of atmospheric carbon-14 between 1950 and 1963 as a result of nuclear tests. Although these levels have declined steadily in recent decades, they have never been as low as those known before 1950.

Since humans incorporated the atmospheric carbon-14 during this period, the concentration of this element in the different tissues can be measured. Depending on their particular rate of cell renewal, some tissues will express atmospheric carbon-14 concentrations in close to the birth date of the individual, while others will show the concentration of this element near the time of death. Next, the radiocarbon values reflected in the different tissues are compared with the annual averages of the atmospheric carbon-14 concentration curve defining the time during which that person lived.

In 1990, 20 bags containing mummified human remains were recovered from a mass grave within the Pisagua cemetery, in the north of Chile. They were identified as 19 victims executed during Pinochet's dictatorship. However, there was one bag with different characteristics, called "Bolsa Nº 20", which could not be associated to the same inhumation context. The uncertainty surrounding this case lingered for over 15 years until 2008 when a radiocarbon analysis showed that these corresponded to a prehistoric inhumation.

Since this case, the Unidad Especial de Identificación Forense has sent several samples such as hair, teeth, and bone for radiocarbon analysis; these samples were related to more than thirty cases without a clear temporal context. Through this method, it has been possible to define time-of-death with a high level of accuracy, including cases within the temporal framework of forensic relevance, or excluding cases that belong to periods of prehistoric or historic colonial interest.

Artificial Radiocarbon, Time of Death, Skeletonized Human Remains

H45 Craniometric and Non-Metric Assessment of Skulls of Hispanic Descent

Sarah Johnson Peacock, MS, 1320 North Windsor Avenue, Bay Shore, NY 11706; and Debra Prince Zinni, PhD, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA 02118*

The goal of this presentation is to provide attendees with some initial guidelines for determining the ancestry of skulls of Hispanic descent. After attending this presentation, attendees can also expect to gain a greater awareness of the difficulties associated with conducting ancestry assessments on skulls of this type.

This presentation will impact the forensic science community by demonstrating the need for and potential application of further research in ancestry assessment of individuals of Hispanic descent, encompassing individuals from a wide range of geographic and genetic backgrounds.

The common methods of estimating ancestry are through visual assessment and osteometric analysis. However, these methods become less accurate when dealing with individuals of Hispanic descent.[1] In the United States, the term 'Hispanic' is usually associated with Spanish-speaking people of North, Central, and South America who genetically are an admixture of European, African, and Native American ancestry.[2-6] The discrepancies between actual genetic background and perceived genetic background can make definitively assigning Hispanic origin to skeletal remains more difficult, as well as creating incongruities between the ancestry determined by a forensic anthropologist and the ancestry listed on official documents such as a missing person's report.

The goal of this project is to provide methodology for accurate and reliable determination of ancestry for skulls of Hispanic descent by identifying traits that are consistent and unique to skulls from this ancestral group. This study examines the metric and non-metric features seen in a sample of 40 Hispanic skulls from the William M. Bass Donated Skeletal Collection, located in the Forensic Anthropology Center in the Department of Anthropology at the University of Tennessee, Knoxville (UTK) and the Pima County Office of the Medical Examiner (PCOME) in Tucson, Arizona. Non-metric data were collected and scored numerically. Craniometric data were obtained and analyzed using FORDISC 3.0.[7] Following the FORDISC 3.0 analyzes, the ranges and averages for each measurement across the 40 skulls were compiled and compared to similar datasets of African, European, and Native American individuals.

The results of the study indicate some significant metric differences exist between Hispanic skulls and skulls of other populations. Out of 24 cranial measurements, fourteen were found to show significant differences between Hispanics and Europeans, ten were found to show significant differences between Hispanics and Africans, and four were found show significant differences between Hispanics and Native Americans. Only one measurement (Biauricular Breadth) was shown to significantly separate the Hispanic sample from all three of the other populations.

In addition, several combinations of non-metric traits were observed more often in the Hispanic skulls than in other ancestral groups. The most common traits observed were absent post-bregmatic depressions (observed in 88.9% of the sample), prominent anterior nasal spines (observed in 83.3% of the sample), closed but visible supranasal suture (observed in 72.2% of the sample) and intermediate nasal aperture widths (observed in 66.7% of the sample). Due to the diversity of individuals from Hispanic backgrounds, future research is needed to determine the applicability of these findings to all Hispanic groups. In addition, future studies should include a larger sample size of Hispanic individuals, encompassing individuals from multiple geographic locations and including both sexes.

Forensic Anthropology, Hispanic, Ancestry Assessment

H46 Integrating the Differential Global Positioning System and Geographic Information Systems for Mapping and Analysis of Skeletal Dispersals

Brittany S. Walter, BA, John J. Schultz, PhD, University of Central Florida, Department of Anthropology, PO Box 25000, Orlando, FL 32816; and Ronald A. Murdock, MFS, Orange County Sheriff's Office, Forensic Unit, 2500 West Colonial Drive, Orlando, FL 32804*

After attending this presentation, attendees will have a better understanding of the benefits of implementing the Differential Global Positioning System (DGPS) and Geographic Information Systems (GIS) in the mapping and presentation of skeletal dispersals.

This presentation will impact the forensic science community by comparing different data collection techniques using the DGPS in the mapping of a simulated skeletal dispersal and to discuss the benefits of mapping these scenes using the DGPS and integrating GIS for data analysis and presentation.

Scene mapping is an integral part of processing a scene with scattered skeletal remains. By utilizing the appropriate mapping technique, investigators can accurately document the location of human remains and maintain a precise geospatial record of this evidence and additional features at the scene. The determination of the appropriate mapping technique can be influenced by the extent of the skeletal dispersal as well as the environment. While baseline and grid mapping methods are typically used for smaller scenes, compass survey or total station methods may be used for mapping skeletal dispersals. Another mapping option is DGPS, as common units now provide decreased positional error suitable for mapping skeletal dispersals. As forensic archaeology is becoming more integrated into forensic anthropology, controlled research is essential to determine the benefits of this technology. The purpose of this presentation is to discuss the accuracy and practicality of using DGPS in mapping scattered human remains. Also, recommendations concerning data collection and the integration of DGPS scene data into a GIS will be discussed.

GPS is a satellite-based positioning system involving twenty-four satellites circling the earth. A GPS receiver uses positional information from the satellites to calculate the position on earth. A DGPS is a more accurate enhancement of a standard GPS that requires two receivers; one remains stationary while the other records positional data. The stationary receiver, a base station, relates all of the satellite measurements onto a single local reference. The base station measures the timing errors and provides correction information to the other receiver. In differential post-processing, the base station information can be obtained via the internet and then compared to the mapped point data for increased positional accuracy. The GPS geospatial data is commonly integrated into a GIS program which allows the user to display and analyze the mapped scene.

A simulated scene was assembled with a widely scattered partial skeleton in an urban environment. A Trimble GeoXH GeoExplorer 2008 Series DGPS with a Trimble Zephyr antenna, which can produce up to 10cm accuracy with post-processing, was used to map the scene. The first data collection used an average of 50 readings at one-second intervals, and the second used an average of 100 readings at one-second intervals. The data were then post-processed using GPS Pathfinder Office and exported into ArcGIS 10. After data were processed, the average corrected difference was 126.95cm for the 50-second collection time and 115.35cm for the 100-second collection time. Areas with tree cover demonstrated a corrected difference of 173.25cm for the 50-second collection time and 148.56cm corrected difference for the 100-second collection time. Areas without tree cover showed a corrected difference of 113.05cm for the 50-second collection time and 105.38cm corrected difference for the 100-second collection time. Overall, the most accurate method was using processed data with an average collection time of 100 seconds for both tree cover obstructed and unobstructed areas. However, the 50-second collection time was sufficient in unobstructed areas for mapping a skeletal dispersal. Furthermore, the distance between bones is a consideration when mapping individual bones or clusters. It is recommended to map individual features when bones are at least 25cm apart, and map clusters of two or more bones that are less than 25cm apart as one feature.

Generating GIS maps with DGPS data has numerous benefits for mapping skeletal dispersals. Aerial maps are easily added to the mapped scene data as a base layer, and site features such as trees, sidewalks, and structures can be included on the map for scene context. The DGPS software (TerraSync 3.0) also allows recording of attribute data for features through preset data dictionaries, such as bone type and side that can be accessed in a GIS using an attribute table. The user may then label the map with the desired information. Furthermore, distance between features can be easily calculated with a measuring tool. This may be useful in a court setting where the distance between bones and scene features can be easily determined while testifying.

Mapping Skeletal Dispersals, Differential Global Positioning System, Geographic Information System

H47 Changes to the Integrity of Bone Marrow during Decomposition

Corinne B. Tandy, MS, 2223 Chicago Avenue, Knoxville, TN 37917; and Donald F. Siwek, PhD, Boston University School of Medicine, Department Anatomy and Neurobiology, Program in Forensic Anthropology, 72 East Concord Street, Boston, MA 02118*

After attending this presentation, attendees will be familiar with the microscopic changes that occur to bone marrow throughout the postmortem interval.

This presentation will impact the forensic science community by introducing a potential semi-quantitative indicator of time-since-death from skeletal remains.

The objective of this study was to investigate the potential utility of histological analyzes of bone marrow for use when estimating the time-since-death.

The impetus for this pilot study is a response to recent legal decisions (the *Daubert* criteria), the National Academy of Sciences (NAS) Report on forensic science research, and best practice recommendations from the Scientific Working Group for Forensic Anthropology (SWGANTH) that have encouraged increased quantitative assessment of forensic techniques.

The purpose of assessing the histological appearance of bone marrow throughout the postmortem interval is to determine if bone marrow biopsy can be used as a quantifiable predictive indicator of time-since-death. Six pigs (*Sus scrofa domesticus)* carcasses were acquired from the Cummings School of Veterinary Medicine of Tufts University in Grafton, MA. All animals were euthanized at the same time by captive bolt, an AALAC and USDA approved technique for euthanasia. Each animal was placed in a wire cage, to limit scavenger access, on the ground at the Boston University Outdoor Research Facility in Holliston, MA during September, 2010. Experimental carcasses were placed approximately 15 feet apart. Two bone marrow plug biopsies were obtained from each pig on a graduated schedule, beginning with daily collections during earlier decomposition and ending with one in the fourth and last week of the experiment, as the pigs had skeletonized. Jamshidi Biopsy needles were used and all samples were immediately placed in small bottles containing 10% buffered formalin. The schedule was devised with the hypothesis derived from previous literature that the early decomposition process would exhibit the fastest changes and would gradually slow throughout the decomposition process.

A total of 122 bone marrow biopsy samples were collected over a 30-day period. They were rinsed in distilled water, decalcified in a rapid decalcifying solution, embedded in 5% gelatin and cut using a vibratome. The 40mm-thick sections were then microscopically assessed and scored based on three criteria: Cellular diversity and appearance, osteocyte abundance and appearance, and cancellous bone structure appearance. The three criteria were assigned a numerical value for each sample and then

correlated with the known time-since-death to determine the changes that are observed in the biopsies as decomposition proceeded. The average summary scores of the daily samples were also correlated with the average temperature and accumulated degree-days (ADD).

The results showed a positive linear correlation between the scored traits and both time-since-death and average temperature with the exception of the cancellous bone structure. In addition, the results suggest that a strong relationship exists between bone marrow appearance and integrity and the postmortem interval. These observations are encouraging and indicate this approach may have utility as a semi-quantitative predictive tool for estimating the time-since-death from skeletal remains.

PMI, Histology, Bone Marrow

H48 Estimating the Postmortem Interval from the Pattern of Staining on Skeletal Remains

Kelly Sauerwein, MA, and Michelle D. Hamilton, PhD, Texas State University, Department of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will understand the value of bone staining in estimating time-since-death from skeletal remains, the necessary procedures for the successful application of this method, and the types of predictions that can be made regarding soil and environmental characteristics, soft tissue concentration, and time-since-death.

This presentation will impact the forensic science community by providing a new method for identifying the causal factors that affect bone staining to provide an estimate of time-since-death in medicolegal death investigations.

Taphonomic analyzes have become fundamental aspects in forensic anthropological investigations, especially with reference to the estimation of time-since-death for medicolegal and identification purposes. This study examines the causes and sequence of one such taphonomic process, bone staining. While staining has been reported in the literature (Calce and Rogers; Huculak and Rogers; Jaggers and Rogers; Sauer), detailed quantitative data on its causes and sequence are limited.[1-4] Therefore, the patterning, timing, and properties of bone stains were analyzed to determine if estimates of the postmortem interval could be accomplished. The appearance and progression of bone staining were examined utilizing 45 fleshed and defleshed juvenile pig long bones that were placed in a burial context at the Forensic Anthropology Research Facility at Texas State University-San Marcos. Half of the sample retained a large amount of tissue (fleshed group), while the other half was processed to remove as much tissue as possible (defleshed group). The remains were buried and then collected at one-week intervals over a period of four months and extensively photographed. Soil samples were also taken at deposition and collection times and analyzed for changes in pH, nitrogen, phosphorous, and potassium levels across these two time points. Additionally, ambient temperature, humidity, and soil temperature were included to account for any influence of environmental factors on the staining process. A Miniscan XE Plus© color scanner from Hunter Laboratories was utilized to quantitatively and objectively measure the color of the stains present on the bones.

It was determined that staining occurred as early as two weeks post-deposition. Statistical analysis of the data revealed that differences existed between the fleshed and defleshed remains in soil chemistry, color, and environmental variables. Specifically, pH and nitrogen levels increased only in the fleshed group due to decomposition and the chemical byproducts associated with that process (Carter and Tibbett 2008; Hopkins, Wiltshire and Turner 2000; Rodriguez and Bass 1985) and not the soil environment.[5-7] The color analyses demonstrated that the fleshed remains exhibited darker, redder, and yellower coloration than those in the defleshed group. In the defleshed group, the surrounding environment, including the soil, ambient temperature, and humidity levels were responsible for the coloration seen on those remains. The correlational data between color and the environmental variables indicated that temperature (both soil and ambient) and humidity levels had more of an influence on the defleshed remains than on the fleshed ones. It is hypothesized that the lack of copious amounts of tissue allowed the soil to interact more directly with these bone compared to the fleshed remains, where decomposition was the primary staining agent.

This study demonstrated that an understanding of the process of bone staining and the agents responsible for its occurrence is critical for establishing a depositional and chronological sequence. Even though time-since-death could not be estimated past two weeks, these results highlight the fact that taphonomic processes, such as bone staining are not limited to single causes, but result from a multitude of sources. While in its infancy, bone staining research has the potential to make important contributions to both forensic anthropology and other medicolegal professions. For medical examiners, death investigators, and forensic anthropologists, awareness of the potential causes, especially decomposition, climate, and depositional context can provide some information regarding the circumstances of an individual's death. Future research may be able to expand on these results to extend time-since-death estimates from two weeks to whole seasons.

Taphonomy, Time-since-death, Bone Staining

H49 An Investigation on the Relationship of Postmortem Interval to the Microbial Biomass of Bone

Aphantree Tanittaisong, MS, American Registry of Pathology, 1413 Research Boulevard, Rockville, MD 20850; and Franklin E. Damann, PhD, National Museum of Health and Medicine, PO Box 59685, Washington, DC 20012-0685*

After attending this presentation, attendees will be informed about current research and development of methods for providing estimates of postmortem interval (PMI). The methods being evaluated are based on microbial biomass extracted from bone of varying postmortem intervals.

This presentation will impact the forensic science community by demonstrating how multidisciplinary approaches, which fall under the heading of forensic taphonomy, may be used to estimate time-since-death. The testing and analysis in this project are based on changes in the microbial community found in bone over a four-year PMI.

Bacteria and fungi contribute to the decomposition of a corpse and their taphonomic effects on the body and bone are well recognized and presented in the literature. This research investigates the temporal trends in bacterial and fungal community composition isolated from bone. The null

hypothesis is that as the quality of the resource (i.e., the corpse) decreases with advancing time-since-death, the bacterial load will also decrease, and the relative abundance of fungi will increase. If the hypothesis holds true, then the ratio of bacteria to fungi will decrease over time as well.

To test this hypothesis, a cross-sectional sampling of lower ribs from 14 bodies in different stages of decomposition was performed. The stage of decomposition varied from active decay with skeletal exposure at 10 days postmortem to dry remains at 48 months postmortem. Each recovered rib was thin sectioned, mounted undecalcified, and analyzed for signs of microbial bioerosion. Subsequent to histological preparation and analysis, 200mg of bone powder was pulverized and DNA was extracted. Extracted DNA was purified using the Qiagen MinElute PCR Purification Kit following the manufacture's procedures.

A quantitative real-time PCR for the evaluation of bacteria and fungi from each bone sample was performed. Standard curves, inhibition tests, and primer efficiencies were evaluated through a series of SYBR Green assays using PCR products of the 16s rRNA gene from *E. coli* and an Internal Transcribed Spacer region (ITS), which is a highly conserved fungal rRNA gene, from *Fusarium solani*. Five serial dilutions of known concentration of PCR products were generated and run in triplicate for a single standard curve and used to estimate DNA concentration from unknown samples. Amplification of test specimens were completed using previously reported universal bacterial primers targeting a 200 base pair fragment of the bacterial 16S rRNA gene and fungi were amplified using the ITS primer sets.

Bacterial universal primers were efficient for detecting bacteria in mixed samples according to the obtained qPCR efficiency of 99-100%, while ITS primer sets gave a 10% lower efficiency than the bacterial primer set. Inhibition issues occurred in the early amplification step, but were resolved partially by double purification using the Qiagen purification kit. Given the analytical conditions provided, the amount of bacterial and fungal DNA found in the samples varied from 0.2 to 17.0pg/uL for bacterial DNA and 0.0 to 3.0pg/uL for fungal DNA. Based on the results, bacterial concentrations were highest in the samples of 9, 11, and 12 months postmortem, while the highest concentration of fungi were found in samples with a PMI of 12, 18, and 21 months. The relative abundance of bacteria to fungi, determined by the ratio of total bacteria to total fungi concentrations suggested an overall increase in the ratio over the four-year postmortem interval. This finding is contrary to our hypothesis, suggesting instead an early abundance of fungi relative to bacteria, which changed to a greater relative abundance of bacteria to fungi during the 12 to 18 month time period.

Quantitative PCR is an efficient tool to study a variety of microbial communities in different types of samples. However, primer specificity and inhibition are the most common issues that encounter PCR-based analysis methods. Further research is required that is directed at using primer sets with more specificity for bacterial and fungal groups, rather than using universal sets.

This project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. Forensic Taphonomy, Postmortem Interval, Microbial Biomass

H50 Stages of Decomposition of Human Remains in a Subtropical Humid Environment

Joan A. Bytheway, PhD, Sam Houston State University, Box 2296, Huntsville, TX 77341-2296; and Ashleigh Gallaway, BS*, Montgomery County Sheriff's Office, 95 Wood Manor, The Woodlands, TX 77381*

After attending this presentation, attendees will gain an understanding of the stages of decomposition of human remains in a subtropical humid environment, similar to that found in Louisiana, Mississippi, Alabama, Georgia, most of Florida, South Carolina, and portions of North Carolina. Attendees will understand how the physical changes within the stages of decomposition differ from those in temperate, arid and cold climates. Attendees will be introduced to a new two-tier system of categorizing physical changes that occur during the decomposition process.

This study will impact the forensic science community by emphasizing to attendees through the present study how human decomposition is regionally specific and that some characteristics seen in advanced decomposition in temperate environments occur in the beginning of early decomposition in a subtropical humid environment.

Medical examiners, law enforcement agents, and forensic specialists who deal with human decomposition have based their assessment of the postmortem interval on stages of human decomposition established in temperate, cold, and arid environments (Bass, Galloway, Komar, Weitzel).[1-4] Four stages of decomposition have been established from the work of Bass and Galloway. The stages include fresh, early decomposition, advanced decomposition and skeletonization. The descriptions within these stages are based on various colors and general physical characteristics. Although helpful, the present study found that color should not be a predominant factor in the assessment and that there are more physical characteristics present that should be used in the determination of the decomposition stage. In addition, due to the subtropical, humid environment of southeast Texas and the regional scavengers and insects the decomposition process is quite different than temperate or cold climates.

The present study was conducted at the Southeast Texas Applied Forensic Science Facility (STAFS) at Sam Houston State University, Huntsville Texas, a human decomposition research facility.

Over a two-year period human cadavers were placed on the surface, in a natural outdoor facility and allowed to decompose to the stage described in previous research as "skeletonization."

Subjects were placed, unclothed, in areas that received both sun and shade throughout the day. Cages comprised of wooden frames and galvanized mesh wire were placed over some of the individuals in order to prevent scavenging activity. Other subjects were not caged and were accessible to scavengers. The subjects were photographed and observed daily. Climatic data were also collected daily.

Results show that in both sun and shade the skin mummifies. Scavenging is predominantly done by vultures and scavenging begins in early decomposition and extends through advanced decomposition but ceases at skeletonization. In addition, desiccation begins in early decomposition, and once the remains are desiccated, they stay arrested in that state indefinitely and rarely progress to skeletonization. The skeletal elements of subjects that were not accessible to scavengers were blanketed by mummified tissue with minimal hair loss. Skeletal elements in some subjects accessible to scavengers were categorized as reaching skeletonization, but only as a result of vultures pulling the soft tissue away from the bone. Although the bones were exposed, the soft tissue was laying in the vicinity of the body.

In early decomposition, none of the subjects in this study could be described as "pink-white appearance with skin slippage and some hair loss.". Nor could any subjects be categorized in the advanced stage as "moist decomposition." In the trunk region, the decomposing tissue does not "sag" as described in advanced decomposition, but rather crinkles as a result of desiccation of the tissue.

These findings show that descriptions of the physical characteristics occurring during decomposition need further clarification and detail. The findings also show that decomposition is regionally specific and the need for research in various climate zones is necessary.

Forensic Anthropology, Human Decomposition, Subtropical Humid Climate

H51 A Group-Generic Stature Estimation Equation from the Calcaneus and Talus

Paul D. Emanovsky, PhD, Joint POW/MIA Accounting Command-Central Identification Laboratory, 310 Worchester Avenue, Hickam AFB, HI 96853; Atsuko Hayashi, MA, 310 Worchester Avenue, Building 45, Hickam AFB, HI 96853-5530; John E. Byrd, PhD, 95-033 Hokuiwa Street, #51, Mililani, HI 96853-5530; and Thomas D. Holland, PhD, DoD JPAC, Central Identification Laboratory, 310 Worchester Avenue, Hickam AFB, HI 96853*

After attending this presentation, attendees will learn of a new stature calculation technique based on a group-generic equation from the calcaneus and talus. The sample from which this equation was developed is a composite sample of African and European Americans, and Japanese.

This presentation will impact the forensic science community by verifying the findings of Holland (1995) with an Asian sample: lengths of the calcaneus and talus have a linear relationship with stature compared to major long bones, which are affected by ancestral, sexual, and secular differences. Therefore, when remains are missing or too fragmentary to determine ancestry and sex, and long bones are not available, forensic practitioners have a viable alternative using the calcaneus and talus.

Measurements for the three independent variables: maximum length (MCAL) and posterior length of the calcaneus (PCAL), and maximum length of the talus (MTAL) were obtained following the methods of Holland (1995). African Americans (males: n=85 and females: n=58) and European Americans (males: n=85 and females: n=52) are comprised of individuals from the Hamann-Todd Human Osteological Collection (HTH) and JPAC-CIL, while the Asian sample is represented by Japanese (males: n=69 and females: n=31) individuals from the University of Chiba, School of Medicine (UCSM) and the University of Jikei, School of Medicine (UJSM). All individuals were born during the 19th or early 20th Centuries.

Before the equation was formulated, multivariate normality, multicollinearity, and residual tests were performed using SPSS 15.0. All three variables are highly ($r > 0.7$) correlated with each other; therefore, they were combined (summed) as a single independent variable to avoid the effect of multicollinearity (Adams and Byrd, 2008). Next, Mahalonobis distance was adjusted from the critical value of chi-square distribution in order to achieve multivariate normality. Four outliers were removed as a result. MANOVA was performed to examine the impacts of sex and ancestry on stature.

The results demonstrate that the main effect of both sex and ancestry are statistically significant: Wilks' $\Lambda = 0.589$, $F = (2, 361) = 136.964$, *p-value* < 0.001, multivariate η^2 (partial eta squared) = 0.431 and Wilks' $\Lambda = 0.479$, $F = (4, 722) = 80.309$, *p-value* <0.001, multivariate $\eta^2 = 0.301$ respectively. The interaction of sex and ancestry was not significant; only 0.9% (multivariate $\eta^2 = 0.009$) of variance was explained by these variables. The distributions of the residual plots in all cases appeared random, which indicate that the general model performs equally well for all three groups. The SPSS interaction profile plots demonstrated a nearly parallel relationship among ancestry and sex. The formulated equation (Living Stature (L.S.) = 5.826 * (MCAL+PCAL+MTAL) + 54.062) demonstrate a SEE of 5.24 cm, $r = 0.874$, and $r^2 = 0.763$.

After formulating the group-generic regression equation for estimating stature, 28 control samples consisting of a combination of individuals from the UCSM, UJSM, HTH, and the JPAC-CIL were tested. There were no statistically significant differences between predictions from the group-generic equation and the Holland equations (combined sex and race: African and European Americans): $F (4, 28) = 0.76$, *p-value* = 0.55. While Holland equations using MCAL and MTAL overestimated living stature by an average of 2.01cm and 3.83cm, respectively. Using Holland's (1995) combined sex and race (African and European Americans) for PCAL underestimated L.S. by an average of 0.51cm. Using the new equation presented here which includes three ancestral groups underestimated L.S. by an average of only 0.63cm. These results illustrate that a new group-generic stature equation, which includes Asian samples accurately estimates living stature. These results also support Holland (1995) suggesting the foot elements are more linearly related to stature than other long bones, which have demonstrated an allometric scaling relationship to stature.

Group-Generic Stature, Calcaneus and Talus, Biological Profile

H52 Distinguishing Features of Thermal Destruction on Fleshed Wet and Dry Remains

Natalie Keough, MSc, University of Pretoria, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; Kerri Colman, BSc, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; Steven A. Symes, PhD, Mercyhurst Archaeological Institute, Mercyhurst College, 501 East 38th, Erie, PA 16546; Luis L. Cabo-Pérez, MS, Mercyhurst College, Department of Applied Forensic Sciences, 501 East 38th Street, Erie, PA 16546*

After attending this presentation, attendees will have knowledge of differences in burn characteristics found on fleshed, wet, and dry burned bone. These features may be used to speculate the condition of human remains (fleshed, wet or dry) prior to a burn event.

This presentation will impact the forensic science community by contributing to knowledge regarding the condition of remains prior to the burn event.

The discovery of burnt bone often evokes questions about the condition of the body prior to burning. Although several observational and experimental studies (Krogman, Baby, Binford, Symes *et al*) have defined features on bones that were burnt in fleshed, wet, or dry states, contradictions in interpretations exist.[1-4] Color change, heat-induced fracture patterns, joint shielding, as well as shrinkage and warping have been found most useful in distinguishing burned, fleshed and wet bone from dry burned bone.

The purpose of this study was to score traits attributed to thermal damage on burned skeletal elements as a means to evaluate the reliability of these traits and to assess the relationship of these features to the body's condition (fleshed, wet or dry).

For the current study, 94 skeletal elements from 23 forensic cases (2 fleshed, 9 wet, 12 dry) were used. The South African Police Service had brought these remains to the Department of Anatomy, University of Pretoria for skeletal analysis between 1998 and 2009. Traits that are associated with burned bone were scored as either 0 (absent) or 1 (present). These included: greasy surface; joint shielding; defined tissue border; white tissue border; brown tissue border; predictable cracking in tissue border; minimal cracking around burned area; a heat line; cortical delamination; calcined bone; charred bone; and decomposition staining. Three observers independently scored these traits on each bone. A chi-squared test was performed to evaluate inter-observer error and differences in bone condition (fleshed, wet or dry).

No statistically significant difference was observed among observers. This demonstrates reliability in scoring these traits in a binary form. When all ten traits were compared, a statistically significant difference was noted among fleshed, wet and dry bone (*p-value* < 0.001) and between fleshed and wet bone (*p-value* < 0.001). The presence of joint shielding, defined tissue borders, white border, predictable cracking in tissue border and charred bone were found more often in fleshed than wet bone. As expected, wet bone was more likely to have a greasy surface, defined tissue border, white tissue border, predictable cracking in tissue border, and cortical delamination than dry bone (*p-value* < 0.001).

Differences between fleshed, wet, and dry bone are observable and can be easily quantified among researchers. Fleshed skeletal remains show a normal burn pattern as previously defined by Symes *et al*.[5] Whereas, wet bone, which has retained enough organic content and moisture, presents with similar changes in warping and shrinking as fleshed bone but results in a burn pattern that is different from fleshed and dry burned bone. Dry bone has lost all its organic components and moisture; thus, responding differently to thermal alteration. Warping of dry bone does not occur and therefore thermal related fracture patterns differ in comparison to fleshed or wet bone. Ultimately, the condition and organic composition of the remains at the time of burning affect the manner in which a bone will burn.

Further research is needed to assess sequential changes in the burn patterns with the progression of decomposition. This can aid in the taphonomic profile of unidentified skeletal remains and possibly in the estimation of time-since-death.

Burned Skeletal Remains, Taphonomy, Observational Study

H53 Subadult Age-at-Death Estimation From Human Metatarsals

Nicholas V. Passalacqua, MS, 1559 Mount Vernon, East Lansing, MI 48823; Jennifer M. Vollner, MS, 354 Baker Hall, East Lansing, MI 48824; and Christina L. Fojas, MS, Binghamton University, Department of Anthropology, PO Box 6000, Binghamton, NY 13902*

The goal of this presentation is to inform attendees about new methods for estimating the age-at-death of human subadult remains using linear measurements taken on the developing metatarsals, as well as transition analysis from epiphyseal union of the metatarsal heads.

This presentation will impact the forensic science community by demonstrating two simple methods for estimating subadult age-at-death from the developing human metatarsals.

Accurate estimation of age-at-death from the human skeleton can be especially difficult in cases of fragmentary or incomplete remains. While developmental age estimates from subadults are generally both precise and accurate, they tend to rely on certain skeletal regions, which, when unavailable hamper the ability of the practitioner to generate an age estimate. There is currently no method for estimating the age-at-death of subadults from the growth (size) or development (epiphyseal fusion) of the metatarsal (MT) bones of the human foot. The fusion of the epiphyseal heads of MT2 - MT5 is said to occur during the mid-teens, while the fusion of the head of MT1 occurs much earlier (Scheuer and Black 2000 and references therein).[1] Previous research has demonstrated a strong association between metatarsal size and fetal age (Ayres de Vasconcellos and Ferreira) as well as metatarsal development and age in primates and hominins (Susman et al.).[2,3] The approach taken here is similar to that of Passalacqua (In Press) regarding subadult age estimation from the calcaneus.[4]

The present sample consists of 67 European American and African American males and females with ages ranging from 1-25 years from the Hamann-Todd Collection. Transition analysis using a cumulative probit model was conducted on the timing of epiphyseal union of the calcaneal epiphysis using Nphases2 (Konigsberg).[5] Fusion was scored as (1) *unfused* (no bony bridging); (2) *fusing* (presence of bony bridging between epiphysis and calcaneal body); or (3) *completely fused* (obliteration of epiphyseal line). This method allows for the mean age-of-transition from one phase to the next to be determined in addition to associated standard deviations using a maximum likelihood method (Boldsen et al. 2002; Langley-Shirley and Jantz 2010 and references therein).[6,7]

Results indicate that bony fusion of the metatarsal head epiphyses to the metatarsal bodies for MT2-5 (transition from score 1 to 2) occurs at 12.5 +/- 10.2 years and complete fusion (transition from score 2 to 3) occurs at 15 +/- 10.2 years (2S). The bony fusion of the metatarsal head epiphysis for MT1 occurs much younger at 2.5 and 5 +/- 4.6 years (2S); however the posterior epiphysis for MT1 fuses at similar ages to the metatarsal heads of MT 2-5. The wide standard deviations for the ages of fusion for the metatarsal heads for MTs 2-5 are likely a factor of limited sample sizes for teen individuals in the present sample.

In addition, maximum length for each of the metatarsals was collected from a sub-sample of individuals where the metatarsal heads were not completely fused. In order to determine if there are any significant differences in bone growth/size related to sex or ancestry, an ANCOVA was performed. No significant differences ($p\text{-value} < 0.05$) were found for sex or ancestry, and all individuals were pooled into a single sample (n=33). Because the subadult metatarsals may not be distinguishable in younger individuals, especially in the context of incomplete sets of remains, the lengths of MTs 2-4 were pooled and averaged to create a more applicable method.

Linear regressions against age (in yrs) resulted in r^2 values of 0.92 for MT1, 0.90 for pooled MTs 2-4, and 0.88 for MT5 all with standard errors of the estimate lower than 1.8 years.

Results demonstrate that the linear regression models fit the data well and allow for age estimates with narrow standard errors. Additionally, transition analysis results for the fusion of the MT heads roughly correspond to age ranges cited in Scheuer and Black (2000) though it should be noted that Langley-Shirley and Jantz (2010) have demonstrated shifts in age-of-fusion of the medial clavicle due to secular changes.[1,7] The Hamann-Todd Collection (utilized here) is no longer contemporary and secular changes in the timing of epiphyseal fusion may be present, necessitating further research on a contemporary sample before widespread forensic application can be recommended.

H54 The Role of Forensic Sciences in Humanitarian Operations: Lessons Learned by the International Committee of the Red Cross

Morris V. Tidball-Binz, MD, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND*

After attending this presentation, attendees will understand how the implementation of forensic sciences, including forensic anthropology, in humanitarian operations often pose unique challenges that require innovative approaches to resolving and preventing the tragedy of persons missing as a result of armed conflict and major catastrophe. Experiences and lessons learned from the International Committee of the Red Cross (ICRC) will be used to highlight how some of the distinctive characteristics of forensic sciences can be applied to humanitarian investigations.

This presentation will impact the forensic science community by preparing practitioners to adapt the application of their scientific skills to the unique challenges faced in broader humanitarian contexts.

The International Committee of the Red Cross (ICRC) is a Swiss-based international humanitarian organization founded in 1863, which provides protection and assistance worldwide for victims of armed conflicts, and other situations of violence and catastrophes, in a neutral, independent, and impartial way. The mandate of the ICRC stems from international humanitarian law (IHL), especially the four Geneva Conventions and their Additional Protocols. In 2003, the ICRC organized an International Conference on "The Missing and Their Families." This saw the adoption by the international community of a set of recommendations for preventing and resolving the tragedy of the missing. The recommendations are framed by international humanitarian law provisions, making them universally applicable. Many of these recommendations relate to forensic best practices for the management of human remains and the identification of the dead. In that same year, the ICRC acquired its own forensic capacity to help promote and implement those recommendations worldwide. The activities of the ICRC's Forensic Department are based on IHL provisions, and they center on families' *right to know* the fate of their missing loved ones and on State parties' obligations related to the proper and dignified management of the dead from armed conflicts.

The use of forensic sciences in humanitarian operations for resolving and preventing the missing from armed conflicts and major catastrophes pose a number of unique challenges for practitioners and concerned institutions involved in these investigations. Some of these factors include security, and logistical and resource constraints, which affect the work of forensic investigations. If the number of missing persons and unidentified remains is large, needs often exceed available resources for all stages of the process. As a result, existing structures often cannot cope with the large caseload, and cases are either not investigated appropriately or the process moves painfully slowly for the families. Even in contexts where international actors are able to provide assistance, it is difficult to maintain local and international support, including funds, if the process extends for years, or sometimes decades. Also in contexts affected by armed conflicts, the normal (i.e. peace-time) domestic legal and operational frameworks - which provide for the necessary checks and balances and for the smooth running of forensic investigations respectively - may be frail or absent. In addition, the political will and institutional commitment required to address the issue of missing persons is frequently limited. Families of missing persons as a result of armed conflicts and large catastrophes often experience unique legal, economic, and psycho-social needs, which forensic practitioners involved in those investigations should be aware of.

Many forensic investigations into the missing are long-term projects which require local capacity building and ownership of the process for ensuring their sustainability. This requires appropriate planning, resources, and specialists, including forensic archaeologists and anthropologists, who play a key role in investigations involving decomposed and skeletonized remains. These factors impact the efficiency and feasibility of the forensic recovery and identification process in humanitarian operations. To the concerned forensic practitioners, they pose particular dilemmas which may be rarely encountered in normal domestic settings.

The lessons learned by the ICRC's Forensic Department have confirmed the validity and usefulness of the recommendations from the International Conference on The Missing and their Families, for resolving some of the dilemmas faced by practitioners and for implementing forensic best practices in challenging contexts related to humanitarian operations.

International, Humanitarian, ICRC

H55 The Importance of Proper Data Management: General Considerations and Grassroots Implementation in Guatemala

Shuala M. Drawdy, MA, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND; Juliana Padilla, BA, International Committee of the Red Cross, 18 calle 24-69, Zona 10, Edificio Empresarial Zona Pradera, Torre 2, Oficin, Guatemala City, GUATEMALA; and Ute Hofmeister, MA, International Committee of the Red Cross, Calle 76 No 10-02, Bogota, COLOMBIA*

The goal of this presentation is to increase awareness in the forensic science community on issues related to proper management of data on missing persons following armed conflicts. Implementation of a data management strategy in Guatemala is used as a case example.

This presentation will impact the forensic science community by broadening perspectives on data management for practitioners working with large numbers of missing persons and human remains, particularly in situations of violations of international law.

The International Committee of the Red Cross (ICRC) is a neutral, impartial, independent humanitarian organization that provides protection and assistance to victims of armed conflicts, other situations of violence and catastrophes. The ICRC Forensic Department participates in activities worldwide related to the promotion of scientific best practices on the management of human remains and identification of the dead, in contexts such as Central and South America, the Balkans, the Caucasus and the Middle East.

Proper data management involves the organized collection, handling, archiving and analysis of data, recognizing issues of chain-of-custody, data protection and confidentiality, access rights, etc. In situations involving large numbers of missing persons and unidentified remains, proper data management is integral to any strategy to identify human remains and fulfil families' right to know the fate of their missing loved ones. Data management can be enhanced with a centralized database in which to process varying types of data. Therefore, the ICRC developed the Antemortem/Posmortem Information Management Tool (AM/PM), an electronic database application, which is freely distributed to authorities, forensic practitioners and other parties involved in the management of data on missing persons. The AM/PM includes modules for multiple types of data (AMD, PMD, Events, Field data, etc.) as well as tools for analysis of that data.

During the 1960-1996 internal conflict in Guatemala, approximately 40,000 individuals went missing, the majority belonging to one of the indigenous Mayan ethnic groups. To date there is no centralized missing persons register, and it is difficult to estimate the actual number of persons missing from the conflict. Dozens of NGO's have developed following the conflict, many of them devoted to the issue of missing persons. These NGO's range from professional human rights organizations offering legal and counselling services for families of missing persons, to scientific NGO's recovering and analyzing remains and small grassroots associations of families of missing persons. These organizations possess a wealth of information on missing persons in varying degrees of detail, quality, and format. However, this information is difficult to access and in danger of loss as it is stored mainly in old paper files in unsecured offices. In addition,

a lack of standardized format and terminology has hindered efforts to exchange and consolidate the information between the various organizations.

In order to help organize, archive, update and consolidate the existing dispersed information, in 2010 the ICRC began a data consolidation project with 15 Guatemalan NGO's. The first phase of this project aimed at organizing the individual archives and digitizing them in a standardized format. For this purpose, the ICRC provided the AM/PM database, together with intensive training and coaching, and facilitated discussions on standardization of terminology and data entry. As a result, a consensus on national data entry standards has been developed, and the various organizations now have compatible digital archives of missing persons' information. The large number of organizations involved, their varying degree of organizational and educational levels, and very limited resources have posed challenges to the project. In addition, the need for clear and enforced data entry Standard Operation Procedures became evident early on and thus were integrated into the project. The second phase will focus on data cleaning and consolidation among the institutions in order to reach a consolidated list of missing persons for Guatemala. Such a list will enable authorities and NGOs' to access all the necessary available information and better focus their investigations.

Data Management, Humanitarian, ICRC

H56 Working Towards Unified Forensic Protocols for Mexico

Ute Hofmeister, MA, Calle 76 No 10-02, Bogota, COLOMBIA; and Dina A. Jimenez Mora, International Committee of the Red Cross, Calderón de la Barca No. 210, Colonia Polanco, Delegación Miguel Hidalgo, MEXICO C.P., 11550, MEX*

After attending this presentation, attendees will learn about the problematic issues concerning the unidentified dead in Mexico, particularly the problem of deceased migrants and the efforts to achieve better management and eventual identification of their remains.

This presentation will impact the forensic science community by creating a better understanding of the challenges of forensic human identification in a context of large-scale migration and of the importance of regionally standardized protocols and centralized data management, and of the ICRCs endeavours to support authorities in developing such tools.

Thousands of persons from various - mainly Central American - countries enter Mexico every year to cross the country and migrate to the United States and Canada. Many die on the way, due to accidents, environmental hazards, and attacks and killings by armed groups and drug trafficking gangs.

Having entered the country without any documentation or bureaucratic trace, the identification of these persons poses a major problem. While the individual medicolegal services around the country may have autopsy reports and information that might help identify those dead, there is so far no mechanism for exchanging this information and no standardized format. As a result, bodies usually end up as undocumented no name (NN) burials in mass graves, without possibility of further identification and restitution to their loved ones. Families looking for a missing person, on the other hand, do not have a clear contact point on where to report a missing person and where to start their search. They depend on informal networks, and those who can afford it often end up travelling from one morgue to the other in order to see if they can recognize the bodies. Only in a few high profile cases, which created a lot of publicity and thus alerted families, who in turn contacted the authorities in the respective countries, was it possible to identify a large majority of the bodies, such as in the case of the Tamaulipas massacre.

Mexico has 32 different state medicolegal systems which depend on different structures, each one with varying resources, and working protocols. In 2010 the ICRC sponsored a first national meeting of Medico Legal Services (SEMEFOs - Servicios de Medicina Forense), in which the lack of standard protocols and centralization of information was identified as one of the main challenges in the identification of the dead in Mexico.

In order to tackle this problem, the Mexican SEMEFOs, in close cooperation with the General Prosecutors Office and with the support and advice of the ICRC, have started to develop a unified protocol for the management, documentation and identification of the dead in Mexico. The protocol consists of a manual and standardized data collection forms. It takes into account the international recommendations on management of dead bodies and forensic human identification while being adapted to the reality of the country. Pilot projects have been started to digitize the information collected in these unified formats into a standardized electronic database (the AMPM, provided by the ICRC), for later integration into a nation- or region-wide centralized system. Unified and centralized information, both on unidentified bodies and on missing persons is easily accessible for those who require it, and adherence to standards of best practice will be an important step towards decreasing the number of bodies being buried without names, and will help bring answers to those families trying to find out about the fate of their loved ones.

Protocols, Migrants, ICRC

H57 Building Forensic Capabilities in Iraq

Lourdes Penados, MSc, International Committee of the Red Cross, Al-Abasea, Palestine Street, Basrah, IRAQ; and Monged Rezali, MSc, Medico Legal Institute Baghdad, Al-Rusafa Side, Baghdad, IRAQ*

After attending this presentation, attendees will be aware of the current forensic capabilities in Iraq and of the various efforts to build and improve them since 2003.

The presentation will impact the forensic science community by providing a view of the challenges faced by forensic practitioners dealing with large numbers of missing persons and thousands of human remains still being recovered from mass graves in Iraq.

Since 2003, hundreds of mass graves have been located throughout Iraq. The Iraqi authorities have undertaken numerous steps to clarify the fate of missing persons, which have included the creation of specialized teams to manage information, collect data, and to recover and analyze human remains.

In relation to the clarification of the whereabouts of missing persons, the Iraqi authorities and the ICRC are involved in tripartite mechanisms related to two international conflicts (Iran-Iraq, Iraq-Kuwait). The development of forensic capacities has been supported since 2005, with resources and training provided to the national bodies involved in the management of information and identification of human remains.

The number of persons unaccounted for from the various conflicts that have plagued Iraq over the past few decades is estimated to be between one and two million. The Ministry of Human Rights is the national entity responsible for the collection and management of information and for the recovery of human remains from mass graves. They have one specialized archaeology team which carries out exhumations throughout the country. The Medico Legal Institute (MLI) of Baghdad, which depends on the Ministry of Health, is responsible for the analysis of human remains. Both bodies coordinate efforts for identification. The work load for these two national agencies is exceptionally large, ranging from one to several hundred sets of human remains per month.

With the support of several international organizations, including the ICRC, the MLI has continuously increased their capacity to deal with these cases and invested in the enhancement of their premises. Because of the large caseload, the MLI created a specialized forensic anthropology team and is in the process of developing a dedicated DNA laboratory to handle the samples taken from these remains and from relatives of missing persons who approach them. However, as happens in many other countries affected by international and internal conflicts, the Iraqi forensic services face many challenges these include: limited resources, few opportunities for high level education in forensic sciences, including forensic anthropology, lack of local standards for the analysis of skeletal remains, as well as no specific

legislation regarding missing persons, data protection, large scale management of human remains and genetic databases.

The MLI and the Ministry of Human Rights in Iraq still face an enormous task which encompasses the development of their capacities, the establishment of standard procedures, the creation and continuous education of specialized teams, the creation of specialized laboratories and the creation of solid mechanisms to provide answers to the thousands of families that continue to approach them.

Forensic Capabilities, Missing Persons, Iraq

H58 The Missing From the South Caucasus: Perspectives From the Georgian Context

Megan Bassendale, MSc, MA, International Committee of the Red Cross, 4 Kedia Street, Tbilsi, 0154, SWITZERLAND*

After attending this presentation, attendees will have an understanding of the implementation of humanitarian forensic sciences in the post-Soviet Georgian context.

This presentation will impact the forensic science community by discussing the challenges that are faced in forensic human identification projects and lessons learned regarding implementation of identification efforts in this region.

As a result of the conflict in 1992 and 1993 in Abkhazia, there are approximately 1,750 Georgians and 114 Abkhaz that remain unaccounted for. This conflict is unresolved, and it is a region where territory distinctions, the political environment and different levels of forensic capacity have made it difficult for the authorities to systematically address the issue of missing persons. As a result, families of the missing are left not knowing the fate of their missing loved ones.

While there have been several attempts in the past to implement identification efforts related to this conflict, there have been consistent obstacles to establishing a long-term, systematic identification process. However, in 2010 a new coordination mechanism was established, which included Abkhaz and Georgian representatives with the ICRC acting as the neutral intermediary. Under the auspice of this mechanism, some progress in determining the fate of missing persons from the 1990's has been made. A project has been initiated incorporating both the Georgian and Abkhaz forensic structures with the goal to exhume, analyze, and identify human remains following best practices, while adapting to the specific challenges of the context and increasing local capacity to address the different aspects of forensic human identification. This includes the collection and management of information such as antemortem, gravesite and postmortem data, as well as actively coaching local scientists in exhumation and analysis techniques.

Within this context there are significant trust issues between the parties that greatly influence the working modalities that are acceptable by all. While efforts can be time-consuming, confidence building between the parties is an important aspect of this project. In addition, the lack of local infrastructure has been a significant obstacle from the level of where to store and analyze human remains, to finding an acceptable location for genetic analysis. The set-up of the regular forensic facilities is not such that they can incorporate the additional workload and the needs for physical space associated with the identification process. On-going discussion and negotiation at different levels has been necessary in order to develop the infrastructure required by this project.

Data collection, from antemortem to postmortem and the management of this data have also presented many challenges. The context highlights the need for in-depth training of data collectors and close monitoring of the data that is collected. Furthermore, having experienced people coordinating the process and conducting quality control of the information throughout the identification efforts is fundamental to having reliable and usable data. While these have been new areas of work for many of the people involved in the project, the coaching approach has been successful in terms of building local capacity.

Working very closely with each set of authorities bi-laterally as well as within the coordination mechanism has been essential in order to tailor the project to the specific needs of each yet maintaining a process where the information that is gathered is consistent and the approaches systematic. Experience has shown that theoretical lectures alone are not sufficient to train local scientists in forensic archaeology and anthropology. Close working relationships, hands-on, tailored coaching, and the presence of a consistent team working on the issue with a multi-faceted approach have been essential to the process thus far.

Identification Project, Humanitarian, ICRC

H59 Mechanisms to Address Missing Persons: The Sub-Working Group on Forensics in Kosovo

Oran Finegan, MSc, MA, International Committee of the Red Cross, Pashko Vasa str. no.15, Pristina, 10000, KOSOVO*

After attending this presentation, attendees will become aware of the complex nature of the recovery, analysis, and identification of human remains of missing persons, particularly in situations of armed conflict. This presentation will highlight the long-term nature of such projects, and the inevitable challenges that are faced throughout such a process. The main goal at this presentation will be to highlight the need for a mechanism to effectively coordinate the various participants in the field to successfully address these complex challenges; examples of such mechanisms and the lessons that can be learned from these models for the future will be provided.

This presentation will impact the forensic science community by highlighting the need for having a long-term perspective and plan to address the problem of missing persons. In addition, by making attendees aware of how work carried out at the start of a project can have serious ramifications later on, the need for continuity throughout the process will be demonstrated.

The issue of missing persons is a worldwide problem and the integral importance of forensics in trying to successfully address this matter continues to grow. The Western Balkans, in particular, Bosnia, Croatia, Serbia, and Kosovo, has seen a massive involvement of international and national forensic experts to recover, analyze, and identify persons who went missing as a result of the 1990's armed conflicts in this region. However, following all these efforts, approximately 14,000 persons remain unaccounted for (Bosnia @ 10,000, Kosovo @ 2,000, Croatia @ 2,000). Some of the main challenges today, are limited information on new gravesites, poor coordination between the actors early on in the process, many different actors involved at different times in the process, potential misidentifications, and large numbers of unidentified human remains stored in facilities in Kosovo (300-400), Bosnia (3,000), and Croatia (900). The reasons for these unidentified remains are numerous and complex, and to address them successfully will require a coordinated strategic approach.

While mechanisms have tried to address the challenges that the process faces from a forensic point of view, it is also important to highlight the need to involve the families and the wider community in assisting in the resolution of these issues. One example of a mechanism that has focused on these technical challenges is the Sub Working Group on Forensic issues in Kosovo. In 2005, the Working Group on Persons Unaccounted for in Connection with Events in Kosovo, realized the need for the involvement of forensic specialists and better coordination of concerned actors, established the Sub Working Group on forensic issues (SWG). The main goal of this forum is better management and acceleration of the forensic process.

For the construction of future mechanisms it is important to evaluate the successes and failures of this mechanism. Many challenges still face the process today; indeed these are not exclusive to Kosovo; across the Western Balkans similar challenges are being faced concerning the recovery, examination, and identification of missing persons from the conflicts of the 1990's. The need for a regional approach to these issues must be considered.

Mechanisms, Missing Persons, ICRC

H60 Advances in Victim Identification in Colombia

Elizabeth A. DiGangi, PhD, ICITAP-Colombia, Calle 125 #19-89, Office 401, Bogota, COLOMBIA; and Maria Morcillo, MD, and Jairo H. Vivas Diaz, MD, National Institute of Legal Medicine and Forensic Sciences, Carrera 7A No. 12-61, Bogota, COLOMBIA*

After attending this presentation, attendees will understand how victim identification is achieved in Colombia through a multidisciplinary team approach and how the construction of a new human identification center aims to streamline the identification process by increasing training, implementing research as a major goal, and introducing country-wide protocols into the process.

This presentation will impact the forensic science community by demonstrating how a country with serious human rights and victim identification challenges is attempting to meet its responsibilities through practices geared towards scientifically accurate identifications using a team approach.

Colombia has been ensconced in internal conflict with illegally armed groups for the past 40 years which has resulted in tens of thousands of victims, many of whom are buried in clandestine graves, buried by the authorities as John or Jane Does, or interred by family members in plots not reported to the government. Additionally, human rights abuses exist in situations where the armed forces kill poor civilians so they can pose them as armed combatants, increasing their kill quota for those illegal groups.

Eighteen years ago, the Colombian government began hiring anthropologists to help in the effort towards identification of the victims from the different conflicts. Today there are four different government agencies that employ forensic anthropologists with a total of about 50 practicing anthropologists. Each agency has a slightly different function and protocols in use for human identification and field exhumations differ between the agencies. Efforts have been made over the past few years to streamline the process between the agencies in terms of viewing the skeletal analysis as a forensic autopsy, which involves a team of a pathologist, anthropologist, and odontologist who examine the remains. The anthropologist constructs the biological profile and analyzes the skeleton for taphonomy while the odontologist analyzes the jaws and teeth. The pathologist and anthropologist work in tandem to analyze pathology and trauma. The pathologist ultimately determines the cause and manner of death, when possible, and issues the death certificate. Once analysis has been completed, a report will be generated that is signed by all individuals involved with the analysis. At that point, DNA samples are processed.

After this analysis process, a dedicated team works on determining whether or not an identification has been made based on the forensic autopsy report and DNA report. This overall teamwork approach has been adopted by the two agencies currently involved in skeletal analysis, but there is still much to be done in terms of training and protocol development.

The Human Identification Center is a joint undertaking between ICITAP-Colombia, the Colombian Attorney General's office (CTI-Fiscalia), and the Colombian national morgue (National Institute of Legal Medicine and Forensic Sciences). It will be the first center of its kind in Colombia and possibly Latin America. The center has been developed to process the large number of human remains that derive from clandestine burials and other illegal methods of body disposal. While laboratories doing this type of work already exist in Colombia as mentioned above, the backlog is typically 12 months or more, the labs are short on space, and the workers are taught within the culture of the agencies that quantity is more important than quality. The center's goal is to combat all of these issues.

The Center is a morgue that has been designed specifically for forensic autopsies of skeletal remains. In addition to the forensic autopsy floor, the center includes a bone pulverization lab for DNA purposes. Further, three key goals of the center are protocol development, training, and research. In addition to casework, each scientist on staff will be expected to generate research and participate in the training of their colleagues on rotation at the center. Further, the Center will be compliant with the ISO 17025 accreditation standard, the first laboratory analyzing human remains in Colombia to do so. The collaborative effort of the different government agencies involved and the different scientific disciplines involved in creating the center demonstrates a renewal in the commitment that the Colombian government has towards identifying victims of the Colombian conflict.

Colombia, Victim Identification, Human Identification Center

H61 Burial Patterns during Times of Armed Conflict in Cyprus in the 1960s and 1970s

Maria Mikellide, MA, Committee on Missing Persons in Cyprus, Ledra Palace Hotel, United Nations Buffer Zone, PO Box 21642 Nicosia, Nicosia, 1590, CYPRUS*

After attending this presentation, attendees will understand the patterns of burial during times of armed conflict in Cyprus, as learned from the Committee on Missing Persons in Cyprus (CMP).

This presentation will impact the forensic science community by introducing the mission of the CMP, the CMP Bi-Communal Forensic Team's (BCFT) archaeology program, and the observations and patterns of burial practices during armed conflict that occurred in Cyprus in the 1960s and 1970s.

Between 1975 and 1979, the United Nations General Assembly implemented three resolutions, and as a consequence, an investigatory body was established to determine the fate of approximately 2,000 people that were registered as missing from the inter-communal violence of the 1960s and the events of July 1974 and onwards. The Committee on Missing Persons in Cyprus (CMP) was established in 1981 under the auspices of the United Nations following an agreement between the Greek-Cypriot and Turkish-Cypriot communities. The CMP project is unique, as it is the only institutionalized bi-communal program where individuals from both communities, which were once fighting, are now working together at every stage of the project. The goal of the BCFT is to maximize the recovery of skeletal elements and document the spatial relationship of all physical evidence as to provide as much information as possible that would help in the final identification process. As such, the BCFT uses standard archaeological methods and techniques that have been adapted to the specific conditions of the "Cypriot recovery scene."

To date, 555 sites have been investigated after obtaining information from witnesses from the two communities. Of those, 213 contained human remains that are being analyzed by the bi-communal Anthropology and DNA teams for identification. The BCFT has excavated multiple burial sites across Cyprus, where specific patterns of burial during armed conflict have emerged. Thus far, BCFT excavations can be consolidated to five main types based on similarities in archaeological context, which include: (1) *in situ*, primary burials; (2) burial in wells; (3) deposition in stream beds; (4) surface deposition on mountain tops; and, (5) burial inside or next to abandoned cemeteries.

From the outset of the project, many informants and witnesses came forward to provide information on burial location. The first sites to be excavated were those with persistent and reliable witness statements, which invariably involved primary in situ burials. Of the 555 sites, 51 involved *in situ* primary burials.

In the mid-twentieth century, much of Cyprus moved to municipality water supply and in the years that followed wells became redundant and fell out of use. During the events of the 1960s and 1970s wells became a convenient place to dispose of bodies. Consequently, the BCFT has excavated 82 wells, of which 24 contained human remains.

Seasonal streams were also popular locations to dispose of bodies. The formation processes that dominate streambeds ensure that human remains would be dispersed and difficult to find. The BCFT has excavated

38 streambeds, of which 15 contained human remains. The remains in most cases consisted of isolated skeletal elements.

According to historical information, intense fighting took place on the Kyrenia Mountains in July and August 1974 resulting in a large number of missing persons. Many were left unburied resulting in dispersion by various taphonomic processes. The recovered remains typically consist of isolated skeletal elements that are often sun-bleached. Since the start of the project 46 sites have been excavated in the Kyrenia Mountains, of which 20 contained human remains.

The BCFT has excavated 22 sites in abandoned cemeteries, of which five contained remains related to the inter-communal fighting of the1960s or the events of July and August 1974 and onwards. The archaeologists assigned to these cases must determine the forensic significance by drawing on their understanding of the various burial practices of an island where Christian and Muslim religions have dominated for centuries.

In excavating the island's past the forensic archaeologist becomes aware of the various burial practices that prevailed during armed conflict, which become informative for locating future burial sites. The five main categories of CMP recovery sites are reflective of the environmental and cultural parameters that characterized Cyprus during the 1960s and 1970s. Today, in conducting excavations for the CMP, the forensic archaeologists from the two Cypriot communities contribute to the overall mission for the recovery and identification of missing persons, in order to find a reconciled future.

CMP, Burial, Post-Conflict

H62 Recovery of Missing Persons in Cyprus: Methods and Techniques of Complex Well Excavations

Deren Ceker, BA, Committee on Missing Persons in Cyprus (CMP), Ledra Palace Hotel, United Nations Buffer Zone, PO Box 21642, Nicosia, 1590, CYPRUS*

After attending this presentation, attendees will learn the methods and techniques that were developed by thebi-communal forensic teams of the Committee on Missing Persons in Cyprus (CMP) in order to recover remains of missing persons buried in deep wells at several sites across Cyprus during the 1960s and 1970s.

This presentation will impact the forensic science community by sharing best practices of the CMP forensic archaeologists to overcome the difficulties and safety risks associated with excavating human remains from deep wells.

The Bi-communal Forensic Team (BCFT) of the CMP has been conducting excavations since 2005 in order to find persons reported missing from the inter-communal fighting between the years 1963 and 1974. As a result of the violence during those times, a total of 494 Turkish-Cypriots and 1,493 Greek-Cypriots were officially reported as missing by both communities to the CMP. From our experience over the past five years, 145 individuals have been recovered from 82 deep-well excavations.

Well excavation methods vary according to the type, the depth, and the type of soil surrounding the well. The wells in Cyprus are mostly wheel wells for drawing water, dry wells, drainage wells, and reservoir wells, which are typically shallow wells. The depth of the wells excavated thus far varies from 5 meters to 30 meters. The well depth depends on the soil type and water level of the area. As a result, the BCFT establish an excavation plan, which includes decisions about what type of heavy machinery will best serve the excavation process. Management of the excavation process begins with gathering historical and circumstantial data related to the missing person(s), and dominant landforms, land use, and geomorphology of the excavation area. These data inform the necessary excavation methods and techniques.

Due to the prevalence of well excavation sites, the CMP forensic archaeologists developed a system of access ramps for heavy machinery, pockets, and pools, which are excavated next to the mouth of the well to manage excess ground water. Initially, a well feature is opened on three sides by an excavator, not only for safety and timeliness, but also to allow access for the team to recover remains and additional evidence in situ. The excavator does not disturb the sediment inside the well; rather it makes a ramp with the assistance of a wheel loader, which transports large amounts of loose soil out of the excavation area. This method enables CMP archaeologists to excavate the deepest wells successfully by maintaining provenience of recovered evidence, while reducing excavation times and keeping costs low. For example, the CMP archaeology team excavated and recovered remains from wells in Gökhan/Voni and İskele/Trikomo that were 28 and 31 meters deep, respectively.

Over the past five years, the CMP Bi-communal Forensic Team has developed methods and techniques for excavating deep wells, which enables efficient excavation and recovery of remains. In doing so, the CMP forensic archaeologists overcome archaeological, logistical, and physical difficulties to reach human remains of individuals that went missing as a result of the inter-communal across Cyprus during the 1960s and 1970s.

Forensic Archaeology, CMP, Well

H63 Thinking Outside the Box (of Bones) in Forensic Anthropology: Revisiting Roles, Components, and Naming Rights of the Discipline

Dennis C. Dirkmaat, PhD, Mercyhurst College, Department of Applied Forensic Sciences, Glenwood Hills, Erie, PA 16546; and Luis L. Cabo, MS, Mercyhurst College, Department of Applied Forensic Sciences, 501 East 38th Street, Erie, PA 16546*

After attending this presentation, attendees will fully understand the relationship between forensic archaeology and forensic anthropology and the significance of this role in the determination of a wide range of issues critical to the medicolegal investigation of the outdoor death scene.

This presentation will impact the forensic science community by discussing the diversity of roles forensic anthropology plays beyond just the determination of biological profile from human bones.

Forensic anthropology was formally defined in the early 1970's as a laboratory-based discipline focused almost exclusively on aiding the process of establishing the identity of the victim. Typically, law enforcement and coroner/medical examiner officials brought human remains to the forensic anthropologist only after other mainstream identification efforts such as analysis of soft tissue features, dental comparisons, and even clay reconstructions failed.

The bulk of these cases involved, therefore, skeletal remains or bodies altered or decomposed to a point at which the forensic pathologist could get little information from the soft tissues. As is the case today, most of these remains came from environments in which the body had gone undetected for long periods of time: burials and outdoor scenes. While their indoor counterparts were subjected to increasingly sophisticated mapping, documentation and information retrieval techniques, outdoor scenes were deemed by law enforcement as too altered and complex to receive the same treatment. Animals, weather conditions, and other natural processes would have erased most of the evidentiary information originally present at the scene. The absence of walls and other fixed spatial references made indoor mapping techniques impracticable, and burials were shoveled or backhoed to retrieve the body in order to send it ASAP to the morgue.

It was in this environment of hastily processed outdoor scenes and laboratory-based anthropologists that the field of forensic anthropology was defined and incorporated into the AAFS as an independent section. At the time, many forensic anthropologists saw the potential utility of archaeological techniques to process outdoor scenes and burials. A few of them took an active role in the recovery of the body and associated contextual information. However, for a variety of reasons, the initial

acceptance of archaeologists into the Physical Anthropology section of AAFS was delayed.

During the last four decades, the evolution of the field has resulted in a completely different reality. Paralleling a similar trend in paleoanthropology, forensic anthropologists gradually realized the need to collect and analyze scene information in order to answer many of the old and new questions posed by investigators and tribunals. For example, interpretation of skeletal trauma may be confounded by taphonomic and site formation processes, which cannot be reconstructed without carefully recorded scene data. Accurate methods of bone detection and recovery also required the involvement of an osteologist in the analysis and processing of the recovery scene. Archaeology and paleontology methods were demonstrated to be superior over conventional criminalistics techniques, and their adaptation into the medicolegal context translated into the development of forensic archaeology.

The application of archaeological techniques and methods to crime-scene recovery resulted in increased analytical capabilities that go well beyond the assessment of the biological profile for identification purposes. Forensic archaeology and taphonomy allowed for the reconstruction of events surrounding death, including factors such as original position and location of the decedent, and the estimation of postmortem intervals.

Today, forensic archaeology has been embraced and is an integral part of the work of forensic anthropologists. In addition, archaeologists have taken an active part both in the research and development of new forensic archaeological techniques, and in their application in forensic investigations. This presentation argues in favor of the necessity of acknowledging this reality within the Forensic Anthropology Section of AAFS, by accepting and incorporating forensic archaeologists into the section and renaming it accordingly.

Forensic Archaeology, Scene Context, Forensic Taphonomy

H64 The 40th Anniversary: Research Trends in the Physical Anthropology Section of the AAFS

Hugh H. Tuller, MA, Joint POW/MIA Accounting Command, JPAC CIL, 310 Worchester Avenue, Hickam AFB, HI 96853-5530*

After attending this presentation, attendees will gain an understanding of the trends and depth of research that has been conducted in the Physical Anthropology Section of the AAFS during its 40 year history.

This presentation will impact the forensic science community by identifying forensic anthropological research trends over time. Specifically, this presentation will outline what forensic anthropologists do and how much effort they put into particular types of research.

In 1972, the AAFS welcomed a new section of forensic investigation into its organization: the combined Odontology/Physical Anthropology section. A few years later this combined group split forming their own sections. Cooperation with other sections was common during the first twenty years, where combined sessions highlighted interdisciplinary collaboration. More recently, as the field of forensic anthropology has become more established and welcomed in the forensic community, and as AAFS itself has matured, the number of presentations in a given year has increased dramatically. In 1972, anthropologists presented two papers, today the Physical Anthropology Section averages over a hundred oral and poster presentations. In addition, the Physical Anthropology section regularly hosts workshops and breakfast/lunch seminars, as well as presenting research in other AAFS sections.

This presentation, given on the Physical Anthropology section's 40th anniversary, is timely. Twenty years ago the section hosted a session recalling the advances within the discipline. It was a look back at the last twenty years of work anthropologists have conducted in the AAFS. Recently, members of the section have expressed an opinion of possibly expanding our ranks with the inclusion of other branches of anthropologists (archaeologists, cultural anthropologists, and linguistic anthropologists). Now on the 40th anniversary, instead of looking back on the history out of curiosity, the research trends should be reviewed with an eye towards truly understanding all the things the discipline is involved in. How much of the presentations and publications actually include archaeological research? How do the fields of cultural and linguistic anthropology influence research? Are we incorporating enough of our sister disciplines to acknowledge their contribution and inclusion into the Physical Anthropology section (if they so desire)?

This review of Physical Anthropology history in the AAFS builds upon Benedix and Belcher (2006), who presented a poster on the subject. Some of the categories that they originally included in their study have been modified, the recent AAFS meetings have been added, and years that were not represented in their original study have now been included. Ten categories of research have been identified: biological profile, identification, case studies, taphonomy, archaeology, trauma, pathology, human vs. non-human identification, discipline/history of the Physical Anthropology Section, and other (a loose collection of research that does not fit with the other categories). The specific details of each category will be outlined in the presentation.

A total of 1,976 presentations have been made in the Physical Anthropology section meetings of the AAFS between 1972 and 2010. The following table displays the ten research categories, the number of presentations that have been made in each category, and the percentage that category represents in the history of the section.

Category	Number	Percentage
Biological Profile	565	28.5%
Identification	252	12.8%
Case Studies	191	9.6%
Taphonomy	248	12.6%
Archaeology	96	4.9%
Trauma	147	7.4%
Pathology	20	1%
Human/Non-Human	23	1.2%
Discipline/History	260	13.2%
Other	174	8.8%

Through an examination of the annual AAFS meetings presentations and anthropology publications in the *Journal of Forensic Sciences*, a discussion will be presented on the trends in the Physical Anthropology Section and its ever expanding research directions. It is hoped that with this history in mind, the attendee will have a clear understanding of the research done and will thus be better prepared to discuss the future direction of the Physical Anthropology Section.

Physical Anthropology, Trends, History

H65 Roles of the Forensic Anthropologist at the New York City Office of the Chief Medical Examiner

Christian Crowder, PhD, Christopher W. Rainwater, MS, and Kristen Hartnett, PhD, Office of the Chief Medical Examiner, Forensic Anthropology, 520 1st Avenue, New York, NY 10016; Jeannette S. Fridie, MA, Forensic Anthropology Unit, 520 First Avenue, New York, NY 10016; Benjamin J. Figura, PhD, NYC Jennifer Godbold, BA, and Scott C. Warnasch, MA, and Bradley J. Adams, PhD, New York Office of the Chief Medical Examiner, 520 1st Avenue, New York, NY 10016*

After attending this presentation, attendees will have a greater understanding of the growing role of the forensic anthropologist in medical examiner/coroner systems with particular attention to anthropology at the New York City's Office of Chief Medical Examiner (OCME-NYC).

This presentation will impact the forensic science community by discussing the expanding role of the forensic anthropologist and demonstrate the holistic approach needed in forensic anthropology casework.

T. Dale Stewart classically defined forensic anthropology as "that branch of physical anthropology which, for forensic purposes, deals with

the identification of more or less skeletonized remains known to be, or suspected of being, human" (Stewart 1979:xi). By this definition, the forensic anthropologist is a specialist in the reconstruction of the biological profile from skeletal material. Over the past 30 years following Stewart's definition there has been a paradigm shift in the conceptual framework by which the forensic anthropologist operates with specific reference to forensic taphonomy, forensic archaeology, and trauma analysis (Dirkmaat et al. 2008). This shift has increased the need for anthropological analyzes in the medical examiner's setting and expanded the role of forensic anthropology. As noted by Austin and Fulginiti (2008), anthropologists within the medicolegal system frequently perform roles in addition to standard forensic anthropological analyzes. The Forensic Anthropology Unit at New York City's Office of Chief Medical Examiner (OCME-NYC) has developed the largest dedicated staff of forensic anthropologists outside of the Department of Defense and currently consists of eight full-time anthropologists. In this setting, the roles and responsibilities of the forensic anthropologist are diverse and span into several operational areas beyond the classic laboratory based analyzes, specifically as they relate to field operations and decedent identification.

With expertise in archaeological techniques and methods, forensic anthropologists can assist medicolegal investigators with scene investigations where decomposed, skeletonized, fragmentary, burned, or buried remains are discovered. An archaeological approach to crime scene documentation is used to thoroughly and efficiently assist with the search and recovery of human remains and associated evidence. This approach also provides contextual details that may contribute to a better understanding of the crime scene. Scene maps provide a valuable addition to the case file and at the OCME-NYC, hand drawn maps are produced but specialized mapping technologies (GPS, total station, etc.) may also be employed when appropriate.

Forensic anthropologists at the OCME-NYC are also taking an increased role in the identification of decedents. No unidentified case is released for burial without an anthropological estimation of age. Analysis of sex, ancestry, and stature are performed as needed. Furthermore, electronic data are compiled and entered into national missing/unidentified databases such as the National Missing and Unidentified Persons System (NamUs) and the National Crime Information Center (NCIC).

Outside of daily operations, the forensic anthropologists are a critical component of OCME's disaster response team. In response to a disaster, the forensic anthropologist may fill standard roles such as mapping the scene of a mass fatality incident or assisting at the anthropology section of the disaster mortuary. Non-traditional roles are also evident in a disaster response. For instance, the forensic anthropologist may be involved with the Family Assistance Center, dissemination of information to family members, review of antemortem information, and coordination of the identification process. The forensic anthropologist may also take a leadership role with the body recovery effort. Similar roles are currently being assumed by the OCME's forensic anthropologists with the on-going efforts surrounding the World Trade Center disaster, both in field recovery operations and identification efforts.

It is apparent from the current work performed at the OCME-NYC, as well as by the increased employment opportunities over the past decade for forensic anthropologists that forensic anthropology has grown beyond the scope of its classic definition. As the result of this growth, the required education/training and qualifications of those pursuing a career as a forensic anthropologist is also changing. A comprehensive anthropological background is necessary considering that forensic anthropology draws methods and theory from physical anthropology, archaeology and cultural anthropology. Forensic anthropologists benefit from this broad training and expertise within these sub-fields of anthropology.

Forensic Anthropology, Roles, Medical Examiner

H66 Redefining the Scope of Forensic Anthropology: Embracing Archeology Would Help to Guide the Development of Best Practice for Field Recoveries of Human Remains

Stephen P. Nawrocki, PhD, and Krista E. Latham, PhD, University of Indianapolis Archeology & Forensics Laboratory, 1400 East Hanna Avenue, Indianapolis, IN 46227*

After attending this presentation, attendees will understand: (1) why forensic anthropologists should formally recognize archeology as a subfield of forensic anthropology; and, (2) why anthropologists must more actively advertise their field recovery skills to the medicolegal system.

This presentation will impact the forensic science community by clearly defining the five basic skill sets required for field recoveries of human remains and presenting a "best practice" argument for an increased reliance on archeologists in such cases.

Traditionally, forensic anthropology has been defined in terms of laboratory skills in skeletal analysis and human identification. Less appreciated by the medicolegal system is the fact that most American anthropologists are trained broadly in multiple subfields, including archeology. As a result, many jurisdictions continue to rely on crime scene investigators to process outdoor human remains scenes. However, compared to other types of forensic cases, decomposed human remains are relatively rare. The typical CSI will have little practical experience with these cases, and few agencies will invest the resources to properly train their personnel in all aspects of field recovery. CSI's tend to come from criminal justice and other non-science backgrounds and have little formal training in field methods. Short continuing education courses do not provide enough theoretical background or experience for them to conduct adequate recoveries, particularly of buried remains.

Five major skill sets are necessary to conduct controlled field recoveries. First, one must identify and inventory human bones and decomposed soft tissues in any condition so that missing elements can be noted and found before the scene is released. This skill requires coursework in osteology and anatomy. Second, one must interpret soil stratigraphy and understand how various processes have altered the soils, helping in the search for clandestine graves and the exclusion of irrelevant areas from continued investigation. This skill requires coursework in geology and sedimentology. Third, one must understand the techniques of controlled archeological recovery to minimize damage to the remains, to maximize evidence recovery, and to prepare effective maps. This skill requires coursework in archeological methods, surveying, and an intensive archeological field school. Fourth, one must recognize unusual forms of evidence, such as plants and insects that can link a suspect to the crime scene or help to estimate the postmortem interval. One must also trace all evidence back to specific soil strata so that its temporal association with the remains can be firmly established. This skill requires coursework in biology and the laboratory analysis of archeological materials. Fifth, one must recognize and interpret phenomena that alter the crime scene through time, including scavengers, water action, and agricultural practices, so that the final distribution of remains and evidence can be understood. This skill requires coursework in taphonomy, ecology, and site formation processes.

Only anthropologists with formal training in archeology are likely to possess all of these skills. At a time when the qualifications of all forensic practitioners are falling under scrutiny, the question must be asked whether the inconsistent, unregulated approach to human remains recovery in this country constitutes best practice. Systematically extending our established expertise in field recovery techniques into the forensic realm can significantly improve the quality of death investigations and increase the sophistication of interpretations drawn from the available evidence. Otherwise, we may witness more situations where, under informed cross-examination, a police recovery "expert" may not be able to render opinions regarding assailant activities, the original deposition point of the body, how

the scene was altered in the postmortem interval, and how the evidence helps to explain the circumstances of death. Worse, crucial evidence may be impeached for lack of proper contextual associations.

Anthropology has an opportunity to increase its public impact by encouraging its professional archeologists to participate more frequently in local medicolegal investigations. We must partner with law enforcement to find ways of educating archeologists in the unique problems and specific needs of forensic casework. In support of these initiatives, we should expand the traditional definition of "forensic anthropology" to include the subdiscipline of archeology, formally define minimum professional qualifications for field recoveries, and establish an appropriate certification process in forensic archeology.

Forensic Archaeology, Field Recoveries, Decomposed Remains

H67 An Atypical Burn Pattern Associated With Forensically Significant Human Remains

Nicole C. Larison, BS, 11701 Metric Boulevard, Apartment 1814, Austin, TX 78758; and Joan A. Bytheway, PhD, Sam Houston State University, Box 2296, Huntsville, TX 77341-2296*

The goal of this presentation is to demonstrate patterns of heat alterations on fresh bone, and more specifically the identification of atypical characteristics of heat alteration to human remains that decomposed for approximately two weeks before being burned. In addition, this presentation present a more typical burn pattern and color to fresh bone while in a pugilistic pose to decomposed remains configured in a tightly flexed position.

After attending this presentation, attendees will understand typical burn patterns on fresh bone including the initial, secondary, and final areas to burn on bone, the color range on burned bone, and how to identify possible trauma caused to an individual prior to heat alteration.

This study will impact the forensic science community by serving as an example of an atypical burn pattern seen in a homicide case and demonstrate the effects that heat has on bones.

Forensic anthropologists analyze burned remains to aid medical examiners in determining the manner in which an individual died. Burning human remains can destroy or alter evidence and is used to attempt to obscure the identity of an individual. Proper recovery of burned skeletal remains is important for identification of the individual and possible trauma sustained antemortem. Heat can cause bone fractures making it difficult to distinguish trauma from heat altered fractures. Recovery and thorough reconstruction of the skeleton is helpful in determining if there was any trauma to the bones prior to the body being burned (Herrmann and Bennett).[1] Heat altered bones also exhibit a range of colors indicative of the amount of time the bone was exposed to heat in a sequence (from the highest exposure to heat to the lowest) of calcined, charred, border and heat-lined (Ubelaker).[2] Teeth exhibit a similar range of colors which are categorized (from highest heat to lowest heat exposure) as incinerated, charred, scorched and intact. Some teeth may burst apart from high amounts of heat as well (Delattre).[3]

This presentation is based on an analysis of a decedent that was decomposing in a large garbage can for two weeks and then set on fire in an attempt to cover up a homicide. The remains were analyzed at the Southeast Texas Applied Forensic Science (STAFS) Facility in Huntsville, Texas. During the recovery process some skeletal elements were recovered approximately fifteen feet from the concentration of remains. In the laboratory, the skeletal remains were reconstructed, placed in anatomical position, and inventoried. In the anatomical position the burn pattern of the skeletal and dental remains was evaluated. The burned bone ranged from no burn to calcination. The burn pattern of "initial, secondary and final areas to burn on bone" was not consistent with that typically seen on fresh bone in the pugilistic pose. In addition to the atypical burn pattern, a triangular-shaped unburned bone fragment, from the left parietal bone, measuring approximately 23mm on each side, was recovered. With the exception of the posteroinferior tip of the bone no surfaces, including edges, were burned. When reconstructed the edges of this bone were part of radiating fractures that extended from a tool mark located approximately 15mm anterior to the unburned bone fragment. The tool mark, radiating fractures, and the unburned parietal bone are consistent with blunt force trauma prior to thermal alteration.

In fresh bone burn patterns of the skull, the squamous portion of the frontal bone is typically one of the first areas to burn while the occipital is one of the last areas to burn. In the present case, the occipital was calcined while the frontal bone was charred with small areas of unburned diplöe. Other atypical burn patterns of the bone and dentition will be compared to the more typical heat-altered pattern. The results of this presentation will give insight into the importance of proper recovery and reconstruction and the recognition of an atypical burn pattern as a result of unusual body positioning during burning. The information provided in this study will be helpful to forensic anthropologists and medical examiners presented with burned human remains.

Forensic Anthropology, Heat Altered Human Remains, Atypical Burn Pattern

H68 Contaminated Cremains? Evaluation of Biological Characteristics Derived From Ash Weight

Eric J. Bartelink, PhD, and Colleen F. Milligan, PhD, California State University, Chico, Department of Anthropology, Butte 311, 400 West First Street, Chico, CA 95929-0400; and Traci L. Van Deest, MA, University of Florida, Gainesville, Department of Anthropology, Turlington Hall Room 1112, Gainesville, FL 32610*

After attending this presentation, attendees will gain a better understanding of the value of anthropological assessments of cremated human remains. The goal of this presentation is to highlight methods used to evaluate whether suspected cremated human remains match the biological profile of the decedent.

This presentation will impact the forensic science community by providing awareness of the value of cremains weight in estimations of sex and assessment of other attributes of the biological profile.

The growing popularity of cremation in the United States has increased the likelihood of civil litigation involving commercial crematories and funeral homes.[1] Forensic anthropologists are often consulted to determine whether alleged cremains are in fact cremated bone and if aspects of the biological profile are consistent with the decedent. There are numerous limitations to the forensic analysis of cremains, due to the standard practice of pulverizing bone into small, unidentifiable fragments following cremation. Despite these challenges, several studies have documented a significant sex difference in average cremains weight, with males weighing approximately 1,000 grams more than females.[2-5] Sectioning points generated from cremains weights reported in these studies have shown reasonable predictive accuracy for sex estimation, although significant variation in average weights has been documented between regions.[2,5]

In 2011, the California State University, Chico Human Identification Laboratory (CSUC-HIL) was contacted by an attorney to examine a cremains case suspected of contamination. The family of the decedent notified the law office that a funeral home had misplaced an urn containing

the remains of a relative (a 60 year-old male). After further legal inquiry, the funeral home claimed to have relocated the urn. Due to the family's suspicions, the law office contacted the CSUC-HIL to analyze the contents of the urn to determine whether the cremains are consistent with that of the decedent.

Upon receipt, the urn contained a conglomerated block of material, which was removed from the plastic bag liner and placed into aluminum trays. Using geological sieves (1/8 inch mesh) and a strong magnet for small ferromagnetic metal items (screws, staples, etc.), the contents were separated into either osseous or non-osseous material. The majority of the urn contents were non-osseous material having the consistency of damp sediment (e.g., concrete dust, sand, cat litter). Following removal of the osseous remains from the sieves, radiographs of the remaining material showed very little cremated bone had passed through the 1/8 inch mesh. None of the cremains showed diagnostic anatomy; thus, it was not possible to determine if the cremains were human or nonhuman in origin.

Several lines of evidence supported the initial suspicion of contaminated cremains. First, the urn's contents weighed 544.3g more than originally recorded in the cremation log. Second, the urn contents weighed 4,173.5g, with non-osseous material (e.g., sediment, metal, stones) comprising 86.4% (3,604g) of the total weight, the majority of which (85.7%; 3,575.3g) was sediment. Only the remaining 569.5g (13.6%) represented cremains, well below even minimum reported weights for both sexes. Third, based on the reported stature of 154.9cm for the decedent, cremains weight is predicted to be 2,021.8g using equations reported in Warren and Maples.[4] The predicted weight for the decedent's stature is less than one-half of the actual weight of the urn contents. Additional testing, including x-ray florescence and x-ray diffraction analysis, will soon be undertaken to chemically characterize the urn's contents.

The results of this study highlight the value of cremains weights in evaluating aspects of the biological profile, as well as in settling legal disputes regarding potentially contaminated cremains. Estimations of sex and other biological parameters in cremation litigation cases should be applied cautiously due to reported regional differences in mean cremains weights. Further, additional studies, such as x-ray florescence and x-ray diffraction, can also be used to aid in the distinction of bone from other non-osseous materials.

Cremains, Biological Profile, Forensic Anthropology

H69 Validation Study of Microscopic Analysis of Saw Marks in Bone

Jennifer C. Love, PhD, and Sharon M. Derrick, PhD, Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Charles Peters, PhD, The University of Houston, 4800 Calhoun Road, Houston, TX 77004*

The goals of this presentation are to review the current method of microscopic analysis of saw marks in bone, showcase the variables utilized in the analysis, and present the results of an independent validation study of the method.

This presentation will impact the forensic science community by increasing the general knowledge of the method of microscopic analysis of saw marks in bone and providing specific information regarding interobserver error and the potential error rate associated with the method.

Microscopic analysis of saw marks in bone is a well published, generally accepted, and commonly used method. The strength of the method is that it is based on the use of standard laboratory equipment, a stereomicroscope, to analyze easily recognized qualitative and quantitative characteristics of a saw mark. Despite the method's attractiveness, it has not been independently validated, nor has the potential error rate been defined.

In 1975, Bronte published a seminal article on microscopic analysis of saw marks. He expanded the then current method of measuring the width of a saw mark to the analysis of the shape and pattern of striations observed in the walls of the saw mark.[1] He disproved the hypothesis that saw marks on bone destroy themselves with each consecutive stroke of the saw and showed that several class characteristics of the saw are recorded in the mark. In 1978, Andahl expanded on Bronte's work. He divided a saw mark into two components: the floor and the wall.[2] Andahl found features recorded in the floor of the mark, both in partial cuts and on the breakaway spur of complete cuts, that reflected the number of teeth per unit length, tooth set, degree of wear, direction of cut and condition of the blade. Symes contributed to previous works in his doctoral dissertation.[3] He evaluated experimental saw/cut marks made using 26 types of saw blades and serrated knives. Through microscope analysis, Symes observed and described numerous features of the marks that reflected the class characteristics of the tool.

Harris County Institute of Forensic Sciences Anthropology Division designed a validation study of microscopic analysis of saw marks in bone. Experimental saw marks were examined by three analysts following the current method as described by Symes.[3,4] Experimental saw marks were made using three hand saws and one power saw. The hand saw blade types were an 18 teeth per inch (TPI) wavy set, an 18 TPI raker set, and an 8 TPI raker set. The power saw was a reciprocating saw with a 10 TPI raker set blade. The four saws were used to create 58 samples in four human femora. Each sample consisted of a false start and both surfaces of a complete cut. The samples were separated using a Stryker saw and each Stryker saw cut was scored to differentiate it from the experimental cut surfaces. Each sample was analyzed using a Keyence digital microscope and indirect fiber optic light. Fourteen variables were evaluated on each sample. Eight variables were quantitative: minimum kerf width, tooth width, trough width, floor dip length, pull out striae interstriation distance, number of directional changes of striae, inter-tooth hop distance and inter-harmonic distance. Six variables were categorical: breakaway spur, kerf wall shape, kerf flare, trough morphology, entrance shaving and exit chipping.

Initially, a pilot study was conducted with 10 randomly chosen samples. Consistency among the three analysts for each feature was measured. The analysts agreed on the kerf wall shape and exit chipping six out of 10 times, consistency of cut seven out of 10 times, presence of pull out striae eight out of 10 times, kerf flare, trough morphology and entrance shaving nine out of 10 times, and harmonics 10 out of 10 times. The difference in minimal kerf width measurements ranged from 0.01 – 0.67mm and the difference in inter-tooth hop distance ranged from 0.14 - 2.54mm.

Not all variables showed equal sensitivity. Harmonics were found to be absent in all of the samples. The floor morphology of the false start was found to be flat in all but one of the samples. Also, entrance shaving was found to be absent in all but one of the samples.

Following the pilot study a review of the variable definitions and results of the study was conducted. The complete study was initiated and is ongoing. The statistical analysis of the complete data set will show the discriminative value of each variable, the associated interobserver error, and the potential error rate of the analysis.

Validation Study, Saw Marks, Bone

H70 A Prospective Study of Hyoid Fractures in Cases of Fatal Blunt Force Injuries to the Upper Body

Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; Steven A. Symes, PhD, Mercyhurst College, Mercyhurst Archaeological Institute, 501 East 38th, Erie, PA 16546; Lenne Marnewick, BSc, University of Pretoria, Department of Anatomy Private Bag x323, Arcadia, 007, SOUTH AFRICA; Piet J. Becker, PhD, Medical Research Council, Biostatistics Unit Private Bag x385, Pretoria, 0001, SOUTH AFRICA; and Jeanine Vellema, Forensic Pathology Services Johannesburg, 25A Hospital Street, Braamfontein, 0083, SOUTH AFRICA*

After attending this presentation, attendees will better understand the relationship of hyoid fractures to mechanism of injury, sex and age-at-death, stage of bone union, and soft tissue hemorrhage.

This presentation will impact the forensic community by providing a clearer understanding of hyoid fractures, which will affect the manner in which forensic anthropologists and pathologists interpret this type of trauma, especially when the context of the injury is unknown and soft tissue has been lost.

The cause of hyoid fractures and its contribution to assessments of cause and manner of death are unresolved issues in forensic sciences. Neck compression injuries, strangulations and hangings, are often examined for fractures of the hyoid, as well as thyroid and cricoid cartilages. Due to an increase in death from motor vehicle accidents, anecdotal statements have been made that injuries associated with rapid deceleration, such as hyper-flexion or hyper-extension of neck, are more likely to fracture the hyoid than either strangulation or hanging. Isolated hyoid fractures have been reported in sports injuries, falls, and profuse vomiting (Padgham 1988; de la Grandmaison 2006; White 2010). While copious literature is available on the incidence of hyoid fractures with various mechanisms of death, the results are contradictory and do not provide a systematic approach to the assessment and interpretation of throat organ fractures. The purpose of this study is to assess the relationship of hyoid fractures with six mechanisms of injury, sex, age, bone fusion, and presence and location of soft tissue hemorrhage.

A total of 276 hyoids associated with motor vehicle accidents (MVA) (79), pedestrian vehicle accidents (PVA) (74), falls from heights (44), strangulations (15) (manual strangulations six; ligature strangulations six; and unknown two), and hangings (64) were examined. The sample was predominantly male (n=209) with 56 females; mean ages were 36.29 years and 38.05 years, respectively. Cases were examined during autopsy at the Forensic Pathology Services (FPS) in Johannesburg, South Africa from September 2009 to June 2011. The University of Witwatersrand authorized ethical clearance (R14/49; MO90728).

Neck structures were dissected in situ and in accordance with the Gordon method, a standard dissection technique for the neck. Presence and location of hemorrhage was recorded at autopsy. The hyoid bone was retained and processed free of soft tissues. The probability of obtaining a fracture with the above-mentioned independent variables was tested with logistic regression.

Fractured hyoids comprised 24% (n=67, 55 males and 12 females) of the sample. Fractures were noted on the greater horns; at the articular facets; and on the body, and were associated with two strangulations; eight falls; 14 PVAs; 20 MVAs and 23 hangings. Mechanism of injury, sex, and hemorrhage did not increase the probability of a bone fracture and did not show statistical significance. But, persons older than 50 years had a 4.3 increased likelihood of a fracture than younger persons (p-value < 0.003). Likewise, unilateral fusion of the greater horn on the left or right side were 2.9 and 2.7 times more likely to fracture than un-fused or completely fused bones (p-value = 0.019 and p-value = 0.041, respectively).

Although inconsistent with forensic anthropology and pathology literature, it appears that mechanism of injury, sex, and hemorrhage are disassociated with the presence of fractures in the hyoid. The interpretive circumstances surrounding a neck injury is likely biomechanical in nature, i.e. magnitude, direction, duration, and location of force. While older persons demonstrated a greater incidence of fractures, horn failure should not be associated with complete fusion of the greater horns of the hyoid to the body. The unique configuration of a unilaterally fused U-shaped structure, the histological composition of the bone, and the composition of muscle and cartilage may contribute more to fractures in older persons. While an association with hemorrhage and fracture indicates injury during life, an equal number of cases with fractures (n=27) and without fractures (n=30) presented with hemorrhage to neck structures. At autopsy, only 27% (n=18) of the above-mentioned fractures were recorded.

Recognition, physical examination and correct interpretation of trauma from the skeleton are invaluable tools to understanding total body trauma in violent deaths. This can only be achieved with accurate contextual information and a closer examination of fractured or presumed fractured bones.

Trauma Interpretation, Neck Structures, Mechanism of Injury

H71 San Bruno Gas Pipeline Explosion: Responding to a Neighborhood-Wide Disaster

Colleen F. Milligan, PhD, Eric J. Bartelink, PhD, and Turhon A. Murad, PhD, California State University, Chico, Department of Anthropology, 400 West First Street, Chico, CA 95929-0400*

The goal of this presentation is to examine the complexity of applying forensic archaeological methods to a neighborhood-wide disaster. This presentation will include an overview of the recovery efforts following a gas pipeline explosion in San Bruno, California and highlight the challenges of working within various local, environment, and personnel constraints.

This presentation will impact the forensic science community by providing an example of a complex forensic recovery and the collaboration with various local first responders. As disasters requiring the assistance of forensic anthropologists are difficult to anticipate, this presentation addresses the need for outreach efforts to connect forensic scientists to other individuals and agencies involved in the recovery efforts before, during, and after a disaster occurs.

On September 9, 2010, a Pacific Gas and Electric (PG&E) natural gas pipeline exploded in a neighborhood located in San Bruno, California. The explosion occurred at 6:11 p.m. and quickly engulfed surrounding houses in the residential area. Escaping natural gas was ignited for more than an hour as PG&E personnel worked to shut down valves above and below the line rupture. Fires associated with individual homes were brought under control within 24-hours of the initial explosion. In total, the explosion destroyed 38 homes, damaged 70 other residences, and resulted in eight fatalities.

The California State University, Chico Human Identification Laboratory (CSUC-HIL) was contacted on September 11, 2010 to assist in the recovery efforts. A team of six faculty and staff members from CSUC-HIL and San Francisco State University, and 13 California State University, Chico students and alumni arrived on-site on September 12, 2010. Other

agencies involved in recovery operations for the San Bruno area included the National Transportation Safety Board, the San Mateo County Coroner's Office, San Bruno Fire and Police, San Mateo County Search and Rescue, and personnel from PG&E. The focus of the CSUC-HIL forensic recovery was a single residence near the scene of the explosion.

The CSUC-HIL recovery efforts included locating and mapping the remains of three individuals found in the residence. As a result of the exposure to intense and prolonged heat, the remains recovered were highly fragmented and calcined, making the distinction between the osseous material and the surrounding matrix extremely difficult. The residence, like all the homes in proximity to the initial blast site, was completely destroyed with no standing structures except for the chimney and an exterior concrete fence. The matrix from the collapsed structure was contained in the footprint of the house and was between one and two feet in depth. No interior walls or supporting structures survived the fire.

Several factors encountered added to the complexity of the recovery operation. First, the destruction from the gas pipeline explosion was a neighborhood-wide disaster with dozens of residences completely destroyed. As a result, the recovery operations took place in a large area with no existing infrastructure, such as clear streets, electricity, phones, or running water. Second, the length of time of the fire and the intensity of the heat from the ignition of the natural gas main created a large debris field up to three feet high across the neighborhood. The attempts to control the fire in the two days prior to the recovery included several fire departments and aerial fire suppression efforts, which greatly disturbed this scene. Third, the nature of the fire created a scene unlike those normally encountered by local fire personnel. As a result, early efforts to recover victims of the house were halted when the highly fragmented condition of the remains became apparent. The subsequent recovery by the CSUC-HIL team included examining remains in situ within the residence, and also identifying which elements had been recovered the previous day during the initial search for remains. This ensured maximum recovery of human remains from the site. Lastly, the lack of surrounding infrastructure and the duration of the recovery effort hindered the acquisition of proper safety equipment for the CSUC-HIL team. This limited the number of personnel the CSUC-HIL team could actively have conducting the forensic archaeological operations at any given time, which became a concern given a timeframe of less than 10 hours for the recovery.

This presentation will discuss the approach and recovery methods used by the CSUC-HIL team and will examine the lessons learned from the limitations encountered. The collaboration with local personnel will also highlight the role of forensic anthropologists in communicating proper recovery methods to a larger community of first responders.

Forensic Anthropology, Forensic Archaeology, Fire Scene Recovery

H72 Determination of Impact Direction Based on Fracture Patterns in Human Long Bones

Todd W. Fenton, PhD, Michigan State University, Department of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Ashley E. Kendell, MA, 721 North Capitol Avenue, Apartment 4, Lansing, MI 48906; Trevor S. DeLand, BS, Michigan State University, East Fee Hall, East Lansing, MI 48824; and Roger C. Haut, PhD, A407 East Fee Hall, Orthopaedic Biomechanics, Michigan State University, East Lansing, MI 48824*

After attending this presentation, attendees will have a better understanding of how to determine the direction of impact on long bones based on fracture pattern. The main goal of this research is to show that under controlled laboratory conditions, fracture patterns in human long bones display consistent characteristics that allow the determination of impact direction.

This presentation will impact the forensic science community by clarifying the relationships between characteristic features of fracture patterns and directionality of impact on human long bones.

The current forensic literature suggests that the direction of blunt force trauma to human long bones can be determined by the presence and orientation of a butterfly fracture. However, a recent study by Thomas and Simmons (2010) using a sheep bone model suggest that the butterfly pattern was an inconsistent finding. They then conclude that blunt force direction should not be assumed based on the presence or orientation of a butterfly fracture pattern. A series of experimental studies using 550 human long bones (Kress, 1996) also generated various patterns of fracture, including the typical butterfly, inverted wedges, oblique and transverse fractures. However, a variety of impact loading conditions and devices were used. Therefore, it remains unclear whether a butterfly wedge is a consistent finding during blunt force trauma, or, when present, if its orientation accurately predicts direction of loading.

Based primarily on the mechanics literature, this study hypothesized that under controlled laboratory conditions of impact loading and defined constraint of the bones, a consistent set of fracture features will result that can be used to predict impact direction on human long bones. While previous research typically focuses on the presence of butterfly fractures to determine impact direction, the current study examined the presence of complete as well as incomplete fracture characteristics to determine directionality of blunt force trauma to a long bone. Since it is believed that human long bone fracture initiates on the tension side and then propagates along lines of shear on the compression side to form a butterfly fracture, the current study also examined the location of fracture initiation and the pattern of fracture propagation.

In this study, 15 dry human femora were impacted with a rounded 2.5-inch cylinder perpendicular to the long axis of the bone. The anvil was connected to the hydraulic actuator of a material's testing machine (MTS, model 810). The ends of the bones were potted in room-temperature curing epoxy resin and inserted into cylindrical cups that allowed translational and rotational motions. The femora also had an axial load of 100 lbs. applied during the three-point bending tests. Impact loads transverse to the long bone axis were applied in the anterior-posterior and posterior-anterior directions by controlled displacement of the anvil at 0.2 m/s. In numerous experiments, fracture initiation and propagation were captured with a high-speed camera at 10,000 fps.

Results indicate that on a gross scale, 9 of 15 (60%) fractures were oblique, 4 of 15 (27%) fractures were transverse, and 2 of 15 (13%) were comminuted. But the gross fractures did not tell the whole story. A lesson learned is that one must also inspect the incomplete fractures. Closer examination of the bones revealed four common long bone fracture patterns: (1) incomplete butterfly fractures (tension wedges) in 80% of the cases; (2) transverse fractures on the tension (initiation) side in 80% of the cases; (3) failure angle shifts from approximately 45° to parallel (to the long axis) in the oblique gross fractures in 87% of the cases; and, (4) breakaway spurs on the compression side in 73% of cases. These common fracture patterns represent criteria that enabled us to determine the blunt force impact direction in 14 of 15 experiments.

In summary, the current study indicated that in a controlled laboratory setting, examination of distinct fracture characteristics help determine impact direction on human long bones. Specifically, a set of four criteria, outlined above, can be evaluated and used to quite accurately determine the direction of traumatic forces on tubular bone. The results also show that fracture consistently initiated on the tension side of the bone, opposite to the side of blunt force trauma, and that fracture propagation typically followed theoretical lines of maximum shear stress.

Fracture Pattern, Blunt Force Trauma, Directionality of Force

H73 Citrate Content of Bone for Time-since-death Estimation: Results from Burials with Different Physical Characteristics (Wooden Coffins Versus Plastic Body Bags) With Known PMI

Fabian Kanz, PhD, Christian Reiter, MD, and Daniele U. Risser, MD, Medical University of Vienna, Department of Forensic Medicine, Sensengasse 2, Vienna, 1090, AUSTRIA*

After attending this presentation, attendees will better understand how determining the content of citrate in bone of skeletal remains can help estimate time-since-death or postmortem interval (PMI) and how covering the body in a plastic body bag during the burial also affects the outcome of these determinations.

This presentation will impact the forensic science community by increasing knowledge, competence, and performance by describing how the citrate content determination in bones can be used to estimate the PMI and how to apply the proposed method properly. Problems arising from different physical characteristics of the burial will be identified. Finally, a protocol to implement this method in forensic practice will be recommended.

The reliability of methods for PMI determination of skeletonised human remains found at crime scenes is still far from satisfactory; these methods include macroscopic reaction to UV light, an analysis of the histological quality of cross-sections, chemical determination of nitrogen, carbon or amino acid content or the reaction of bone tissue to luminal. Recently, a new, extremely promising method was introduced, analyzing the citrate content of bone and establishing an equation for calculating the PMI.[1] In this study, it was postulated that there has to be direct contact between bone and soil in order to initiate and prolong the process of decreasing citrate content in the bone over time. Therefore, our study was conducted using skeletal remains with known PMIs but with different physical burial characteristics. One group was buried in conventional wooden coffins and the second group was additionally covered in plastic body bags, which should hypothetically lead to an underestimation of their PMIs.

The study included a total of 20 individuals (10 females and 10 males) of known age, ranging from 54 to 83 years. They were exhumed at Vienna Central Cemetery during a routine transfer of remains following the removal from their graves. Their documented PMI ranged from 29 to 52 years and they were buried at a depth of 1.4 to 3 meters in a uniform loess soil. All bodies studied were clothed and buried in wooden coffins as standard. Half of them were also covered before their burial in air and water-tight plastic body bags. This kind of burial was a common way of preventing the escape of decay gases when awaiting burial between the 1950s and the 1970s in Vienna.

In most cases, clothing remains were still present at the time of exhumation. None of the exhumed bodies had been in contact with ground or backwater. In the "normal" burial group, the coffin walls were largely destroyed and the skeletal remains were completely embedded in the ground. Soft tissue and ligaments were completely degraded. In the "body bag" group, the situation was similar because decomposable back panels were used with the body bags, which meant that body bags lying in the earth over time could be penetrated. Thus the soft tissue and ligaments had completely decomposed and the corpses skeletonized. However, in almost every case, the extremities showed traces of grave wax formation. Bone samples were taken from the midshaft of the femora and from the temporal bone of the skull of every individual. Citric acid content was determined according to the procedure described by Schwarcz and his colleagues.[1]

A clear trend of decreasing citrate content was observed. As time-since-death elapses, the process seems to accelerate. There were only slight differences in the behavior of the citrate decomposition between the burials in the body bags and the wooden coffins. This might be explained by the decomposable back panels which allowed the buried bodies to decompose faster.

The results of this study have shed new light on the impact of burial environments on the possibility of the citrate content of human skeletal remains to decrease. Even partial contact with the surrounding soil seems to be enough to initiate the process. Nevertheless, with this new method forensic science appears to have gained access to a powerful tool for estimating the PMI of skeletonized human remains found at crime scenes.

Postmortem Interval, Skeletal Remains, Citrate Content

H74 The New Kid on the Block: Trials and Tribulations of Building an Outdoor Research Facility and the Preliminary Results on the Rate and Pattern of Decomposition in Southern Illinois

D.C. Martin, MA, and Gretchen R. Dabbs, PhD, Southern Illinois University, Department of Anthropology, 1000 Faner Drive, Room 3525, Carbondale, IL 62901*

After attending this presentation, attendees will gain knowledge of the decomposition rate and pattern sequence of buried and surface remains over a one-year period in southern Illinois. Scientists and law enforcement officials involved in human remains investigation will benefit greatly from both the data and visuals presented. Furthermore, attendees will experience the announcement of the newest open air forensic research facility, the Complex for Forensic Anthropology Research (CFAR) at Southern Illinois University-Carbondale. Information on the establishment and maintenance of an open air facility such as CFAR will be given, citing political and social issues that have arisen during formation.

This presentation will impact the forensic science community by instituting a baseline of information for the decomposition of soft tissue in the southern Illinois region. The findings of studies at CFAR will prove more applicable to forensic cases in climatological and environmentally similar regions than those from any other comparable facility.

CFAR is located within the city limits of Carbondale, in Jackson County, IL and is a unit of the Department of Anthropology at Southern Illinois University - Carbondale. This location represents a geographic area which is located farther north, has the lowest average temperature, the most acidic soil, the worst soil drainage, and is the second lowest in elevation of all forensic anthropology research facilities in the United States. CFAR is roughly 1/3 an acre of fenced lightly-wooded grounds that provide intermittent periods of areas of shade and sunlight. The open-air location is supplemented by a freestanding office.

Unlike the most recently developed research facilities, CFAR is a bottom-up endeavor, with the driving force of the facility being the founders, a graduate student, and a first year faculty member. Political and social obstructions have played a significant role in the formation of CFAR. Due to university constraints, the location of CFAR has changed twice. City ordinances of animal and human rights were investigated and law enforcement was notified of the project. University administration meetings have been undertaken up to the Chancellor level. Even through this barrage of potential stumbling blocks, CFAR has been approved to carry out animal and human experiments, the public has been notified of the facility, and the facility has hosted two law enforcement training seminars.

Currently, 10 pigs *(Sus scrofa)* are being assessed to establish baseline rates and patterns of decomposition at CFAR. Seven of these subjects were buried at varying depths (25-46cm) and five have been placed on the surface in both sunny and shaded areas. The surface subjects have been covered with 18-gauge wire fencing to prevent scavengers from removing them. Research subjects were deposited at two experimental conditions (October and December 2010). iButton Link thermochrons (DS1921G)

have been placed at CFAR to monitor temperature at the site for use of accumulated degree days as the method of quantifying decomposition rate. Observations of the decomposition stage for each subject were collected daily following the method of Megyesi et al., using the Total Body Score (TBS) for each subject. Motion-activated cameras were used to record still photographs and video of research subjects in the absence of the authors. This proved extremely useful in identifying the types and activities of avian and mammalian scavengers in the region.

The recorded data show significant differences in both the rate and pattern of decomposition when CFAR is compared to other facilities. CFAR has exhibited a range of scavengers, such as opossum and turkey vultures, which consume buried and surface internments from one day to six months after burial. Furthermore, CFAR has exhibited slower progression in time between decomposition stages, and several of the subjects mummified unexpectedly. Preliminary results suggest the postmortem interval at CFAR may be delayed by as much as three weeks when compared to other regions, although this may be the direct result of cooler temperatures in late fall. Further research is necessary and ongoing.

Outdoor Research Facility, Taphonomy, Forensic Anthropology

H75 Taphonomic Impacts of Small and Medium-Sized Scavengers in Northern New England

Marcella H. Sorg, PhD, University of Maine, Margaret Chase Smith, Policy Center, University of Maine, Orono, ME 04469; William D. Haglund, PhD, 20410 25th Avenue, NW, Shoreline, WA 98177; Jamie A. Wren, University of Maine, Department of Anthropology, 5773 South Stevens Hall, Orono, ME 04469-5773; and Andrew Collar, Digital Spirit Media, 753B West River Road, Waterville, ME 04901*

After attending this presentation, attendees will better understand the impact small and medium-sized scavengers can have on postmortem processes and on the estimation of postmortem interval (PMI).

This presentation will impact the forensic science community by emphasizing the role of regionally specific scavenger guilds in outdoor cases.

Published models of decomposition generally assume a progressive skeletonization that includes fresh, bloat, early decay, late decay and skeletal phases, a process that includes insect involvement and excludes mammalian and avian scavengers. However, when scavengers remove soft tissue, they can truncate this process, skip bloat and/or decay phases, and move directly to skeletonization.

Apart from increasing the skeletonization rate, scavengers may disarticulate, scatter and consume elements, altering PMI estimations. Furthermore, insect PMI indicators may be limited or absent in scavenged cases. First, when scavengers remove flesh, although insects may be attracted to the odor, there is little left for larval stages to feed on. Second, in colder climates, much of the year is too cold for insect activity, whereas carnivorous scavengers are active year-round.

Three pig cadavers were placed in similar forested, highland environments on October 20, 2010, in northern New England, about one mile apart. Replicating modal forensic cases, pigs were placed 15-30 meters off unpaved access roads. Cadavers were clothed to provide human scent. Each site was equipped with two trail cameras for 24-hour surveillance. Temperature and humidity data loggers at each site were set for hourly monitoring. Sites were visited approximately weekly and at that time, close-up photographs were taken of the cadavers.

Between October and early April temperatures at all three sites (Sites M, N, and O) remained below 5°C. From late December to early April the sites were snow-covered. All three cadavers were scavenged, but scavenger patterns differed. The Site M cadaver was unscavenged until late April, when turkey vultures consumed and scattered the remains. Insect infestation was concurrent. Sites N and O had no insect infestation.

At both Sites N and O, when snow was approximately 2.5 feet deep, raccoons built snow tunnels to access cadavers. The Site N cadaver, unscavenged until February 17, was then defleshed in 60 days, while snow-covered. Scavenging at Site O began in early December, prior to snowfall, and continued throughout winter, defleshing the remains by April 15. Ravens, turkey vultures, and a bobcat also utilized the snow tunnels.

The scavenger guild included pine marten, raccoon, bobcat, porcupine, skunk, ermine, turkey vultures, crows, ravens, blue jays, and chickadees. Coyotes, bears, and eagles visited the sites, but did not feed. Insect infestation and bloating did not begin until six months postmortem. Two of three sites had no insect involvement, but were entirely defleshed during winter, mostly while under snow cover.

By June, scatter extended approximately 15 meters at each site. Most bones were still present and there was very little bone chewing. The original body location at Sites N and O were identifiable due to the presence of clothing. At Site M clothing is associated with a decomposition island. Sites N and O have characteristics that may have influenced scatter. The N Site was located on a gentle slope, and scattering of this cadaver was dispersed down-slope from the original deposition. The O site, located on flat terrain, had a game trail; scatter extended primarily along this trail.

These sites exhibit modification and scatter from small and medium-size scavengers in a wooded environment from late fall through spring. More research is needed to explore whether these patterns are typical of these taxa in this environment.

This project is supported by the National Institute of Justice, Office of Justice Programs, U. S. Department of Justice. The opinions, findings, conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Taphonomy, Scavenging, Decomposition

H76 High Soil Acidity Associated With Near Complete Mineral Dissolution of Recently Buried Human Remains

Diego A. Casallas, Attorney General's Office, DIAG 22B # 52-01, Edificio L, Piso 5, Bogota, COLOMBIA; and Megan K. Moore, PhD, University of Michigan-Dearborn, Department of Behavioral Science, 4901 Evergreen Road, Dearborn, MI 48128*

After attending this presentation, attendees will better understand how highly acidic soil can almost completely dissolve human bones within a short postmortem interval (8-10 years).

This presentation will impact the forensic science community by providing a well-documented postmortem interval for extreme microbiotic and chemical environments where the acidity is high. In addition, this research may help preliminary review and search teams in Colombia narrow down the list of graves to be excavated when similar conditions are present given the possibility of complete bone dissolution.

This research explores the potential causes of complete diagenetic bone mineral dissolution in graves of unidentified individuals buried between 2000 and 2002 in Colombia. The bodies of unidentified persons were documented and buried by an undertaker in a cemetery at the request and authorization from the local government agency of the municipality of La Macarena in the department of Meta, Colombia. The bodies were reportedly buried in coffins and wrapped in cloth or covered with plastic. A team of forensic scientists was sent by the government in February of 2010 to the cemetery in order to investigate reports of a possible mass grave in the area. However, they were able to determine that instead of a mass grave, there were approximately 450 single interments of unidentified individuals, each with its own grave marker. The investigation was initiated by complaints from community members looking for their loved ones.

The investigators were surprised to find that most of the skeletal material found was nearly completely eroded and destroyed by the action of unknown taphonomic agents. The location is described as an artificial terracing on a plain, surrounded by trees of medium height, grasses, and shrubs. The weather is mostly hot and humid year round in this location.

During the excavation, the anthropologists excavated an archaeological test trench in order to detect changes in the soil and determine the exact location of individual graves. The trench revealed partial grave outlines of four graves. Many of the grave outlines could only be distinguished by discoloration of the soil and coffin nails outlining the graves. Of the graves that the trench revealed, it was observed that clothing remained in some of the graves, but the bones were almost completely absent. Only one grave was completely excavated in order to detect the alteration suffered by the bones.

At the time of excavation, soil samples from different levels within the cemetery were collected and stored in plastic containers. The chain of custody was maintained as the samples were sent for testing at the Institute of Geography Agustín Codazzi, Department of Agrology - National Soil Laboratory in Bogotá, Colombia. The soil samples were tested for fungus, bacteria and chemical solvents. The samples do not exhibit a high level of flora that would indicate that the samples had dissolved as a result of the organic processes, especially phosphates that are normally active in this type of sample. The analysis did yield several genera of fungus: *Penicillium*, *Fusarium*, *Aspergillus,* and *Sclerotinia*. The most unique signature of this soil, however, was the extreme acidity. The abnormally low pH levels in the samples ranged from 4.2 to 4.5. According to the soil analysis from the laboratory, "highly acidic" soil ranges from 5.1 to 5.5. This acidity range is much lower than the "extremely acidic" range. As the pH scale ranges from 0 – acidic to 14 – alkaline, the samples here are even more acidic than what the laboratory reports as "highly acidic." Such a low pH can facilitate the degeneration of the bone mineral (hydroxyapatite) and facilitate the structural dissolution by opening the microscopic canals in bone and increasing the available surface area so it is subjected to greater taphonomic activity.

This research provides evidence of a taphonomic process of the near complete dissolution of human osseous material within a very short and well documented postmortem interval (8-10 years – burial to excavation).

This presentation will impact the forensic community by providing a well-documented postmortem interval for extreme microbiotic and chemical environments where the acidity is high. In addition, this research may help preliminary review and search teams in Colombia narrow down the list of graves to be excavated when similar conditions are present; given the possibility of complete bone dissolution.

Taphonomy, Soil Acidity, Human Skeletal Remains

H77 Where Are the Missing Bones? Structural and Material Properties of Bone and Differential Survivability

Jennie J.H. Jin, PhD, 3029 Lowrey Avenue N-2110, Honolulu, HI 96822; William R. Belcher, PhD, Joint POW/MIA Accounting Command, Central Identification Lab, 310 Worchester Avenue, Building 45, Joint Base Pearl Harbor-Hickam, HI 96853-5530; Yin Lam, PhD, University of Victoria, Department of Anthropology, PO Box 3050 STN CSC, Victoria, BC V8W 3P5, CANADA; and Joshua J. Peck, PhD, 91-737, Ewa Beach, HI 96706*

After attending this presentation, attendees will be able to understand how various bone properties can affect bone preservation and skeletal element representation, which is essential in order to make a more robust and thorough assessment of commingled assemblages.

This presentation will impact the forensic science community by providing baseline data regarding human bone structural density and survivability in forensic contexts. Of the most useful contexts are those that are common in forensic settings – that of commingled remains.

While many intrinsic properties of bone affect its potential for preservation, the property that has received the greatest amount of attention in taphonomic studies has been bone density. The definition of "bone density" has been the source of significant confusion among anthropologists and archaeologists. This confusion is warranted, given that this term has been used to refer to different properties or other similar terms (e.g., "bone mineral content," "bone mineral density," "structural density," "bulk density," "true density," "apparent density") have been used in the same context, and that "bone density" has been measured using several different methods that vary in accuracy. What one may typically think of as "bone density," the (dry) mass of a bone divided by its volume, is also known as its apparent density (Martin et al.) or structural density (Lyman).[1,2]

Bone density data have been collected for a number of animal species and for humans, and density has become, by far, the most commonly used proxy value for a bone's potential to survive destructive processes. Bone density studies with a zooarchaeological focus have far outnumbered those conducted with a forensic objective on human material. This reflects the comparatively high frequency in which zooarchaeologists encounter large bone assemblages that include commingled remains of multiple individuals often representing multiple species. However, bone density data for human are of particular relevance to forensic studies by providing guidance as to how to most accurately determine the number of skeletal elements (and individuals) present in the assemblage. Although previous studies have documented bone mineral density in humans (Galloway et al., Willey et al.), these data have not been widely used to explain the actual skeletal element representation. This study offers a larger sample size (MNI=432) discovered from various macro-environments, such as South East Asia, Korea, the Pacific Islands, and Northern Europe.[3,4]

In forensic and archaeological cases, in which the remains of large numbers of individuals are commingled, the determination of the number of individuals is a common research objective. Archaeologists seek to determine the minimum number of individuals (MNI), with the tacit assumption that an accurate determination of MNI provides a plausible estimate for the actual number of individuals represented. Ubelaker noted the relevance of zooarchaeological methodology to the study of commingled human remains.[5] In particular, he cited the observation that, when long bones are consumed by carnivores, the shaft fragments are more likely to survive than the epiphyses and would therefore provide the highest counts for long bone elements. In fact, reconstruction of shaft fragments has allowed a more accurate understanding of prehistoric diet and procurement activities (Bunn; Bunn and Kroll).[6,7] In forensic cases, the use of DNA analysis can be an important tool in determining the number of individuals represented in a commingled assemblage. Where DNA analysis is constrained by financial limitations or poor preservation, the determination of MNI rests largely on the morphological assessment. Under these circumstances, an understanding of the patterns of bone density and their effect on bone preservation is essential.

Skeletal remains recovered by the Joint POW/MIA Accounting Command (JPAC) provide multiple assemblages to test the relationship between bone structural density and survivability in human bones; specifically, this study tests the hypothesis that more dense bone will display increased survivability regardless of contextual background. In most cases, bone structural density and survivability show statistically significant correlation, which indicate the presence/absence of certain skeletal elements can probably be best explained by the natural process of bone degradation. Particular case studies originate from the Democratic People's Republic of Korea (DPRK; aka "North Korea"), related to human remains originating from the Korean War, between 1950 and 1953. One specific commingled case originates from a secondary, fluvial deposit from a POW holding area. The structural density and bone survivability showed significant correlation, and the MNI count of nine was based on the femoral shaft. The DNA data then confirmed that there were nine individuals. This example shows the importance of correctly identifying the most dense long bone shafts to calculate the most accurate MNI. Other examples come from a large commingled assemblage of remains that were turned over by the DPRK to the United States government, collectively referred to as the K208.

Taphonomy, Bone Density, Commingling

H78 Taphonomic Signatures of Animal Scavenging: The Benefits of Using Remote Recording Equipment to Monitor Scavenging Activity

Lisa N. Bright, MA, 1259 Hobart, Chico, CA 95926; and Robert J. Morton, MS, National Center for the Analysis of Violent Crime, Critical Incident Response Group, Federal Bureau of Investigation Academy, 2501 Investigation Parkway, Quantico, VA 22135*

The goals of this presentation are: (1) to provide an assessment of regional variation in relation to animal scavenging behavior; (2) to provide an evaluation of the benefits of using remote recording equipment; and (3) to encourage a discussion using actual experimental data including surface deposit and burial scenarios.

This presentation will impact the forensic science community by providing a critical evaluation of taphonomic research and present the benefits of using remote recording equipment to enhance taphonomic analysis.

Historically anthropological research was based on direct observation of the research subjects. The practice of direct observation causes minute changes to the test sites and test subjects. Further, the continued presence of human activity at a site can discourage the natural scavenging and decomposition progression. Daily observation introduces human scent, and human presence affects an accurate picture of activity at the site. This tradition can be modified using remote recording equipment to monitor scavenger behavior. The taped video recordings and motion activated still images provide actual observations of scavenger behavior and feeding as it occurs. This research was conducted in ecological reserve in rural northern California and in a wooded area of suburban northern Virginia.

The California portion of the study was conducted in October 2009 and November through December of 2011. Common northern California scavengers include the black bear, western spotted skunk, gray fox, coyote, raccoon, as well as the domestic dog and cat. Digital game cameras were positioned at six sites within the Big Chico Creek Ecological Reserve (BCCER) to monitor scavenger activity on a single adult mule deer, and five 100 pound pig carcasses. Two pictures were taken each time the motion sensitive laser was triggered, with a delay of one minute between pictures. Sites were monitored daily and the camera was repositioned if the carcass had been moved out of the cameras' field of view. The carcasses were placed on the surface and to prevent immediate removal from the site location, each carcass was tied down to rebar stakes with lengths of wire wrapped around the forelimbs and hindlimbs. Documented scavengers include: black bear, gray fox, turkey vulture, red-tailed hawk, golden eagle, and common raven.

The Virginia portion of the study occurred in three phases, from May 1999 through July 1999, May 2000, and from November through December 2000. Common scavengers in this area of northern Virginia include coyotes, domestic dogs, turkey vultures, red foxes, opossum, and the common crow. Site scenarios included surface deposit and shallow burial of less than one foot involving child-sized pigs (approximately thirty pounds). The 1999 study used four high-resolution video cameras with an infrared light source. Cameras used on site focused on a site overview and/or on a close up of the remains. The cameras were set to record for various lengths of time. The researcher also monitored the sites physically. Documented scavengers include: turkey vultures, crows, red foxes, raccoons, striped skunks and opossums.

The use of remote recording equipment allowed researches to document a clear division of diurnal or nocturnal predilection amongst the scavengers, as well as a hierarchy within the specific scavenger niches. This study also highlights the differences in large-body scavengers (black bear) versus small-bodied scavengers (raccoon and opossum). Although there are now several studies regarding the effect of scavengers on human remains, direct evidence of scavenging is still scant. Traditional anthropological techniques can be updated using modern technology, and regional studies should be conducted to create contextual information regarding scavenger behavior across the country.

Taphonomy, Scavenging, Remote Recording

H79 Hanging in an Outdoor Context: An Actual Perspective Using Human Cadavers

Alicja K. Lanfear, MS, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996-0720; and Rebecca J. Wilson-Taylor, MA, University of Tennessee, 3108 Rennoc Road, Knoxville, TN 37918*

After attending this presentation, attendees will appreciate how hanging changes the decomposition process to include the colonization of particular arthropods, the amount of biomass reduced, and the subsequent effects these factors have on estimating the postmortem interval.

This presentation will impact the forensic science community by describing and defining the decomposition process of hanging cadavers in the outdoors, the entomological activity associated with the hanging of human cadavers, the resulting skeletal deposition, and how these relate to time-since-death estimations of outdoor hangings.

Most suicidal hangings occur indoors, but outdoor hangings often create more questions than answers for investigators (Komar et al., Spitz and Fisher).[1,2] Shalaby et al. are one of the first studies to evaluate how hanging can affect decomposition using a carrion model.[3] This research highlighted how the pattern of decomposition in a hanging versus surface deposition followed similar patterns; however, they did not explain the long-term preservation of hanging remains or the lack of biomass reduction. Komar et al's. retrospective study, on Edmonton medical examiner cases, indicated a high rate of mummification and a large quantity of desiccated tissue being recovered in hanging contexts.[1] Despite these studies, few researchers have systemically evaluated how the stages of decomposition are affected by hanging a human cadaver.

The goals of this project were three-fold: to document the basic stages and differences in decomposition of cadavers that are hanging compared to those on the surface of the ground; to document the entomological activity associated with a hanging scene (including defining the "drip zone"); and to determine the final skeletal deposition related to the hanging environment. A 10-foot high wooden device was built with a pulley/crank system to ease the force required to lift individuals into the hanging position approximately one to two feet above the ground surface. The number of variables, such as clothing or knot type, was limited so that seasonal differences could be appreciated. Eight cadavers from the University of Tennessee's Forensic Anthropology Center's body donation program were used in this experiment (8 males ages 50-60, weighing less than 200 lbs).

Four cadavers were hanged and four were placed on the surface about 10 feet from the hanging contraptions at the Anthropological Research Facility, the University of Tennessee, Knoxville, in the summer and fall 2009.

Similar series of decomposition events including oviposition patterns were observed for the control and hanging cadavers; however, significant differences, including the rate of decomposition, and biomass reduction were observed. These differences can primarily be explained by the fact that hanging cadavers maintained ambient temperatures while surface cadavers were able to maintain more constant and significantly higher temperatures even in the winter months. Coupled with limited continual larval activity, the hanging individuals exhibited putrefaction and advanced decomposition much later than the control/surface individuals. This corresponds with previous surveys indicating that decomposition rates are significantly slower in hangings at higher heights as opposed to individuals partially on the ground (Komar et al.).[1]

The most significant difference in the decomposition process occurred between the individuals hanged in the summer as opposed to the late fall months. The summer trials experienced rapid decomposition and subsequent purging of the internal cavities through the loss of the perineum, while the late fall trials had a settling of the internal materials, but no loss of the perineum. Instead of being hollow, these bodies maintained biomass for a longer period of time, falling from the noose prior to those in the summer trials. In fact, the summer trials have been hanging for over two years.

Expanding our understanding of the decomposition process and subsequent skeletal deposition in situations other than an individual lying on the ground is necessary for the continued development of our field. The limited nature of published research evaluating hanging scenarios, both indoor and outdoor, necessitates the continuation of this project over the long term, as there is potential to determine characteristic markers to differentiate between skeletal remains that decomposed on the surface as opposed to those from a hanging situation.

This research was supported by the William M. Bass Endowment.

Human Decomposition, Hanging, Forensic Anthropology

H80 Multi-Factorial Estimation of Skeletal Age-at-Death Using the Sugeno Fuzzy Integral

Melissa Anderson, MA, 559 White Oak Lane, Starkville, MS 39759; Derek T. Anderson, PhD, Mississippi State University, Electrical and Computer Engineering Department, Simrall Building, Hardy Road, Box 9571, Mississippi State, MS 39762; Daniel J. Wescott, PhD, Forensic Anthropology Center, Texas State University, Department of Anthropology, 601 University Drive, San Marcos, TX 78666; James M. Keller, PhD, University of Missouri, Department of Electrical and Computer Engineering, 501 Thilly, Columbia, MO 65203*

After attending this presentation, attendees will understand the basic principles of how to use the fuzzy integral to obtain a multifactorial age-at-death estimation for a single skeleton.

This presentation will impact the forensic science community by providing a new standardized method for combining multiple indicators of age along with their respective accuracies, into a single, accurate, age-at-death estimation. It will also cover a feature-based method to determine the degree to which age-at-death fuzzy set results belong to different anthropological classes. The final topic is an OWA-based contrast approach to measure the amount of specificity in an age-at-death fuzzy set.

Accurate and precise estimations of chronological age-at-death based on skeletal remains are vital in forensic anthropological analyzes to help narrow the search for potential missing persons and to aid in the identification of the skeleton. Combining multiple indicators of biological age (multifactorial method) from different regions of the skeleton provide a more accurate estimation of chronological age than using any single indicator. However, most currently published multi-factorial methods are not appropriate for forensic anthropology because they cannot be applied to a single skeleton, do not provide a confidence in the point estimate or prediction interval, or are restricted to a certain types of age indicators. Currently there are no "best practice" guidelines in forensic anthropology for combining multiple indicators of age. As a result, forensic anthropologists frequently develop their own guidelines for combining multiple indicators, often based on their past experience and the skeletal remains present for a specific case. A standardized method for combining multiple indicators of age from a skeleton into a single, accurate, and repeatable age-at-death estimation is needed in forensic anthropology.

A novel multifactorial approach is presented that uses the Sugeno fuzzy integral to analyze skeletal age and takes into account as much information as possible, including the accuracy of the method and the quality of the bone, to reach a decision about a hypothesis. Fuzzy integral acquired fuzzy sets are then used to provide results about the age-at-death estimation that are reproducible and can be understood by different scientists. Using this approach, forensic anthropologists obtain an age-at-death estimation, a measure of the confidence in the estimation, and additional results (numeric, graphical, and linguistic) regarding the type of graph and degree of specificity of the age-at-death estimation. This method has multiple advantages over other multifactorial methods. The procedure allows investigators to use nearly any well established and tested age-at-death indicator methods and fuse the information about the accuracy of the methods with other types of quantifiable information that cause uncertainty in the age-at-death estimation. No other method allows for the fusion of additional information such as the quality of the bone, the appropriateness of the method for the target age group, or inter-observer error in the methods used. Other advantages of the fuzzy integral method are that it does not require the use of a population so it can be easily used for a single skeleton, it can be used for both adult and immature skeletons, it can be customized to meet the investigator's needs on specific cases, and it provides informative graphs and a standardized reproducible way to generate linguistic descriptions of age-at-death estimations.

To demonstrate the use of the fuzzy integral method, we apply it to three aging methods commonly used by forensic anthropologists (pubic symphysis, auricular surface, and cranial suture closure) on a known-age skeletal sample from the Terry Anatomical Collection. The research shows that the fuzzy integral method produces results that are more accurate with smaller intervals than single indicator methods. Unlike other multi-factorial methods, the fuzzy integral approach allows investigators to estimate age-at-death for a single skeleton by applying the well-established age methods they are comfortable using and that are available to them based on the bones present, the condition of the bones, and the equipment they have accessible. Furthermore, unlike other methods, the fuzzy integral method allows the investigator to incorporate additional information about the quality of the bone or any other quantifiable variable about the uncertainty of the method.

Forensic Anthropology, Age-at-Death, Sugeno Fuzzy Integral

H81 A Comparison of Site-Specific Versus National Weather Service Temperature Data and its Applicability to Estimation of Postmortem Interval Using Accumulated Degree Days

Gretchen R. Dabbs, PhD, Southern Illinois University, Department of Anthropology, 1000 Faner Drive, MC 4502, Carbondale, IL 62901*

After attending this presentation, attendees will gain knowledge on how retroactively collected National Weather Service (NWS) temperature data from the closest NWS weather station to a recovery site are not necessarily directly applicable to the temperatures occurring at a recovery site, regardless of the proximity of the two.

This presentation will impact the forensic science community by correcting the previous assumption that the closest NWS station to a recovery site provides acceptably accurate temperature data for estimation of the postmortem interval using accumulated degree days. It should serve as an impetus for future research into the correlation of the rate and pattern of decomposition with site-specific Accumulated Degree Day (ADD) data, improving our ability to estimate the postmortem interval accurately.

Following the "best practices" guidelines of the Scientific Working Group for Forensic Anthropology, an increasing number of anthropological studies of human decomposition are utilizing accumulated degree days (ADD) to quantify the postmortem interval (PMI) at given decomposition stages and to estimate the number of ADD required for certain events, such as tooth exfoliation, to occur. This study addresses the utility of applying retroactively collected temperature data from the National Weather Service (NWS) station closest to the recovery site to these calculations, as prescribed in the past. Using iButton Link thermochrons (model DS1921G), hourly temperature readings were collected at 15 sites throughout the eastern half of the United States (Arkansas-one site; Connecticut-one site; Illinois-six sites; Kansas-three sites; Louisiana-one site; New York-one site; Mississippi-one site; Vermont-one site). With the exception of one, all research sites represent private property owned by an individual who volunteered to participate in this study upon the request of the author. There is no intentional bias in the selection of sites, the patterning merely reflecting the extent of the author's social network. The non-private research site is located at the Complex for Forensic Anthropology Research (CFAR) at Southern Illinois University. Each thermochron was placed 25 cm above the ground surface on the north side of a support made of natural fiber, most being attached to trees or wooden fence posts. The thermochron was placed at least 3m from any permanent structure (house, shed, driveway, etc.). This placement protocol was designed to ameliorate the possibility that reflected and radiant heat from synthetic materials may increase the recorded temperatures at research sites. The preliminary analysis reported here is based on data collection periods ranging from 135 to 169 days (mid-December 2010 through May 2011). Data collection is ongoing and the total data set will increase to at least 365 days per site by February 2012. The average daily temperature was calculated by averaging the daily maximum and minimum hourly temperature readings for each site, as prescribed by the NWS. In order to maintain consistency with the average daily temperature as reported by the National Weather Service a day was considered to be the 24-hour period from 0000-2400 XST or 0100-0059 XDT. In 2011, Daylight Saving Time began on March 9th. National Weather Service temperature data (F6 data) for the weather station closest to each of the fifteen research sites were retrieved from an official reporting website for the NWS (www.wunderground.com). The direct linear distance between each research site and the closest NWS weather station averaged 7.0km. The NWS stations ranged between 0.5km and 15.3km from the individual research sites. The site-specific and NWS data were matched by date, and a paired-samples t-test (SPSS 17.0) was used to identify statistically significant differences between the temperature data recorded at the research sites and those recorded by the National Weather Service. The difference in average daily temperature between NWS data and site-specific data ranged between 0.05°C and 3.03°C. All 15 sites presented high correlations between NWS and site-specific data ($0.809 \leq r \leq 0.989$). The observed differences were statistically significant for 11 of the 15 research sites (73.3%) (*p-value* ≤ 0.021). Four sites exhibited no statistically significant differences between the temperature data recorded by the NWS and the site-specific data (*p-value* ≥ 0.094). These four sites are suburban and rural, far from the NWS station and close, both west and east of the Mississippi River, coastal and mountainous—in short, there is no clear, observable difference in environmental conditions that may cause these sites to be more consistent with the NWS data than other sites. The results of this study demonstrate that utilizing retroactively collected temperature data from the nearest NWS station to a site without investigation into the correlation between the microclimates of the site and the NWS facility is unwise at best and unacceptable at worst, particularly if the intended purpose is the development of methods of estimating PMI.

This project is partially funded by a Lucas Grant from the Forensic Sciences Foundation.

Forensic Anthropology, Postmortem Interval, Accumulated Degree-Day

H82 A Forensic Pathology Tool to Predict Pediatric Skull Fracture Patterns - Part 3: Entrapped Porcine Head Impacts vs. Controlled Head Drops

Todd W. Fenton, PhD, Michigan State University, Department of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Nicholas V. Passalacqua, MS, 1559 Mount Vernon, East Lansing, MI 48823; Brian J. Powell, BS, Timothy G. Baumer, MS, Michigan State University, Orthopaedic Biomechanics Laboratories, East Lansing, MI 48824; and Roger C. Haut, PhD, Michigan State University, A407 East Fee Hall, Orthopaedic Biomechanics, East Lansing, MI 48824*

The goal of this presentation is to inform attendees about research on fracture initiation and propagation caused by controlled head drop experiments onto the parietal bone in a developing porcine (*Sus scrofa*) model.

This presentation will impact the forensic science community by describing comparisons between controlled head drops and the previous data presented using an entrapped head impacted by a gravity-dropped mass with compliant and rigid interfaces.

Pediatric deaths involving head injury with associated cranial fractures represent one of the greatest challenges to forensic professionals. The ability of the forensic investigator to establish the circumstances of death in these cases is severely hampered by the lack of skull fracture standards for infants and young children. This research aims to understand the basic principles behind infant cranial fractures in the porcine model which may then be used to help guide future human research.

Previously, findings were reported from a porcine head model entrapped in a bed of epoxy that was used for constraint during impact onto the parietal bone using a dropped mass impact interface. Fenton et al. showed multiple fracture initiation sites on the porcine cranium away from the impact site, and more recently Passalacqua et al showed that when the impact energy was doubled, there was extensive fracture propagation in both the parietal bone and into adjacent frontal and occipital bones.[1,2] The phenomenon of remote fracture initiation in this infant porcine model has also been documented using high-speed video (Passalacqua).[2]

Because forensic cases often involve situations in which free fall head drops are suspected, this next phase of research dealt with fracture initiation and propagation in controlled head drop experiments onto a rigid interface at energy levels comparable to the previous study of Powell et al. using the entrapped head model.[3]

In order to compare head drops versus the entrapped impacts, 31 porcine specimens aged 2-17 days were used. To produce the necessary impact energy, the head was attached to a drop tower trolley, which was raised to the necessary drop height. In the experiments a solenoid disengaged, allowing the trolley to fall freely. Upon impact, the head was disengaged from the trolley allowing it to impact a rigid aluminum interface once, by using an electromagnetic solenoid to catch the head after impact. The impact energy levels for various aged specimens in the current study were matched to the energy levels documented in Powell et al. for the entrapped heads. The fracture patterns were compared between experiments using a GIS image-analysis approach, as previously described by Marean *et al*.[3,4]

Results from these controlled head drop experiments demonstrated that the impact duration was significantly shorter than for the entrapped head experiments of Powell et al. (*p-value* < 0.001), however the peak impact force data was not different at each specimen.[3] There was significantly less skull fracture at each age for the free fall experiments than for the entrapped heads (*p-value* < 0.001). GIS fracture pattern results demonstrated that fracture initiation was located primarily along the anterior parietal bone in all free fall specimens. A simplified, theoretical model analysis of each experiment, using the finite element approach, showed that large tensile stresses develop around the periphery of the entrapped head, near the epoxy constraint, that likely produced extensive fractures remote to the site of impact. The tensile stresses in the head model were lower and located more near the impact site in free fall experiments.

While further research is necessary in order to define any potential relationships between the infant porcine model and the infant human, these results showed that head entrapment provides a significant stress riser that enhances the potential for cranial bone fracture compared to an equal amount of energy to a freely falling head impacting a rigid surface.

This project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. H83 Geometric Morphometric Analyzes From Dental Orthopantogram Images: A Regional Anatomical Analysis of Sexual Dimorphism in the Adult Mandible

Patrick Randolph-Quinney, PhD, Centre for Anatomy & Human ID, College of Life Sciences, University of Dundee, Dundee, DD1 5EH, UNITED KINGDOM; Emilio Nuzzolese, DDS, PhD*, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, 70124, ITALY; Caroline Wilkinson, PhD, Katie Nicoll Baines, BSc, Centre for Anatomy & Human ID, College of Life Sciences, University of Dundee, Dundee, DD1 5EH, UNITED KINGDOM; and Giancarlo Di Vella, PhD, Section of Legal Medicine - University of Bari, P.zza G. Cesare 11, Bari, 70124, ITALY*

After attending this presentation, attendees will have a better understanding of a new method of sex assessment through the analysis of clinical panoramic X-ray images.

This presentation will impact the forensic science community by introducing a novel method of sex determination following a skull assessment.

The human mandible has routinely been utilized in forensic assessment of age at death, sex determination and biological affinity. However, such studies have generally utilized conventional assessments of size and shape variables, and as such fail to record the true nature of shape differences due to dimorphism in this functional skeletal element. The research here presented utilizes geometric morphometric techniques to investigate and quantify shape and size variation in the morphology of the mandibular corpus and ascending ramus, and consequently the potential for forensic human identification. The results of a novel morphometric study using clinical panoramic scanning x-radiography to study the extent of morphological variation within a modern Italian sample population are presented.

Clinical digital orthopantogram images (OPG) were acquired of the upper and lower jaws of 50 male and 50 female participants. Ten type I and type II 2D landmarks were applied to the symphysis, and condylar and coronoid processes. One hundred equidistant semi-landmarks were established along the inferior border of the corpus, and the posterior border of the ascending ramus. The resulting landmark configurations (*n* 100) were subjected to Generaliszd Procrustes Analysis (GPA) with Full Tangent Space Projection. Principal Components Analysis (PCA) was applied in order to assess population variation. Factor loadings were subject to Canonical Variates Analysis with stepwise and leave-one-out classification in order to assess the effects of sexual dimorphism on mandibular shape. The results showed individuals to be correctly classified for sex in 89.6% of cases, (males were correctly classified in 90.1% of cases, and females in 85.6%).

Analyzes of the mandible were subsequently broken down into anatomical regions based on the mandibular body, the bony processes and the ascending ramus in order to investigate regional functional differences in the expression of dimorphism in mandible. A partial least squares (2-block PLS) method was further applied, in order to examine patterns of covariation between shape variables and the exploration of patterns of functional modularity. Most interestingly the results indicate the greatest level of individual and sex-specific variation is found in the shape-curve and pattern of the inferior corpus, in contrast to that of ramal flexure. Stepwise permutation tests and analyzes of regional covariation indicate functional coupling, with a moderate degree of modular integration between the corporal and ramal regions suggesting that functional ties between the units are correlated in influencing sex-based morphological trait expression between anatomical regions, indicating that the geometric relationship between the mandibular corpus and the ascending ramus offers significant power for forensic identification purposes. Consequently such units may be studied together or in isolation, and this may allow for the development of identification criteria based on modular unit shape variables which may be applicable for both whole specimens and fragmented remains depending on the forensic situation. Overall the results are strongly significant and suggest that both dependently and independently that the

shape relationship between the mandibular corpus and the ascending ramus offers significant power for forensic identification purposes. Of particular interest is that inferior corpus border shape offers significant discriminating potential in the assessment of sex, with the effects of allometry being strongly implicated. These and other implications of the shape analysis will be discussed.

Sex Assessment, Geometric Morphometrics, Forensic Anthropology

H84 A Comparison of Age-Related Macroscopic Traits of the Ilium and Sacrum

Kyle A. McCormick, MA, Department of Anthropology, PO Box 6000, Binghamton, NY 13902-6000; and Nicholas V. Passalacqua, MS, 1559 Mount Vernon, East Lansing, MI 48823*

After attending the presentation, attendees will have a better understanding of age-related traits of the auricular surfaces of the ilium and sacrum in terms of age-at-death indicators

This presentation will impact the forensic science community by demonstrating potential differences in the development of three macroscopic traits of the auricular surfaces of the sacrum and ilium as well as the potential significance for estimating age-at-death from these structures.

Accurate age-at-death estimation from human skeletal remains is critical for establishing a comprehensive and forensically significant biological profile of an unknown individual, which in turn facilitates the victim identification process. While many regions of the human skeleton have methods to facilitate adult age estimation, the auricular joint of the pelvis presents a unique structure to compare similar traits across the sacrum and ilium. Interestingly, while both the sacrum (Passalacqua) and the ilium (Lovejoy et al., Buckberry and Chamberlain, Osborne, among others) have age-at-death estimation methods, there has been little work relating the adult degenerative changes which occur on the paired auricular surfaces.[1-4] In fact, Lovejoy et al. state: "The sacral [auricular surface]...does not reflect the age changes described below [in regard to their method of scoring the ilium] and cannot be used to determine age."[2] This presentation tests that assertion.

The primary aim of this study was to assess three degenerative traits (apical changes, microporosity and macroporosity) found on both the sacrum and ilium auricular surfaces and compare the timing of appearance for each trait across the auricular joint. Paired ilia and sacra from the Hamann-Todd (n=380) and Bass (n=234) collections comprise the samples used in this study. Individuals from the Hamann-Todd collection consist of males and females, mainly of African and European ancestry, ranging in age-at-death from 10 to 96 years and individuals from the Bass collection consist of males and females of European ancestry, ranging in age-at-death from 16 to 97 years. Previous research (Lovejoy et al.; Passalacqua) found no significant sex or ancestry differences in regard to age-related changes of the ilium or sacrum.[2,1]

These traits develop over a continuum and each morphological character was scored according to multiple trait variants as described in Passalacqua and Buckberry and Chamberlain.[1,3] However, in order to limit observer error and deal with discrepancies in method scoring procedures, these traits were re-scored on a presence or absence scale (1 and 0, respectively). A Kruskal-Wallis test was then used to assess differences in presence and absence of these traits between the ilium and sacrum. Results suggest that macroporosity appears earlier and more often in the ilium (mean age = 50.65) than the sacrum (mean age = 53.8 years, $\chi^2 = 82.926$, df = 1, *p-value* = 0.000). However, apical change ($\chi^2 = 2.145$, df = 1, *p-value* = 0.143) and microporosity ($\chi^2 = .464$, df = 1, *p-value* = 0.496) show no significant difference in presence or absence frequency.

While Lovejoy and colleagues may have failed to recognize corresponding traits appearing on the sacral auricular surface, our results suggest similar ages of onset for microporosity and apical changes. However, much of the auricular changes of the ilium are more subtlety expressed on the sacrum, likely as a function of thicker cartilage covering the sacral auricular surface (Schunke).[5] While the etiology of macroporosity on the auricular surfaces is unclear, overall it was found in much greater frequency on the auricular surface of the ilium. This could be a function of the degeneration of the ilium's cartilage due to the thinner cartilage covering that portion of the auricular joint; however, further research is required to investigate the cause.

Forensic Anthropology, Age-at-Death Estimation, Auricular Surface

H85 Metric and Non-Metric Assessments of Sex: Accuracy, Correlation, and Corroboration

Michael W. Kenyhercz, MS, 6327 Catawba Drive, Canfield, OH 44406; Alexandra R. Klales, MS, 1133 Taylor Avenue, Apartment #7, Winnipeg, MB R3M 2K4, CANADA; Sara M. Fredette, BS, Mercyhurst College, 501 East 38th Street, Box F1129, Erie, PA 16546; Dennis C. Dirkmaat, PhD, Applied Forensic Sciences Department, Mercyhurst College, Glenwood Hills, Erie, PA 16546*

After attending this presentation, attendees will understand the reliability of non-metric methods, as well as their correlation with metric methods, which are commonly employed in biological profile estimation for unknown individuals.

This study will impact the forensic science and anthropology community by demonstrating the relationship between both types of methods, as well as their relative accuracies, in sex estimation from a forensic context.

Sex estimation is a vital component of the biological profile estimation in forensic identification of skeletonized or badly decomposed unknown individuals. While the forensic anthropological community is moving toward the increased use of metric methods, non-metric methods continue to be routinely employed because of their relative ease of use, their perceived reliability, and because they are frequently "passed-down-knowledge." Because of these factors, non-metric methods are often still utilized for biological profile estimation, in conjunction with metric assessments, particularly with the human skull and pelvis. The skull has historically been the most studied portion of the skeleton for both ancestral and sex related differences, while the pelvis, specifically the innominates, is widely regarded as the greatest indicator of sex due to the dimorphism related to childbirth in females.

Non-metric and metric data were collected from all forensic cases conducted from 2009 to present at the Department of Applied Forensic Sciences at Mercyhurst College in Erie, PA. The non-metric methods utilized for sex estimation include: (1) the Walker method for sex estimation of the crania using the expressions of the supra-orbital ridge, the mastoid processes, the mental eminence, the nuchal crest, and the supra-orbital margin of the orbits; and, (2) the Klales *et al.* (in press) method for estimating sex using ordinal scoring and expressions of the subpubic concavity, the medial aspect of the ischio-pubic ramus, and the ventral arc in the pubic bone as modified from the Phenice method.[1-3] In addition to

non-metric techniques, standard osteometric measurements of the skull and pelvis were also collected for each for individual or case based on the parameters outlined in Buikstra and Ubelaker and were analyzed using FORDISC 3.1 (Jantz and Ousley).[4,5] Graduate students with extensive training in each of the methods collected all measures.

Cases were separated into two groups, those that were positively identified and those that were unidentified at the time of this research. Classification accuracies were calculated for each of the non-metric methods and also for the osteometric measures. This was undertaken in order to evaluate how well the metric assessment corroborates with the results obtained using non-metric methods and vice versa. Additionally, with the positively identified cases, each non-metric method and the osteometrics were examined for accuracy in sex estimation. Lastly, correlation matrices were then used to examine the relationship between standard osteometric measures and non-metric trait expressions.

Preliminary results using the positively identified individuals indicate that metric methods had slightly higher classification accuracies of sex (100% using FORDISC 3.1) than the non-metric methods employed (92.9% combined accuracy for the Walker and Klales *et al.* methods). However, the non-metric methods and metric methods for sex estimation were found to be highly correlated using the entire sample. Finally, metric methods showed high correlation with the Walker non-metric traits: nuchal crest with nasion-occipital length (NOL), and the expression of the mastoids with mastoid height (MDH).[2] As expected, metric methods failed to show a high correlation with the Klales *et al.* (in press) and Phenice traits.[2,3] This suggests that metric measures of the pelvis fail to capture these visual sex differences in the pubic bone which may best explain why these non-metric methods are still frequently employed for sex estimation.

Evaluating the correlation between metric and non-metric methods will aid in the understanding of non-metric traits and will also increase the confidence in their use and reliability for sex estimation in forensic cases. Furthermore, this understanding will improve the practitioner's ability to assuredly utilize both types of methods by revealing the factors contributing to each of the non-metric traits and thus result in more accurate estimates.

Sex Estimation, Osteometrics, Non-Metric Methods

H86 Evaluation of Vertebral Lipping in Age Estimation in a Modern Skeletal Sample of Colombian Individuals

Monica Chapeton, BA, and Edgar Bernal, BA, National Institute of Legal Medicine and Forensic Sciences, Cra. 7A #12-61, Bogota, COLOMBIA; Laura Polo, BA, National Institute of Legal Medicine and Forensic Sciences, Cra. 2 #24-83, Villavicencio, COLOMBIA; and Jorge Franco, MD, National Institute of Legal Medicine and Forensic Sciences, Cra. 7A #12-61, Bogota, COLOMBIA*

After attending this presentation, attendees will understand that while one of the signs of osteoarthritis (lipping) in a modern skeletal collection of Colombians is associated with advanced age, it is a weak association. However, it can be useful when assigning fragmented remains to an age cohort.

This presentation will impact the forensic science community by encouraging gross observation of degenerative spinal diseases as an age indicator that may contribute to an overall age-at-death estimate. In addition, it contributes to the literature suggesting that vertebral osteoarthritis is not the most reliable sign of age.

In addition to the typical four aspects of the biological profile, it is essential to record and analyze other individualizing features such as antemortem injuries, diseases, or physiological alterations as these may lead to a presumptive or positive identification. Of these other features that should be taken into account, the most frequently found in the analyzes performed by the Forensic Anthropology Laboratory of the National Institute of Legal Medicine is the presence of a suite of traits compatible with degenerative spinal disease. For Colombia, its frequent presence in forensic cases is anecdotal and has not yet been scientifically studied. Therefore, the purpose of this presentation is to fully document its scope, beginning with the feature of lipping, typically associated with osteoarthritis.

For this research, 127 individuals from the Colombian modern skeletal collection were analyzed. This included 81 males and 46 females, with an age range of 18 to 93 years old; a mean age 47 with a standard deviation of 23 years. Each bone of the vertebral column was analyzed in addition to the first sacral segment. For this part of the project, the investigators focused on the superior and inferior portions of each vertebral body and recorded the presence of lipping on a 0, 1, 2, or 3 scale of severity after Rojas-Sepúlveda et al.[1] While data were also collected on osteophytic growths, porosity, and eburnation, this phase of the project focused on the analysis of lipping; specifically, its frequency, severity, and age-at-transition from one stage of expression to the next. For the types of forensic cases that are often analyzed in Colombia, namely, commingled and/or severely fragmented/deteriorated, this type of analysis may help with assigning an age cohort category to remains that are missing other more reliable age indicators. Further, it helps to fully document the extent of degenerative spinal disease in modern Colombian individuals.

Frequency statistics for males and females combined of the severity of lipping were calculated indicating that lipping rates were low overall, with the highest frequency of moderate/severe lipping on the fourth lumbar vertebra (26%). The highest Pearson correlation coefficient for age and lipping was 0.657 for the second lumbar vertebra (L2), indicating that age and lipping are not highly correlated in this research sample. The next step included transition analysis in order to determine the average age-at-transition from one stage to the next using L2. The cumulative probit option in NPHASES2 was used for these calculations. Individuals transition from no lipping to slight lipping at 41 years (standard deviation 23 years); from slight to moderate lipping at 69 years (standard deviation 27 years); and from moderate to severe lipping at 93 years (standard deviation 19 years).

These results are concordant with the findings of Listi and Manhein,[2] which showed that while vertebral osteoarthritis is associated with age, it is a weak association. The large standard deviations in the transition analysis show that an individual can transition from one stage to the next within age categories that are decades wide. Essentially, the use of vertebral lipping as an indicator of age-at-death for identification purposes in Colombia is limited, but will provide useful information if attempting to assign fragmented remains to a general age cohort, and if sorting commingled remains.

Degenerative Spinal Disease, Lipping, Presumptive Identification

H87 The Role of Oral and Labial Devices in the Identification of Human Skeletal Remains

Tiffany B. Saul, BS, Forensic Institute for Research and Education, Middle Tennessee State University, Box 89, Murfreesboro, TN 37132; and Hugh E. Berryman, PhD, Department Sociology & Anthropology, Middle Tennessee State University, Box 89, Murfreesboro, TN 37132*

After attending this presentation, attendees will recognize the potential of using wear patterns and damage caused by oral and labial dental devices to assist in the identification of human skeletal remains.

This presentation will impact the forensic science community by demonstrating the types of oral and labial devices that create wear and damage to the dentition and how observations of these patterns can aid in the identification of remains.

For purpose of this study, an oral and labial device will refer to any object inserted or implanted into the oral cavity. Oral and labial devices include, but are not limited to the following: bridges, partials, dental implants, braces, fixed or removable retainers, crowns, veneers, night guards, tongue or lip rings, and grills.

This presentation represents the preliminary findings of an on-going study to determine if: (1) oral and labial devices produce discernable wear and/or damage to the dentition; (2) if this wear and damage occurs in a repetitive pattern among individuals; and, (3) if this wear and damage can be used to assist in the identification of skeletal remains. This study was primarily conducted using online surveys. One survey was created for participants with fixed or removable oral or labial devices. A second survey was developed for dental professionals, including dentists, hygienists, and dental assistants. Both surveys were used to collect data regarding the types of devices that may create dental wear and damage, as well as determine the observable nature of this wear and damage to both the patient and the dental professional. Both dental professionals (n=8) and lay participants (n=31) reported observations regarding wear on teeth caused by oral devices. Seventy-one percent of lay participants reported observing wear or damage to teeth and soft tissue as result of an oral or labial device. The devices reportedly causing wear or damage included cosmetic and therapeutic dental devices, as well as oral piercings. One hundred percent of dental professionals surveyed reported observations of tooth and soft tissue changes caused by oral devices. The number of patients represented by the dental professionals totaled 31,952. Of these patients, it was reported that approximately 40% have some type of fixed or removable oral device.

This preliminary report also utilized a case study to demonstrate the effects of oral piercings upon the dentition. The subject of this case study had a metal tongue ring for approximately seven years. The piercing was removed six years prior to the study; however, the effects of the piercing upon the dentition were clear and observable. The individual suffered severe enamel erosion on the lingual surfaces of both anterior and posterior teeth. Significant chipping in both anterior and posterior teeth was also observed. The subject reported an extraction of a molar due to damage sustained from the piercing, as well. In addition to these findings, another piercing under the lower lip induced significant gum erosion that was also observable. The subject had soft tissue scarring of the tongue and upper chin resulting from the piercings. The details of the damage observed upon the dentition and soft tissue were recorded in the dental record provided by the subject's dental care provider, as well.

The preliminary findings of this study suggest there is potential for the use of observable wear patterns on the dentition created by oral and labial devices to assist in the identification of human skeletal remains. It is important to note that dental professionals must be diligent in documenting the types of wear and/or damage present on patients' teeth, as well as the possible causes. All eight dental professionals surveyed reported patients with oral or labial piercings; however, only six reported that they note this information in their patients' records. At minimum, dental wear and osseous changes may allow the forensic anthropologist to speculate that the unidentified had a specific oral or labial device. However, through detailed observation and documentation by the dental care provider, wear and damage observed in the dentition of skeletal remains could be matched with thorough dental records.

Oral Device, Identification, Wear Patterns

H88 Fluvial Transport of Human Remains in the Sacramento River, California

Susan S. D'Alonzo, BA, Chico State University, Department of Anthropology, 400 West 1st Street, Chico, CA 95929-0400; Shannon J. Clinkinbeard, BA, 400 West 1st Street, Chico, CA 95929; and Eric J. Bartelink, PhD, California State University Chico, Department of Anthropology, Butte #311, 400 West First Street, Chico, CA 95929-0400*

After attending this presentation, attendees will gain a better understanding of the dynamics involved in the fluvial transportation of human remains in the Sacramento River. The goals of this presentation are to examine key variables involved in the transport of human remains and to evaluate their influence on decomposition and disarticulation rates.

This presentation will impact the forensic science community by outlining a framework for future predictive modeling for search strategies of river victims.

The fluvial transport of human remains has received significant attention by paleontologists and forensic anthropologists over the past several decades.[1-4] Pioneering work with animal carcasses by Voorhies and with human crania by Boaz and Behrensmeyer have provided a preliminary framework from which to study the movement of human remains in riverine systems.[1,2] In an early forensic application, Dilen used mannikins to simulate the transport of human remains in the Chattahoochee River, Georgia.[3] More recently, Bassett and Manhein have conducted a retrospective examination of Mississippi River cases to establish a predictive model for locating human remains.[4] While fluvial transport rates for human remains have been studied within a few river systems in the eastern United States, no published research exists for the western United States. More importantly, studies must take into account the specific hydrological factors of a particular river, including seasonal variation in water discharge rates. Focusing on the Sacramento River, this project is the first step in the development of a regional river victim database to evaluate rates of fluvial transport.

The Sacramento River is California's largest river, flowing 335 miles north to south from Mount Shasta to the Sacramento-San Joaquin Delta. The annual average river discharge is 350 m^3/sec^{-1}, which derives from both precipitation and snowmelt (USGS). Discharge rates are also controlled by dams, and vary depending on flood and drought conditions. Each year, the river claims many lives, including boating accidents, drownings, and suicides. It is also a common dump site for homicide victims. An understanding of how the dynamics of this fluvial system influence the transportation of human remains can be used to establish a predictive model for narrowing down search parameters for victims who entered the river on known dates (e.g., date missing).

Modeled after Bassett and Manhein's study, data collection for this project involved two broad categories of variables.[4] The first category focuses on variables relating to the biological profile of the river victims, as well as date missing, date found, location and side of river entry and recovery, distance traveled, and the reported cause and manner of death. The second category includes data on river dynamics such as water temperature, depth, bed load, and average rainfall at the time and location of entry and recovery. Collectively, these variables have been shown to have a relationship with transport rates of human remains in different fluvial systems. Data from this study will also be compared with other rivers to explore variation in fluvial transport rates.

As part of this preliminary study, we highlight two case studies of drowning victims that demonstrate long distance fluvial transport of human remains within the Sacramento River. Case #1, an elderly male drowning victim, was transported intact approximately 180 river miles (PMI=7 months). Case #2 also involved an elderly male drowning victim, but only

an intact foot (within a shoe) was recovered 46 river miles away from the where he entered the river (PMI=19 months). Using average river discharge rates for these locations, estimated fluvial transport intervals for each case were significantly less than the postmortem interval. Both cases show unusual transport distances, but the reported missing dates for each corresponded to peak discharge rates for 2005 and 2007, respectively. In this study, the hypothesis is tested that long distance fluvial transport is correlated with high discharge rates at the time a victim entered the river. The addition of known death and recovery dates from a large sample of case files from multiple counties, in conjunction with river discharge rates, will permit more precise estimation of transport rates for different sections of the river.

H89 Applicability of Common Age-at-Death Estimation Methods in Cold Case Analysis

Alice E. Fazlollah, MS, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996*

The goal of this presentation is to explain the statistical comparison of six age-at-death estimation methods commonly used by practicing forensic anthropologists. Additionally, the applicability of these methods to cold case work is explored.

This presentation will impact the forensic science community by highlighting the limitations of these methods and posit modifications of their use when developing a biological profile.

The most commonly employed methods for forensic age-at-death estimation from adult skeletal remains utilize gross morphological changes of the auricular surface of the ilium, the pubic symphysis, and the sternal end of the fourth rib. Due to their frequency of use, age estimation methods should be subject to continued accuracy of use assessments. As such, this research utilized three standard methods of skeletal age estimation (Lovejoy et al., Brooks and Suchey, and Işcan et al.,) as well as, three recently published methods, which modify these standard methods (Osborne et al., Hartnett) to identify the differences in error and accuracy of each method using known aged individuals.[1-7] Additionally, the limitations and applicability of each method for populations with known and unknown age-at-death was assessed. The research was completed with two goals in mind: first, to determine if the more recent methods more accurate assessed the age of a known-age individuals than the older standard methods, and second, to examine the statistical properties of each of these methods to ascertain the practical application of each with regards to an unknown sample.

Forty individuals from the William M. Bass Donated Skeletal Collection were examined using these six aging methods. The data were analyzed for accuracy and error across all six methods. Using the McNemar statistical test, the researcher found that the Osborne et al. method provided correct age ranges significantly more often than the Lovejoy method (*p-value* < 0.0001); neither the Hartnett nor the Brooks and Suchey method provided correct age ranges significantly more often (*p-value* 0.4142); and the Işcan method provided correct age ranges significantly more often than the Harnett method (2010b) (*p-value* < 0.0001). It was determined that the accuracy of some methods was due to the large prediction intervals for a given phase.[5,1,6,2,7]

For this sample, the linear regression results were not associated with age using the Osborne et al. and Lovejoy et al. methods (Root MSE 8.58, R-square 0.13, Root MSE 8.65, R-square 0.12, respectively).[2] Results also show that the age phases using Hartnett (2010a; Root MSE 8.63, R-square 0.12) are more closely associated to actual age than Brooks and Suchey (Root MSE 8.99, R-square 0.05).[6,2] Overall, the Hartnett (2010b) method proved to have the closest relationship between phase and age.

These results suggest that when the Işcan et al. method is used to predict age, the inclusion of either the Lovejoy et al. or the Brooks and Suchey methods will not significantly improve the estimated age of the individual in this sample. The same is true for the newer methods; the estimated age cannot be significantly improved by including estimations from the Osborne et al. method or the Hartnett pubic symphysis or rib methods. Finally, the statistical relationship between phase and age for each method was used to develop six regression formulas that could be utilized to calculate age intervals based upon the user's determination of phase for that individual.

Following this analysis, thirty sets of unidentified skeletal remains from the Georgia Bureau of Investigation (GBI) were examined. After sex, ancestry, and stature had been determined, the regression formulas from this study were applied to calculate skeletal age estimation for each individual.

While this research does not ultimately point to a single of the six methods studied as superior to others, it provides a validation for these methods using a modern sample and applies the conclusions to a contemporary morgue sample in order to observe the shortcomings of each of the methods.

Age-at-Death Estimation, Biological Profile, Unknown Sample

H90 A Radiographic Positive Identification from a Foot Altered by Diabetes Mellitus

Jennifer M. Vollner, MS, 355 Baker Hall, East Lansing, MI 48824; Carolyn V. Hurst, MA, 354 Baker Hall, East Lansing, MI 48824; Julie M. Fleischman, MS, 6138 Farrington Court, #D10, East Lansing, MI 48823; and Todd W. Fenton, PhD, Michigan State University, Department of Anthropology, 354 Baker Hall, East Lansing, MI 48824*

The goals of this presentation are to reveal how quickly destructive skeletal changes can occur in cases of diabetes mellitus and to demonstrate that even in the event of advanced stages of diabetes, comparative medical radiography can be successfully employed to make a positive identification.

This presentation will impact the forensic science community by addressing how the growing epidemic of diabetes may potentially impact forensic casework and strategies for successfully meeting this challenge.

Forensic anthropologists are routinely called upon to positively identify individuals using comparative medical radiography. Such cases are made more difficult when there is a significant amount of time between the antemortem and postmortem films. Since bone is a living tissue, it is subject to continual remodeling over a person's life. Work by Sauer et al. (1988) reported that despite normal progressive bone maintenance and degenerative change over time, it was still possible to positively identify individuals using antemortem radiographs taken ten to twenty-three years prior. What has not been accounted for is the utility of comparative medical radiography in the cases of diseases, like diabetes mellitus, that significantly impact skeletal structures.

The growing epidemic of diabetes in the western world means more individuals will be passing through forensic laboratories afflicted with this disease. Thus, it is imperative that forensic scientists understand the disease process and its timing for appropriate interpretations and analyses. Although the exact mechanisms for skeletal changes are debated in the clinical literature, it is agreed that diabetes can have an impact on bone mineral density.

The complicated nature of such changes is highlighted by a forensic case in which comparative medical radiography was employed to make a positive identification. The decedent had suffered from hypertension and diabetes, with a history of hospitalization for a diabetic coma. The antemortem radiograph was an anterior-posterior film of the left foot taken five years prior with no noticeable osseous pathology. Examination of the postmortem radiographs revealed that the distal half of the first metatarsal and the associated proximal and distal phalanges had completely resorbed. The second metatarsal displayed resorption of its distal aspect in conjunction with prolific ossification around the mid-shaft. The remaining phalanges, with the exception of the proximal fourth and fifth, all showed either degenerative or proliferative changes. These changes are consistent with Aufderheide and Rodríguez-Martin (1988: 342) who report that diabetes induced ischemia may cause bony breakdown of the distal metatarsals and proximal phalanges and, without treatment, may eventually lead to gangrene of one or more toes.

Despite the significant skeletal alterations that had occurred in the five-year period between the decedent's antemortem medical radiograph and the postmortem films, it was still possible to use overall morphology, trabecular patterns, cortical bone thickness, and osseous spurs to make a positive identification.

As forensic practitioners, it is important to recognize the extreme osseous changes that can occur in a relatively short period of time with diabetes mellitus. Although it is possible to successfully employ traditional radiographic identification methods in these cases, they must be applied conservatively and within the bounds of sound practice.

Positive Identification, Comparative Radiography, Diabetes Mellitus

H91 Sex Determination Based on Clavicles from a Sample of Modern Colombian Mestizos

Juan M. Guerrero, BA, and Carlos A. Villalobos, BA, National Institute of Legal Medicine and Forensic, Cra. 7A Nº 12-61, Bogota, COLOMBIA*

The goal of this presentation is to provide insight into new research on sex estimation that has been recently conducted in Colombia. This project aims to document sexual dimorphism in the modern Colombian population by investigating metric differences of the clavicle between males and females.

This presentation will impact the forensic science community by demonstrating significant sexual dimorphism of the clavicle of modern Colombians. In addition, it presents three discriminant function equations that can be utilized by Colombian forensic anthropologists and potentially by other workers in South America.

Sex determination in forensic anthropology is a critical pillar of the biological profile, as this variable often informs other biological parameters such as stature and age. Considering that Colombian forensic practitioners frequently receive incomplete, dismembered, and decomposed bodies, metric analyzes of various postcranial skeletal elements are often required for sex estimation. Based on the above scenarios and the need to develop standards specific to the Colombian population, this research developed three discriminant function equations based on four measurements of the clavicle.

This research used a sample of clavicles drawn from the Colombian Modern Skeletal Collection from a total of 102 individuals (38 females and 64 males), with an average age-at-death of 50 years. Four measurements were utilized: maximum length (XLN), anterior-posterior diameter at midshaft (APD), superior-inferior diameter at midshaft (SID), and circumference at midshaft (CIR). In cases where both right and left clavicles were present, each was measured so that bilateral asymmetry could be tested.

The mean measurement values of the left clavicle were as follows: XLN (137.23 mm females; 154.33 mm males), APD (10.18 mm females; 11.82 mm males), SID (8.69 mm females; 9.92 males), and CIR (43.02 mm females; 51.43 mm males). The resulting mean measurement values of the right clavicle were as follows: XLN (136.66 mm females; 153.13 mm males), APD (10.54 mm females; 11.99 males), SID (9.43 mm females; 10.03 males), and CIR (33.23 mm females; 37.12 mm males).

The results obtained show that the differences between the means of male and female individuals were statistically significant (*p-value* < 0.05). Bilateral asymmetry was also statistically significant between right and left sides (*p-value* < 0.05), which resulted in the calculation of discriminant function equations for both the right and left clavicle. One equation was also calculated that utilized measurements from both the right and left clavicle together.

The following discriminant function equations for sex estimation were developed:

- Left Clavicle: (0.082*XLN) + (0.192*APD) + (0.363*SID) – 17.788);
- Right Clavicle: (0.085*XLN) + (0.141*APD) + (0.073*CIR) – 16.761);
- Right/Left Clavicle: (0.085*XLNR) + (0.067*APDR) + (0.079*XLNL) + (0.361*APDL) – 16.361.

In each of the above equations the sectioning point was 0, with females falling below this value and males falling above it. When the formulae were applied to the sample, the equation for the left clavicle classified 89.0% of cases correctly, the equation for the right clavicle classified 87.9% of cases correctly, and the equation utilizing both right and left clavicle data achieved a correct classification rate of 85.7%. Further testing of these equations on other known Colombian cases is necessary in order to discern a wider applicability of these formulae.

This research is expected to contribute to the improvement of the quality of forensic anthropological analyzes in Colombia by generating population-specific sex estimation criteria. It will expand forensic knowledge at both national and international levels as researchers continue to investigate population variation throughout Latin America.

Sex Determination, Clavicle, Colombian Population Standards

H92 An Experimental Study of Scavenging in Aqueous Environments

Jennifer A. Hertzog, MS, 2129 West 25th Street, #2, San Pedro, CA 90732*

After attending this presentation, attendees will have an increased understanding of the process of decomposition in different types of aquatic environments and knowledge of how fast certain organisms consume animal remains in a controlled aquatic tank setting.

This presentation will impact the forensic science community by demonstrating the need for decomposition studies to include macro-scavengers. The presence of macro-scavengers can actually delay decomposition before it accelerates decomposition and therefore are important factors in estimating postmortem interval.

The hypotheses of this study are that tanks with organisms (experiments) would decompose faster than those without organisms (control), that the salt experiment would decompose faster than the fresh experiment, and that both controls would precede at the same rate.

Four tanks (two freshwater and two saltwater) were assembled including sediment, filtration system, air pumps, thermometers, and light control timers. The saltwater experiment tank held six red-legged hermit crabs, one fiddler crab, and six Nassariid snails. The freshwater experiment tank contained six ghost shrimp, one red-clawed crab, and six mystery snails. Two rabbits (sold as food) were weighed, photographed, measured, and quartered. One hind leg was photographed, weighed, and measured for each tank before being placed into a cage secured with zip-ties and lowered into the tank and held into place with suction cups. During two experimental trials, remains were allowed to decompose for 45 days. On a daily basis, tanks were photographed and water quality tests (pH, ammonia, nitrite, and nitrate) were performed. Hourly (minimum of four hours a day and maximum of 12 hours a day) water and ambient temperature readings were taken as well as other observations on the appearance of the remains, color of the water, odor of the water, level of foam and organism activity. At the end of the experiment, the cages were removed, photographed, and opened. The bones and remaining flesh and adipocere were weighed.

During the first trial, the water temperature in the saltwater tanks was lower than the water temperature in the freshwater tanks. The ambient temperature had a broader range during the second trial, but the tanks matched more closely to the ambient. Except for brief periods, the water temperatures in the first trial were higher than the second trial. The appearance of the remains in all four tanks looked obviously different: both freshwater tanks had filamentous algae; whereas the saltwater tanks had encrusting algae, but the controls had more, longer, and thicker algae than the experimental tanks did. Furthermore, gas bubbles that were trapped in the adipocere and algae appeared different between the salt tanks: the control's bubbles were short and flat whereas the experiment's bubbles were tall and peaked. Stages of decomposition were defined as float, total float, floating decay, disarticulation, and sunken remains for this experiment. The presence of scavengers initially delayed decomposition and then decay preceded faster in the experiment tanks than the controls. In the first trial, the freshwater experimental tank hit floating decay a day before the saltwater experimental tank, but in the second trial, the saltwater experimental tank hit floating decay 14 days before the freshwater experimental tank. In both trials, the freshwater remains reached a further stage of skeletonization than the saltwater remains, even though the saltwater remains occasionally entered the next stage first. The remains from the first trial had less flesh, less algae, and less adipocere on the bone than the remains from the second trial.

In conclusion, scavengers affect the rate of decomposition by direct consumption, indirect consumption of the microbial layer, or by disbursing the algae growing on the remains. This research showed that changing the number of macro-scavengers present greatly changed the visible qualitative results of the appearance of the remains.

Despite the problems and limitations with laboratory settings, this experimental study suggests that studies that exclude scavengers are not showing the entire picture and might lead to inaccurate models of decomposition in a specific region.

Aquatic Decomposition, Scavenging, Taphonomy

H93 The Influence of the Topical Application of Cosmetic Products on the Rate of Decomposition and Insect Activity on Pig Carcasses

Sophie Radicke, and Tal Simmons, PhD, School of Forensic and Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM*

The goal of this presentation is to provide attendees with information about the effects of the topical application of three commonly used cosmetic products on the rate of decomposition and insect activity on the carcass and how this might affect the estimation of the postmortem interval.

This presentation will impact the forensic science community by suggesting that the rate of decomposition and insect activity on a corpse is not affected by the application of cosmetic products. As a result the potential presence of cosmetic products on a dead body does not have to be taken into account estimating the postmortem interval.

The total body score (TBS) appearance of decomposition of a cadaver can be helpful to determine the time-since-death. The TBS is a combination of point scores, which are derived from the individual assessment of the decomposition stage of head and neck, trunk and limbs (Megyesi *et al.*).[1] The characteristics of decomposition appear a more or less fixed sequence; however, the rate at which these appear is highly variable. A number of factors have been shown to influence the rate of decomposition. One of the most influential factors is insect access to the cadaver (Simmons *et al.*).[2] Circumstances restricting insect access and activity on a corpse may include its placement, whether it has been wrapped or covered and whether insect repellent substances are present on the body.

Charabidze *et al.* found that the application of HCl, patchouli perfume, insecticide and petrol significantly delayed the arrival of flies to rat carcasses in comparison to the control group.[3] Under laboratory conditions it was also observed that mosquito citronella repellent, HCl, insecticide, petrol and paradichlorbenzene have a repellent effect on female flies (Charabidze *et al.*).[3] A similar insect-repellent effect of insecticides has been noted by Vass, which also led to initial underestimation of the postmortem interval.[4] The previously mentioned research shows that the application of varying substances have an effect on insect activity on the carcass and as a result may influence the rate of decomposition and thus also the estimation of time-since-death.

However, no literature exists that considers the effect of commonly used substances that are applied to a large portion of the body such as cosmetic products. Considering the widespread use of these products, it is important to establish any potential effects on the rate and/or pattern of decomposition that could lead to a miscalculation of time-since-death.

As a model for human cadavers, carcasses of the domestic pig (*Sus scrofa*) were used in this research. Three experimental groups and one control group were set. Each group consisted of four carcasses that were laid out on the ground. In each of the experimental groups, either sunscreen, fake tan or insect repellent was applied to the animal's body surface. The area covered included the head, trunk and limbs, but excluded the anal and groin area. This was done to represent a realistic application pattern as closely as possible.

The stage and pattern of decomposition was assessed using Megyesi *et al.*'s scoring system and carcasses were observed approximately every 50 Accumulated Degree Days (ADD).[1] Insect activity was measured by the body surface area covered with superficially visible maggot masses, which was converted into a maggot mass score (MMS). The MMS increased with the amount of the body surface area being covered. Furthermore, samples of maggots were taken from the maggot masses and reared to the adult stage to determine the insect species attracted to the carcasses.

The experiment ran for a total of 694 ADD during which the rate of decomposition was consistently similar in all four test groups and did not show any significant differences (Mixed effects model, DF = 3, F = 0.556, *p-value* = 0.654). Superficial maggot masses were first noted in all groups

at 141 ADD. As a general trend, the MMS increased until 376 ADD and then dropped again in all groups. The increase in the MMS was, however, not linear and fluctuated until reaching its highest value. At the end of the experiment no superficial maggot masses were observed in most carcasses.

Identification of collected and reared larvae showed the most abundant fly species in all groups was *Calliphora vomitoria*, followed by *Protophormia terraenovae* and *Calliphora vicinia*. In contrast, *Lucilia sp.* were observed less frequently.

The results of this study indicate that the topical application of cosmetic products to a large portion of the body surface area does not have any notable effects on the rate of decomposition; neither did insect activity, as measured by the size of superficial maggot masses, differ between the control and test groups. As insect activity has a key influence on the rate of decomposition, these two findings are concordant and consistent with previous research. In conclusion, applied cosmetic products cannot be considered to be a factor that needs to be taken into account when determining the time-since-death.

H94 Human Grave Identification Using GPR and Its Implications for Recognizing Covert Burials of Greater Antiquity

Charles C. Boyd, PhD, Department of Anthropological Science, Radford University, Radford, VA 24142; and Rhett B. Herman, PhD, Radford University, Box 6939, Curie Hall, Radford University, Radford, VA 24142*

The goal of this presentation is to investigate the effectiveness of Ground Penetrating Radar (GPR) for identifying longer-term (e.g., cold case) covert human graves in diverse burial environments. By comparing GPR signals of known historic human graves across diverse burial environments and treatment, the effect of these variables on GPR signals can be visualized. This will lead to a clearer understanding of the effectiveness of identification of longer-term covert burials in a modern forensic context.

This presentation will impact the forensic science community by providing guidelines for the use and interpretation of GPR technology in detecting long-term human covert graves. Attendees will learn the significant impact that burial environment and time have on the GPR signal. The outcome of this presentation will be the description of GPR-produced grave images which distinguish more formal grave sites from those potentially produced to hide a criminal act. This presentation will also raise awareness of the utility of geophysical remote sensing in searching for covert burials of greater antiquity.

Ground-penetrating radar is arguably the best geophysical tool to use for covert burial searches in forensic contexts.[1] Several researchers have recently illustrated the potential for GPR to successfully identify covert graves over short to moderate periods of time. [2,3] These studies have utilized pigs as human models and have suggested that pig graves with additional burial treatment (e.g., wrappings, tarpaulin, rocks) showed clearer signals than those without.

This poster examines variation in ground-penetrating radar (GPR) images from human burial sites of greater antiquity and differing burial environment to test the following hypotheses: (a) GPR signals are capable of detecting covert graves of greater antiquity than those created for experimental study; and, (b) GPR signals are capable of identifying graves of individuals who have less "formal" burial preparation (a situation comparable to covert forensic burials) than those with more grave preparation.

The burial sites examined are two historic cemeteries on the R.J. Reynolds Homestead in Critz, Virginia. The Reynolds family cemetery contains 24 marked graves dating from 1849 to 2004, representing individuals from the wealthy and prominent Reynolds family (founders of the R.J. Reynolds Tobacco Company and Reynolds Metals [Aluminum]). Approximately 200 meters north of this cemetery in a wooded area is the second cemetery for slaves and (after 1865) former slaves who worked in tobacco production or as servants for the Reynolds family. At the slave cemetery are 54 probable graves (based on ground depressions and field stones); only four of these manifest marked "formal" stones. These two cemetery samples represent economically and ethnically distinct historic individuals who varied significantly in terms of their burial treatment and environment. While individuals from the Reynolds family cemetery were encased in burial vaults and underwent more formal burial treatment, those from the slave cemetery were in pits with wood coffins and shroud coverings (representing the "less formal" burial more typical of a modern covert grave).

GPR surveys of both cemeteries were conducted in July and November 2008, and for the slave cemetery again in May 2011. All surveys were conducted using a PulseEKKO GPR system, with a 500-MHz antenna being used for the July 2008 surveys and a 100-MHz antenna for the later surveys. The 500-MHz antenna produces better resolution of smaller subsurface targets but has a shallower penetration depth, especially in the clay soils of the survey area. The lower frequency 100-MHz antenna provides lower resolution but deeper penetration (more than two meters).

The 500-MHz scan of the Reynolds Family cemetery identified anomalies correlated with graves; however, some anomalies were inconsistent with the position of above-ground gravestones. The survey of the slave cemetery using this antenna was less productive, due to the damp, forested environment. The soil conditions resulted in expected signal loss, but the scan did identify anomalies correlated with a previous map of grave sites.

The November, 2008 scan of the Reynolds cemetery used the 100-MHz antenna along a 0.5 meter grid, with the instrument reading north-south transects along this grid. Scans produced much clearer images of graves in relation to their markers. Also, the grave of a four-day old child that was not seen in the 500-MHz scan was revealed.

The 2011 slave cemetery 100-MHz scan also produced clearer associations of GPR signals with mapped grave locations in many cases. However, the GPR signals for graves became much more subtle and in several cases disappeared at shallower depths (1.5 meters from the surface) as opposed to 2.0 meters for the signals for the Reynolds family. This suggests a shallower depth and less grave preparation for the slave burials - a scenario common to modern covert burials. This study indicates that GPR surveys for covert graves of considerable antiquity in similar moist, clay-rich soils can be productive if the appropriate antenna is used. However, the signals for such graves will be far more subtle and diffuse than those from a formal cemetery setting.

Ground-Penetrating Radar, Covert Human Graves, Long-Term Burial Environments

H95 Microscopic and Macroscopic Changes to Peri-Mortem Pediatric Trauma Following Burial

Donna C. Boyd, PhD, Radford University, Forensic Science Institute, PO Box 6939, Radford, VA 24142; Cliff Boyd, PhD, and Lucy A. Hochstein, BS, Radford University, Department of Anthropological Sciences, Radford, VA 24142*

The goal of this presentation is to examine the effect of burial on peri-mortem (blunt force and sharp/blunt force) pediatric trauma. This is accomplished by documenting taphonomic changes in the microscopic and macroscopic signatures of traumatized bone in a sample of frozen stillborn pigs undergoing trauma immediately after thawing and burial immediately following trauma. After attending this presentation, attendees will have a clearer understanding of the microscopic and macroscopic temporal changes affecting traumatized subadult remains undergoing burial.

This presentation will impact the forensic science community by enhancing attendee's ability to recognize and interpret peri-mortem trauma in remains subjected to extended burial and the ability to differentiate this trauma from postmortem damage.

This poster is the first in a series of research projects exploring the relationship between time and the microscopic and macroscopic signatures of pediatric trauma. This study examines the effects of extended burial on subadult remains undergoing peri-mortem trauma. SWGANTH guidelines for trauma analysis (www.swganth.org) have called attention to the need for great caution when identifying peri-mortem blunt and sharp force trauma altered by postmortem processes.[1] This characterization is important not only for understanding the effects of taphonomic variables on peri-mortem trauma, but for differentiating peri-mortem and postmortem processes. A previous study by Calce and Rogers found significant alterations in peri-mortem (blunt force) trauma signatures in adult pig skulls in a surface environment in Canada over a period of 12 months, primarily due to the freeze/thaw cycle of this region.[2] The effects of a varied postmortem environment (e.g., burial rather than surface, more temperate climates) on peri-mortem trauma are not known, particularly with regard to subadult remains.

The current study examines the effect of burial over extended periods of time on peri-mortem blunt force and blunt/sharp force traumatized subadult remains. Eleven (unprocessed) stillborn pigs (*Sus scrofa*), frozen at death, were used in the study. Eight of the 11 pigs were subjected to trauma after thawing for 24 hours. Four of these eight pigs underwent blunt force trauma by means of a standardized drop-force mechanism using a concrete cylinder weighing 1,109g. Pigs were placed on a hard substrate (a metal plate which measured impact force) and impacted by the concrete cylinder on both their left and right sides. Right side impacts (two per pig—one focused on the lateral cranium, the other, the lateral shoulder) were delivered via a drop mechanism through a stabilized 50cm long PVC pipe. Similarly, two impacts on the same areas (cranium, shoulder) on the left side were dropped through a 108cm long PVC pipe. The remaining four traumatized pigs were similarly treated, although the impact tool was a sharpened steel wedge (simulating both sharp and blunt force trauma) weighing 2,100g. The final three pigs underwent no trauma.

Within 24 hours after trauma, nine of the eleven pigs (both traumatized and non-traumatized) were individually buried supine in 40cm deep burial pits at a decay facility in the spring season. After four months, six pigs (representing all three treatment categories) were exhumed; after seven months, the remaining three pigs (again, representing all three treatment categories) were exhumed. All exhumed pigs were skeletonized. The final two pigs (one traumatized with blunt force trauma, the other with blunt/sharp force trauma) were not buried, but processed immediately, serving as controls.

Comparisons were made across the buried and non-buried, traumatized and non-traumatized bone by means of a Keyence VHX 1000 Microscope (using 5 – 50x and 20 – 200x lenses) as well as through visual examination. Variables examined included: number, type, pattern, and dimensions of fractures and fracture lines, fracture surface morphology (e.g., smooth vs. jagged) and angle (e.g., obtuse, right), presence of color differential, hematoma staining, hinging, and inbending/outbending.

Although observed taphonomic damage included microfractures, root etchings, erosion, and split and frayed bone ends, bone samples from pigs undergoing burial after four and seven months retained the characteristic signatures of peri-mortem blunt force trauma, including presence of identifiable inbending/outbending, hinging, radiating fracture lines, and sharp, irregular fracture outlines. Analysis of samples under light microscopy enhanced the identification of these signatures, particularly in samples buried for seven months. Low power magnification of fracture outlines in the extended (seven month) buried samples revealed feathering and serration of fracture edges, making their edges more irregular compared to the non-buried samples (although still recognizable as peri-mortem fractures). Similarly, pigs with blunt force/sharp force trauma retained characteristic signatures of this trauma after seven months of burial.

These comparisons suggest that although microscopic and macroscopic alteration of bone occurs after periods of extended burial, characteristic signatures of blunt force and blunt/sharp force pediatric trauma may not be erased. It is recommended that light microscopy be utilized to examine subadult bone suspected of peri-mortem trauma.

Pediatric Peri-Mortem Trauma, Blunt/Sharp Force Trauma, Burial

H96 A Method for Standardization of Anatomical Axes and ROIs in Femoral Thin Sections of Unknown Orientations

Megan E. Ingvoldstad, MA, Ohio State University, 4005 Smith Laboratory, 174 West 18th Avenue, Columbus, OH 43210; Timothy P. Gocha, MS, and Marissa C. Stewart, MA, Ohio State University, Department of Anthropology, 4034 Smith Laboratory, 174 West 18th Avenue, Columbus, OH 43210; and Jesse R. Goliath, MA, Ohio State University, Department of Anthropology, 4005 Smith Laboratory, 174 West 18th Avenue, Columbus, OH 43202*

After attending this presentation, attendees will learn how midshaft cortical distribution observable via microscopic slides can be utilized to standardize femoral anatomical axes and histological regions of interest (ROIs) when skeletal orientation is unknown.

This presentation will impact the forensic science community by extending a technique for standardizing thin section anatomical axes and histological regions of interest, which may ultimately help identify areas of the femur most suitable for age-at-death estimation.

Different regions of the femur are in contact with separate lower limb muscle groups and subject to differential biomechanical demands. As both periosteal loads and far-field intracortical stresses influence remodeling—and, hence, osteons, the basic structures forensic histomorphologists quantify for an age estimate—it is imperative for correct anatomical orientation of investigated microscopic slides to be known. When working with fragmentary remains and thin sections removed from dissecting room cadavers, exact determination of anatomical axes locations becomes problematic if the samples are not expressly marked at the time of

extraction. While anterior and posterior surfaces are easily identified through the presence of the femoral linea aspera, medial and lateral anatomical locations are not easily distinguishable.

To address this issue, Goldman and colleagues suggest using Sharpey's fiber insertion direction, and White (2000) suggests the lateral posterior femoral surface is usually more concave than the medial posterior surface. The accuracy of these techniques has yet to be demonstrated.[1,2] Nobel and colleagues extended a metric solution to the problem of identifying medial and lateral femoral cortices.[3] Seeking to identify the best placement for femoral midshaft medical implants, they measured 80 adult femora at their anatomical axes via radiographs. The authors found that the posterior cortical thickness on average was thickest (7.7mm), followed by the lateral cortex (7.6mm), the medial cortex (7.2mm), and finally the anterior cortex (5.1mm). Corroborating these findings, Stephenson and Seedhom (1999) measured 16 adult femoral midshaft and found anterior cortical thickness to be the thinnest, the posterior cortex the thickest, and medial and lateral cortices similar, but with the lateral side slightly thicker on average.[4]

To test the reliability of these observations, 200 femoral midshafts of known orientation were harvested from GWU Medical School Dissecting Room cadavers and processed for histological assessment. A 1200 dpi resolution image of each of the thin sections was obtained using an HP 4850 Scanner. ImageJ (version 1.44) and MomentMacroJ (version 1.2) were used to draw the principle axes of maximum and minimum bending rigidity on each femoral image. To standardize anatomical axes and histological ROI locations when a complete femur is not present for analysis, the A-P anatomical axis was consistently determined by drawing a vertical line, and the M-L anatomical axis by drawing a horizontal line, through the mathematically determined centroid of the section. To distinguish between medial and lateral cortices, each femoral cross-sectional image analyzed by ImageJ with observable axes was additionally placed over a background that standardized cortical width measurement every 22.5°. Analysis of this data suggests cortical width at the 292.5° lateral location is consistently thicker than at 112.5°, the medial location on the axis 180° across. These measurements were determined to be significantly different from each other using a paired comparison test and can therefore be used to distinguish medial and lateral cortices when femoral anatomical orientation is unknown.

Here, a method is extended for standardization of anatomical axes and histological ROIs in femoral thin sections with unknown skeletal orientations, with an additional technique for distinguishing between medial and lateral femoral cortices. While a useful technique when confronted with unlabeled femoral thin sections, standardized ROIs can also help to improve repeatability and reduce operator subjectivity in the field of histomorphology. Further research is underway that utilizes these techniques in an effort to uncover patterns in histomorphometric variation in biomechanical versus anatomical sampling locations in midshaft femoral cortical bones. Discovery of such patterns will be of great assistance to forensic anthropologists who use histomorphometric techniques by suggesting ROIs most suitable for age-at-death estimation.

H97 REFACE: New Features Addressing the Needs of Forensic Identification Professionals for Objective Facial Approximation

Terrie L. Simmons-Ehrhardt, MA, Federal Bureau of Investigation Laboratory Division, Counterterrorism and Forensic Science Research, 2501 Investigation Parkway, Quantico, VA 22135; Adam H. Richard, MA, Texas State University, Department of Anthropology, 601 University Drive, San Marcos, TX 78666; Connie L. Parks, MA, 8802 Feather Hill Road, Austin, TX 78737; Peter H. Tu, PhD, GE Global Research, Imaging Technologies, 1 Research Circle, Niskayuna, New York 12309; and Keith L. Monson, PhD, Federal Bureau of Investigation Laboratory, Counterterrorism and Forensic Science Research, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will become aware of REFACE, understand how it generates facial approximations, be informed of new features that have been incorporated, and appreciate the usefulness of those features for forensic identification professionals.

This presentation will impact the forensic science community by illustrating the advantages of statistically-based computerized facial approximation (CFA) as well as the possibilities of a system that can quickly and objectively generate multiple images of an unidentified decedent for eventual presentation to the public.

REFACE was developed during a long collaboration between the Federal Bureau of Investigation's Laboratory Division and General Electric Global Research to complement traditional clay modeling techniques with an objective, repeatable, and less labor-intensive means to generate facial approximations based on large, diverse sample sizes, and whose methods could be fully documented for forensic purposes. Literature assessing traditional facial approximations has repeatedly shown that presenting the same skull to different artists can result in very different approximations. Additionally, many tissue depth studies have been based on small sample sizes.

Modern computed tomography (CT) technology allows three dimensional viewing of facial skin, or the underlying bone, or both together. This technology, which links facial and skeletal data, forms the foundation for REFACE. A CT database of approximately 400 individuals of both sexes and four ancestry groups was collected to form the reference database for a statistically-based CFA program. REFACE applies registration, warping, and principal components analysis to the known relationships between skin and bone of each head in the reference database to approximate the skin for an unknown skull that is scanned and imported into the system.

One of the advantages of REFACE is time. Generation of an approximation using an 8-core processor takes 20 minutes. Because of this speed, users can efficiently generate multiple approximations per day, including the option of estimating the face in alternate groups if ancestral attribution is ambiguous. Users can also address cases of mixed ancestry by specifying a different ancestry group for the nose tip regression if recommended by a forensic anthropologist's analysis of the skull. Export formats for 3D approximations include VTK, STL, OBJ, and DXF, as well as two-dimensional JPEG or PNG formats. Users can also record an AVI video of the rotating 3D approximation. These export options allow the user to perform post-approximation artistic modifications with a software package of their choice or to present multiple images/image formats to the public.

Another advantage of a system such as REFACE is documentation. Users assign unique identifiers for each imported skull and generated approximation, and every aspect of user input, approximation parameters, modifications, etc. is automatically saved and documented. Additionally each unknown skull must be CT- or laser-scanned before import into REFACE, providing agencies with permanent electronic storage of each of their unidentified cases. REFACE also has security features that allow an organization's designated administrator to control user access to specific software features and to specific approximations. These features allow

strict control within a facility that may have multiple individuals generating approximations and provide documentation for exactly how each approximation is generated, so that the process can be repeated or presented in court, if either is necessary.

Although nationwide standards for the generation and presentation of facial approximations do not currently exist, features within REFACE allow forensic anthropologists/artists the flexibility to address future developments or changes in the field through the use of multiple export formats and presentation types (3D, 2D, video, multiple images), whether for post-approximation modification, public display, craniofacial superimposition, or for use in facial recognition software aimed at matching unidentified decedents to missing persons. In summation, REFACE provides agencies a way to generate facial approximations objectively and efficiently, the ability to document and secure data for each approximation, and the flexibility to address any changes that may arise within the field of facial approximation.

REFACE, Facial Approximation, Forensic Identification

H98 The Potential of the Angle of the First Rib, Head to Tubercle, in Sexing Adult Individuals in Forensic Contexts

Paige W. Elrod, BA, 9989 Burbank Drive, #9, Baton Rouge, LA 70810; and Mary H. Manhein, MA, Department of Geography & Anthropology, Louisiana State University, Baton Rouge, LA 70803*

After attending this presentation, attendees will understand the potential application of using the angle of the first rib, head to tubercle, in the successful sexing of unknown individuals, the calculation of the angle of the first rib and the statistical probability of correctly sexing an individual using the angle.

This presentation will impact the forensic science community by providing another tool for sexing unknown individuals using skeletal material, which can aid in identification.

Accurately assessing the sex of an adult human skeleton is fundamental in forming the biological profile used in forensic anthropology. The first rib was chosen due to its distinct shape, compact size and increased sustainability to taphonomic processes. The first rib has been examined in past research, but all focus has been on the sternal end of the rib and none on the angle created between the tubercle and head. This angle is present when the rib is viewed in its non-anatomical orientation. In some cases the angle is not present and the anatomical positioning is necessary to determine the siding for a rib with an angle of 0°. When a rib is sided in anatomical position the head will, in most cases, point downward and the subclavian grooves will be on the inferior surface.

This study was conducted using males and females, both African and European American, from the William M. Bass and Hamann-Todd Skeletal Collections. The left and right first ribs of 286 individuals were measured for total length, internal length, height of head off of a surface and length from tubercle to head. The angle was determined using a sliding caliper to measure the length from the head to the tubercle and the head to a surface, and then calculating the inverse sine to obtain the angle from the measured hypotenuse and height.

The calculated angles were then compared using logistic regression analysis, to determine the likelihood that a given angle was either male or female. Of the 572 measured samples, 555 were calculated, 17 were excluded for missing angle or length measurements, with 266 angles being male and 289 female. Logistic regression showed that angle alone is 60.2% concordant, while angle, total length and internal length combine to yield a 70.5% concordance. These results suggest that the angle can be used to predict sex of an individual, while the addition of total rib length and internal rib length increase correct classification by 10%.

This research shows that the angle of the first rib is able to determine the sex of an individual with a high statistical probability, using several measurements of the bone that are likely to survive prolonged taphonomic exposure. The probable sex information could be combined with aging methods of the first rib to assess both age and sex of an unknown individual. Since few skeletal elements can both age and sex an individual, this research could have great potential for further forensic applications in adding reference information to the field.

First Rib, Sexing, Identification

H99 Asymmetry of the Deltoid Tuberosity and the Possible Impact on Osteometric Sorting

Jolen Anya Minetz, MA, Joint POW/MIA Accounting Command, Criminal Identification Command, 310 Worchester Avenue, Building 45, Hickam AFB, HI 96853; Carrie B. LeGarde, BS, University of Montana, Anthropology Department, Missoula, MT 59812; and John E. Byrd, PhD, 95-033 Hokuiwa Street, #51, Mililani, HI 96853-5530*

After attending this presentation, attendees will gain an understanding of how individual asymmetry may affect the sorting of humeri in a commingled assemblage.

This presentation will impact the forensic science community by emphasizing the variability in skeletal elements and how such variability and individuating characteristics related to asymmetry need to be taken into account when using osteometric sorting to segregate individuals from a commingled assemblage.

This research investigates whether asymmetry of the humerus, specifically the deltoid tuberosity, can be great enough to cause elements to be determined an unsuitable match when utilizing osteometric sorting. Osteometric sorting is used to assist in the evaluation of associating human skeletal elements based on size.[1] The sorting of skeletal elements from a commingled assemblage into individuals is potentially adversely impacted by varying degrees of asymmetry in individuals. Asymmetry is the degree of variability between the contralateral sides of the body, and occurs naturally due to the exertion of various forces over time. Since these forces vary on an individual level, based on factors affecting the growth and muscularity of elements, further evaluation of the methods used to associate contralateral elements in an individual was conducted.

Osteometric sorting, a sorting method created by Byrd and Adams, was produced to provide an objective use of size to sort through commingled skeletal assemblages. This method is currently being used in the sorting of a large, commingled assemblage at the Joint POW/MIA Account Command – Central Identification Laboratory (JPAC-CIL) that involves U.S. losses in the Korean War. This assemblage is largely fragmented and has been heavily sampled for DNA, which limits the number of measurements that can be obtained. Due to the nature of the remains, measurements recommended by Byrd and Adams for use in osteometric sorting will typically comprise the overall number of measurements that can be taken. One of the humeral measurements(maximum diameter of diaphysis at the deltoid tuberosity), is often one of the only measurements that can be taken on a humerus due to survivability. This measurement is strongly influenced by individual muscularity. The measurement includes the attachment site of the deltoid muscle. As the muscle increases in size, the tuberosity changes shape and often enlarges.

The reference data utilized for osteometric sorting at the JPAC-CIL was used as the reference sample for this study, and data collected from JPAC-CIL reference skeletons was added to this dataset. The total sample size used in this analysis is 59 individuals. The measurements were added to a spreadsheet and the osteometric sorting formulae for pair matching elements were utilized.[1] This method, which utilizes multiple measurements on the humerus, was used to assess asymmetry by assigning as a cut-off-any *p-value* less than 0.10, and declaring any individuals below the cutoff to be asymmetrical. Of the 59 individuals, 37 had larger right side measurements. Five individuals (8%) had significant *p-values*, which rejected the element, implying they were not from the same individual due

to their dissimilarity in size. Note that this number falls below the expected Type I error rate of 10%. The analysis of the maximum diameter at the deltoid tuberosity combined with the maximum epicondylar breadth of the humerus resulted in 10% of the individuals having significant *p-values*. However, the analysis of the maximum diameter at the deltoid tuberosity combined with the maximum length of the humerus resulted in 21% of the individuals having significant *p-values*. In this case, 10 of the 11 individuals with significantly small *p-values* had larger right measurements. These results suggest that the asymmetry of the humerus as reflected in the deltoid tuberosity must be taken into account in order to mitigate the potential errors stemming from varying degrees of asymmetry on an individual level when sorting large comingled assemblages.

Osteometric Sorting, Deltoid Tuberosity, Asymmetry

H100 Skeletal Maturation of the Medial Clavicle and First Sacral Segment in Modern Colombians

Andrea Velasco Ordonez, BA, Fiscalia General de la Nacion, Cra. 19 #24-63, Bucaramanga, COLOMBIA; Natalie R. Shirley, PhD, Lincoln Memorial University, DeBusk College Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; and Milton Andres Acero Acero, BA, Calle 168 #65-37, Casa 10, Bogota, COLOMBIA*

The goal of this presentation is to provide important information about skeletal maturation in modern Colombians as a first step in addressing the dearth of research in this area. This project is part of a larger collaboration aimed at providing Colombian forensic practitioners with population-specific standards for establishing a biological profile from skeletal remains.

This presentation will impact the forensic science community by demonstrating ages-at-transition for the medial clavicle and first sacral segment in modern Colombians. This information can be immediately applied in Colombia as one tool for young adult age estimation.

In the last two decades, the field of forensic sciences in Colombia has implemented important age estimation methods, including standards that have not been fully validated for the Colombian population. The purpose of the this paper is to present preliminary results of ongoing research on age estimation of young adults, specifically focusing on the medial clavicle and first sacral segment. These two skeletal maturation indicators are particularly useful in forensic contexts, as they are highly diagnostic for age estimation in the 20-30 year old range, which comprises a large portion of forensic case work in Colombia.

The skeletal sample for this study is a subset of the Colombian Modern Skeletal Collection from the Institute of Legal Medicine and Forensic Sciences in Bogotá, Colombia (39 individuals aged 19 to 33 years). The mean age of the sample is 25 years, and 80% of the sample is comprised of males. Whereas it is important to analyze male and female fusion separately because females are typically precocious in skeletal maturation, the small sample size in this preliminary investigation does not permit a statistically sound analysis of the female sample (n=9). Consequently, the sample was analyzed in two ways: as a combined sample, and males only. Each author independently scored the two age indicators in order to facilitate inter-observer error analyzes. The epiphyses were scored as unfused, fusing, or fused. Transition analysis, or probit regression, was performed using the cumulative probit option in NPHASES2 in order to determine the average age of the transition from one fusion stage to the next.

The combined and male-only analyses did not yield significantly different results, likely on account of the small female sample size. For the medial clavicular epiphysis, males transition from unfused to fusing at 20 years and from fusing to fused at 27 years. The combined sample gave similar results: the transition from unfused to fusing was 20 years, and the transition from fusing to fused was 26 years. These results differ from those obtained by Langley-Shirley and Jantz (2010) on a modern American sample with respect to the first transition (modern American males transition from unfused to fusing at 16 years), but not with respect to the second transition. This difference in the first transition is more likely a result of the sample age distribution of the Colombian sample than actual differences in age-at-transition. Consequently, American standards may be appropriate for the Colombian population, but further investigation is necessary to ascertain this for certain.

Transition ages of the first sacral segment were similar to those of the medial clavicle. Males transition from unfused to fusing at 20 years and from fusing to fused at 27 years. The combined sample also transitioned from unfused to fusing at 20 years and from fusing to fused at 29 years.

This presentation will discuss the implications of these results to forensic practice in Colombia and evaluate epiphyseal union in the Colombian population compared to other modern populations, taking into consideration the country's political history and general socioeconomic status. More importantly, the humanitarian impact of this project will contribute to the search for the truth and the protection of the most vulnerable sectors of a population exposed to the rigors of ongoing conflict.

H101 Evaluation of Methodologies for Stature Estimation Based on Tibiae in Colombia: Forensic Stature Versus Cadaver Stature

Carlos A. Villalobos, BA, and Juan M. Guerrero, BA, National Institute of Legal Medicine and Forensic, Cra. 7A Nº 12-61, Bogota, COLOMBIA*

The goal of this presentation is to provide insight into new research on stature estimation that has been recently conducted in Colombia. This project aims to utilize centralized stature data from national identification cards in order to generate stature equations for the tibia.

This presentation will impact the forensic science community by demonstrating how stature can be generated from the tibia of positively identified individuals. In addition, it presents two discriminant function equations that can be utilized by Colombian forensic anthropologists to estimate stature and considers the difference between self-reported stature (FSTAT) and cadaver stature (CSTAT).

The country of Colombia is fortunate to have an infrastructure that includes a government-sponsored database which maintains stature data of the entire Colombian population aged 18 years and older. These data are sourced from self-reported identification cards that all Colombian citizens are required to carry. However, studies have not been conducted to prove the reliability of this source and its usefulness for the forensic area. Stature information is frequently used to compare the forensic identification of missing individuals, even though no methods have been developed for stature estimation based on this information. This study evaluates the reliability of the first stature formulae developed on the basis of forensic stature data (FSTAT) from tibiae in Colombia.

Right and left tibiae of positively identified male individuals were analyzed (n=63). The mean age of the sample was 48 years old and stature information was recorded on each individual's identification card. Two types of stature data were available in this study: stature recorded on the identification card (FSTAT) and the cadaver stature obtained during autopsy (CSTAT). Maximum length (XLN), as defined by Buikstra and Ubelaker, was measured for each complete tibia.[1] Regression equations for left and right tibiae were obtained: [FSTAT = 86.0 + 2.24(XLNL) ± 3.384] and [FSTAT = 84.7 + 2.27(XLNR) ± 3.286]. These new equations were applied

to a control sample (n=22) and compared with five other stature estimation methods developed on various Hispanic populations. The figures estimated for each formula were compared to known statures of the control sample.

The results show that the stature data recorded on the identification card provide a high level of correlation (0.84 and 0.83) and standard error of the acceptable estimation (3.2% and 3.3%) in the stature equations developed for this research. Paired t-tests demonstrated that the formulae of this study were reliable, both for forensic stature estimation and cadaver stature estimation, while the other tested methods generated statistically significant differences (*p-value* < 0.05) between estimates and known statures.

On the other hand, the comparison of the Mean Square Error (MSE) showed that the equations developed in this research are more precise when estimating FSTAT than CSTAT. The results of the remaining methods evaluated do not differ significantly between FSTAT and CSTAT estimates. The analysis showed that the equations presented here are more reliable for the estimation of both FSTAT and CSTAT than other methods developed earlier in Colombia.[2]

To conclude, it must be noted that the database sponsored by the Colombian Vital Statistics Office is a valuable source of forensic information, not only for data comparison but for the development of stature estimation methodologies. On the other hand, a study should be undertaken in Colombia on the relation between living stature and data recorded on the ID cards, in order to establish the potential biases that may arise when these data are used. Finally, this research is expected to contribute nationally and internationally to an understanding of the importance of using forensic stature for the identification of missing persons. The data generated will also strengthen forensic services in Colombia.

Forensic Stature, Cadaver Stature, Colombian Population Standards

H102 Isotopes and the Future of Region of Origin Identification: Geochemical Boundaries, Political Boundaries, and Modeling Methods with a Mexican Sample Population

Chelsey Juarez, PhD, University of California Santa Cruz, Department of Anthropology, UCSC Social Science 1, 1156 High Street, Santa Cruz, CA 95064*

The goal of this presentation is to discuss the latest methodologies currently in use in the creation of isotope-based databases for identification. Using examples from a Mexican population, this presentation will identify when and where each database methodology can be practically and successfully applied. This presentation will investigate identification databases consisting of "authentic known samples" and discuss the statistical success of political/state groupings versus geochemical separations. In addition, this presentation will compare databases consisting of "authentic known samples" with those based on predictive models. After attending this presentation attendees will, understand the two major types of isotope databases currently in use (authentic sample, and predicative model), and be able to identify when and where these database types will be most successful.

The use of isotopic analysis for the purposes of forensic identification has become a focus in recent years. As more isotope databases are constructed it is critical to understand the pitfalls and limitations of different types of databases and to recognize the influence that country of origin may have on successful identification. This presentation will impact the forensic science community by opening a dialog on isotope databases to maximize the creation of successful isotopic identification and encourage the increased use of this powerful identification tool.

Isotope ratios in teeth, bones, hair and nails have been analyzed by archaeologist and forensic scientists to investigate patterns of residential mobility and region of origin. Much of the isotope work coming out of the forensic anthropology community has utilized samples of known origin for identification comparison (Juarez, Regan).[1,2] In 2011, a comparative isotope database documenting (∂18O, ∂13C, 87/86Sr) for 10 states in Mexico was completed. In its initial form, this database focused on political separations for samples of known origin as a comparative method.

Recently, the focus on isotope identifications has begun to turn towards predictive modeling (Ehleringer).[3] Ehleringer initiated the development of a model to predict the geographic region of origin for humans living in the United States based on the ∂18O and ∂2H values of scalp hair.[3,4] The most recent results from this research suggest that database comparison studies have limited predictive power when compared to predictive model studies (Ehleringer).[3] In principle, this claim has significant merit when the robustness of available models are analyzed and compared. The Ehleringer *et al*. predictive model achieved an overall 86% correct success rate between observed and predicted region of origin locations for training samples.[4] This is compared to a variable rate of success for the comparative model of modern Mexican populations, which achieved 46-86%. In practice, the difference in robusticity between the predictive and the comparative models and the sample regions suggests some interesting trends that merit further analysis. First, the predictive model based on U.S. populations suggests that oxygen and hydrogen isotopes alone have the power to discriminate between different regions of origin even for contiguous areas. This is in contrast to the results from the comparative Mexican data set, where d18O values alone separate the Mexican states involved into only two major groups, with d18O values contributing only minimally to the discriminant function. Individuals that had a close relationship to the local water mainly represented the samples in predictive model. This relationship was not naturally occurring in the Mexican population studied, and it is clearly documented that Mexican populations have the highest bottled water consumption in the world. In addition, the possible range of tap water δ18O values in the predictive model was much larger (-5 to -20‰) than the range of precipitation values in the Mexico sample (-2.9 to -10). This suggests that the sample areas themselves may not be of equal quality and that Mexico may not be an ideal location for region of origin discrimination on the basis of oxygen.

Second, the Mexican comparative model had a more significant problem with misclassifications than the predictive model. The Ehleringer model is a predictive isoscape model. Isoscapes provide expected isotope values for a given geographic coordinate. This method is useful for studying processes that lead to changes in isotope values over space. Essentially this model type can provide a sense of the extent to which distributions of isotope values from different locations are the same. This is something that does not happen with a comparative model.

This presentation will impact the forensic science community by opening a dialog on isotope databases to maximize the creation of successful isotopic identification and encourage the increased use of this powerful identification tool. As more isotope databases are constructed it is critical to understand the pitfalls and limitations of different types of databases and to recognize the influence that country of origin may have on successful identification. In certain locations like Mexico were the relationship between local food and water intake is complicated by the pervasive use of bottle water comparative models offer valuable insight. The study comparison suggests that the best models take into consideration the unique limiting factors in each given situation and push for careful analysis of a given situation and the creation of a flexible hybrid database when and where appropriate.

Isotope, Database, Identification

H103 Unveiling Ancestry in Colombia through Morphometric Analysis

Maria A. Lopez, BA, National Institute of Legal Medicine and Forensic, Calle 24 #5A-61, Tunja, COLOMBIA; Diego A. Casallas, Attorney General's Office, Diag 22B # 52-01, Edificio L, Piso 5, Bogota, COLOMBIA; Daniel Castellanos, MS, National Institute of Legal Medicine and Forensic, Calle 4B #36-01, Cali, COLOMBIA; Francia V. Soto, BA, Prosecutor General's Office, Fiscalia General de la Nacion, Cra. 19 #24-61, Bucaramanga, COLOMBIA; and Jonathan D. Bethard, MA, Boston University, School of Medicine, Boston, MA 02118*

After attending this presentation, attendees will understand the complexity of accessing ancestry in Colombia given its heterogeneous population history. In addition, attendees will learn that recent analyzes of a documented modern Colombian skeletal collection have initiated a quantitative approach to understanding variation in Colombia.

This presentation will impact the forensic science community by presenting results on the first geometric morphometric ancestry study in Colombia. In addition, this presentation will contribute to recent research that has attempted to quantify population variation in Latin America.

Colombia is a multiethnic and multicultural country where various human groups of European, African, and Indigenous ancestry have intermixed and therefore shared the social, cultural, and biological characteristics of their place of origin. The concept of ancestry in Colombia is more complicated than in many other countries as a result of the particular demography, history, anthropology, and genetics of its inhabitants. Genetic research has found marked mtDNA differences among contemporary Colombians, indicating numerous geographic haplotypes, all of which have contributed to the regional division of the country´s population.[1] To date, these differences have not yet been compared to the morphological and morphometric cranial features of the same populations.

In forensic anthropology, ancestry estimations have traditionally and generally been done on the basis of physical anthropological principles, such as craniofacial morphology. This morphology has been used to create categories of different groups of human beings, showing that there are perceptible metric and morphological differences between populations. Traditionally-used categories (European, African, and Asian) may correspond to the social categories used for ancestry in Colombia (Indigenous, African-Colombian, and Mestizo). However, ancestry analysis in the forensic context has been based primarily on foreign population studies, which have recently sparked discussions on the credibility of these studies in Colombia.

This project is the first geometric morphometric characterization to study ancestry in Colombia. Based on Buikstra and Ubelaker, the craniometric landmarks of 127 adult individuals, 48 females and 79 males, were registered with a MicroScribe GT using the modern skeletal collection curated by the National Institute of Legal Medicine and Forensic Sciences.[2] The individuals in the sample came from five of the six natural regions of the country, mostly from the Andean area. The data obtained were processed with the 3D-ID software package in order to compare the population categories generated by the program with morphological features of each cranium.

Not surprisingly, results from 3D-ID indicate a diverse array of potential population groups. For example, 13% of the sample was classified as having African descent, 34% were classified as having a European origin, 10% were classified as Mesoamerican, and 33% were classified as South American. We argue that these results confirm a heterogeneous population structure and are a good first step in unveiling ancestry in Colombia. It is hoped that through increasing the sample size and additional statistical analyzes (i.e., k-means cluster analysis), we might begin to better understand population variation in Colombia and contribute to discussions surrounding population variation throughout Latin America.[3]

This is a useful analysis in the forensic context because it is the beginning of a series of geometric morphometric studies of the modern Colombian population. It will facilitate comparisons with other Latin American samples as programs such as 3D-ID and FORDISC begin to incorporate these new data. It is our hope that in the Colombian forensic context, the human identification process and the estimation of ancestry will contribute to the accuracy of presumptive and/or positive identifications.

Colombian Ancestry, Geometric Morphometrics, Population Variation

H104 Univariate Sex Discrimination from the Postcranial Skeleton for a Colombian Population

Francis P. Niño, MA, Cuerpo Técnico de Investigación, Medellín, Antioquia, COLOMBIA; Oscar Hidalgo, MA, Cuerpo Técnico de Investigación, Pasto, Nariño, Pasto, Nariño, COLOMBIA; and Megan K. Moore, PhD, University of Michigan-Dearborn, Department of Behavioral Science, 4901 Evergreen Road, Dearborn, MI 48128*

The goal of this presentation is to present a discriminant function analysis of the postcranial elements from a new human skeletal collection of known individuals in Colombia.

This research will impact the forensic science community in the development of population standards for sex discrimination in Colombia and South America. This research may help pave the way for future courtroom validation methods.

This research explores the best univariate indicators for sex estimation using measurements of the postcranial elements. In a recent study of African Americans and European Americans from the Forensic Database, the postcranial elements that demonstrated the most effective sex discrimination were the femur, tibia, humerus and scapula (Spradley et al. 2011). The hypothesis for the current study is that the population from Bogotá, Colombia will follow a similar pattern with the femur and tibia at the knee demonstrating the highest classification rates.

The sample consists of 134 individuals (50 females, 84 males) between the ages of 19 and 93 with a mean age of 47 years. The sample is part of a new collection, the Modern Colombian skeletal collection of Colombia, from cemeteries in Bogotá, Colombia. These skeletons are curated at the National Institute of Legal Medicine and Forensic Sciences (INML y CF). The collection of known individuals includes data on age, sex, stature (as reported on identification cards) and place of birth. The

collection represents remains that were either unclaimed after a four-year burial period and were collected before becoming comingled in a common grave. All individuals died in 2005. The methods include discriminant function analysis and univariate ANOVA using SPSS. Only the bones of the left side of the body were included in the analysis in order to lessen the effect of handedness and potential occupational markers, especially in the upper limb.

The results for this Colombian population indicate the same general pattern of classification effectiveness as seen in the North American sample using the univariate ANOVA and cross-validated discriminant function analysis. The humerus performs slightly better than the distal femur and proximal tibia as demonstrated in the North American sample. The percent correct classification for the postcranial elements ranges from 72.9% to 92.1%, with all of the humeral measurements correctly discriminating sex more than ninety percent of the time (*p-value* < 0.00). The highest classification rate was for the humeral head diameter (92.1%), the humeral epicondylar breadth (91.4%) and the humeral maximum length (90.7%). Only one femoral measure achieved just at 90.0% correct classification, which was the femoral midshaft transverse diameter.

In conclusion, these univariate results for the femur and tibia are very similar to the previous study by Spradley et al. (2011), but the higher discrimination in the humerus approaches some of the higher multivariate success rates achieved in the same study. This could be extremely useful for identification, as the humerus is more resistant to taphonomic properties than many of the bones. Furthermore, the ability to achieve such a high degree of success from a single bone is more efficient and thus preferable for the fast paced forensic laboratories in Colombia that see hundreds to thousands of forensic anthropology cases each year. This research will potentially play an important role in the development of population standards in Colombia and South America. This research hopes to help pave the way for courtroom validation methods not currently required in the Colombian medicolegal system, but validation methods will likely play an important role in the near future.

Sex Estimation, Postcranial Skeleton, Colombia

H105 Sexual Dimorphism in Argentinean Populations: A New Approach

Ivana Wolff, MS, Mercyhurst College, 501 East 38th Street, Erie, PA 16546; Luis L. Cabo, MS, Mercyhurst College, Department of Applied Forensic Sciences, 501 East 38th Street, Erie, PA 16546; and Mercedes Salado Puerto, PhD, Argentine Forensic Anthropology Team, Av. Rivadavia 2443, Piso 2 Dep.4, Buenos Aires, 1034, ARGENTINA*

After attending this presentation, attendees will gain a better understanding of the expression of sexual dimorphism in Argentinean populations, as well as to explore a new methodological approach for the examination of inter-group differences

This presentation will impact the forensic science community by contributing to knowledge of the nature and magnitude of sex variation in Argentinian populations. These results will affect the way in which anthropologists interpret sex differences from the skeleton.

The assessment of sex is the first analysis performed on an unknown skeleton. Due to different environmental and genetic factors, the osteometric proportions of a skeleton vary significantly within and between populations. Thus, it is not possible to devise universal formulae and standards for evaluating sexual dimorphism. Population specific standards need to be constructed for each group, not only for improving forensic analysis, but also for establishing a better understanding of the patterns of sexual dimorphism. Generally, males are larger and more robust than females. However, researchers have yet to determine which suite of measurements express the greatest amount of sexual dimorphism in the human skeleton.

The purpose of this research is two-fold. Firstly, to obtain population specific standards for an Argentinean population using discriminant function analysis (DFA). Secondly, to explore the idea that if allometry is statistically detected and describes the shape variable which covaries with size, then explanations may be found in terms of growth and biomechanics. Once these patterns are found in one population, several comparisons of sexual dimorphism can be made between populations. From a methodological perspective, differences between sexes can be analyzed through DFA, and as shown in this research, by principal component analysis (PCA).

The sample is comprised of 124 unidentified adult skeletons (64 female and 60 males) which were exhumed from cemeteries in the Buenos Aires area by the Argentinean Forensic Anthropology Team (EAAF). Sex was ascertained through DNA, though positive identifications are still pending. The skeletons were buried between the years of 1976 and 1979.

Standard anthropometric post-cranial measurements were taken and collected in a database. Variables selected through DFA were examined to explain their contribution to sexual dimorphism (females/males). In particular, whether they were expressing merely sex size dimorphism (SSD) or true sex differences in developmental patterns.

Univariate discriminant functions were constructed using direct methods for each of the metric measurements. Multivariate discriminant functions were developed for each bone using a stepwise procedure for all the dimensions.

When using univariate discriminant function, the breadth measurements from all the bones had the highest percentages of correct classifications. The humerus yielded four measurements with correct classification higher than 90%. When using multivariate discriminant functions, all elements within the study show correct classifications higher than 94%.

On the other hand, when pooled groups were analyzed through PCA, only one component was obtained. The traditional interpretation of PCs indicates that the main differences between sexes are size differences (SSD); this result is also supported by DFA. When eliminating the differences between groups, the differences within groups are expressed. Both DFA and PCA by group show that within-group allometric patterns are masked when using pooled groups. Group size differences often result in spurious correlations when multiple variables are considered. Therefore, the more size dimorphic variables enter both the PC1 and DF. This research shows that PC1 is including size, allometric shape, and also size free shape. From a geometric point of view, PCA and DFA are doing very similar things.

Among the Argentinean sample, DFA detected overall size disparity between the sexes rather than differences in allometric patterns, even though the latter do exist. When comparing populations, it is necessary to assess whether the group differences are related to allometric patterns or solely raw size.

Discriminant Function Formula, Principal Components Analysis, Allometry

H106 A Radiographic Study on the Utility of Cranial Vault Outlines for Positive Identifications

Ashley B. Maxwell, MA, North Carolina State University, Department of Sociology & Anthropology, 334 1911 Building, Campus Box 8107, Raleigh, NC 27695; Ann H. Ross, PhD, North Carolina State University, Department of Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107; and Sam Simmons, MD, North Carolina Office of the Chief Medical Examiner, Campus Box 7580, Chapel Hill, NC 27599-7580*

The goal of this presentation is to explore the applicability of radiographs in medicolegal investigations.

This presentation will impact the forensic science community by highlighting the importance of biological variation and the utilization of radiographs in unidentified remains.

The visual and statistical assessment of the utility of radiographs for positive identification was examined in accordance with the *Daubert* and

the 2009 National Academy of Sciences Report, which calls for more testable and reliable scientific research. Currently, there has been a surge in research pertaining to morphological variation in the crania and post-crania for positive identification. The areas most explored include the frontal sinus, chest, and vertebrae. The availability of antemortem radiographs of particular areas of the body can be used for positive identifications in cases where other measures of identification cannot be employed. The utility of radiographs for medicolegal purposes is shown by the uniqueness of certain features of the skeleton in previous research; however, there is a need to quantify their uniqueness to appease the *Daubert* ruling and National Academy of Sciences Report. The purpose of this research is twofold: (1) to test the visual accuracy of positive identification in antemortem and postmortem radiographs of the lateral cranial vault outline among practitioners with different levels of forensic experience; and, (2) to use shape analysis (elliptic Fourier analysis) to evaluate the uniqueness of vault outlines and its applicability to positive identifications.

A sample of 90 individuals with varying levels of education participated in a visual accuracy test, which included: Ph.D. (n=34), M.D. (n=6), M.A. or M.S. (n=39), and B.A. or B.S. (n=11). Along with education, forensic case experience was also recorded, which included: none (n=13 or 14%), 1-10 cases (n=23 or 25%), <50 cases (n=25 or 27%), and >50 cases (n=31 or 34%). The visual test was comprised of left lateral radiographs taken from 14 crania (labeled A-O) representing the "antemortem" radiographs, and the "postmortem" radiographs were comprised of five randomly chosen crania from the same sample of 14 crania comprising the "antemortem" set that were radiographed a second time. Participants were asked to match the "postmortem" radiographs with the "antemortem" radiographs. Out of the 90 individuals, 38 (or 42%) correctly assigned all of the radiographs, with accuracy rates ranging from 70-93% for each of the five radiographic comparisons. Individuals with the highest level of education (PhD) and the lowest level (BA or BS) also had the most correct responses (45% correct) along with individuals with the highest forensic case experience (50% correct). Participants were also asked to list the skeletal markers that aided in their assessments and the inion hook (22%) and overall vault shape (21%) were listed as the most useful for identification.

Vault shape was compared among the 14 antemortem cranial vault outlines and the five postmortem vault outlines with geometric morphometric methods of contour shapes using the statistical program SHAPE 1.3, which performs an elliptic Fourier analysis. A principle component analysis was run on 30 harmonics to examine the variation in the morphological features of the cranial vaults. Paired t-tests were computed on the effective principle components to assess significant differences between each of the five antemortem and five postmortem radiographs and a two tailed t-test was computed between all of the antemortem and postmortem radiographs. The results indicate that there were no significant differences between any of the radiograph comparisons.

The visual comparison test and shape analysis was performed to evaluate the uniqueness of cranial vault outlines in radiographs, accuracy rates, reliability, and their utility in positive identifications. The visual accuracy test shows that the visual assessment of radiographs is not useful for positive identifications under the *Daubert* criteria due to the low accuracy rates (only one comparison had over 90% accuracy). However, education and experience did appear to affect the ability to correctly assign the radiographs. The shape analysis also indicates that vault outlines are not useful for positive identifications alone, although they could be used in conjunction with other features (such as the frontal sinus) for positive identifications.

Cranial Vault Radiographs, Elliptic Fourier Analysis, Positive Identification

H107 Identification of a United States Airman Using Stable Isotopes

Thomas D. Holland, PhD, Department of Defense JPAC, Central ID Lab, 310 Worchester Avenue, Hickam AFB, HI 96853; Gregory E. Berg, PhD, JPAC-Central ID Laboratory, 310 Worchester Avenue, Hickam AFB, HI 96853-5530; and Laura A. Regan, PhD, Armed Forces Medical Examiner System, 1413 Research Boulevard, Building 102, Rockville, MD 20850*

After attending this presentation, attendees will become familiar with a recent identification of an individual using stable isotopic analysis of his dental remains.

This presentation will impact the forensic science community by raising awareness of the possibility of employing isotopic analysis in the identification of human skeletal remains.

In February 1969 a U.S. Air Force pilot was attacking an anti-aircraft artillery position in Savannakhet Province, Laos, when his F-100D Super Sabre was struck by enemy fire and crashed. Crewmen of three other American aircraft involved in the mission reported seeing no parachute or any other indicator that the pilot of the F-100 had successfully exited the aircraft or survived the impact. He initially was placed in the status of Missing In Action; however, a military review board subsequently amended his status to Killed In Action.

In 1991, 1992, 2005, and 2009 joint U.S./Lao People's Democratic Republic teams located and excavated the 1969 crash site, which was located within 100 meters of the reported historic map coordinates for the incident. Over 450 m^2 was excavated using standard archaeological procedures and the site yielded human remains, pilot related material evidence, and aircraft wreckage. The U.S. Air Force Life Sciences Equipment Laboratory (LSEL) confirmed that the life-support equipment found at the site was consistent with the pilot being on board at the time of impact, and in the LSEL's opinion, the crash was non-survivable. The remains consisted of a single crown fragment from a human left maxillary canine (tooth #11). The tooth was unrestored and lacked any morphological characteristics that would allow for individualization.

Analysis of stable isotopes in the enamel from the tooth fragment—specifically, carbon and oxygen—revealed typical Western values consistent with those seen in individuals raised in the United States. The permanent maxillary canine completes its crown formation by approximately age six; thus, isotopes present in the enamel reflect exposure (through diet) to these isotopic ratios during this early period of growth. Conversely, the isotopic values differed significantly from those seen in indigenous Southeast Asians. Based on this analysis, it was inferred that the human tooth fragment was that of a Westerner (e.g., American) and did not derive from an indigenous native to Southeast Asia.

In sum, the pilots of other U.S. aircraft involved in the same February 1969 mission witnessed the F-100D aircraft crash into a mountainside in Savannakhet Province, Laos. No parachute was observed and they believed the crash was not survivable. An aircraft crash site that was located within 100 meters of the incident map coordinates was located and excavated from 1991 to 2009. The site yielded wreckage exclusive to that of an F-100D aircraft; historical records indicate that there is only one F-100 that crashed within 40 kilometers of that location. Identification media purportedly found at the site by Laotian nationals living nearby consisted of two military identification tags that correlated to the pilot by name, service number, blood type, and religious preference. Based on aircraft type and location, the site was correlated to the 1969 loss of a specific F-100D aircraft to the exclusion of all other reasonable possibilities. Analysis of the tooth fragment found amid the wreckage field revealed it to be human. Isotopic analysis of the enamel excluded the reasonable supposition that the tooth was that of an indigenous Southeast Asian and thus precluded the probability that the tooth fragment was a site contaminant. Given the totality of the evidence, including the exclusion of all reasonable alternatives, the human remains found at the crash site were identified as

those of a U.S. serviceman who died in 1969 when his aircraft was shot down over Laos.

Forensic Science, Stable Isotopes, U.S. Military Identification

H108 Ongoing Development of the Novel Computer-Assisted Radiograph Identification Method

Sharon M. Derrick, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; John A. Hipp, PhD, Medical Metrics, Incorporated, 2121 Sage Road, Houston, TX 77056; Jennifer C. Love, PhD, and Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; and N. Shastry Akella, PhD, Chenghao Shi, MS, and Zulun Tan, BS, Medical Metrics, Inc., 2121 Sage Road, Suite 300, Houston, TX 77056*

After attending this presentation, attendees will receive a brief description of the ongoing development of the enhanced version of QMA® and fine-tuning of this quantitative approach to identification basis for the computer-assisted radiograph comparison method and the proposed practical application of the method in medical examiner/coroner offices. Milestones achieved in the development of the method in the previous 12 months will be discussed and plans for an imminent large-scale validation study will be outlined.

The presentation will impact the forensic science community by describing successes in the development and validation progress of a new practical identification method responsive to the National Academy of Science Report recommendations and post-*Daubert* evidence admissibility standards.

A statistically validated, time-sensitive and relatively inexpensive scientific identification method is under development for routine use in the medical examiner/coroner setting. The method is based on an enhanced version of "Quantitative Motion Analysis" software. QMA® has been validated in multiple clinically based peer-reviewed studies of spinal biomechanics and spinal treatments. The software allows for computer-assisted matching of specific skeletal elements, such as vertebral bodies, by tracking them through multiple radiographic images.

Forensic identification of unidentified or tentatively identified remains through comparison of antemortem and postmortem radiographs currently relies on a visual assessment by a forensic anthropologist. The accuracy of the method is dependent on the experience level of the anthropologist and the presence or absence of features traditionally believed to vary significantly among individuals. To objectify this process, QMA® was developed to quantify how well specific anatomic features "match" in a set of radiographs. The ultimate goal of the project is to validate an objective image matching system for forensic radiograph-based identification. The pilot study of this project began with the development of a processing algorithm that provided QMA® with the ability to successfully calculate the required quantification of the match, the "match score."

Several different algorithms have been developed over the course of this project that can be used successfully to quantify a match score. There are also multiple ways to arrive at a composite match by combining match scores for multiple features in one set of radiographs. The final match score reported by the software must be scientifically validated and this requires a systematic method to find the optimal protocol out of the many available options.

The strategy of this study to identify the optimal protocol is to apply the various permutations of the available options to a large collection of radiographs and assess the resulting data based on the sensitivity and specificity for detecting a correct match. As a test, multiple options for preprocessing images and the various successful match score algorithms were applied to a collection of paired radiographs, some of which were correctly matched and others incorrectly matched. A spatial registration process was applied to the images prior to preprocessing to minimize variability caused by the relative position of anatomic features within the radiographs. The preprocessing filters that were tested included histogram equalization, unsharp masking, and shadow enhancement filters. Testing of the match scores included mutual information, image correlation, Dice similarity, and the Jaccard coefficient methods. The resulting data were analyzed to identify the algorithms with the highest sensitivity and specificity for identifying correctly matched images. As expected, the type of preprocessing filter applied and the match score algorithm were significantly associated with the resulting match score (Correlation: sensitivity 71.43, specificity 77.78, p-value < 0.001). The sensitivity and specificity tended to be higher using the Dice (sensitivity 85.71, specificity 88.89) and Jaccard (sensitivity 92.86, specificity 88.89) match score algorithms.

The large number of potential preprocessing protocols available and the multiple options for calculating match scores in QMA® require an optimization scheme to identify and validate the optimal protocol for the computer-assisted identification method. The results of this study demonstrate that the optimization process can be completed using sensitivity and specificity data as the primary outcome measures, and that sensitivity and specificity are highly dependent on the combination of preprocessing steps and match score algorithm used. Testing of the optimization process is underway using large sets of example imaging until the sensitivity and specificity data converge to steady values in the optimal protocol for the matching process.

Radiograph Identification, Forensic Anthropology, QMA®

H109 Virtual Anthropology: A Comparative Study of Real Bone vs. Virtual Bone Surface

Tanya Uldin, MA, University Center of Legal Medicine, Lausanne – Geneva, CURML, UMF, Rue Michel-Servet 1, CH-1211 Genève 4, SWITZERLAND; Sébastien De Froidmont, MD, University Center of Legal Medicine, Lausanne – Geneva, Rue du Bugnon 21, CH-1011 Lausanne, SWITZERLAND; Paul Vaucher, MSc, University Center of Legal Medicine, Lausanne – Geneva, University of Geneva, Rue Michel-Servet 1, 1211 Geneva 4, SWITZERLAND; Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; and Silke Grabherr, MD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND*

After attending this presentation, attendees will understand the advantages and limits in applying anthropological methods on virtual bones.

This presentation will impact the forensic science community by demonstrating the future role of cross-sectional techniques for anthropological studies

In recent years, modern cross-sectional imaging techniques such as multi-detector computed tomography (MDCT) have pioneered applications in various postmortem investigations. Since 2008, MDCT is used in the routine investigation of all bodies examined by the University Center of Legal Medicine in Lausanne. This data pool is opening new opportunities in several research fields. Concerning forensic anthropology, problems, such as insufficient sample composition and lack of individual data, could be solved, if those data can be made available. For this reason, we started to create the anthropological data base of virtual skeletons of Lausanne. Consequently, basic research should focus on data comparability in order to understand limitations of applying conventional anthropological methods on virtual bones.

Preliminary studies in the field of virtual anthropology have shown that anthropological investigations can only be performed if the radiological data are of highest quality. Accordingly, special scanning protocols are important to gain sufficiently high resolution to investigate details. The

purpose of this study was to evaluate the application of anthropological-morphological methods of age estimation to 3D reconstructions of virtual bones and to develop appropriate scanning parameters.

Therefore, the reliability of the applied methods and their validity for MDCT data were tested. Eleven skulls and 21 hip bones, which originate from archaeological, anatomical and medicolegal collections, were examined by two experienced and four inexperienced observers. First, each bone was classified by conventional anthropological methods. In a second run, which was performed within an appropriate time lag, the virtual bones have been investigated using the same scoring system. The method applied on the hip bone is based on four traits of the sacro-iliac joint and the aspect of the iliac tuberosity. The method used for the skull is based on the 16 sections and five scoring stages of the ecto- and endo-cranial sutures. The bones were scanned on an eight-row MDCT using a high resolution (slice thickness of 0.625 mm). The 3D reconstructions were made on the CT-workstation.

Our study shows that, in general, estimating age of virtual bones shows a higher risk of false classification. While correlations between real and virtual bone-age estimations are quite sufficient in case of ecto-cranial sutures, the endo-cranial sutures and the sacro-iliac area are showing very low correlations. Two problems that interfere with the age estimation of virtual bones could be observed: The first is caused by areas of low bone density, which are not recognized by the software program of the workstation and which are therefore not calculated for the 3D image of the bone. This leads to a loss of substance during the 3D reconstruction that renders impossible its interpretation. Secondly, an automatic smoothing of the surface occurred during the reconstruction process. Thus, the examination of fine structures became infeasible and it affected the scoring of higher stages.

Besides, significant differences could be observed between the raters for estimations performed on virtual as well as on real bones. The reliability of estimates is increased by experience.

These results indicate firstly, that MDCT does not permit a sufficiently precise 3D reconstruction of the surface of dry bones in order to apply conventional anthropological methods. Consequently, the development of a special scanning protocol will be inevitable. Secondly, modifications of classical anthropological-morphological methods will be necessary for using the reconstructed surface of virtual bones.

Virtual Anthropology, Bone Imaging, MDCT

H110 Multidisciplinary Combination of Traditional and New Techniques in the Determination of Identity: The Utility of the Sphenoid Sinus Rediscovered

B.G. Brogdon, MD, University of South Alabama Medical Center, Department of Radiology, 2451 Fillingim Street, Mobile, AL 36617; Marcella H. Sorg, PhD*, Margaret Chase Smith Policy Center, University of Maine, Orono, ME 04469; Jamie Elifritz, MD, University of South Alabama, University of Maryland Medical, Diagnostic Radiology, 22 South Green Street, Baltimore, MD 21201; Richard M. Scanlon, DMD, 27 Sandy Lane, #206, Lewistown, PA 17044-1320; Hal G. Brown, Office of the Chief Medical Examiner, Forensic Science Laboratory, 200 South Adams Street, Wilmington, DE 19801; and Jamie A. Wren, University of Maine, Department of Anthropology, 5773 South Stevens Hall, Orono, ME 04469*

After attending this presentation, attendees will learn of factors limiting the usefulness of the frontal sinuses in identification of unknown decedents by radiological comparison. A model of multidisciplinary cooperation will demonstrate the utility of the sphenoid sinus for that purpose.

This presentation will impact the forensic science community by demonstrating how successful comparison of the sphenoid sinus or other structures difficult to image by conventional x-ray examination can be achieved with CT equipment available in almost any community hospital or diagnostic center.

For 85 years the frontal sinuses have enjoyed the enthusiastic focus of forensic investigators as a prime site for identification by radiological comparison. The usefulness of other paranasal sinuses, particularly the sphenoid sinuses, has been largely ignored. Increasing acceptance and availability of CT as the primary method of imaging the skull promotes utilization of the more protected and, hence, most imperishable of the paranasal sinuses for the same purpose.

Boaters discovered a human skull on the tidal flats of the Delaware River just 300 yards south of the Port of Wilmington. The skull was removed from its original site to higher ground and the police were notified. The skull was discolored, covered and impregnated with gravely mud from the waterway. A portion of the skull had been damaged, and the mandible was missing. A single maxillary tooth (#2) was in place and contained an occlusal restoration. Photographs of the skull were sent to a physical anthropologist who provisionally reported them as an adult male, probably under 50, with possible Asian or Native American morphology.

There were several persons missing from aquatic accidents or suicides in the area. This description best fit a 43-year-old male who had fallen off a boat into a tributary of the Delaware River 38 months earlier— but he was listed as Black.

The skull was sent to a forensic odontologist along with dental radiographs of the possible decedent. The single tooth in the skull (#2) was compared with the antemortem radiographs. The occlusal amalgam restoration in that tooth had a similar radiographic outline consistent with a match but not sufficient to reach the level of positive dental identification.

The skull was then sent to the anthropologist who confirmed the initial assessment from the photographs as to age and sex, refining the age estimate to 35-46, and suggesting a postmortem interval less than five years. She reiterated that the cranium exhibited primarily mongoloid characteristics, supported with a FORDISC 3.0 osteometric assessment, although with very few (non-metric) African-American traits. In view of the racial ambiguity, she requested further interrogation of the presumed victim's family. They readily revealed that there was Native American ancestry in both maternal and paternal lines, and added that their missing relative had a CT examination of the head a year prior to his disappearance. This examination (actually a CT of the paranasal sinuses in the coronal plane) was compared with a frontal x-ray of his skull obtained by the anthropologist, who could not rule out the match. She suggested the case be referred for forensic radiology for possible identification.

The postmortem x-ray and the antemortem CT were examined by forensic radiologists who confirmed some similarity, but successfully argued the necessity of a postmortem CT of the skull. Meticulous positioning of the skull enabled reconstruction of images to almost exactly replicate the antemortem CT, which produced many compelling, matching features, particularly in the sphenoid sinuses and, finally, an unequivocal positive identification.

This case is presented as a model of multidisciplinary cooperation and tenacity. We believe it is the first successful identification of an unknown body by comparison of the sphenoid sinuses on CT images of a skull when visualization of frontal sinus by conventional radiology was compromised.

Identification, Computed Tomography, Sphenoid Sinuses

H111 Forensic Anthropology and the Art of DNA Sampling

Krista E. Latham, PhD, University of Indianapolis, Biology Department, 1400 East Hanna Avenue, Indianapolis, IN 46227; and Lori E. Baker, PhD*, Baylor University, Department of Anthropology, Forensic Science and Archaeology, One Bear Place, #97173, Waco, TX 76798-7173*

The goals of this presentation are to outline the best skeletal sampling strategies for forensic DNA analysis and the importance of basic genetic

knowledge when working within a field that strives for the positive identification of human remains.

This presentation will impact the forensic science community by discussing the benefits and advantages of various ways to sample the human skeleton for DNA analysis, the elements of the skeleton most likely to yield subsequent DNA profiles and how depositional environment or alteration of the remains may impact the ability to produce a DNA profile for positive identification.

The use of DNA technology for the positive identification of skeletonized and decomposed remains has become increasingly relied upon within the forensic community. While the forensic anthropologist plays an essential role in estimating descendant characteristics from skeletonized remains, such as age-at-death, biological sex and ancestry, as well as discerning peri-mortem trauma, estimating the postmortem interval and taphonomy, the actual positive identification is often done by the forensic DNA analyst. Therefore, the positive identification of human remains is most often a collaborative process incorporating multiple specialties within forensic sciences.

The process of obtaining analyzable DNA from bone is a destructive, timely and costly process. As experts in the human skeleton, forensic anthropologists are often responsible for the selection of skeletal elements for DNA analysis or consulting with coroners and medical examiners on appropriate samples for successful DNA profiling. Choosing the appropriate area of the skeleton to sample or amount of bone to be submitted for DNA typing can influence the success of subsequent examinations. It is important for the consulting anthropologist and DNA analyst to recognize how different sampling strategies influence subsequent osteological analysis, as some strategies involve cutting and removing large portions of the bone or sending entire skeletal elements for genetic analysis and therefore losing landmarks for discrete or metric investigations. In addition, sampling strategies can influence subsequent DNA analyzes as some skeletal elements can be more or less likely to produce genetic profiles based on intrinsic factors of the bone itself. Lastly, environmental factors such as heat and moisture play a large role in DNA preservation and having a basic working knowledge of those factors that are detrimental to DNA preservation may save time and money on fruitless genetic analyzes in situations where no analyzable DNA is likely to remain within the bone.

The goal of this presentation is to explore differences in basic DNA knowledge between forensic anthropologists working within different institutional contexts, such as government versus academic organizations and highlight the frequency at which forensic anthropologists are sending skeletal samples for genetic analysis. The different sampling strategies performed by practicing forensic anthropologists will be presented along with a discussion of the benefits and disadvantages of each technique. The intrinsic and extrinsic factors influencing molecular taphonomy will be discussed within the context of recent research and case studies to highlight the importance of a working knowledge of DNA and genetic technologies for a practicing forensic anthropologist.

Forensic Anthropology, DNA Sampling Strategies, Genetic Profile

H112 Anthropological Facial Approximation in 3D (AFA3D) – Computer-Assisted Estimation of Facial Morphology Using Geometric Morphometrics

Pierre Guyomarch, MS, Universite Bordeaux 1, UMR 5199 PACEA, Universite Bordeaux 1, Av des Facultes, Bat B8, Talence, 33405, FRANCE*

The goal of this presentation is to describe a new method that produces three-dimensional (3D) facial approximations using geometric morphometrics.

This presentation will impact the forensic science community by proposing an objective tool for facial approximation based on statistics and craniometrics.

According to the Scientific Working Group for Forensic Anthropology (SWGANTH), the aim of facial approximation is to estimate the antemortem facial appearance, suggest the identity of the person, and capture public attention. This study seeks to improve accuracy and reliability of the facial shape estimation process. Quantitative evaluation of the morphology of both facial features and soft tissue depths (STD) was performed through 3D measurements of Computed Tomography (CT) exams.

Five hundred CT-scans of French adult subjects (known age and sex) have been collected in medical centers after approval of ethical committees (265 males, 235 females; age range: 18-96 years; mean=52; sd=20). DICOM files were treated with TIVMI (Treatment and Increased Vision for Medical Imaging, developed by Bruno Dutailly, UMR 5199). This software (freely downloadable at http://www.pacea.u-bordeaux1.fr/TIVMI/) allows for the 3D surface reconstruction of both osseous and cutaneous faces of the patients, using the Half-Maximum Height algorithm. Cranial and facial landmarks (n=178) were collected using reference planes based on the Frankfurt Horizontal in order to enhance their repeatability and reproducibility.

Because the sample contained several partial exams (approximately 2/3 of superior and inferior faces for 1/3 of complete exams), eyes, nose, mouth and ears regions were studied independently. Geometric morphometrics offered objective form quantification in 3D through Procrustes superimpositions; asymmetry, influence of age, sexual dimorphism, and allometry were evaluated. Partial Least Square (PLS) analysis was used to evaluate the covariation between bone and skin matrices (landmarks configurations). Results allowed for the definition of four bony matrices optimally correlated with the facial organs matrices (eyes, nose, mouth and ears). Soft tissue depths were explored in parallel, which enabled the estimation of the corpulence of the 500 individuals, based on the literature. Regression formulas were elaborated using craniometrics, age, sex and corpulence, in order to predict subject-specific STD at 59 landmarks (right and left included).

The module AFA3D has been integrated to TIVMI. It requires the 3D coordinates of 78 skull landmarks that can be positioned directly in the module (on a surface reconstructed from CT or laser scanner). The landmarks may also be imported in AFA3D, if previously digitized. The user can specify sex, age (under or over 40 years) and corpulence (normal or overweight) if such factors are known. A geometric morphometric routine superimposes each facial region of the referential on the unknown subject, and computes Principal Component Analyzes on both osseous and cutaneous parts. Principal Component (PC) scores of the skull configurations of the unknown, along with the biological factors, are used to estimate the PC scores of the facial organs. PC scores are thus transformed into 3D coordinates with the PC coefficients to render the shape of the eyes, nose, mouth and ears independently. Once the STD predicted with the formula, AFA3D produces a total of 100 skin landmarks. A neutral synthetic face is then used (for more objectivity), and distorted according to the target landmarks. The distortion (developed in collaboration with the LaBRI, UMR 5800) allows for a smooth warping of the global face, and a more precise deformation at the anatomical landmarks around the facial organs.

Mathematical validation on 17 subjects is proposed, using a leave-one-out resampling. Each individual is thus treated after being excluded from the reference sample. A comparison of the standard error of the estimate induced by traditional facial reconstruction guidelines indicates that the approximation performed by AFA3D enhances the accuracy of the technique. Theoretical reliability is also assessed, if the cranial morphology of the subject falls into the variability of the French population.

AFA3D produces an estimation of the face shape, which is an objective basis for facial approximation. The next step, suggesting identity of the person, may be performed with computer-assisted forensic art. The 3D surface can be exported to other software, refined, and individualized according to the case investigated, before public diffusion. Further tests will have to be performed in order to validate the resemblance and the recognition potential of faces approximated with AFA3D.

Facial Reconstruction, Facial Reproduction, TIVMI

I1 The Cowl Does Not Make the Monk: A Case of Sexual Abuse Committed by a "Bogus Priest" on a Group of Minors

Ignazio Grattagliano, PsyD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY; Isabella Berlingerio, PhD, Department of Criminology University of Bari, Piazza Giulio Cesare, Bari, Bari 70124, ITALY; and Roberto Catanesi, MD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will have a better understanding how psychological damage to the developmental processes in minors is much more severe when the abuser is a significant figure who is emotionally tied to the victim, especially when the abusers are parents. In this particular instance, the abuser was a bogus priest who, in a sense, was a parental figure. The fact that he was not even a genuine priest served to further amplify the victims' feelings of confusion and betrayal.

This presentation will impact the forensic science community by highlighting the concept that sexual abuse committed by a priest, albeit a bogus one in this case, is just as psychologically damaging to a child as sexual abuse perpetrated by a close family member.

Introduction: It seems paradoxical, but the more rational a society becomes, the more its need for spirituality grows. The phenomenon of magical religiosity is not associated with any particular social class, but may be found in all social strata of the population. People often turn in this direction at times when they are unable to face negative life events. Unscrupulous criminals, who take advantage of such weaknesses and problems of others, exploit these characteristics of fragility. The case presented demonstrates this concept.

The Case: The subject is a 53-year-old man who is legally declared as blind, and who has various previous convictions for fraud and sexual abuse on minors. He would convince people that he was a Catholic clergyman and organized masses and personal appearances in which messages from God would supposedly come through him. In addition to overseeing two religious centers where he would gather groups of the "faithful" who believed in his visions, he would also make visits to people's homes in order to pray and perform religious rites, as well as to offer his assistance in order to help them with their various problems.

The case of this "bogus priest" came to attention following new allegations of sexual abuse of five juvenile males; four of them belonging to one family (ages 10, 13, 14, and 17), and the other, their 14-year-old-cousin. The minors belonged to families with a multitude of problems resulting from economic hardship and relational difficulties. They had come to know the "bogus priest" during prayer meetings. When the imposter had learned of the two families' problems, he began to make "pastoral visits" where he would offer to host the boys in his sanctuary homes during school breaks and the summer holidays. He eventually requested that custody of the boys be given over to him. He reported the families' difficulties to social services in a manipulative way. He also stated that the boys had been sexually abused and neglected, but some of the investigations into this alleged abuse had brought his true identity to light.

Judicial investigations revealed that the boys had been the objects of sexual abuse at the "priest's" hands over a period of time. It was found that these episodes had occurred during prayer, at confession, and when receiving spiritual guidance. The victims recounted stories of a well-planned strategy by the abuser. In addition to isolating them from their families and their home environments, the "bogus priest" touched them on their genitals, asked them to perform sexual acts on each other, tried to engage in oral sex with them, masturbated them, showed them pornographic films, and asked them very intimate questions during "phony confessions." The fake clergyman also gave the boys money in order that they not reveal what had happened. Moreover, he threatened them, saying that if they divulged what had transpired; they would be institutionalized and would lose all contact with their families. In order to prevent the parents from speaking to each other, or with social service representatives, he spoke badly to each one about the others, thereby creating isolation and conflict between the families. After being exposed, the "bogus priest" was arrested and found guilty.

Conclusions: The literature, as well as clinical and rehabilitation experience on juvenile victims of sexual abuse, all demonstrate that the psychological damage to developmental processes on minors is much more severe when the abuser is a significant figure who is emotionally tied to the victim, particularly mothers and fathers. For this reason, intrafamilial sexual abuse is particularly serious and harmful to a child. It can be hypothesized that a priest is perceived as a father insomuch as children have fewer instruments to separate the concept of God the father from a concrete figure who represents him. Therefore, it is probable, that abuse by a priest would result in wounds just as deep as those caused by a family member. In this case; however, the damage is double because the perpetrator in question was not even a real priest. For a long period of time he presented himself as genuine to the children. For this reason it is concluded that beyond the psychic damage caused, the associated feelings of confusion and betrayal are amplified.

Intrafamilial Sexual Abuse, Bogus Priest, Psychological Damage

I2 Female Sexual Offenders: Five Italian Case-Studies

Ignazio Grattagliano, MD, University of Bari, Piazza Cagnola, 3/B, Casamassima, 70010, ITALY; Robert J. Morton, MS, Federal Bureau of Investigation, National Center for Analysis of Violent Crimes, Critical Incident Response Group, 2501 Investigation Parkway, Quantico, VA 20135; Jessica N. Owens, MA, Federal Bureau of Investigation, National Center for the Analysis of Violent Crime, 2501 Investigation Parkway, Quantico, VA 22135; Carlo P. Campobasso, MD, PhD, University of Molise, Department of Health Sciences, via De Sanctis, snc, Campobasso, 86100, ITALY; Felice F. Carabellese, MD, University of Bari, Sezione di Criminologia, Policlinico, p.za G. Cesare, 11, Bari, 70124, ITALY; and Roberto Catanesi, MD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will understand how little the subject of sexually abusive mothers is studied and that a more comprehensive exploration of this offender population is needed in order to more appropriately understand and classify female child sex offenders.

This presentation will impact the forensic science community by helping to increase sensitivity and awareness of the phenomenon of female sexual abusers.

Historically, there has been an assumption that women do not commonly perpetrate acts of sexual abuse against children (Wakefiled & Underwager, 1991). Recent interest in women offenders has brought attention to the issue, and challenges the perceptions regarding women who abuse children. The growing interest in the topic of female-perpetrated incidents of sexual victimization has produced some empirical research on the subject. A brief search of the current literature also yields a few published case studies, consisting primarily of reports on personality characteristics and developmental information from female perpetrators.

Although this "provides a necessary starting point in understanding female sexual abuse perpetrators" (Wakefield & Underwager, 1991, p. 56), the findings from this data should be seen as preliminary, and may not describe the full range of women involved in the perpetration of sexual abuse (Grayston & De Luca, 1999).

Women who sexually abuse minors are rare and case histories are scarce; even less is known about sexually abusive mothers. Current data suggests that females are responsible for only a small percentage of sexual offenses against children in the general population, and men remain the most common perpetrators of child sexual abuse. Unlike male offenders, however, females can often disguise sexual offending by performing normal daily activities associated with childcare (i.e., affection, bathing, and dressing). Their behavior may appear to be nothing more than excessively protective mothering. Moreover, mothers may also commit more overt and highly eroticized, seductive behaviors, even going so far as to bestow the role of "lover" upon the child. Due to the low number of cases in which women sexually abuse minors, more in-depth studies on this subject are needed. The clinical files of five women who are currently serving time in Italian prisons for the sexual abuse of minors are presented here. The cases involved varying degrees of participation in the abuse by the mothers, and ranged from active sexual engagement to allowing others to abuse their children. Records of the abuse cases and other records were utilized. In three cases, the women revealed an antisocial personality disorder (ASPD), while in two cases a borderline personality disorder (BPD) was diagnosed according with DSM-IV criteria.

While existing studies of female child sex offenders provided a range of insight and knowledge regarding women who sexually abuse, the current literature does not adequately represent the full spectrum of female-perpetrated child victimization (Grayston & De Luca, 1999). Considerably more well-documented empirical research is required to guide law enforcement and clinical professionals in their understanding of female sex offenders. In recent years, several preliminary typologies of female sex offenders have begun to emerge in an effort to more clearly specify characteristics, dynamics, and offense patterns of female sexual perpetrators. However, the current review has shown that most female sex offenders fall into several suggested typology models. Therefore, the existing typologies used to describe these women are insufficient. It is recommended that more comprehensive exploration of this offender population continue in order to more appropriately understand and classify female child sex offenders.

Female Sexual Offenders, Sexually Abusive Mothers, Cycle of Abuse

I3 Violence and Intimacy-Seeking in a Female Adolescent Stalker

Felice F. Carabellese, MD, University of Bari, Section of Forensic Psychiatry, Policlinico, p.za G. Cesare, 11, Bari, 70124, ITALY; Donatella La Tegola, Section of Criminology and Forensic Psychiatry University of Bari, p.za G. Cesare, 11, Bari, 70124, ITALY; Egle Alfarano, PsyD, Sezione di Criminologia, Università di Bari, Piazza G. Cesare, Bari, 70124, ITALY; and Manuela Tamma, PsyD, and Roberto Catanesi, MD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will recognize characteristics and nature of stalking by juveniles.

This presentation will impact the forensic science community the role of family and psychosocial factors in the etiology of stalking among juveniles.

The case presented here is of an adolescent female stalker who came to attention when Juvenile Court of Justice requested an expert opinion. This case led to reflection on the characteristics and peculiarities of juvenile stalking as compared to the adult phenomenon. As is well known, Mullen (2000) classified adult stalkers as intimacy-seekers, rejected, incompetent, resentful, and predatory stalkers. The only systematic study in a large sample of adolescent stalkers (Purcell et al. 2009) introduced the classification of this stalking as an extension of bullying, retaliating stalkers, rejected stalkers, disorganized and disturbed stalkers, predatory stalkers, and intimacy-seeking stalkers. According to this study there are substantial differences between adult and adolescent stalkers. Firstly, there is a greater prevalence of female stalkers than in the adult population. Again unlike the situation in adult stalkers, in which the "rejected" stalker seeking revenge is the most common, among adolescents stalking as an extension of bullying seems to be the most prevalent, the only motive seeming to be the desire to intimidate and torment the victim. Moreover, whereas among adult stalkers, the greater the prior intimacy between the stalker and his/her victim the greater the risk of violence, among adolescents the category of disorganized and disturbed stalkers seems to show the greatest degree of violence. These youngsters are unhappy, angry adolescents at war with the whole world. Various studies (McCann, 1998; Vaidya et al. 2005; Purcell et al., 2009; Evans & Meloy, 2011) have reported specific features of adolescent stalking, also based on case reports. The victim is most commonly a peer, although Purcell (2009) stated that for adolescent disorganized and disturbed stalkers, the victim is generally an adult. Another important point made in the same study is that among adolescent stalkers, females are statistically significantly more prone to involve accomplices in their intimidatory behavior. In literature, the data were not sufficient to distinguish a single category in which to classify the case observed, which led to further exploration and examination of the correlation between stalking and pathological attachment. In this regard, various authors (Devis et all., 2000; MacKenzie et al., 2008; Kienlen et al., 1997; Langhinrichsen-Rohling et al., 2000; Meloy, 1996) have shown that insecure attachment is highly correlated with persecutory behavior. In fact, often in the infancy of stalkers the reference attachment figure was lost or parental negligence was present for various reasons: death, a jail sentence, drug addiction, or mental disease of a parent, so the child was handed over to other family members or community facilities (Meloy, 1996). In this sense, it can be claimed that, the stalking could be interpreted as an exaggerated form of protest against the loss of the attachment figure. Another possible explanation is seeking approval from the most important attachment figure, to reinforce the subject's lack of self-esteem (Dutton, 1995).

In this case, a 16-year-old girl in the second year of high school came in contact with the new math teacher. From March 2010 until she was taken in custody in February 2011, she perpetrated a series of intimidatory and violent actions against the man and his family (unwelcome phone calls, insults, threats, molesting behavior, lurking, burning the car, damaging property, and slander, to include social networking sites). During this period, despite the intervention of the police and warnings from the headmaster, she continued the persecution which became progressively more violent as the victim was seen to be "indifferent" to her advances. It should be noted that these actions were often carried out in the presence of peers. The stalker was diagnosed with a borderline intelligence and came from a multi-problem family assisted by social services. Her mother was diagnosed with a delusional disorder, her father, an ex drug addict with a criminal record, was out of stable work. Related to the precarious family situation, the young girl had been living together with the two youngest of the five siblings at a community home for minors since the age of 11. The stalking began while she was living in this community.

In this case, in agreement with the literature, accomplices were involved in this case of adolescent harassment but the choice of victim was less common, being an adult. In literature, violent stalking is largely reported in adolescent disorganized and disturbed stalkers. In this case, instead, the young girl's primary motivation was a desire to establish a relationship with the victim (an "intimacy-seeking stalker"). To gain a better understanding of the complex variables involved in juvenile stalking it is important to explore the psychological, family, and social factors that play so important a role at this age.

Juvenile Stalking, Violence, Family and Psychosocial Factors

I4 Predictors of E-Therapy and Face-to-Face Therapy Use for Internet Users: Personality, Attitude, Gender, and Ethnicity

Janise M. Pratt, PhD, Janise M. Pratt, PhD Forensic & Media Psychology, PO Box 9373, Laguna Beach, CA 92652*

After attending this presentation, attendees will be provided information about how personality and dysfunctional thinking relate to an individual's attitude about seeking assistance for psychological distress. Further, the presentation will provide new knowledge about what types of individuals would be more inclined to seek professional assistance online versus those who prefer traditional face-to-face therapy arrangements. The study's findings hold important implications in terms of addressing the problem of underutilization of mental health services among neurotic individuals despite there being an increase in the provision of these services. Exacerbation of symptoms as a result of not receiving professional help can result in suicide attempts and violence directed at others. This presentation will help to inform professionals about how e-therapy services are perceived and the types of clients that may be well suited for e-therapy services.

This presentation will impact the forensic science community by showing how the findings potentially provide prospective research that focuses on the wide-spread problem of underutilization of mental health services by those who need help the most and how personality and attitude variables play a role in this problem. E-therapy is proposed to offer a viable alternative for individuals who find face-to-face therapy arrangements too uncomfortable due to the symptoms of their mental disorder and may provide a way to reduce suicide attempts as well as violence toward others among those who are psychologically distressed.

Hypothesis: This study explored whether attitudes toward seeking professional help in face-to-face therapy (Attitude Toward Seeking Professional Psychological Help; ATSPPH, Face-to-Face Counseling Attitudes Scale; FCAS) and e-therapy formats (Online Counseling Attitudes Scale; OCAS, Pratt Survey Instrument) could be predicted by personality traits (NEO Personality Inventory-Revised; NEO PI-R), dysfunctional attitudes (Dysfunctional Attitude Scale; DAS), gender, and race.

Methods: This study utilized a non-experimental study design to examine attitudes toward seeking professional help in traditional face-to-face format and with various forms of e-therapy. Personality and dysfunctional attitudes were also measured. The design employed self-report measures to assess these areas of interest. The participants for this study were recruited exclusively from an online research panel maintained by United Sample, Inc. drawn from a pool of adult internet users who were recruited using a controlled by invitation only method to comprise a sample that closely parallels the U.S. population proportions on all key profile characteristics ($\underline{n} = 199$).

Results: Data were analyzed utilizing hierarchical multiple regression. Results revealed that gender (male) and the dysfunctional attitude, cognitive imperatives (DAS) were inversely related to recognition of need for professional help (ATSPPH). Analysis of the data also revealed that race (Latino), the dysfunctional attitude, avoidance of appearing weak (DAS) were inversely related, and the personality trait, openness to experience (NEO PI-R) was positively related to interpersonal openness regarding one's problems (ATSPPH). Further, results showed that openness to experience and self-consciousness (NEO PI-R) were positively related to online counseling attitude (OCAS) and extraversion (NEO PI-R) was positively related to face-to-face counseling attitude (FCAS). Standard discriminate analysis revealed that those who prefer some form of e-therapy are likely to be low in extraversion and high in openness to experience and self-consciousness.

Conclusion: This study adds clarification about what personality and dysfunctional attitude variables relate to attitudes toward seeking professional help in e-therapy and face-to-face formats. This study sets forth a direction for future research to parallel the explosion of the online universe in a necessary effort to reach countless individuals in need of professional assistance.

Help-Seeking Attitudes, E-Therapy, Online Psychotherapy

I5 Cybertherapy: Fad or Future of Mental Health Care?

Karen B. Rosenbaum, MD, 49 West 24th Street, Suite 908, New York, NY 10010; and Melina D. Rosenberg, MS*, 172 1st Street, Apartment 3M, Jersey City, NJ 07302*

The goals of this presentation are: (1) to present and discuss the technology of cybertherapy and other technological means of communication that are being used more and more in mental health care; (2) to understand the uses of these technologies and the ethical issues involved in them; and (3) to discuss the responsibility of forensic psychiatrists and other health professionals in providing standards for this technology that seems here to stay.

This presentation will impact the forensic science community by underscoring the ethical issues and the impact of cybertherapy on mental health care today.

Cybertherapy is a technology that has been around for over a decade and is becoming increasingly more mainstream, as evidenced by a new Showtime show called *"Web Therapy."* It is important that clinicians as well as forensic scientists understand this technology because it is being used more commonly around the country and the world. This presentation will discuss the literature on cybertherapy including the treatment outcomes, and the ethical considerations involved with using this remote form of therapy as a treatment for mental health issues. The ethics of cybertherapy have been addressed as early as 1996 in an article in *Ethics and Behavior* called *"Case vignette: Cybertherapy"* where a case is described in which someone across the country from the web therapy doctor threatens suicide and hangs up.[1] Ethical issues also include going beyond one's area of expertise, and issues of confidentiality. The ethical and boundary issues presented by cybertherapy are important concerns and need to be constantly considered as the technology is growing and taking over some parts of the U.S and the world. Therapy over the internet may become more cost effective during economic crisis, and these considerations for some may potentially outweigh ethical issues and treatment considerations.

For over a decade, clinicians have been relying more and more heavily on other means of communication besides traditional face-to-face and telephone contact. These include email, texting, videophone, and the use of cybertherapy. These tools have both benefits as well as possible detriments to the clinician-patient interaction. It is important for clinicians, researchers, and forensic scientists to understand the technology and its impact on the psychiatry and psychology as it is practiced today. An Italian study entitled "New tools in Cybertherapy: the VEPSY web site" discusses this concept and provides a framework for the integration of old and new technology in mental health care.[2] When reviewing the literature, it is clear that there is a lack of standardization and professional leadership in the field of cybertherapy and the use of technology in medicine, particularly in mental health care.

Experiences in the United States and in Italy will be compared. Arguments for and against the technology will be addressed and discussion among the audience will be encouraged. Because the technology is constantly in flux, it is important for forensic psychiatrists and other health care professionals to have knowledge and a voice in the direction that cybertherapy as well as other forms of communication through technology is taking. The ethical issues of using technology in psychotherapy and other mental health treatments will be presented and discussed. Research possibilities and future areas of interest in this field will also be addressed.

Cybertherapy, Technology, Ethics

I6 Update on Forensic Considerations for Gender Non-Conforming Individuals

Stephen B. Billick, MD, 11 East 68th Street, Suite 1B, New York, NY 10065-4955; and Daniel R. Reilly, MD, Forensic Psychiatry Division, New York University, School of Medicine, 462 First Avenue OBV-CD 230, New York, NY 10016*

After attending this presentation, attendees will be familiar with terms and definitions associated with gender non-conforming, transgender, and intersexed individuals. This presentation will also provide understanding of the psychosocial stressors specific to this population by identifying the intersections of this population with the criminal justice system and understanding the unique dilemmas facing gender non-conforming individuals in confinement.

This presentation will impact the forensic science community by raising awareness about a particularly vulnerable, marginalized, and victimized inmate population within the corrections system. By raising awareness in the forensic community, efforts can be mobilized to develop empirically driven studies to better understand the experience of gender non-conforming individuals in confinement, which can then result in thoughtful and humane policy change.

Homosexual and bisexual individuals have moved over the last four decades from marginalization in society into mainstream American society. Same sex marriage is legal in six states and many states have non-discrimination laws. Psychiatry has also changed its assessment of gays and lesbians with the removal of the former diagnosis of homosexuality as being pathological. Many NATO countries permit gays and lesbians to be open members of their armed forces and the United States has taken steps to make this transition too. Gays and lesbians still experience discrimination and victimization in the correctional settings, but even here there is progress. Gender non-conforming individuals; however, have not experienced this progressive acceptance in society and certainly not in the correctional setting.

Gender non-conforming individuals merit special consideration in correctional facilities to preserve human dignity and equal protection under the law. There is very little empirical data on the experience of gender non-conforming individuals in confinement, in large part because correction systems do not collect data on the number of gender non-conforming individuals in their institutions or the experiences of these individuals while in confinement. However, there have been legal cases that have documented the targeted violence perpetrated against this population, as well as gender-related medical discrimination while in confinement. Large, empirically driven studies are needed to better characterize the experience of the confined gender variant individual.

In the community, gender non-conforming individuals are a marginalized population. They face discrimination in housing, employment, education, and have decreased access to healthcare. Because of this pervasive discrimination, these individuals are also disproportionately poor, homeless, criminalized, and imprisoned. Moreover, they are at increased risk for depression, anxiety, and substance abuse. The most up-to-date epidemiological findings regarding the psychosocial stressors of gender-non-conforming individuals will be reviewed. While incarcerated, discrimination and distress related to their gender variance is exacerbated.

Correctional facilities are sex segregated according to a prisoner's birth sex and/or genitalia. As such, gender non-conforming individuals are placed in facilities where their gender identification is not recognized and where they are visible and frequent targets of violence and discrimination by other prisoners and correctional officers. These individuals have unique medical needs to maintain their gender identity, which may include hormone treatment and sex re-assignment surgery. These treatments may not be readily available in the correctional setting, which may result in severe and profound psychological suffering on the part of gender non-conforming individuals. This presentation will review the current case law regarding the gender non-conforming individual's right to protection from violence, as well as their right to medically necessary treatment.

Transgender, Gender, Incarceration

I7 Minimizing Malpractice Exposure in Plastic Cosmetic Surgery

William L. Ericksen, MSci, 850 Park Avenue, Suite 1B, New York, NY 10075; and Stephen B. Billick, MD*, 11 East 68th Street, Suite 1B, New York, NY 10065-4955*

The goals of this presentation are to understand psychiatric issues in cosmetic plastic surgery, recognize patient groups that that tend to be the most satisfied with cosmetic plastic surgery procedures and their motivations to seek surgery. This presentation will also recognize psychiatric conditions that prevent patients from achieving satisfaction with their cosmetic plastic surgery and recognize patient groups that tend to be the most litigious.

This presentation will impact the forensic science community by identifying and understanding the psychiatric issues in plastic surgery which will help surgeons identify patients that are suffering from or are likely to suffer from Body Dysmorphic Disorder/minimal defects, personal crises, multiple revisions, and loss of identity. These patients may be unable to achieve satisfaction with the result of their cosmetic plastic surgery procedures. Limiting exposure to these patients will minimize liabilities a cosmetic plastic surgery practice is exposed to.

The most common reason for litigation in cosmetic plastic surgery is patient dissatisfaction. Therefore, a physician must strive to accept only patients that are capable of being satisfied with a cosmetic plastic surgery procedure in order to limit the liability of a cosmetic plastic surgery practice.

The objective of cosmetic surgery is increased patient self-esteem and confidence. Most patients undergoing a procedure report these results post-operatively. With these goals in mind, the success of any procedure is measured in patient satisfaction. In order to optimize patient satisfaction, psychiatric literature suggests careful pre-operative patient preparation including a discussion of the risks, benefits, limitations, and expected results for each procedure undertaken. As a general rule, the patients that are motivated to surgery by a desire to align their outward appearance to their body-image tend to be the most satisfied. Patients that are not motivated by self-improvement tend to be less satisfied.

There are some psychiatric conditions that can prevent a patient from being satisfied without regard to aesthetic success. The most common examples found in psychiatric literature are Body Dysmorphic Disorder minimal defect, the patient in crisis, the multiple revision patient, and loss of identity. Patients that fall into these categories also cannot make fully reasoned decisions regarding cosmetic plastic surgery. This presentation will familiarize the audience with these conditions, symptoms, and related illnesses. Case examples from clinical practice are described and then explored in terms of the conditions presented. A discussion of the patient's motivation for surgery, goals pertaining to specific attributes, as well as an evaluation of the patient's understanding of the risks, benefits, and limitations of the procedure can help the physician determine if a patient is

capable of being satisfied with a cosmetic plastic surgery procedure. If each potential patient is screened, then the practice limits its exposure to a class of patients that tend to be the most litigious.

Plastic surgeons can screen patients suffering from these conditions relatively easily, as psychiatry is an integral part of medical school education. If a psychiatric referral is required, then the psychiatrist needs to be aware of the nuances of each of these conditions.

Plastic Surgery, Psychiatry, Malpractice

I8 Psychiatric Evaluations in Immigration Cases in the United States

Vivian Shnaidman, MD, Jersey Forensic Consulting LLC, 812 State Road, Suite 220, Princeton, NJ 08540*

After attending this presentation, attendees will be familiar with the types of immigration cases in which psychiatric opinion and testimony is utilized, and will learn how to apply their knowledge of psychiatry and forensic psychiatry in this growing niche field.

This presentation will impact the forensic science community by addressing one of the big issues in the United States and across the world today — immigration. This year's meeting theme, *Global Research: The Forensic Sciences Edge*, illustrates how small the world has become. The desire of individuals to move from one country to another for a variety of reasons makes this area of psychiatric expertise very current and important, and psychiatrists and other mental health practitioners should be aware of their potential roles in assisting with this process in a responsible and ethical manner.

In this presentation, the legal basis for utilizing psychiatric expert testimony in the immigration courts will be presented. The various legal applications will be discussed, in addition to relevant case law. The topics of removal and cancellation of removal, as well as the concept of asylum will be detailed in both legal language and plain English. The various situations that can lead to removal will be identified, described, and differentiated. The fact that the laws are actually written to protect American citizens or permanent residents, and not the alien subject to removal will be explained. Certain recent cases that have been in the news will be shared with the participants in order to illustrate the importance of this work.

Specific topics will include:

- General classes of aliens ineligible to receive visas and ineligible for admission; Waivers of inadmissibility and exceptions
- Cancellation of removal – adjustment of status
- The concept of extreme and unusual hardship/exceptional and extremely unusual hardship
- Special rules for battered spouses or children
- Other examples of automatic or potential asylum

The presentation will then focus on how to formulate the psychiatric-legal question, as the statutes are non-specific in this regard. Understanding an immigration evaluation as a risk assessment is critical and is the crux of why these evaluations are best performed by psychiatrists/psychologists with forensic training.

Specific topics will include:

- Who is eligible for evaluation/petition?
- How to work with an attorney in an immigration case
- How do you write your report?
- What sources of information should be used?
- How to get this type of work!

Finally, specific cases will be presented and attendees will engage in a see-one-do-one discussion of how to approach these cases within the framework of the statutes. Cases will be presented illustrating a variety of possibilities, including risk assessment based on existing psychiatric disorder (the easiest type), asylum (more difficult because of documentation), and possible future psychiatric or medical issues (most difficult especially when postulating future psychiatric problems). Hopefully, a spirited discussion will ensue and international participants will bring forward parallels from their own countries.

Immigration, Deportation, Removal

I9 Mental Illness and Legal Fitness (Competence) to Stand Trial in New York State

Eugene Lee, MD, 130 East 77th Street, 3rd Floor, New York, NY 10075; Richard Rosner, MD, 140 East 83rd Street, Suite 6A, New York, NY 10028; and Ronnie B. Harmon, PhD, 340 West 28th Street, Apartment 9D, New YorkN, NY 10001*

After attending this presentation, attendees will be able to describe recent scientific data on the association between mental illness and fitness to stand trial. Specifically, attendees will be able to describe a statistically significant association between findings of mental illness and forensic opinions on fitness to stand trial. In addition, attendees will be able to describe further, in-depth analysis of the "Not Fit" cases, including the statistical analysis of the significance or lack of significance of the BPRS scales. This analysis includes both individual symptom constructs and also the clusters of symptom scales as informed by the literature.

This presentation will impact the forensic science community by emphasizing research methodology and statistical analysis in achieving its educational objectives.

The proposed presentation is a report on the outcome of a research study conducted under the auspices of the New York University (NYU) School of Medicine Forensic Psychiatry Training Program. It was approved by the Institutional Review Boards of both NYU (R#11-00503) and the New York City Health and Hospitals Corporation (Bellevue Hospital #030711-Bel-S0069). The study was a case-controlled review of charts at the Forensic Psychiatry Clinic of Bellevue Hospital, a large, urban general and specialty care public hospital in New York City. This clinic provides evaluations of Fitness to Stand Trial for criminal defendants referred under New York State Criminal Procedure Law 730.

"Fitness" to stand trial is an important issue in the adjudication of criminal defendants with known or suspected mental illness. When adjudicating a criminal defendant, the assessment of the defendant's fitness to stand trial can be a crucial decision point in legal disposition. Most defendants are presumed to be fit (competent) to stand trial. When a defendant's competence is called into question, lawyers and judges consult psychiatrists and psychologists for forensic opinions on the defendant's capacity to stand trial. "Competence" to stand trial is the legal term for fitness, as designated by a judge. "Capacity" is a finding of competence as opined by the forensic clinician.

In 1960, *Dusky v. U.S.* (362 U.S. 402), a landmark case, established what is usually taken to be the minimal constitutional standard for adjudicative fitness in the United States. In this case, the U.S. Supreme Court stated that the test for competence to stand trial was "whether [Dusky had] sufficient present ability to consult with his lawyer with a reasonable degree of rational understanding—and whether he [had] a rational as well as factual understanding of the proceedings against him."[1] Psychiatrists and psychologists generally rely on *Dusky* as the standard when evaluating defendants' fitness to stand trial. New York State's Criminal Penal Code defines Incapacitated Persons as those defendants who, as a result of mental disease or defect, lack either the capacity to understand the proceedings against them, or lack the capacity to assist in their own defense.[2] Incapacitated persons are then court-ordered for interventions to restore fitness.[3]

Many clinical instruments have demonstrated validity and reliability in quantifying the degree of functional incapacity resulting from mental disorders. The Brief Psychiatric Rating Scale (BPRS) is an instrument developed to quantify psychiatric symptomatology.[4] The BPRS is a very

widely used and relatively brief scale that measures major psychotic and non-psychotic symptoms in individuals with major psychiatric disorders, particularly schizophrenia. The BPRS rating is based upon observations made by clinicians during clinical evaluations, and is generally accepted as appropriate for evaluating baseline psychopathology in outpatient as well as inpatient populations.[5] Numerous studies utilize the BPRS as a highly efficient and rapid evaluation procedure to yield a rather comprehensive description of major psychiatric symptom characteristics.[6,7] Sixteen symptom constructs were originally listed for rating on a seven-point scale, which document the intensity of symptoms in relatively independent areas. The sixteen original items were: conceptual disorganization; unusual thought content; anxiety; guilt feelings; grandiosity; depressed mood; hostility; somatic concern; hallucinatory behavior; suspiciousness; blunted affect; tension; emotional withdrawal; mannerisms and posturing; motor retardation; and, uncooperativeness. Subsequent additions to the scale were two additional items of excitement and disorientation. The 18-item BPRS is perhaps the most researched instrument in psychiatry.[5] A more recent publication highlighted the need for replicating BPRS factor analysis in forensic samples.[8]

The study's research methodology and resulting data structures have important implications for the reliability and validity of its interpretations. Inter-rater reliability, test-retest reliability and inter-method reliability, all apply to both the scales of the BPRS and the findings of Fitness/Unfit. In addition, the BPRS is being explored as possibly to become an initial screening tool, to aid New York lawyers and judges in deciding which criminal defendants to refer to the clinic for Fitness assessments. Thus, the degree of validity of the BPRS as a screening tool for Fitness will be discussed.

The study's limitations will also be discussed, including the reliability of the clinic's slightly-modified version of the BPRS. Separately, the evaluators' training in using the BPRS instrument will be discussed as well.

Forensic Psychiatry, Mental Illness, Fitness (Competence) to Stand Trial

I10 One Academy, Eleven Sections, How Many Ethics Codes?

John L. Young, MD, Yale University, 203 Maple Street, New Haven, CT 06511-4048*

After attending this presentation, attendees will grasp the major complexities involved in the creation, evaluation, and application of ethics rules for their forensic disciplines.

This presentation will impact the forensic science community by deepening awareness of critical ethics issues shared across disciplines and enabling informed responsible dialog that will result in progress towards the goals of the 2009 National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward*.

The 2009 call from the National Academy of Sciences (NAS) for the establishment of a regulatory body to be known as the National Institute of Forensic Science has been stirring up a vigorous conversation across AAFS membership. Upon taking office in 2010, President Bono required an *Academy News* newsletter column from each section providing an account of its responses to the NAS document. This was carried out over the succeeding year and the subsequent annual scientific meeting program included a variety of sessions devoted to aspects of quality improvement in forensic work. Building on that foundation, this presentation addresses critical issues that inevitably require further discussion in order to achieve success in our efforts to codify quality concerns into ethics guidelines.

Those who would attempt to develop any set of professional ethics codes immediately face two obstacles. First, the past generation has experienced an explosion of access to information, with no corresponding means for judging its quality and thereby its potential ethical weight. Second, professions have not appeared eager to embrace ethics codes, economists being an interesting example.

In addition, the sheer volume of material involved is formidable. Hundreds of ethics codes are already in existence, readily available on the internet along with detailed instructions for composing more of them, including potential examples. Although it runs to 4 ½ pages, one model code presented at the Chicago AAFS meeting is by design incomplete.

Certification issues are crucial. Some have boldly proposed that certification be required in order to testify in court. There are forensic disciplines with their own recognized certification systems unrelated to AAFS. For psychologists certification is highly demanding, and earning a license is normally considered a sufficient practice qualification. Also certifying boards are costly to establish and operate.

In order to be effective an ethics code must address the issue of enforcement provisions, with due process including qualifications for its administrators. The experience of AAFS indicates that lawsuits are to be expected. Enforcement help from civil law seems meager at best. Once censured, there may be no legal bar to keep an expert from continuing to testify.

Any set of ethics rules, codes, or guidelines must be a living document, a practical representation of professionals' daily experience. By their nature such guidelines reflect a current and substantial consensus, a willingness to support a general expectation of adherence. Over time such agreement can be expected to evolve, requiring a mechanism for revision. It is highly useful to provide a means for practitioners to submit queries or consultation requests to their organizations' ethics leadership. This encourages membership's striving to practice ethically and provides leadership an opportunity to anticipate emerging issues.

The existing ethics provisions of AAFS (Bylaws, Article II, appended to the annual *Directory of Members and Affiliates*) already provide a solid foundation for responding to the challenge from NAS. Whatever the legislative outcome of its proposa,l it is clear that the public is expecting more from forensic science professionals. We need to work together to respond to these expectations where they are valid and correct them where they are not.

Ethics, Regulation, Quality

I11 Beyond Medea: A Sacrificing Father

Ignazio Grattagliano, PhD, Departmnet of Criminology, University of Bari, Piazza Cagnola, 3/B, Casamassima, 70010, ITALY; Domenico Suma, MD, Department of Mental Health Brindisi, Via dei Cappuccini 20, Ceglie Messapica, Brindisi , ITALY; Valentina Stallone, PhD, University of Bari Department of Psychiatry, Piazza Giulio Cesare, Bari, 70100, ITALY; Andrea Lisi, PsyD, Sezione di Criminologia, Università di Bari, Piazza G. Cesare, Bari, 70100, ITALY; and Antonello Bellomo, MD, University of Foggia Department of Psychiatry, Via Latilla 16, Bari, 70100, ITALY*

After attending this presentation, attendees will more fully comprehend the psychodynamics involved in a case of filicide perpetrated by a father on his two-year-old son – "reverse" Medea Complex as it were.

This presentation will impact the forensic science community by demonstrating the risks that seriously dysfunctional couples pose to the well-being of their children.

Either a father or mother may commit filicide. According to the data in the literature, mothers most often carry out neonaticides and infanticides. Fathers, on the other hand, more often kill their children when the children are older. In one study of 3,459 cases of filicide, based on data obtained from the FBI, 95% of mothers who committed these crimes did so during the first week of the newborn's life, whereas fathers who kill their children do so when they are between the ages of 13 and 14-years-old, and even more so when they are between the ages of 16- and 18-years-old (Kunz e Bahr, 1996).

Filicide is a crime that may be perpetrated by either parent, or both for that matter, on their child who is between the ages of 0 and 18 years. Although it is not often described in the literature, there are data that show that there appears to be a "Male version of the Medea Complex" in which the fathers take the lives of their own children as a retaliatory measure against the mother. Frequently, the father uses a sharp weapon, a firearm, or strangulation with his bare hands. Some of the elements that might fuel such behavior may include a sense of revenge or omnipotence; a highly attached and/or ill-defined relationship with his child; the inability to respect him or her as a person; or simply thinking about him or her as a "weapon" against his partner. At times, such acts are followed by suicide, indicating the following: the importance placed on the ties to the victim; their symbiotic relationship; the inability to see the child as an individual, but rather as an extension of his own persona, projecting his own experiences and emotions. In the eyes of the perpetrator, murdering one's own child can represent an act of love toward one's offspring in an attempt to eliminate all current and future suffering caused by difficulties between the parents.

This case concerns a child who died at the hands of his 26-year-old father who, in turn, unsuccessfully attempted suicide. The autopsy ascribed the child's death to asphyxiation and hemorrhage. The child had been hanged from a door by a cord that was tied around his neck. Cuts to the musculature of the left side of the neck and left jugular vein, from top to bottom, were identified. Because cardiovascular activity was still present in the child, his father placed him on a bed and cut the victim's left wrist from left to right. Following this, in an attempt to end his own life, the perpetrator proceeded to cut his own wrists, tried to set himself on fire, and swallowed caustic substances. Court ordered forensic psychiatric evaluations were subsequently requested. No significant evidence emerged which indicated the presence of psychopathology or mental illness at the time of the crime. Blood and urine analysis showed no traces of narcotics or prescription drugs such as barbiturates or benzodiazepine. The perpetrator was found to be completely culpable. Investigations revealed that the crime might have been an act of revenge against his partner, a 21-year-old woman, as a way to punish her for the problems regarding their relationship. Their son was the product of an unexpected pregnancy that occurred after the couple had been together for only one month. As a result, the young couple did not have the chance to get to know each other very well before beginning a life together. Due to his immaturity, he was unable to accept his partner and his son. In addition, there were strong feelings of jealousy. All of these factors led the couple into a state of crisis.

This story concerns a relationship rife with distortions, misunderstandings, and resentment; a dominant woman with a highly individualistic nature, along with the perpetrator's sexual dysfunction (premature ejaculation and sporadic erectile dysfunction), which was often pointed out by the woman to friends, relatives, and to her ex-boyfriend. Adding to his misery, she had encouraged him to go out with other women. She was not attracted to him and wanted to leave the relationship. An ill-defined relationship with the child, who the father saw more as "son" than "person," and a relationship with a partner who was resentful of him led the perpetrator to feeling "frustrated" about seeing his "family plans" fall to pieces. He was humiliated, misunderstood by his partner, and felt inadequate in his role as companion. When the man perceived his wife's intentions to psychologically divorce him, he threatened to kill himself. He planned his suicide (a suicide note was found, which included his motives, confirmed this), he declared his intentions, and made the attempt to do so, after having killed his own child.

Filicide, Medea Complex, Murder Suicide

I12 The "Beasts of Satan" Murders

Felice F. Carabellese, MD, University of Bari, Section of Forensic Psychiatry, Policlinico, p.za G. Cesare, 11, Bari, 70124, ITALY; Jutta Birkhoff, MD, PhD, Department of Public Health, University of Insubria, Via O. Rossi, Varese, 21100, ITALY; Michele Bruno, MD, Department of Mental Health Care, P.zza Di Summa, Brindisi, 72100, ITALY; Chiara Candelli, MD, PhD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY; and Stefania Zeroli, MD, University of Insubria, Via O. Rossi, Varese, 21100, ITALY*

After attending this presentation, attendees will recognize some features of group murder and understand principles of forensic psychiatric assessment of members of satanic sects.

The presentation will impact the forensic science community by exploring the role of satanic sects in the etiology of this type of crime.

In January 2004, the body of a young woman was found in the garden of a small house in the woods in the province of Varese (a rich city in northern Italy, about 50 km from Milan). Forensic investigations showed that the woman had been shot in the face, buried alive, and finally killed by repeated beating on the head with a spade.

A few months later, not far from where the woman's body had been found, the remains of two young men were discovered. They had been killed on the January 17, 1998 ("a night of the black moon"), by repeated beating with rods, causing many bone fractures, as well as by knife wounds distributed all over their bodies.

These discoveries hit the national headlines and brought to light the actions of a sect calling themselves the "Beasts of Satan." Although the investigations of the members of this group proceeded smoothly and those responsible for the homicides were easily identified, the news about "satanic" activities occurring in a quiet, hard-working area in the province of Varese was a great shock and provoked turmoil in local society. In the following years, any violent event affecting a young person was inevitably attributed in the public mind to the activities of this sect. In actuality, the activities were much less "occult" than was commonly imagined, as demonstrated by the investigations that easily identified the criminals as nine young factory workers with no criminal record.

The shocking violence of the murders led the judge to request a forensic psychiatric assessment of one of the members (the only one with history of mental disease), but widening the investigations to study the group dynamics and lifestyle of all the members. The assessment revealed that all the young men had a fragile, immature personality, a very low level of education, and were socially disadvantaged. They had built up a crude practice they called "satanism" that was for them an exciting escape from

their humdrum reality, and a uniting element. They carried out improbable rites with a liberal use of satanic words and rites they knew nothing about. Each had a rigidly defined role in the sect, that had a hierarchical structure but no recognized leader.

The historical-cultural phenomenon of satanism, as also of spiritism and other esoteric beliefs, has nothing to do with the sub-cultural climate of violence and terror created by this group. The members of the "Beasts of Satan" were clumsily trying to mask the cultural poverty of their lives by carrying out cruel, violent actions, and identifying with a name that strikes superstitious terror ("Beasts of Satan"). The violence was aimed particularly at members who tried to renege on the group.

Although judges generally request a forensic psychiatric opinion in particularly shocking cases of murder for no apparent reason (except for mafia crimes), on the suspicion of a relationship between insanity and murder, in this case the experts did not find any trace of such a relation. The trial of the members of the "Beasts of Satan" sect was concluded with the verdict of deliberate murder by all the members, who were all given long jail sentences.

A striking point in this tale was the suicide of one of the members, before other members of the group were identified, who drove into a stone wall. The dynamics and possible responsibilities for this death remained obscure.

Satanic Sects, Psychiatric-Forensic Assessment, Group Violence

I13 Utility of a Grief Services Program for Medical Examiners' Offices

Ryan S. Berry, BS, 1516 Princeton Drive NE, Albuquerque, NM 87106; Michelle B. Aurelius, MD, Office of the Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131; Nancy Barickman, MSW, 2600 Marble Avenue Northeast, Albuquerque, NM 87131; and Sarah Lathrop, DVM, PhD, Office of the Medical Investigator, MSC 07 4040, 1 University of New Mexico, Albuquerque, NM 87131*

After attending this presentation, attendees will understand the range of services provided by a grief services program at a centralized, statewide medical examiner's office, the frequency of utilization of these services by bereaved individuals, and a framework for the implementation or improvement of a grief services program at a medical examiner or coroner's office.

This presentation will impact the forensic science community by presenting the first study, to the best of our knowledge, which explores the utilization of a grief services program at a centralized, statewide medical examiner/coroner's office, and will initiate discussion of future work in this area of forensic science.

Medical Examiner/Coroner's (ME/C) offices investigate deaths that are often sudden, violent, and unexpected, leaving family members and those close to the deceased suffering a traumatic loss with little in terms of support and counseling. Since its inception in 1976, the Grief Services Program (GSP) at the New Mexico Office of the Medical Investigator (OMI), the statewide medical examiner's office, has assisted families and communities across New Mexico with education, crisis intervention, counseling, and psychotherapy, regardless of the cause or manner of death. The utility of a grief services program at statewide medical examiner's office was investigated in order to better understand the needs of bereaved individuals, demonstrate the scope of services provided, and propose the findings as a model for other medical examiner/coroners offices. The OMI investigated 5,120 deaths in 2009, during which 1,085 grief services contacts were recorded. The majority of these visits occurred on-site at OMI (60.5%) by individuals residing in the same county (Bernalillo County, home to 1/3 of the state's residents) as OMI (62%). Telephone sessions (23.1%) and off-site visits (15.7%) were the next most prevalent type of contact. The number of individuals present at each session held at OMI ranged from 1 to 22 (mean 1.6) and the range of attendees for sessions held off-site was 1 to 130 (mean 2.5). Off-site sessions included memorial services, group sessions, and school presentations. The highest frequency of visits involved one-on-one sessions (78.6%) followed by sessions with two clients (9.1%). People seeking the services of the GSP for the first time consisted of 28.4% of the contacts, with the remaining 71.6% returning to the GSP for follow-up appointments. Ninety-one percent of the people who sought services offered by the GSP were immediate family, followed by extended family (5%), friends (1.9%), and community group (0.8%). Support was primarily provided to those suffering a loss due to homicide (28.8%), followed closely by suicide (26.1%), natural causes (20.0%), and accident (13.9%). It is believed, this is the first report looking at the utilization of a grief services program at a ME/C office. The service most frequently used by clients of the GSP was counseling related to the loss of a family member or loved one. However, grief counselors provided many additional types of assistance to grieving families, including discussions of autopsy results in conjunction with a staff pathologist, sharing information with family members, escorting families for viewings, showing family members photos of the decedent or scene, and assisting families who plan to transport the decedent. In this era of reduced resources GSPs may not be a priority for ME/C offices. Given the large number of people utilizing OMI's GSP; however, and the diverse reasons for their visits, it is apparent there is a need for GSPs at ME/C offices, particularly given the traumatic nature of deaths investigated by ME/Cs. The goal is that this work will prompt discussion and future work in this important yet seldom published area of forensic science.

Grief Counseling, Bereavement, Medical Examiner

I14 Violent Fantasies in Psychotherapy: Risks of Precipitating Violent Behavior

Andrew H. Kim, MD, JD, University of Southern California Institute of Psychiatry and Law, PO Box 86125, Los Angeles, CA 90086-0125*

After attending this presentation, attendees will become familiar with the theory and practice of psychotherapy techniques that focus on violent fantasies. Readers will also gain an understanding of the net risks involved in the use of violent fantasies in psychotherapy and important measures for the psychotherapist to undertake before, while and after a patient offers a spontaneous or a prompted report of violent fantasies. This presentation will also consider the tradeoffs involved in such measures, including compromises in confidentiality, chilling effects on psychotherapy, and disruptions to the therapeutic alliance.

This presentation will impact the forensic science community by focusing on both violence risks associated with fantasy in psychotherapy as well as affirmative approaches to address such risk. This presentation offers important recommendations to forensic practitioners, psychotherapy providers, and the community in general.

In the context of psychotherapy, the exploration of violent or aggressive fantasies often serves the important function of providing insight into sources of attachment trauma, which in turn facilitates eventual mastery over said trauma and resolution of certain maladaptive defenses and psychological symptoms. Indeed, in some methods of psychotherapy, murderous fantasies are specifically elicited by the psychotherapist, who then assists the patient to experience and elaborate on the feelings of rage as well as relief upon imagining the acting out of those violent fantasies.

The question thus arises as to whether the use of fantasy in therapy affects the risk that the patient will act out on the violent thoughts in reality. More specifically, to what extent must therapists take into account the actual risk of violent behavior in patients who are deliberately asked to develop and articulate their violent fantasies and then encouraged to experience the catharsis of enacting their aggressive urges?

This presentation reviews the current research on the violence risk associated with patient reports of violent fantasies. Though violent fantasies are common and in fact normal in healthy populations, in certain groups, they constitute a risk factor for violent behaviors. In particular, risks may increase in persons with deficits in domains such as judgment,

impulse control, or reality testing, including those with borderline personality or substance use disorders and those with criminal backgrounds. The content of the reported fantasy may also be correlated to the risk of violent behavior; fantasies of rape, beating, or torture may indicate increased risk compared to fantasies of mere murder. Additionally, concern for violent acts increases when therapy patients exhibit preoccupation with or sexual excitement from violent fantasies. Taking these risks into account, the articulation of specific violent fantasies by certain patients against identified individuals may in select circumstances constitute a threat that invokes duties to warn and/or protect under Tarasoff laws.

Accordingly, psychiatrists should be aware of their duties and implement safeguards to protect their patients and the community, to ameliorate risks of both violent behavior and of liability exposure. Appropriate safeguards include proper screening and violence risk assessment to determine if specific patients can appropriately handle the experience of fantasy exploration in therapy; containment of patients who demonstrate or develop a breakdown in ability to control urges to act on violent fantasies; and reporting of patients to law enforcement agencies where identified individuals may be at risk of harm from the patient.

Violence Risk Assessment, Tarasoff, Psychotherapy

I15 Impulsive Aggression: Nature and Pharmacotherapy

Alan R. Felthous, MD, Saint Louis University School of Medicine, Forensic Psychiatry Division, 1438 South Grand, St. Louis, MO 63104-1027; and Pooja Sharma, MD*, 859 Lords Hill, St. Louis, MO 63119*

After attending this presentation, attendees will be able to define impulsive aggression, diagnose impulsive aggression, and make evidence-based decisions in prescribing medication to control impulsive aggression.

This presentation will impact the forensic science community by showing how the ability to define, diagnose, and apply the medication algorithm will assist attendees in gaining improved knowledge and competence in effectively treating impulsive aggression in both forensic and civil patient populations.

Impulsive aggression is defined as, "a "hair-triggered" response to a stimulus which results in a sudden agitated state that lasts a few minutes to several hours (Dodge, 1991), the agitation builds to a crescendo and culminates in an aggressive act. During this state interpersonal communication appears inefficient and recall of events may be poor…Impulsive aggression [IA]…is spontaneous, unplanned, and lacking in self control. Outbursts are explosive and driven more by impulse or erupting affect than by acquisitive or self-promoting goals" (Felthous and Barratt, 2003).

A variety of psychotropic agents representing selective serotonin reuptake inhibitors (SSRIs), anticonvulsants, mood stabilizers, beta blockers, psychostimulants, and antipsychotics have been prescribed for intermittent explosive disorder and IA, either in "pure form" or co-occurring with other psychopathology. The efficacy of anti-impulsive aggression agents is directly related to accurate diagnosis of IA and mental disorder of which impulsive aggression can be secondary (e.g., bipolar disorder, manic). Scientific literature is not consistent in defining and diagnosing IA; therefore, this presentation begins with a description of the nature of IA and an evidence-based explanation for its diagnosis.

Although algorithms for the pharmacotherapy of clinical aggression (e.g., Moeller and Swann, 2007) have been proposed, a medical standard of care for the pharmacotherapy of IA has not gained general acceptance. Based upon a review of the literature, the presenters offer an evidence-based algorithm for treating IA with medication. This algorithm requires accurate diagnosis of IA and co-occurring mental disorder as well as assessment of the severity of IA in terms of intensity and frequency of episodes. Not to be overlooked is a careful history of prior psychotropic medications and their effect on aggressive episodes. Substance abuse and sedative/stimulant seeking behavior can complicate the assessment and treatment of IA.

The suggested sequence in which the medications could be used to treat IA takes into account their efficacy, side effect profile, the ease of administration and the recommended monitoring. With all these in mind, an SSRI such as fluoxetine, sertraline, paroxetine, citalopram, or escitalopram is a reasonable first line medication, particularly if the IA is not severe. There is enough evidence based literature to support their efficacy in these scenarios. They have minimal side effects and are generally well tolerated. If the IA is severe or the SSRI is ineffective, a mood stabilizing anticonvulsant is a prudent selection. Most of the anticonvulsants used in clinical practice have shown to be efficacious, with extensive studies done with carbamazepine, valproic acid, oxcarbazepine, and phenytoin. The drawbacks of anticonvulsants are their side effects and the need for regular blood testing. It is also important to consider the possibility of drug-drug interactions with other medications that the person might be on, before starting them. Another class of drugs which helps control IA are the antipsychotics. Drugs like quetiapine, aripiprazole, olanzapine, and risperidone are used with good clinical effect. They are used for severe IA which is either not controlled by the above two classes of drugs or where side effects have limited their use. It is important to keep the black box warning of sudden cardiac death in mind, which limits their use to particular patient population with IA where the benefits outweigh the risks. Other medications to be discussed will include beta blockers and psychostimulants.

When the IA is secondary to another disorder, in many cases the aggressive behavior subsides with appropriate pharmacotherapy of the primary disorder. This review and algorithm also includes evidence in support of pharmacotherapy of the IA itself, when treatment of the primary disorder fails to control aggression.

Critical to the success of the algorithm and effective pharmacotherapy of the IA in general, is careful monitoring of the IA episodes in the course of the treatment. There will be a discussion about having the patient maintain a diary and also monitoring for these episodes during follow up appointments, by using the Overt Aggression Scale by Yudofski or the Modified Overt Aggression Scale.

Impulsive Aggression, Intermittent Explosive Disorder, Pharmacotherapy of Aggression

I16 Clinical and Forensic Evaluation of Accountability in Homicide Cases: A Study on the Penal Court of Rome in Italy

Laura Volpini, PhD, University of Rome "Sapienza", Via dei marsi 78, Rome, 00185, ITALY; Mario Biagiarelli, MS, La Sapienza University of Rome, Via dei Marsi, 78 00185, Rome, 00185, ITALY; and Melina D. Rosenberg, MA*, 172 1st Street, Apartment 3M, Jersey City, NJ 07302*

After attending this presentation, attendees will improve the relationship between mental illness, crime, and the evaluation of accountability.

This presentation will impact the forensic science community by the evidence based model that is suggested in the forensic psychology and psychiatric area.

Introduction: Italian legislation on evaluation of accountability is introduced and the results of the explorative analysis are discussed. By exploring the interest in analyzing the way in which experts evaluate accountability for trial purposes in based on a growing need for evidence-based and scientific expert evaluation, this presentation will reflect about the relevance of evaluation of accountability for the scientific evidence in the court.

Data Analyzed: An in-depth content analysis was conducted on seven expert testimonies that evaluated accountability.

Seven reports were considered, regarding cases of voluntary murder (articles 575-577 of the Italian Criminal Law) tried in the Law Court of Rome (Italy) between 2002 and 2008. Each report is approximately thirty pages long and reflects the evaluation of a single expert witness. In two cases, the expert witness is assisted by a colleague exclusively for the purpose of test assessment.

Methodology: The content analysis of the expert testimonies follows the theoretical and applied principles of "Content Analysis" (Losito, 2001; Amaturo, 2005).

The unit of context is defined by the sentence; the unit of analysis is formed by a phrase. A series of categories were created for the purpose of content analysis, in order to classify useful areas of interest for clinical-forensic analysis.

The following results emerged from the explorative study:

1. The theoretical model that guides data acquisition and analysis is never explicit.
2. Evaluation criteria of accountability are never explicit; the only explicit literature reference is the DSM IV-TR.
3. Interviews and psychological tests are used as diagnostic instruments; however, they are not to used to explorer the meaning of crime in this study.
4. The areas of diagnosis most frequently explored are clinical symptoms (Axis I of DSM-IV-TR) personality (both according to the criteria of Axis II of DSM-IV-TR e independently of the manual).
5. In general, the areas diagnosed are not explored in reference to the fact or crime and/or to the relationship between author and victim; greater attention to these factors tends to arise in the final phases of the expert testimony.
6. The answers provided for the inquiries submitted are based on the evaluation of the symptoms and of the type and level of personality function, rather than on the assessment of the relation between possible personality disorders and the mental state of the defendant at the moment of committing the crime.

Conclusion and Future Perspectives: Although the sample is obviously quite limited, given the results that emerged from the study, more research is clearly needed in order to develop an integrated model of evaluation of accountability. Such a model would allow consideration and analysis of the action at the same time (Harre' 1990; De Leo & coll. 1991, 1999, 2001, 2004) and the possible pathological functions of the subject that were active during the crime.

In this way, the expertise witnesses would be able to better respond to the juridical needs of evidence-based criteria between the crime and the mental state of the defendant during the crime.

Homicide, Accountability, Diagnosis

I17 Case Study: Paraphilias Carried to the Limit — Child and Dog Victims of a Subject With Schizoid Personality Traits

Luis Alfonso Forero Parra, MS, Attorney General's Office - C.T.I, Dg. 22B No.52-01, Fiscalia General de la Nacion, CTI, Bogota, Distrito Capital, COLOMBIA*

After attending this presentation, attendees will understand how an individual's paraphilic fantasy allowed a lonely 53-year-old man to use his own dog to sexually abuse an 11-year-old boy. In this case, the prosecutor along with the criminal profiling unit, through a behavioral analysis, explained the case to a judge, who finally condemned the man.

This presentation will impact the forensic science community by showing how the investigation of this case led physical evidence and behavioral evidence to the understanding of a man with schizoid personality traits with paraphilic fantasies, who conditioned his dog to respond to sexual erotic maneuvers and who later used his dog to sodomize a child. This unique case is the only one of its kind ever documented, which seems more to be part of the plot of a psychological police thriller than a real criminal case.

The criminal profiling unit was called to assist in the investigation of an extremely complex case. Initial reports came from the preliminary account of an 11-year-old boy, who claimed he had fallen in the forest and had been accidentally injured in the anal area. However, the emergency services found injuries consistent with a possible sexual offense. After analyzing the samples, sperm was found that had a morphology that was not human and was possibly canine. Later, with the support of the profiler, the child was interviewed using the protocol RATAC. In the interview, the child reported that while playing in the woods, a man had approached him and called a dog who penetrated the child's anus with his penis. The offender then fled the area. The case was not "a dog who had raped a child" anymore. With this information, research activities were initiated and corroboration of information and it was during this profiling unit conducted a behavioral analysis of the facts, which yielded a report giving an account of the behavior one would expect the aggressor and as some investigative strategies. Finally, the man was identified, arrested, and the dog found.

Subsequently, the man's psychological tests established the presence of schizoid traits. Meanwhile, the dog was tested and showed a conditioned sexual response to certain kinds of touching. The behavior and concern of the owner toward the dog during these tests suggested a link between pet and master that went beyond the normal link between dog and master. These aspects together suggested that the dog had been used as an object of sexual activity, which in turn become the means of satisfaction of his master, who then wanted to extend it to others.

The case, despite its difficulty, was brought to trial. The profiler attended court as an expert adviser to the prosecution. At the trial the main work was aimed at establishing the conditioning to which the dog had been subjected, that the defendant had used the dog as an implement to violate the child, and therefore the child had told the truth.

The case was decided in favor of the prosecution and the defendant convicted of the crime of "aggravated violent sexual intercourse with child under 14."

Behavioral Analysis, Sex Crime, Schizoid Personality Traits

I18 Writing Forensic Psychological Reports for Police Officer Applicants: First Responders in the War on Terrorism

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

The goals of this presentation are to introduce the IACP pre-employment guidelines as well as the Peace Officers Standards of Training (POST) as a practice foundation for conducting the forensic pre-employment psychological evaluation. This presentation will also explore the essential parts of a proper clinical interview where a significant portion of the report information is obtained. For example, an applicant's job history and contacts with legal authorities are reviewed for the applied for position.

This presentation will impact the forensic science community by showing how long-term outcomes may be observed through a reduction in negligent hire cases highlighted through litigation for officer misconduct.

Police officers are vital front-line responders in the war on terrorism. Therefore, the recruitment, selection, and training of officers assume an essential role in national security. Two useful forensically-relevant references are available for examiners involved in the selection process (i.e., psychological pre-employment screening). The International Association of Chiefs of Police (IACP) and the Peace Officer Standards (POST) both offer guidance for qualified forensic examiners who must evaluate applicants for these safety sensitive positions. Psychological screening must now incorporate psychological issues related to national

security into the evaluation process. After attending this presentation, attendees will understand some the practices used in conducting these evaluations as well as crafting the forensic psychological report that is usually submitted to the hiring authority with national security in mind.

The presentation has three primary learning objectives. First, attendees are introduced to the IACP pre-employment guidelines as well of the Peace Officers Standards of Training (POST) as a practice foundation for conducting the forensic pre-employment psychological evaluation. Second, this presentation explores the essential parts of the clinical interview proper where a significant portion of the report information is obtained. For example, an applicant's job history and contacts with legal authorities are reviewed for the applied for position. The ability to manage or vulnerability to stress is examined within the context of an applicant's coping skills. Finally, the presentation covers writing of the forensic report with considerable attention devoted to the I-Section (i.e., integration section). For example, in some venues, the integration section is the only portion of the report that will be read either because of time or interest constraints on the part of the recipients or because of legal strictures. For example, Federal Rule 803 does not permit the jury to receive the entire report as a written exhibit. In addition, 803 restrict the use of learned treatises attached to the report allowing only the reading of report passages and Rule 702 requires that the psychologists' testimony be grounded in valid constructs and techniques applied to the data in the report rather than relying on biased or stitched together speculation.

These constraints make the integration of the data and reasoning of central importance to the report and the subsequent testimony. The informed use of data, reasoning, and recommendations are by-products of a culturally responsive model that would substantially improve the foundation needed to withstand intensive review during adversarial questioning and cross examination. A case study will be used to illustrate how this process takes place. When carefully crafted, the integration section represents the highest form of evidenced-based practice within this specific forensic context. It is a process that includes forensic research, psychological expertise, and relevant psycho-cultural aspects of the individual being evaluated.

Forensic Psychology, First Responders, Terrorism

I19 Reviewing and Synthesizing Culturally Responsive Forensic Psychological Data in Pre-Employment Psychological Evaluations

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

After attending this presentation, attendees will be able to articulate some of the data information sources frequently used in forensic psychological evaluations conducted on police applicants. The presentation will also cover how the process is explored for using other data to craft a culturally-responsive psychological interview format.

This presentation will impact the forensic science community by presenting how long-term results may be observed through work products noted by negligent hire or appellant hearing outcomes.

The forensic psychological examiner is often confronted with an extremely large data set (e.g., MMPI-2 RF Scales, personal history statement, background reports, etc.). The credibility and defensibility of any forensic evaluation is directly related to synthesis (i.e., sorting and prioritizing) of the most valid data available. And, it is at the integration section that salient cultural factors are at the greatest potential to either augment or detract from the decision-making of the examiner. Cultural factors are identified in several practice reference resources (e.g., APA, ABFP, and the DSM-5) used by for forensic psychologists. The Culturally-Responsive Integrative Model (CRIM) is may function as a practice guide for approaching the forensic evaluation process of police officers. It is hypothesized that forensic examiners exposed to the content of this session will be able to apply this knowledge with the cultural context of the evaluation process.

There are three primary learning objectives expected from this presentation. First, following the completion of this presentation, attendees will be able to articulate some of the data information sources frequently used in forensic psychological evaluations conducted on police applicants. For example, background reports and consultation with background investigators can serve as a value sourced of informing used to frame the semi-structured interview of an applicant. Second, the process is explored for using other data to craft a culturally-responsive psychological interview format. For example, ethical standards set forth by the American Psychological Association require forensic psychologists to administer, adapt, score, interpret, or use assessment techniques, interviews, tests, or instruments in a manner and for purposes that are appropriate in light of the research on or evidence of the usefulness and proper application of these forensic evaluation approaches.

While forensic psychologist may elect use different psychological tests, they are still ethically-bound to be able to defend such evaluation tools under a legal standard (i.e., *Daubert vs. Frye*). In addition, a State's definition of mental health criteria for a police officer may directly impact a forensic psychologist's decision to use or not use certain data sources. In this case, a forensic examiner practicing in several jurisdictions or states may need to be ever mindful that there could be little mobility or transferability of standards from department to department. More importantly, these same factors may be rigorously examined during cross-examination during appeal hearings or subsequent litigation stemming from some action or inaction of an officer screen by the forensic psychologist.

Finally, a rubric is offered for weighing the relevance of information from divergent sources of information over time. For example, psychological tests validated for use with police populations include those that assess psychopathology such as the MMPI2-RF or PAI, those that assess normal psychological functioning such as the CPI, and those that measure cognitive abilities such as the Wonderlic. One forensically-relevant question is how does an examiner consider the problematic tests results in the absence of corresponding negative biopsychosocial information?

A case study will be used to demonstrate how this forensic decision making occurs. It is a process that includes research, forensic psychological expertise, and attention to cultural or racial factors associated with the individual being evaluated. The long-term results of this presentation may be observed through work products noted by negligent hire or appellant hearing outcomes.

Forensic Psychology, Pre-Employment Psychological Evaluations, Culturally Responsive

I20 The Four D's of Decision Making of Police Officer Applicants in Forensic Psychological Evaluations

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

After attending this presentation, attendees will understand a review of the ethical forensic context that is used as a framework for exploring the four D's of decision making.

This presentation will impact the forensic science community by showing how the safety sensitive nature of police work requires that an applicant's behavioral patterns to be placed under a higher level of scrutiny.

Most accredited law enforcement agencies require a series of steps for all applicants that include a post-offer forensic pre-employment psychological evaluation. These evaluations frequently use guidelines from the International Association of Chiefs of Police (IACP) and at the same time relevant psychological dimensions stated in the Peace Officer Training Standards (POST). Both reference sources provide forenic examiners with

direction for using the "rule out" approach designed for identifying counterproductive behaviors related to an officer's decision making. Why? Because police officers have to make appropriate judgments under Action Forcing Moments (Johnson, 2010) where split-second decision making is required during extremely stressful situations. Forensic psychologists conducting these evaluations at a minimum will rely upon several informational sources that include background investigation, personal history questionnaires (PHQ) and objective personality tests (e.g., IPI, MMPI2-RF, PAI, 16PF). Because the quality of an officer's judgment is a critical selection factor, forensic psychological examiners must use samples of an applicant's past behavior and decision-making as a foundation for rendering an opinion. The forensic psychological interview itself may last less than an hour but usually involves about five hours of the forensic examiner's total time that is spent evaluating the applicant (e.g., reviewing files, crafting forensic interview framework, and writing the forensic report). There are many job-relevant areas where the forensic psychological interviewer can probe to secure a scientifically-informed basis for rendering an opinion about the quality of an applicant's decision making and judgment. These job-relevant areas are hereafter referred to as the four D's and include debt, driving, drugs, and drinking. This investigator hypothesizes that a rigorous review of the four D's will significantly enhance the opinions and recommendations offered by forensic examiners working in these law enforcement settings.

There are four primary learning objectives for this presentation. First, attendees are presented a review of the ethical forensic context is used as a framework for exploring the four D's. For example, guidelines from the American Board of Forensic Psychology stress that practitioners use assessment methods in the way that is appropriate based on research or evidence of their usefulness and proper application within a law enforcement personnel selection context.

Second, the safety sensitive nature of police work requires that an applicant's behavioral patterns to be placed under a higher level of scrutiny. The standards for armed police officers are different than civilian and military personnel. Primarily because police officers have discretion in executing an arrest, using deadly force, engaging in pursuit chases, and having to respond to a wide range of diverse citizen contacts under stress. A review of an applicant's history of judgment in the four D's facilitates a forensic examiner's understanding of a distinctive style expected as they would carry out the duties of an armed police officer.

Third, forensic practitioners document all data they considered and used while assessing the four Ds. This documentation includes background reports, letters and consultations, notes, assessment and test data, scoring reports, and interpretations in connection with the pre-employment evaluation. Finally, there are several practice benefits emerging from this presentation. These include sensitizing forensic examiners to ways of crafting probes in the domains of the four Ds based on an integrative discussion of the applicant findings. A forensic case study to demonstrate the practical application of conducting these types of evaluations will be presented. Evidence based practice prompts the recommendation of additional training for mental health professionals practicing in the area of forensic pre-employment psychological evaluations. At a minimum, this would include becoming familiar with POST, IACP, relevant state statutes, high profile cases, and the police psychology research literature.

Forensic Psychology, Pre-Employment Psychological, Decision-Making

I21 Crafting Forensic Psychology Response Reports for Attorneys to Use in Appellant Hearings

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, San Diego, CA 91230*

After attending this presentation, attendees will gain information relating to the forensic practice standards pertaining to psychological reports conducted in law enforcement settings. The presentation also covers an assessment of the validity of the methods and reasoning used to evaluate the opinions, logic and linkages articulated in the Outside Evaluation (OE) report.

This presentation will impact the forensic science community by showing how a reduction in the information gap that results in the selection of personnel who are less likely to be vulnerable to the high stress associated with being a police officer.

Forensic pre-employment psychological evaluations must take place with considerable guidance from recognized professional sources (e.g., International Association of Chiefs of Police, APA, and the Police Officer Standards of Training better known as POST). The forensic examiner is responsible for rendering an opinion (e.g., meets, does not meet, suitable, or not suitable) that is submitted to the hiring authority or their representative. Most large departments, jurisdictions, cities, or states have some type of an articulated appeal process. Typically, the process includes the rejected applicant or appellant to secure an outside evaluation (i.e., OE report) that either may corroborate or offer a dissenting opinion from the original forensic psychological findings or recommendations. In the cases where there is a dissenting OE report, the examiner writing the initial disqualifying report may be called upon to write a forensic response (FR) report that addresses issues identified in the OE report.

There are three primary learning objectives associated with this presentation. First, attendees are briefed on the forensic practice standards related to psychological reports conducted in law enforcement settings. Second, the presentation covers an assessment of the validity of the methods and reasoning used to evaluate the opinions reached in the OE report. Third, the presentation examines the logic of the linkages articulated in the OE report. In this case, the clear and convincing evidence in the OE report that demonstrates a reasonable connection between job-relevant psychopathology, psychological test results, or any functional or judgment impairments that would preclude this appellant from carry out the full scope of the duties of an armed police officer.

The forensic response report is usually written for the attorney representing the hiring authority. The overall purpose of crafting this report is to assist with the cross-examination of the opposing expert as well as allow the initial examiner to have a better idea of the justification used in the original disqualification report. An approach to report writing for practitioners is presented, with practical strategies and examples provided to illustrate the use of the model in a forensically-based setting by outlining five concepts that, if utilized, hold promise to improve the quality and efficacy of response psychological reports.

It is hypothesized that attendees will leave the presentation with a better appreciation for the intricacies of the forensic process as it takes place in the circumscribed arena of police psychology. This process includes discussion of the session with the department's attorney that may allow a refinement of the cross-examination or highlighting other issues associated with the findings or methods in the OE report. For example, some OE reports are plagued by misinterpretation of test reports, ignoring relevant laws, and glossing over or ignoring problematic behavior contained in the appellant's problematic history. After attending this presentation, attendees will understand some of the principles of crafting FR reports within the context of pre-employment psychological evaluations. Although, the guidance offered here may have broader implications for forensic psychology in general.

Forensic Psychology Reports, Appellant Hearings, OE Reports

I22 Use of Law Enforcement Oath of Honor in Forensic Psychological Evaluations of Police Officers

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

After attending this presentation, attendees will be able to articulate the relationship between key elements of the law enforcement oath and relevant job functions of a police officer.

This presentation will impact the forensic science community by improved precision in forensic evaluations. It is believed that public trust is enhanced by awareness that officers are being evaluated on their ability to fulfill standards consistent with what most would view as critical for these safety sensitive positions.

Forensic examiners responsible for psychologically evaluating police applicants or incumbent officers must draw upon several job-relevant sources. The International Association of Chiefs of Police (IACP) provides guidelines for conducting pre-employment psychological evaluations and fitness-for-duty evaluations. Another IACP source not often thought of within the context of the evaluation but is nonetheless instructive in the evaluation process is the law enforcement oath of honor. Experienced and qualified examiners using this oath as an assessment prism will be immediately struck by several ethical behavior elements. First, there is the self-imposed promise to "never betray my badge, my integrity, my character, or public trust." Second, the oath fuels a commitment to "…always have the courage to hold myself and others accountable for our actions…" Third, there is the self-assurance that, "I will always uphold the constitution, my community, and the agency I serve." These three areas collectively and separately offer a firm foundation for evaluating behavior, dispositions, knowledge, and skills that anyone functioning as a police officer should be able to demonstrate through the way they have functioned in the past. Why? A police officer's duty carries critical responsibilities. All police officers must follow core values of the profession that are reflected in the aforementioned oath. A history of slippage in behaviors related to the oath would justifiably call into question a recruit or officer's fitness to appropriately carry out the duties of an armed police officer.

There are three primary learning objectives expected from this presentation. First, attendees will be able to articulate some the relationship between key elements of the law enforcement oath and relevant job functions of a police officer. For example, background reports, personal history questionnaires, personnel records, oral panel statements, and psychological test results can serve as important sources of information used to frame the semi-structured interviews of an evaluee. Second, the same oath may be used in connection with other data to craft a psychological interview format. Third, the guidelines set forth by the IACP and Police Officer Standards of Training (POST) require forensic psychologists to administer, adapt, score, interpret, or use assessment techniques, interviews, tests, or instruments in a manner and for purposes that are appropriate in light of the research on or evidence of the usefulness and proper application of these forensic evaluation approaches.

It is hypothesized that using the Oath of Honor as one assessment prism is a powerful mechanism for understanding an evaluee's capacity for consistently adhering to high ethical standards while functioning as a police officer. A case study will be used to demonstrate how the law enforcement oath can be integrated within the forensic evaluation process. This includes the opinions and recommendations contained in the final forensic report. The benefit to the field of practice may be observed through improve precision in forensic evaluations. In terms of community impact, the author believes that public trust is enhanced by awareness that officers are being evaluated on their ability to fulfill standards consistent with what most would view as critical for these safety sensitive positions.

Forensic Psychology, Law Enforcement Oath of Honor, Ethical Issues

I23 Use of Police Culture and Ethics as a Decision Making Resource in Forensic Pre-Employment Psychological Evaluations of Police Officer Applicants

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

The goals of this presentation are to introduce attendees to the police cultural factors that may compromise, increase vulnerability, or call into question the person being evaluated. Second, involves risk assessment for three types of misconduct that include malfeasance, misfeasance, or nonfeasance. Third, a forensic case study as a practical example of using police ethics during an actual evaluation will be presented.

This presentation will impact the forensic science community by virtue of attenuation in the quality of recommendations coming from forensic examiners that ultimately result in the selection of police officers with lower risk assessment ratings for areas of concern.

Forensic psychologists conducting pre-employment psychological, second opinion, outside evaluations, and fitness-for-duty evaluations are expected to have substantial understanding of the law enforcement culture. Forensic skills used in these evaluations can use awareness of police ethics in formulating opinions while making recommendations to the hiring authority. Ethics pose a major leadership and training challenge within the police culture. For example, one of the elements of the police culture is a high level of allegiance and loyalty that functions as a framework that motivates an officers' willingness to risk personal safety to protect and serve the public. A culture of allegiance and loyalty can also reinforce the "Blue Code" or an unwanted cognitive schema that includes the belief that questionable actions or misbehaviors must somehow be covered up. As a result, this cognitive framework could result in unprofessional and even illegal behavior to be accepted out of a misguided sense of loyalty. It must be emphasized that most psychologically screened police officers are ethical and honest. Police officers are members of a distinct work culture. It is a culture that reinforces certain personality traits that have been covertly endorses as necessary for this type of work. For example, police officers begin to develop a belief in an "us/them" framework that informs officers that while fellow officers are trustworthy (us), they should be cynical and ever cautious of non-police (them). Law enforcement training reinforces the inherent potential dangers stemming from police work (e.g., misconduct and poor quality of judgment). A forensic examiner is charged with the responsibility for evaluating for indicators that rule out those without or vulnerable to lapses in this particular police mindset. Unfortunately, high profile cases of police misconduct still occur. Such cases reduce public confidence and trust whenever questionable ethical misbehavior takes place.

In this presentation, several forensic psychological factors related to ethics as they apply to fulfilling the duties of an armed police officer are examined. There are three primary learning objectives of this presentation. The first learning objective includes introducing attendees the police cultural factors that may compromise, increase vulnerability, or call into question the person being evaluated. For example, these factors may include behaviors inconsistent with the police culture's norms or values, corruption, favoritism, mistake prone, and misconduct.

The second learning objective involves risk assessment for three types of misconduct that include malfeasance, misfeasance, or nonfeasance. The police culture is theoretically intended to shield individual officers. The culture is supposed to function as a base for all officers and protect them from erosion in their judgment. Lapses largely due to carrying out day-to-day duties while managing a boundary separation from distractions coming from the demands in their personal life. The third learning objective, the author presents a forensic case study as a practical example of using police ethics during an actual evaluation. Attendees are expected to be able to operate with an increased sensitivity to the role knowledge of police culture

and ethics can have on the selection process of which forensic examiners are a part.

Forensic Psychology, Police Culture, Blue Shield

I24 A Decision-Making Approach for Offering Risk Assessment Ratings in Forensic Psychological Evaluations of Police Officers

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

After attending this presentation, attendees will be aware of the need to remain sensitive to negligent hire issues in selection of police officers.

This presentation will impact the forensic science community by using the Peace Officer Standards of Training's psychological dimensions as an evidence-based anchoring base for forensic examiners to use while making the risk assessment rating.

Risk assessment in the context of a forensic evaluation of police officer refers to the identification and psychological weighing of potential factors that are expected to compromise judgment or increase concern about stress vulnerability that can fuel misconduct. In the aftermath of a high profile police misconduct incident, once details are disclosed it becomes clear that there were matters that should have previously raised red flags for the department. The financial costs to departments and municipalities for police officer improper action reinforces the need to reduce the lawsuit risks where negligent hire can erode public trust. Insurance rates are also expected to rise in the wake of such cases. Following a high profile police-involved incident, attorneys representing the alleged victim are quick to request copies of all forensic psychological evaluations of the involved officers. What are they looking for or a better question might be, what is their forensic evaluator looking for? In this case, any part of an officer's behavior (i.e., on or off duty), in the distant past or recent can function as a basis for the claim that a particular officer should not have been hired or allowed to remain on the job. For example, an off-duty officer shot and killed his romantic partner with his service revolver. He was convicted of involuntary manslaughter. His blood alcohol count was below the legal limit. There was a long history of domestic violence in this relationship. The victim's family's suit claimed negligent hire on two primary bases. First, the officer had one occasion around the age of 12 when he imbibed a six-pack of beer as recorded on a form used by the department psychologist during the pre-employment psychological interview. The accused officer was said to have an alcohol problem that the department should have used to rule him out as an officer. Second, the department's psychologist failed to write a report on the accused officer.

There are three learning objectives associated with this presentation. First, attendees will be made aware of the need to remain sensitive to negligent hire issues in selection of police officers. For example, what is not as well-known is that police officers must pass a psychological screening in advance to their being sent into the department's academy. The screenings function to eliminate those applicants assessed as poorly suited or in the case of a fitness for duty evaluation, fit or unfit to return to work. The psychological evaluation provides a barometer of the evaluee based on the original referral questions.

The second learning objective of the presentation uses the Peace Officer Standards of Training's (POST) psychological dimensions as an evidence-based anchor for forensic examiners to use while making the risk assessment rating. A practice-relevant forensic case study is used to demonstrate how the POST psychological dimensions can be used in this risk assessment process. The goal is that attendees from this presentation will have a greater understanding of the forensic elements associated with use of the psychological dimensions. The community is expected to gain from the enhanced forensic competencies of examiners who use this recommended approach to risk assessment ratings of police officers.

Forensic Psychology, Risk Assessment, POST

I25 Forensic Applications of the Personality Assessment Inventory (PAI) With Pre-Employment Psychological Evaluations of Law Enforcement Applicants

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

After attending this presentation, attendees will understand the forensic-related standards associated with these types of evaluations, receive an overview of PAI scales and the development of the PAI report used for law enforcement.

This presentation will impact the forensic science community by improving upon the screening and selection process of peace officers who must interact with citizens in a wide range of stressful situations.

Research indicates that at least 80 percent of all law enforcement agencies use some form of personality testing during the psychological screening of applicants. The International Association of Chiefs of Police (IACP) recommends that at least two psychological tests be included in this forensic evaluation process. The Personality Assessment Inventory (PAI) is a standardized test that has been widely used in the evaluation process of law enforcement applicants. The PAI comes with a manual and software program to assist psychologists in the screening and selection of law enforcement applicants. This PAI resource contains a normative sample of PAI scores based upon more than 17,000 police officer applicants of various ethnicities from over 100 different agencies across the United States.

For example, Roberts et al. (2004) randomly selected a subsample of more than 3,000 police officer applicants as well as a cross-validation subsample of over 5,500 police officer applicants in an effort to test the PAI's usefulness in predicting poor performance. The psychological screening procedures resulted in the applicants in both subsamples to be administered a comprehensive psychological evaluation. This process included the California Psychological Inventory (CPI), the MMPI-2, the State-Trait Anger Expression Inventory (STAXI), the Johnson and Roberts Personal History Questionnaire (PHQ), the PAI, and a structured interview. The results obtained from the battery of tests administered, the applicants were assigned into one of five suitability categories – applicants who were assigned ratings of A, B, or C were later assessed as suitable recruits for hire. However, those assigned ratings of D or F were assessed as unsuitable. The PAI test results, Roberts et al. (2004) were used to craft a predictive equation to determine the likelihood that a police psychologist would rank an applicant as "poorly suited" for a career in law enforcement. Known as the Psychological Rating Risk Factor Statement (PRRFS), this probability index places an applicant into one of three categories of risk based upon her/his PAI responses: low risk ($p \leq 24\%$), moderate risk ($p=25\% - 49\%$), and high risk ($p \geq 50\%$). In general, the PAI appears to demonstrate potential usefulness in the police selection process.

A forensic case study of a police applicant will be used to demonstrate the utility of the PAI. The presenter recommends that forensic examiners become familiar with this assessment tool as well as the law enforcement report.

Forensic Psychology, PAI, Police Evaluations

I26 Forensic Applications of the MMPI2-RF With Pre-Employment Psychological Evaluations of Police Officer Applicants

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

After attending this presentation, attendees will understand the forensic-related standards associated with these types of evaluations.

Attendees will also be introduced to the differences between the MMPI2 and MMPI2-RF tests and the use of these testing tools in law enforcement.

This presentation will impact the forensic science community by improving upon the screening and selection process of peace officers who must interact with citizens in a wide range of stressful situations. A forensic case study of a police applicant will be used to demonstrate the utility of the MMPI2-RF.

A large percentage of all law enforcement agencies rely upon personality testing during the psychological screening of applicants. This testing identifies the attitudinal, personality, and psychological aspects of functioning that may significantly interfere with an applicant's ability to carry out the duties of an armed police officer. Forensic tests of this type do not answer questions but generate hypotheses for follow-up review during the face-to-face forensic interview. The International Association of Chiefs of Police (IACP) recommends that at least two psychological tests be included in this forensic evaluation process. The MMPI2 and MMPI2-RF are standardized tests that are widely used in the evaluation process of peace officer applicants. Both the MMPI2 and MMPI2-RF come with manuals and software programs to assist forensic psychologists in the screening and selection of law enforcement applicants. This MMPI2-RF and MMPI-2 are important resources for work done in evaluating police officer applicants of various ethnic groups as well as diverse departments.

From a forensic standpoint, the MMPI has been subjected to extensive critical analysis. In 1965, Congress reviewed the MMPI through hearings because of issues raised about testing employees hired for government positions. The primary concern was whether a test like the MMPI invaded an individual's privacy during employee screening; however, Congress did not find any reason to outlaw the use of the MMPI. Although Congress failed to discover any reason to outlaw the use of the MMPI, the use of this tool to assess an applicant's suitability continues to receive scrutiny. For example, one of the questions is if the tool is designed to evaluate job performance, its normative data for police officers underrepresent women and minorities. The MMPI test elicits responses related to sexual orientation and religious attitudes and fails to measure the construct of conscientiousness (identified as one of the best predictors of job performance and work behavior). There is research indicating that the MMPI was found to be the most frequently used protocols for employment screening.

A side-by-side comparison of the MMPI-2 and MMPI2-RF is expected to highlight key features of both tests. In addition, the usefulness in providing data used in rendering forensic opinions and recommendations are expected to occur as a desirable by-product for examiners as well as the community.

A forensic case study of a police applicant will be used to demonstrate the utility of the MMPI2-RF. It is recommended that forensic examiners become familiar with this assessment tool as well as the law enforcement report.

Forensic Psychology, MMPI2-RF, Police Psychology

I27 Ethical and Professional Issues in Crafting Outside Evaluation Reports (OE Reports) for Police Officer Applicants

Ronn Johnson, PhD, University of San Diego, 3525 Del Mar Heights Road, #302, San Diego, CA 91230*

The goals of this presentation are to provide: (1) the forensic-related guidelines associated with conducting OE evaluations; (2) a recommended format for Outside Evaluation (OE) reports. For example, it may be appropriate to use the typical report format but the referral questions in these evaluations may require a format more consistent with the needs of the hiring authority; and, (3) suggestions for preparing for appellant hearings that may be held in connection with the OE report.

This presentation will impact the forensic science community by improving upon the screening and selection process of peace officers who must interact with citizens in a wide range of stressful situations by assuring professional responsible to conducting evaluations are properly informed about relevant ethical matters. A forensic case study of an OE report is used to demonstrate how ethical issues can arise.

Forensic psychologists must adhere to ethical and professional standards as they deliver services. According to the APA Committee on Professional Practice and Standards (2003), ethics "is defined as the rules or standards governing the conduct of members of a profession" (p. 595)." The main resources for standards of conduct for psychologists are the APA's (2002) Ethical Principles of Psychologists and Code of Conduct (referred to hereinafter as the Ethics Code). The American Board of Forensic Psychology has outlined recommended specific guidelines aimed at forensic psychologists. There are at least three areas of those guidelines that may be useful to forensic psychologists conducting evaluations in law enforcement settings. The areas include documentation and compilation of data considered, disclosing sources of information, bases of opinions, as well as comprehensive and accurate presentation of opinions in reports and testimony. Forensic psychologists are sometimes called upon to craft outside evaluation reports (OE reports) on appellants who have been disqualified or rejected on psychological grounds. It is also possible that an agency, county, or department may contract with a forensic psychologist to perform an independent evaluation of an appellant or incumbent officer. Some departments or hiring authorities have developed standards (e.g., minimum number of police evaluations, licensure, and experience in law enforcement) as pre-requisites for conducting Outside Evaluations; however, there is an absence of standards for conducting such evaluations as well as ethical guidance for qualified forensic examiners performing them.

A less experienced forensic examiner may be tempted to use methods or techniques they commonly rely upon in their customary work but be less aware of the ethical issues in this type of work. As a result, the examiner may unwittingly stumble into ethical dilemmas but still be held accountable for their actions or lack thereof. Second, a recommended format for OE reports is provided. For example, it may be appropriate to use the typical report format but the referral questions in these evaluations may require a format more consistent with the needs of the hiring authority. Third, suggestions are made for preparing for appellant hearings that may be held in connection with the OE report. For example, the entire evaluation has legal implications and the forensic examiner could be subpoenaed to provide testimony regarding the OE report. Examiners with limited experience in these areas may be caught unprepared for the often rigorous cross examination regarding a department's psychological screening standards, professional literature as well as other resources frequently used in police and public safety psychology.

The goal is that this presentation will impact the forensic examiners by sensitizing them to ethical, legal (e.g., negligent hire), and professional issues related to OE reports. The benefits to the community include improving upon the screening and selection process of peace officers who must interact with citizens in a wide range of stressful situations by assuring professional responsible to conducting evaluations are properly informed about relevant ethical matters. A forensic case study of an OE report is used to demonstrate how ethical issues can arise. The presenter recommends that examiners become familiar with problems identified by empirical studies of forensic reports.

Forensic Psychology, Ethical-Legal Issues, OE Reports

I28 Is This a Real Suicide Note? Authentication Using Statistical Classifiers and Computational Linguistics

Carole E. Chaski, PhD*, *ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947; and Denise D. Huddle, BS, Huddle & D'Abre, 900 NE Loop 410, Suite D406, San Antonio, TX 78209*

After attending this presentation, attendees will learn a method of suicide note authentication using both a quantitative, validated software tool Suicide Note Assessment Research (SNARE) and qualitative assessment based on database extraction. Attendees will learn how this method has been used in actual cases of death investigation and how it can be used in psychological assessment. Students will also learn how validation testing is performed for behavioral and linguistic datasets.

This presentation will impact the forensic science community by showing why a suicide note assessment is essential for investigating some deaths which could be classified as a homicide or suicide. The method presented here using SNARE illustrates validation testing for behavioral and linguistic datasets, and thus also advances the methodology of forensic science.

Identifying suicide notes is an extremely difficult task. Part of this difficulty is common to many identification tasks with low accuracy rates. First, if the object to be identified is rare or experience with the object to be identified is low, identification rates are typically low because the identifiers do not have a well-founded grasp of the identifying features. Second, if the object to be identified has low internal consistency, because the object has a wide range of class characteristics, then identification accuracy is predictably low, because the object can be mistaken for so many other types of similar objects.

Suicide notes are difficult to identify accurately because, first, they are rare in most investigators' experience, and second, they are not highly consistent or stereotypical. Suicide notes are found in only the minority of actual suicides (it is estimated that notes only occur in 10 to 15% of suicides).[1] Suicide notes contain elements of other text types, such as apologies and love letters, which can make them easily confusable with other text types. Suicide notes as a whole are internally inconsistent –no one feature set is present in all. It is not surprising then that psychiatrists and psychologists are claimed to have an accuracy rate for identifying texts as suicide notes or not at ranges from 50% to 70% as even this group of professionals may not have consistent experience with real suicide notes, and the experience is informed by a group of documents which are not necessarily similar to each other.[2] Bennell's work on police decision-making mentions the possibility of a quantitative analysis for verifying suicide notes.[3]

SNARE is a computational and quantitative tool for identifying and classifying suicide notes. SNARE currently has obtained an accuracy rate of 80% on a dataset of 400+ real suicide notes and 500 control documents. When the real suicide note data is limited to brief notes (45 words or less) the accuracy rate increases to 86%. The dataset has been vetted. The statistical classifier is a linear discriminant function analysis using leave-one-out cross-validation. The reported accuracy rates are the average of true positives for the real suicide note class and the control document class.

The quantitative method enables the analyst (death investigator, psychiatrist, or psychologist) to start from an objective point in the investigation, since the software analyzes the questioned text without input from the analyst. But given an error rate from 14 to 20%, the analyst should then use SNARE to collect a pool of comparative documents from the real suicide note dataset. By comparing the questioned document to real suicide notes with similar characteristics, the analyst can determine whether SNARE has made a classification error or not.

Methodologically, the most interesting aspect of this second step is the requirement that the analyst seek to disprove the SNARE classification. The two-step analysis based on a quantitative classification followed by qualitative assessment allows for the application of analyst knowledge, preferably in line with Leenaars' work.[4-7]

Suicide Note, Computational Linguistics, Validation Testing

I29 What Happens When a Dream Is Deferred and the Village Erodes: Application of a Diathesis-Stress Model to Risk and Protective Factors for Suicidality in Racial/Ethnic Minority Youth

Natasha D. Gardner, PhD, University of Southern California, PO Box 86125, Los Angeles, CA 90086-0126*

The goal of this presentation is to facilitate an understanding of how a stress diathesis model may be applied to risk and protective factors regarding suicidality for minority youth. After attending this presentation, attendees will better understand how this model applies to conceptualizing the literature's findings regarding societal, community and individual contributions to suicidality in minority youth age 10 to 24.

This presentation will impact the forensic science community by facilitating an understanding of the risk and protective factors of suicidality in minority youth. Specifically, this paper will explore potential individual, relational, community, and society-based factors relevant to suicidal behavior in this population. Recommendations for applying the diathesis-stress model to suicide prevention and intervention will also be provided.

According to the Centers for Disease Control and the National Institute of Mental Health, suicide is a major public health concern for youth; specifically, it is the third leading cause of death for individuals ages 15 to 24. Research indicates clearly that all demographic groups are susceptible to this public health problem. Over the last several decades, suicidality has become increasingly problematic for racial/ethnic minority youth, such that more are attempting and completing suicide; however, suicide within this vulnerable group is poorly understood. As a consequence of this, many warning signs and potential points of intervention are missed, resulting in preventable suffering and death for a notable segment of the population.

Currently, in majority and minority group studies, suicidality is approached as an issue arising from the individual alone or in relationship to others. Occasionally, certain cultural factors such as vulnerability to

academic problems, disproportionate incarceration rates, and health disparities are discussed; however, the effects of community and broader societal changes on mental health functioning for minority youth, particularly suicidality, are rarely considered. The diathesis-stress model may more comprehensively conceptualize the complex interactions between these various factors and suicide-related risk and protective factors for minority youth. According to this model, subsequent to exposure to negative life events, vulnerable persons are more likely to develop psychopathology. This may be due to actual or perceived disparity between contextual demands and resources. For example, an educational environment's demand for appropriate academic performance requires the individual have particular resources, such as sufficient cognitive ability and access to technologies and materials. Perceived disparity between demands and resources, meaning where one's resources seem deficient compared to the environment's demands, generates psychological distress. The greater the perceived disparity, the greater one's distress. Such distress varies widely in intensity and may range from mere irritation to complete hopelessness.

Factors such as age, gender, sexual orientation, and perceived social support are generally related to suicidality within youth populations. Risk and protective factors for suicide; however, may vary among groups of racial/ethnic minority youth. Under the diathesis-stress model, such group-specific factors may indicate changes in individual, relational, community, and societal demands and/or resources that have generated increasing and maintaining high levels of distress for minority youth. Added to increased exposure to suicide, these changes in contextual demands and/or resources, and the distress generated by the perceived discrepancy between the demands placed upon minority youth and their access to necessary resources may result in increased vulnerability to suicide.

This paper will review the public health and social science literature from 1990 to the present for trends in suicidality among minority youth. Empirically supported risk and protective factors among this population will also be reviewed. These trends and factors will be examined for their application to the diathesis-stress model of psychological functioning and distress.

Minority Mental Health, Stress, Suicide

I30 Adolescents and Crime

Ahmet Yillmaz, MS, and Gaye Ozmen, MS, Istanbul University Forensic Science Institute, Istanbul, 34099, TURKEY; and Coskun Yorulmaz, MD, Istanbul University, Istanbul University Forensic Science Institute, Department of Forensic Medicine, Cerrahpasa, Istanbul, 34099, TURKEY*

The goal of this presentation is to present the solution for children in conflict with law, by analyzing socio-economic features, style of crime, characteristics of the family, and the reasons of the juvenile delinquency.

This presentation will impact the forensic science community by underlining the importance of rehabilitation of children in conflict and giving recommendations for the treatment that children in these situations need.

Introduction: Childhood and adolescence are rapid development cycles. Adolescents may not be aware of the meaning and the result of their behaviors because of their rapid biological and psychological fluctuations. Due to this agitated cycle, The United Nations Convention on the Rights of the Child states that every human being below the age of eighteen years is considered a child, unless under the law applicable to the child, majority is attained earlier. Therefore, any crime that they commit is assessed by this rule. The most important attribution that allocates child crime than adult crime is that childhood contains the adolescence which is considered a problematic or alternation cycle. The crime that is committed must be evaluated in the developmental period which the human being is in.

Some theories show that in adolescent criminal behavior, genetic, psychiatric, and psychological problems are important and at the current time it is believed that environmental factors play a more important role.

In recent years, the incidences of juvenile delinquency increases day-by-day. In Turkey, the incidence of juvenile delinquency is progressing rapidly. In order to understand when an action becomes crime known the component of crime, reasons of crime, and punishable situations, because all the actions must be considered within these parameters. The crime theory explains which behaviors are against the law and called crimes and which are not. Since juvenile delinquency is a social problem, there is an urgent need to find solutions to make a healthy society.

Material and Methods: The sample consisted of 121 children and adolescents between the ages of 12 and 17 who entered in the Turkish forensic system as children in conflict with the law between the years 2008 to 2011. All of the children were given psychological evaluations and all the data relating to these children and adolescents were taken from the reports of the court's psychologist.

Results: Of the 121 children included in this study, 89 (73.75%) are males and 32 (26.5%) female. Twenty-three (19%) of all children are between 12 to 14 years, 98 (80.1%) of them are between 15 to 17 years. In females the average age was 15.18 years. In males, this number was 15.93 years. Of all of the offenses, 92 (76%) were crimes against property and 29 (24%) were crimes against persons.

Conclusion: Previous studies considered children between the ages 16 to 17. In this paper 80.1% of the children were between the ages 15 to 17. These data are consistent with the literature. In this paper, 73.5% of the children in conflict with the law are male. It is possible that more boys become involved with the forensic system than girls because boys are more likely to spend time out of the home and out of family control.

A weakness of this study is the fact that all of the subjects came from one specific geographical region and court.

Juvenile Delinquency, Children in Conflict With Law, Child

I31 A Case Study Illustrating Sexual Grooming as Part of the Child Molester's *Modus Operandi*

Marina Genis, MA, Unit 149, 21 Sunset Avenue, Pineslopes, Lonehill, Ext 71, SOUTH AFRICA; and Elmarie A. Myburgh, South African Police Services, 255 Schoeman Street, Pretoria, SOUTH AFRICA*

After attending this presentation, attendees will understand what constitutes sexual grooming, how this forms part of the pedophile's modus operandi in order to successfully offend against the victim as well as the application of grooming laws in South Africa and how this correlates with grooming as a legal concept in other countries.

This presentation will impact the forensic science community by providing law enforcement officers with a better understanding of grooming as part of the modus operandi of child molesters, enabling them as well as the community in general, to be able to identify these behaviors and prevent children from being abused, and to understand these behaviors from a cross national perspective.

Many pedophiles court children like an adult will court a partner with attention, affection, and gifts. In sex offenders, this behavior is referred to as grooming. The grooming process takes time until the child's inhibitions have been lowered and the offender progresses to sexual behavior. In South Africa, grooming is a crime under the Criminal Law (Sexual Offences and Related Matters) Amendment Act No. 32 of 2007.

Grooming behavior includes identifying with vulnerable victims, having access to children through, for example, baby sitting, seducing the child with attention, affection, and gifts. In general child molesters do not use force to engage children in sexual activities but rather count on different forms of psychological manipulation, grooming, and desensitization. Physical grooming entails the gradual sexualization of the relationship between offender and victim. The offender builds the child's trust, makes him or her feel good, and then starts to violate boundaries (e.g., progression from innocent touching to inappropriate touching or showing pornography to children). The victims' repeated acceptance of non-sexual touch early in

the grooming process could lead them to believe that they have given consent to more invasive sexual contact. In this way, the desensitization process seems to promote cooperation and reduces potential for disclosure. When confronted about engaging in such activities, pedophiles commonly justify and minimize their actions or make excuses while others use cognitive distortions or redefine their action as love and support.

The following case study will be presented to illustrate typical grooming behavior and cognitive distortions or excuses of a sentenced child molester in the South African context.

A 62-year-old male groomed his step granddaughter from the age of seven by gaining her and her parents' trust. He sexually molested her from the age of eight and sexually penetrated her from about the age of nine until eleven. He took photos of her vaginal area and was in possession of other child abuse images. He pleaded guilty on five charges of rape and manufacturing of pornographic material. He was sentenced to life for the rape charge, and five years for the charge of manufacturing of pornographic material.

Sexual Grooming, Child Molester, Sexual Abuse

I32 From Classification to Clinical Practice: Current Psychiatric Understanding of Stalking Behavior

Christopher Racine, MD, MPH, Bellevue Hospital, 462 First Avenue, Office #214b, C Building, New York, NY; and Stephen B. Billick, MD, 11 East 68th Street, Suite 1B, New York, NY 10065-4955*

After attending this presentation, attendees will: (1) understand the legal and mental health definition of "stalking"; (2) review the epidemiology of stalking; (3) to review typologies and classification of stalking; (4) understand how stalking behavior is associated with DSM diagnosable disorders; and, (5) use our current understanding of stalking behavior to comment on risk management and treatment strategies.

This presentation will impact the forensic science community by reviewing stalking, an often overlooked behavior, that has a high potential for violent outcomes, from a psychiatric and treatment perspective.

Prior to the 1990's, relatively little research had been performed regarding the conceptualization, understanding, or treatment of stalking behavior. This is somewhat surprising given the high prevalence of stalking in the community. As many as 8% of women and 2% of men state that they have been stalked at some point in their lives and as many as one in four cases of stalking in the United States will culminate in significant violence. Public appreciation of stalking as a behavior was, and in some respects still is, largely limited to sensationalized cases involving the stalking of high-profile celebrities such as Madonna or Princess Diana. What constituted "stalking" has not always been clearly defined as a legal term. Although less than in earlier times, laws defining the crime of stalking can vary dramatically from state to state. It is no surprise, then, that the psychiatric understanding of stalking as a concept has lagged behind study of other potentially violent behaviors and is just recently emerging as an area of study.

As legal definitions of stalking are unique to each jurisdiction, there is no consensus definition of stalking in the mental health literature either. J. Reid Meloy's definition is one of the most widely cited and defines stalking as "the willful, malicious, and repeated following and harassing of another person that threatens his or her safety" (Meloy and Gothard, 1995). Other descriptive terms such as "obsessional following" have also come to be accepted as synonyms for this behavior. In general, the various definitions typically seek to describe a behavior that is: (1) a pattern of intrusive behavior or harassment; (2) a resulting implicit or explicit threat; and, (3) as a result, the threatened person experiences reasonable fear. Numerous typologies have attempted to classify staking behavior for identification, risk stratification, treatment, or other purposes. Most typologies have been based on the stalker's relationship with the victim, the context in which that relationship is based, and the degree to which violence or the potential for violence is an issue. However, no single classification system has ever been agreed upon in the forensic community.

One of the most difficult obstacles in conceptualizing stalking is that it is a behavior that can be the manifestation of numerous currently understood mental health diagnoses. It does not exist as a stand-alone diagnosis in DSM IV-TR nor is there any current plan for inclusion in DSM-V. Those who exhibit stalking behaviors may be classified as having a multitude of different Axis I and Axis II diagnoses. While it is classically taught that obsessional followers have erotomatic delusions or de Clereambalt's syndrome (i.e., erotomania), only a small minority of perpetrators appear to fit this mold. Schizophrenia, schizoaffective disorder, bipolar disorder, delusional disorder, major depressive disorder, adjustment disorders, cluster B personality disorders, cluster A personality disorders, and others have all been seen to manifest in stalking behavior. Because of this complexity, treatment recommendations for stalking behaviors have often been generalized and inexact.

The goal of this presentation will be to review the most recent and accepted stalking typologies and attempt to place them in context of DSM diagnoses that are familiar to practitioners. Current recommendations regarding risk management in the stalking situation will be reviewed. Finally, the current recommendations and evidence base for management and treatment of stalking behavior in the context of typographical description and diagnosis will be described.

Stalking, Obsessional Following, Psychiatry

I33 A Particular Case of Latticed Allegations in a Nursery School in Brescia, Italy

Cinzia Gimelli, PsyD, PhD, Viale Montegrappa, 29/C, Reggio Emilia, 42100, ITALY; and Melania Lugli, PhD*, Viale Montegrappa 29/C, Reggio Emilia, 42121, ITALY*

After attending this presentation, attendees will learn tools to conduct a proper interview in cases of alleged sexual abuse.

This presentation will impact the forensic science community by helping evaluators to better distinguish between correct and incorrect procedures in interviewing children.

Sexual abuse of children is difficult to identify. The phenomenon rarely emerges as objective evidence of the abuse and children are the only witnesses of the alleged facts.

Sexual abuse of children has become the subject of great community concern and the focus of many legislative and professional initiatives. This is evident by the expanding body of literature on sexual abuse, public declarations by adult survivors, and increased media coverage of sexual abuse issues.

There are various reasons why children can make false allegations and a false report may also occur without any responsibility on the part of the child, often due to incorrect interviewing procedures with the child who is the alleged victim of abuse. Moreover, interviewers do not always have enough expertise to avoid errors.

Research has had a tendency to concentrate on the suggestibility of children and neglected other topics that may be of great utility to those who investigate suspected cases of child sexual abuse. More attention should have been paid in the brief to the complexities of assessment. Too much emphasis has been placed on children and not nearly enough attention on remedial actions to minimize the problems associated with suggestion. Finally, research shows that it may be possible to develop reliable and valid techniques to assess child sexual abuse allegations.

The best way for interviewing children is the foundational structure of the interview itself. If the child is approached in the wrong manner with limited efforts to make them feel comfortable during the reconstruction of the incidents, the final product could be useless. It is important to encourage children to tell particulars as well as any detail of the alleged incidents in a spontaneous way.

Cross-contamination between children and/or their families could also, in part, explain the latticed allegation problem.

If most of the alleged victims know one another, then is it possible that children will talk among themselves about their allegation, resulting in contamination.

The purpose of this study was to examine a particular case of latticed allegations involving more than 20 victims between four and five-year-olds in a preschool in Brescia, a city in the northern part of Italy.

In this case, as in all latticed allegations, although some statements stem from real elements, the proliferation of reports is attributed to a range of mutual contaminations made, as this research has highlighted, mainly by bad interview techniques. This research compares the emerging Italian case studies on this phenomenon with the well established cases in the United States.

This presentation will also address how to consolidate the best practice in psychological forensic sciences and how it is important to integrate this practice together with the crime scene activities and lab analyses especially in cases of alleged child abuses.

Latticed Allegations, Brescia, Nursery School

I34 Implementation of a Quality Improvement Program to Predict and Prevent Inpatient Violence

Rebecca A. Lewis, MD, Bellevue Hospital Center, 462 First Avenue, New York, NY 10016; Elizabeth Ford, MD*, Bellevue Hospital Center, 462 First Avenue, NBV 19W21, New York, NY 10016; and Christopher W. Smith, PhD, Bellevue Hospital Center, 462 First Avenue, New York, NY 10016*

After attending this presentation, attendees will understand how to use the Broset Violence Checklist (BVC) to predict violence on an inpatient psychiatric unit and will consider methods of implementing quality improvement projects on inpatient psychiatric services

This presentation will impact the forensic science community by educating forensic scientists about acute violence prediction and strategies to implement systematic programs to reduce violence in hospital settings.

Proposition: This project will investigate the predictive value of admission BVC scores on imminent dangerousness in an acute psychiatric inpatient setting. In addition, methods behind the implementation of a violence reduction quality improvement program will be examined with subsequent proposals for improving and/or continuing staff satisfaction in quality improvement programs.

Synopsis: Bellevue Hospital Center, a public hospital in New York City with over 300 inpatient psychiatric beds, 20% of which are devoted to the treatment of incarcerated males from Rikers Island, implemented a quality improvement project, the Violence Reduction Pathway (VRP), on all of its adult psychiatry units in 2009. The goal was to identify patients who were at imminent risk of violence and then develop specialized treatment plans for those patients in order to reduce episodes of future violence. As part of the VRP, the Broset Violence Checklist (BVC) was used to assess imminent risk of violence.

The BVC measures the presence or absence of one of six behaviors/symptoms that have been shown to have significant relationships with violent episodes within 24 hours: confusion, irritability, boisterousness, physical threats, verbal threats, and attacks on objects. The creators of the BVC, which was designed based on medical records examined at a Norwegian maximum security forensic hospital,[1] recommended a cut-off score of two or greater as this yielded 63% accuracy in predicting violence and 92% accuracy in predicting non-violence within 24 hours of the score being received.[2]

The BVC has been validated in other inpatient psychiatric settings since its developmet,[3,4] although limits of reliability in reporting violent incidents and difficulties with prediction in certain populations,[5] such as female substance abusers have led to at least some concern about the scales' generalizability.[4] Some have suggested changing the cut-off score in order to decrease the rate of false positives or false negatives.[3,4]

Although the VRP was implemented at Bellevue Hospital, there have not yet been any studies to explore its validity, impact on staff work flow, or effectiveness as a quality improvement project. Retrospective data collection on 100 consecutive admissions to the inpatient forensic psychiatric service will be collected. This will include demographic information, admission Broset scores, and information related to violence risk within the first 24 hours, specifically emergency medication administration, crisis management team interventions, and violent incident reports. The data will then be statistically analyzed to determine the predictive value of an admission Broset score of two or higher on the occurrence of each of these three events. In addition to the quantitative analysis, the qualitative arm of the study will describe the way in which the VRP was initially implemented and explore staff opinions about the VRP quality improvement project. A survey, distributed to all of the multidisciplinary staff involved in the VRP's implementation, will help characterize the logistical implementation of the project, the education provided to the staff about the project, the work load associated with its implementation, the perceived utility of the VRP, and any suggestions for improvement. The information provided from this study will help guide future policy decisions regarding inpatient violence risk assessment.

Violence Prediction, Broset, Quality Improvement

I35 The Use of Brain Imaging in Legal Matters

Jonathan Manaoat, MD, PO Box 86125, Los Angeles, CA 90033*

After attending this presentation, attendees will understand some of the principles of brain imaging. Moreover, recent brain imaging findings pertinent to the understanding of criminal behavior will be presented. In addition, applications of brain imaging in legal issues, especially court cases and legal precedent will be discussed. Lastly, the future applications of brain imaging in the forensic and legal setting will be discussed.

This presentation will impact the forensic science community by helping those in the field understand the basis of brain imaging studies and how they have been or may be applied to legal and forensic issues.

Following the decade of the brain in the 1990's, our understanding of the brain has grown immensely. In particular, advances in neuroimaging have worked to further our understanding of the structure, function, and correlations with typical development and disease processes. This paper will review the different brain imaging studies used towards these endeavors. This includes positron emission tomography (PET), single positron emission computed tomography (SPECT), functional magnetic resonance imaging (fMRI), and anatomical magnetic resonance imaging (aMRI). Moreover, an assessment of the strengths and limitations of each technique will be presented, including the replicability and suggestions on how to improve the rigor of these studies.

Applications of these findings and the implications for criminal behavior will also be presented. A review of the legal precedents involving brain imaging will be conducted. An assessment of the present applicability of brain imaging to legal proceedings will be discussed. Moreover, the question of whether the legal standards of *Daubert* and *Frye* should be applied to these studies will be addressed.

Brain Imaging, Legal, Evidence

I36 Causing Parental Alienation is a Form of Child Abuse

William Bernet, MD, Vanderbilt Psychiatric Hospital, 1601 23rd Avenue South, Suite 3050, Nashville, TN 37212-3182*

After attending this presentation, the attendees will understand the concept of parental alienation, how parental alienation comes about, and why parental alienation should sometimes be considered an example of emotional or psychological child abuse.

This presentation will impact the forensic science community by increasing the awareness of mental health and legal professionals regarding parental alienation; increasing the knowledge of mental health and legal professionals regarding emotional and psychological child abuse; and perhaps leading to the adoption of the proposal that causing parental alienation should be considered an example of child abuse.

Parental alienation is a serious mental condition that sometimes occurs in a child when his or her parents are engaged in a high-conflict divorce. In parental alienation, the child allies himself or herself strongly with one parent (the preferred parent) and rejects a relationship with the other parent (the alienated parent) without legitimate justification. Parental alienation should be considered a mental disorder because the child's rejection of the alienated parent is driven by the false or illogical belief that the parent is evil, dangerous, or not worthy of love. In contrast, parental estrangement is normal behavior, not a mental disorder. Estrangement is the rejection of a parent for good cause, e.g., abuse or neglect.

In some instances, parental alienation is brought about by the indoctrination of the child by the preferred parent against the rejected parent. If the preferred parent has indoctrinated the child in a knowing, purposeful, persistent manner to hate and avoid the alienated parent, that behavior should be considered emotional or psychological abuse of the child. In practice, these cases are complex: Parent A might accuse Parent B of physically abusing the child, so it is normal for the child to dislike Parent B. However, Parent B might accuse Parent A of indoctrinating or brainwashing the child, so the child's dislike for Parent B is based on a false belief.

Although emotional/psychological abuse of a child is not currently included in the *Diagnostic and Statistical Manual of Mental Disorders,* it is included in the *International Classification of Diseases.* Emotional/psychological abuse typically includes behaviors such as: rejecting the child; isolating the child from normal social experiences; terrorizing the child verbally and with threats of assault; berating the child; and overpressuring the child. Indoctrinating a child to dislike and reject a parent should be considered emotional/psychological abuse.

There is considerable international research to support this proposal. The work of psychologists, psychiatrists, and legal professionals from Canada, Germany, Italy, Spain, South Africa, the United Kingdom, and the United States will be summarized. In some instances, state and national governments have taken totally opposite positions regarding parental alienation. For example, the governments of Brazil and of the state of Querétaro, Mexico, have made it illegal to induce parental alienation in a child. In some cases, the European Court of Human Rights has recognized the serious nature of parental alienation. In contrast, the legislature of California has considered doing exactly the opposite, that is, making it illegal for a court to consider parental alienation in a child custody proceeding. It is important that parental alienation be understood and recognized by mental health and legal professionals.

Parental Alienation, Child Maltreatment, Emotional/Psychological Child Abuse

I37 Matricide: Criminological Understanding Beyond Psychosis — An Italian Case Series Study

Felice F. Carabellese, MD, and Chiara Candelli, PhD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, 11, Bari, 70124, ITALY; Gabriele Rocca, MD, Section of Forensic Psychiatry, University of Genova, Via De Toni, 12, Genova, 16132, ITALY; and Roberto Catanesi, MD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY*

After attending this presentation, attendees will be able to recognize some of the features of matricide and understand principles of forensic psychiatric assessment of matricidal criminals.

This presentation will impact the forensic science community by assessing the role of the mother-son bond in the etiology of matricide.

Matricide, or killing of one's own mother, is one of the rarest of reported murders, with a rate of about 2% of all homicides worldwide. Historically, this type of crime has been known since ancient times and also has a mythological reference (the Orestes complex). According to the literature, a son who kills his mother is usually a single, unambitious young man with an intense relationship with his mother, a lack of interest in other women, a feeling of social inferiority, and an absent or passive father. Matricide seems to be more common among or specific to individuals with severe psychiatric disorders, especially schizophrenia. Among schizophrenic offenders the paranoid subtype is the most common. Other diagnoses include mood disorders, substance abuse, and personality disorders. Many offenders suffered from psychosis at the time of the crime, and their acts were influenced by persecutory delusions and/or auditory hallucinations.

A history of a problematic relationship between the mother and son is typically present. Offenders often report feeling that their mothers were either ambivalent toward them, or excessively domineering; these relationships have been described as "mutually dependent but hostile." Matricides are classically committed in the victim's home, usually using a weapon, although asphyxia is also common. In some cases "overkill" is reported, involving extreme violence.

To better understand the characteristics of matricidal criminals and the psychopathological mechanisms related to this behavior, a study of ten matricides committed in Italy will be presented. The forensic psychiatric examination reports of the ten offenders (age range 21-53 years, mean age 37) were retrospectively analyzed to study several variables regarding the homicide features as well as offender characteristics and motives. The diagnoses were collected exactly as they appeared in the reports and evaluated on the DSM-IV-TR criteria. The assessment of the degree of criminal responsibility, according to the examining forensic psychiatrist, was extracted (full responsibility/diminished responsibility/no responsibility) and analyzed.

From a medico-legal point of view, there were two deaths by shooting, one deliberately provoked fall, three smotherings, two bashings, and two stabbings in which the injuries were due to more than one weapon or action.

Clinically, the most common diagnosis was schizophrenia (5/10); two offenders were found to have other psychoses and three perpetrators suffered from an Axis II disorder. Of the offenders, seven out of ten (7/10) were found not guilty due to insanity, one was judged to have a diminished responsibility, and two to be fully responsible.

It is interesting to note that although most of the cases were diagnosed with schizophrenia or other psychoses, not all the perpetrators who committed matricide had psychotic symptoms at the time of the offence

(i.e., delusional thinking or hallucinations). On the other hand, in all cases a "pathologic" mother-son bond was found. In particular, in accordance with the literature, the victims were ambivalent mothers, with an intruding, domineering but symbiotic relationship with their sons that was mutually dependent but intrinsically hostile. Against this background many different motives, both "psychotic" and non- psychotic, can trigger the crime. Each of these must be accurately described and analyzed to reconstruct the dynamics of the matricide and understand its genesis.

It is not always persecution delusions, therefore, that cause these crimes. Mental disease is not the only causal factor and is not enough, taken alone, to explain the crime. Indeed, the observation that different psychopathological pictures induced a "perverse," dysfunctional bond over the years, leading to the same tragic epilogue, seems to confirm that something more needs to be searched for, presumably in the history of the mother and son, and especially the way their relationship developed and crystallized over the years, also due to the absence or passivity of the other parent.

A psychiatric-forensic study of the entire existential history of both people, as well as of the socio-economic context, is therefore needed to understand the roots of this tragic crime. The peculiar dynamics of the mother-son relationship, as well as their unique personalities and life experiences, are the key to cases of matricide.

Matricide, Psychosis, Mother-Son Bond

I38 Parricide by Pre-Teens: Case Review and Study

Sandra Hah, MD, Los Angeles County, University Southern California, 2010 Zonal Avenue, Outpatient Department, 1st Floor, 1P-2, Los Angeles, CA 90033*

After attending this presentation, attendees will be familiar with several cases of parricide by pre-teens and be better acquainted with the core issues that are present in the legal, ethical, and psychiatric dilemmas surrounding these cases.

This presentation will impact the forensic science community by providing a platform to discuss the challenges that child parricide cases present to the legal system, as well as highlighting the complex ethical issues that result when the courts must consider punishment versus rehabilitation. This presentation will also serve as a forum in which to discuss several salient psychological and forensic psychiatric issues that arise in child parricide cases.

Parricide is an extremely rare occurrence and parricide committed by pre-teens (children ages twelve and younger) is practically unheard of. On average, there are between two hundred to three hundred parricides a year which represents approximately two percent of all homicides. Only a few of these parricides are committed by minors and of these cases, there may only be a handful of parricides by a pre-teen. The vast majority of parricide cases involve sons murdering their fathers with a firearm. The smallest subgroup of parricide is daughters who commit matricide. There are several etiological theories on parricide by minors. Several studies show that minors who commit parricide are often victims of abuse (physical, sexual, and emotional) or violence, and that they murder as a way to end the abuse. Yet, another theory outlines a shame-rage cycle in the pre-teen that occurs as a result of a contentious relationship with the parent who is the victim of the parricide. There is a smaller subset of children who commit parricide as the result of a severe mental disturbance, and yet an even smaller subset of children who commit parricide for seemingly inconsequential reasons. This presentation will serve as an outline to highlight these theories, and illustrate that there may not necessarily be any pattern or predictability to parricide.

This presentation will also offer insight into the complex issues that must be addressed in the evaluation of the preteen from a forensic psychiatry perspective, as well as the trial proceedings. Several court proceedings and case law files will be reviewed as examples of the specific legal dilemmas that will be discussed. These include; various defense strategies such as battered child syndrome (BCS), how to ensure a fair trial to a child, and how to determine whether the child knew the difference between right and wrong at the commission of the parricide. Ethical dilemmas reflect the strong emotionality of child parricide cases, and include the debate about the fairness of rehabilitating versus punishing children, and whether it is ethical to hold a developing child responsible for a crime for which they may not fully understand the consequences and outcomes. Forensic psychiatric issues focus on examining whether there are any patterns of behavior or psychiatric illness in children who commit parricide. Additionally this presentation will address whether there are any reliable risk factors that can be identified and used to predict this kind of dangerous behavior in a child.

Child Parricide, Forensic Psychiatry, Legal Defenses

I39 Incest: Analysis of a Case

Gaye Ozmen, and Ahmet Yilmaz, Istanbul University Forensic Science Institute, Istanbul, TURKEY; and Coskun Yorulmaz, MD, Istanbul University, Istanbul University Forensic Science Institute, Department of Forensic Medicine, Cerrahpasa, Istanbul, 34099, TURKEY*

After attending this presentation, attendees will be able to: (1) identify the definition and causes of incest; (2) identify the characteristics of offender and victim; and (3) understand the indicators of sexual abuse and the process of the event when it occurs identify the signals of abuse clearly with the presentation of points of sexual abuse and incest with a case. This case is different than the other cases in literature, with the behaviors of victim's mother, who was active in speaking up, bringing the case to court, and preventing the victim from seeing her father.

This presentation will impact the forensic science community by presenting an incest case which is forbidden in every culture throughout history.

Introduction: Child abuse and neglect, a universal problem, causes physical and psychological damage that negatively affect well-being and life-long development of exposed children.

When an adult uses a child for sexual stimulation or satisfaction, this is considered sexual abuse. Likewise, child prostitution or child pornography, touching of the genital area, exhibitionism, pornography, and rape can all be forms of child sexual abuse.

The word ''incest'' comes from ''incestare'' which means contaminating and aspersing and comes from ''incestus'' which means dirty in Latin language.

Incest is a sexual relationship between people related by blood. Because it occurs within family and is also forbidden in every culture, it is hard to reveal incest. It is emphasized that offenders in incest cases are usually fathers, the mother of family is a passive family member and also usually aware of the incest case.

Methods: The case was a 13-year-old girl described as a very successful secondary pupil. She disclosed that she had been a victim of incest for one-and-a-half years by her father. It was said that the beginning of the incest case was with her father's touching offer. She thought by threatening to tell, her father would stay away. Instead, the father began to abuse her and tried to destroy the relationship between the victim and her mother.

Her father began to beat her and tried to touch her sexually whenever he could. She kept quiet in order to keep her family together. After this situation, she disclosed that she began to have nightmares, eating and sleeping disorders. The offender father was born in 1960 and worked as a taxi driver. He had no sexual relationship with his wife for the last five years. He had nervous problems and been in treatment. Mother was born in 1963, house wife, she was economically dependent to her husband. She stated she had been raped by her husband at the beginning of their marriage but for the last five years they had no sexual relationship. She stated that she had found some pornographic scenes on her husband's personal

computer after the case began.

The case arose when some relatives and neighbors told the mother that her husband had offered them sex. The mother talked to her daughter who had been very depressed recently. The daughter told her mother what had happened and the case was brought to law enforcement.

The literature about incest reveals that the mother of victim often chooses to keep the abuse secret, blame her child, and deny the facts because she is afraid of divorcing. In this case, although the mother was economically dependent on her husband, she was the pioneer person who brought the case to light by first bringing her daughter to the hospital and then contacting the police.

Conclusions: Incest is rarely revealed because it is forbidden and also it occurs within the family. This paper attempts to clarify the signals of sexual abuse and incest by describing a specific case. This case is consistent with the literature about the characteristics of offender and victim, but differs greatly in the attitude of the mother, which helped to reveal this case.

Incest, Sexual Abuse, Child

I40 A South African Case Study Illustrating Multiple Intimate Partner Murder: Serial Murder or Not?

Elmarie A. Myburgh, BA, South African Police Services, 255 Schoeman street, Pretoria, SOUTH AFRICA; Marina Genis, MA*, Unit 149, 21 Sunset Avenue, Pineslopes, Lonehill, Ext 71, SOUTH AFRICA; and Susanna M. Knoetze*, South African Police Services, Investigative Psychology Unit, Criminal Records and Crime Scene Management, Head Office, Pretoria, SOUTH AFRICA*

After attending this presentation, attendees will have an understanding of what serial murder is, what intimate partner murder is, and whether a murderer who committed multiple intimate partner murders can be classified as a serial murderer.

This presentation will impact the forensic science community by showing how law enforcement officers, psychologists, and profilers will have a better understanding of intimate partner murders and serial murders, and how intimate partner murderers can repeat these crimes and become serial murderers. It will enable attendees to identify danger signals and prevent more tragic incidents.

Intimate partner murders are often referred to as domestic murders or spousal homicide. This occurs when one person is murdered by their current, or ex-, intimate or romantic partner. Motives for such crimes typically include an element of jealousy, which may be due to real or feared abandonment by the victim. While some such perpetrators have a history of physical abuse towards their partner, a significant number of offenders have no history of violence towards their partners, and often there is no escalation of violence preceding the murder.

A serial murderer murders at least two people at different times and for a primarily intrinsic/psychological reason. Motives include anger, ideology, power, trill, psychosis, and sexually based. Serial murderers tend to stick to one main method of obtaining and murdering their victims. They also tend to keep to a certain victimology in most instances.

The following case study will be presented to illustrate how one person committed three murders, two of which were intimate partner murders, and discuss whether he can be regarded as a serial murderer or not.

A 26-year-old man murdered his high school sweetheart by shooting her seven times in her office at the university where she worked. This occurred when she ended the relationship after eight years and he went to her place of work and murdered her with a pistol he stole from his brother. He was found guilty of the murder and sentenced to 15 years imprisonment.

After 12 years he was released from prison, and he soon became romantically involved with another woman. The relationship was tumultuous and violent, with alcohol abuse by both parties. After an incident where he assaulted his girlfriend, she denied him any contact with their daughter. When he tried to reconcile with her, it resulted in a dispute after which he murdered his girlfriend by stabbing her twice and her mother three times, with a knife.

When the last two murder cases went to court, arguments were heard at sentencing about the possibility of this person being classified as a serial murderer. These were the second and third murders committed by him. There was a clear, inner psychological motive for the crimes which seemed to stem from his interaction with females he was romantically involved with. There were similar features between the first and second incidents: he followed the same *modus operandi* in the execution of the crimes, the victims were adult females he had close associations with, in the first incident he attempted to murder people who intervened, in the second incident he successfully murdered the mother. While serial murderers tend to prefer strangers as victims, there are numerous cases where people known to him fell victim to the murderer.

Intimate Partner Murder, Serial Murder, South Africa

I41 A South African Case Study Illustrating an Intimate Partner Murder Staged as a "Muti" (Ritual) Murder

Elmarie A. Myburgh, BA, South African Police Services, 255 Schoeman Street, Pretoria, SOUTH AFRICA; Susanna M. Knoetze*, South African Police Services, Investigative Psychology Unit, Criminal Records and Crime Scene Management, Head Office, Pretoria, SOUTH AFRICA; and Marina Genis, MA*, Unit 149, 21 Sunset Avenue, Pineslopes, Lonehill, Ext 71, SOUTH AFRICA*

After attending this presentation, attendees will have an understanding of intimate partner murder and muti murder and how it can be established whether an intimate partner murder scene was staged to look like a different crime.

This presentation will impact the forensic science community by showing how law enforcement officers, psychologists, and profilers will have a better understanding of intimate partner murders, muti murders, and staging of a crime scene.

Intimate partner murders are often referred to as domestic murders or spousal homicide. This occurs when one person is murdered by their current, or ex-, intimate or romantic partner. Motives for such crimes typically include an element of jealousy, which may be due to real or feared abandonment by the victim. While some such perpetrators have a history of physical abuse towards their partner, a significant number of offenders have no history of violence towards their partners, and often there is no escalation of violence preceding the murder.

A crime scene can be staged by an offender in an attempt to delay the identification of the body and to delay the investigation. Staging a crime scene is a high-risk behavior, because it implies that the offender is spending more time than is necessary with the body and thus risks discovery. While the offender makes these changes, he is revealing a lot about himself and is likely to provide investigators with more evidence than he is aware of, because he may be under great stress. Comparing injuries to the crime committed, or comparing the scene and forensic reports to witness statements, can help indicate staging.

The word "muti" is a Zulu word meaning medicine. Muti murder happens when human body parts are gathered for use in traditional African medicine and the person dies as a result of the wounds inflicted. The motivation for the use of muti is usually to improve an individual's or community's circumstances. The reason for using human body parts is that they are considered to be more powerful than the usual ingredients like roots, herbs, other plant material, animal parts, and seawater. Characteristically the traditional healer would consult the ancestors to determine the cause of the problem and then prescribe the treatment. The death of the individual is usually secondary to the injuries inflicted while

removing the body parts. The victim must be alive when the body parts are removed as this is believed to increases the power of the muti.

The following case study will be presented to illustrate how one person committed an intimate partner murder, and staged the crime scene to look like a muti murder.

Early one morning the naked body of an adult black female was discovered in an open area. The body was lying on its back and the head, breasts, and external parts of the vagina had been removed postmortem. There were bullet wounds in the torso and left forearm. The victim's clothes were not on the scene. It was clear that the body recovery site was a secondary crime scene. Since the hands of the victim were intact, her fingerprints were taken to establish her identity. The home of the deceased was inspected and the missing body parts were found in the bathroom. When her boyfriend was interviewed he confessed that they had a fight the previous night, during which she ended their relationship. He shot her and removed the body parts in an attempt to stage it as a muti murder.

Intimate Partner Murder, Staging, Muti Murder

I42 The Influence of Personality Traits on Intrafamilial Homicide

Rakel Rozant, MA, Maltepe University, Institute of Social Sciences, Psychology Program, Istanbul, TURKEY; Irem Akduman, PhD, Maltepe University, Department of Psychology, Istanbul, TURKEY; Ersi Abaci-Kalfoglou, PhD, Yeni Yuzyil University, Yilanliayazma Cd., No.26 Cevizlibag, Istanbul, TURKEY; S. Sebnem Ozcan, PhD, and Gavril Petridis, PhD, Yeni Yuzyil University, Faculty of Health Sciences, Cevizlibag, Istanbul, 34098, TURKEY; E. Hulya Yukseloglu, PhD, Istanbul University, Institute of Forensic Sciences, Cerrahpasa, Fatih, Istanbul, TURKEY; and Gokhan Oral, MD, Istanbul University, Cerrahpasa Faculty of Medicine, Department of Legal Medicine, Cerrahpasa, Istanbul, TURKEY*

After attending this presentation, attendees will learn whether the personality characteristics affect the homicide offenders or not, whether sociodemographic and criminological characteristics are related to the homicides, and which personality characteristics might be specific to the offenders of intrafamilial homicides.

This presentation will impact the forensic science community by figuring out the dominant behavioral traits in perpetrators committing intrafamilial homicides.

Several researchers have taken an interest in personal characteristics that may have influence on criminal activities. These studies are of great importance in terms of figuring out which behavioral traits are dominant in perpetrators committing the same crimes in different ways since there might be some differences in the personality traits of intrafamilial and other homicide offenders. Homicide in the family is the most severe type of murder. Personality disorders, cultural differences, and economic issues are some of the risk factors in partner homicides. The aim of this research is to compare the personal characteristics of the intrafamilial and other homicide offenders. The Minnesota Multiphasic Personality Inventory (MMPI) was performed in 93 voluntary male prisoners in Maltepe-Istanbul, accused of or sentenced for murder between 2000 and 2010. Personality traits of the perpetrators were grouped as dependent variants. Independent variants such as sociodemographic (educational background, economic conditions, etc) and criminological characteristics (offensive weapon types, crime scenes, and the causes of murder) were also analyzed via personal information forms filled by volunteers. Intrafamilial homicides were 32.3%, whereas other homicides were 67.7%. The results pointed out that 70% of the intrafamilial homicide offenders were over 36-years-old, whereas 73% of the other homicide offenders were younger than 35-years-old. When the birth places of the offenders were checked, a clear and expressive increase from Western to the Eastern part of Turkey was seen only in the intrafamilial homicide offenders, which might be directly related to sociodemographic and sociocultural characteristics of the region. When MMPI subtests were assessed, the highest score was obtained in schizophrenia (Sc) and the lowest score was obtained in paranoia for both of the offenders of intrafamilial and other homicides. The difference between the arithmetic mean of intrafamilial homicide offenders and the arithmetic mean of other homicide offenders was statistically significant only in psychopathic deviate (Pd) and social introversion (Si). Although there are some research-related limitations such as the specificity of the behaviors, variety of crimes and the closed environment, this study is expected to facilitate further comprehensive research in the field.

Intrafamilial Homicide, Personality Traits, Turkey

J1 A Study on Discrimination Methods of Black Ballpoint Pen Ink Lines on Paper

Mi-Jung Choi, Chungnam National University, 305-764, Daejeon, KOREA; Chang-Seong Kim*, Chungnam National University, 220 Kungdong, Yeousung, Daejeon, KOREA; Yale Shik Sun, PhD*, Hazard Evaluation Center, Korea Testing & Research Institute, Gyunggi-Do, Gimpo, 415-871, KOREA; and Sung-Woo Park, PhD*, Chungnam National University, 305-764, Daejeon, KOREA*

The goal of this presentation is to compare ink discrimination methods UV light by VIS spectrum, thin layer chromatography (TLC), and high pressure liquid chromatography – electrospray tandem mass spectrometry (HPLC-ESI-MS).

This presentation will impact the forensic science community by making a comparison of different ink discrimination methods using UV light by VIS spectrum, TLC, and HPLC-ES as well as detailing how these methods can provide methodology, classification, and identification of ballpoint ink lines.

In forensic examinations of question documents, analyses of ink components and the dating of ink entries are often of considerable importance. Forensic ink examinations are principally concerned with the classification and comparison of complex chemical mixtures. The inks on a questioned document may be examined through analyses that include spectral examination, thin layer chromatography (TLC), high pressure liquid chromatography/mass spectrometry (HPLC/MS), and gas chromatograph/mass spectrometry (GC/MS). Fifty-six different types of black ballpoint pens manufactured from five country groups were collected. Experimental sampling was conducted by extracting samples from ink lines produced on white copy paper. The goal of this work is to investigate the degradation pathways of ballpoint ink dyes using UV light irradiation, TLC, and HPLC-ESI/MS. To study the effects of aging, the fifty-six ink samples on paper were created and stored with varying elapsed-time periods of one, two, and three years. As ink age determination is highly dependent on the composition of the ink and storage conditions of the document, two variables usually unknown in forensic document examination, the study samples were kept in darkness to simulate natural aging and to minimize variance in exposure to UV irradiation.

Individual characteristic data was identified among all of the fifty-six different types of black ballpoint pen ink samples on paper using the Infrared luminescence, ultraviolet light features, TLC, HPLC-ESI/MS, and GC/MS. Ink samples were first totally dissolved in methanol. Ink component reactions were observed and recorded using light radiation and filter pair sets in five groupings of (① 580nm, 420nm; ② 580nm, 550nm, 420nm; ③ 550nm, 580nm, 660nm, 380nm; ④ 580nm; and ⑤ 580nm, 550nm.) A mobile phase system for TLC analysis was conducted using n-butanol: ethanol: water: acetic acid at ratios of 6: 1: 2: 0.05, which were effective in separating nearly all dye mixture samples. In this system, the spot capacity more than 21 was achieved. Dyes of black ballpoint ink lines were analyzed using HPLC-ESI/MS and completely detected 15 samples of which the ten violet dyes indentified were: ① crystal violet (CV, Hexamethyl pararosaniline); ② CV-CH2 (Pentamethyl pararosaniline; ③ CV-2CH2 (Tetramethyl pararosaniline); ④ CV-3CH2 (Trimethyl pararosaniline); ⑤ CV-4CH2 (Dimethyl pararosaniline; ⑥ CV+OH-2CH2 (Tetrahydroxy methyl pararosaniline); ⑦ DLPM-3CH2(bis(4-(dimethylamino)phenyl)methanone; ⑧ DLPM-CH2; ⑨ DLPM+OH-2CH2; and ⑩ basic violet 14 and basic yellow 33, basic yellow 2 of yellow dye, basic blue 26, basic blue 9 of blue dye, and Megawhite PL of fluorescence. The results of this study indicated that analysis of UV-VIS spectrum, TLC and HPLC-ESI/MS could make a discriminating tool of ballpoint inks dye for forensic purposes and can supply methodology for the classification and identification of ballpoints pen ink lines.

The absorption maximum of the spectral bands shifts hypsochromically from 580 to 560nm with UV irradiation. This hypsochromic shift (blue shift) of crystal violet absorption band is presumed to result from the formation of series of N-demethylated intermediates in a stepwise manner. Aging curves for the N-demethylated intermediates of crystal violet and equations from elapsed time and UV irradiation samples were identified. Crystal violet (hexamethyl pararosalinine) was transformed to its decomposition product pentamethyl pararosalinine by demethylation. Pentamethyl pararosalinine is transformed to tetramethyl pararosalinine and latter to trimethyl pararosalinine. UV accelerated aging mimics natural aging from a dye perspective and can be characterized by UV-Vis spectrum and HPLC-ESI/MS. Irradiation for 1.6h produces the same extent of degradation as what occurs naturally over a period of one year. The relative abundance of the intact dye molecule (m/z 372) decreases as the relative abundances of the degradation products (m/z 358, 344) increase with irradiation time.

Question Document, Black Ballpoint Pen Ink, Discrimination

J2 Study on the Dye Components of Black Gel Pen Inks by HPLC-Tandem/MS

Chang-Seong Kim, Chungnam National University, 220, Kungdong, Yeousung,, Daejeon, KOREA; Yale Shik Sun, PhD*, Hazard Evaluation Center, Korea Testing & Research Institute, Gyunggi-Do, Gimpo, 415-871, KOREA; and Mi-Jung Choi*, and Sung-Woo Park, PhD*, Chungnam National University, 305-764, Daejeon, KOREA*

After attending this presentation, attendees will learn about black gel pen discrimination methods.

This presentation will impact the forensic science community by identifying the dye components in black gel pen ink using high pressure liquid chromatography- tandem/mass spectrometry (HPLC-Tandem/MS).

In order to determine and identify the dye components in black gel pen ink, sixteen black gel pen inks produced from three different countries (Korea, Japan, and Germany) using an HPLC-Tandem/MS were analyzed. Nine different dyes at varying compositions within the sample inks were detected. The dye types included: methyl violet B base (MVB), crystal violet (CV), methyl violet (MV), acid orange 10 (AO10), sudan black B (SBB), victoria pure blue BO (VPBBO), patent blue VF (PBVF), acid red 52 (AR52), and aniline blue diammonium salt (ABDS). Among the dyes, CV, AO10, SBB, and VPBBO were found in all inks, while the other dyes were differentially observed. MV was detected in samples 6-8 (Korea), 11 and 14 (Japan); ABDS was detected in samples 1-3 (Korea) and 11 (Japan); and AR52 was detected in samples 1 (Korea) and 12 (Japan). PBVF was only detected in the Japanese ink sample 13.

Sample inks were divided into five groups by statistical analysis. Group 1: GP1, GP2, GP3 (Dong-A, Korea), and GP11 (Pental, Japan); Group 2: GP4 (Dong-A, Korea), GP5, GP9 (Monami, Korea), and GP10 (Japan); Group 3: GP6, GP7, GP8 (Monami, Korea), GP14 (Sakura, Japan), GP15, and GP16 (Germany); Group 4: GP13 (Zebra, Japan); and Group 5: GP12 (Pental, Japan).

An accelerated weathering test was performed with the black gel pens and the dye components of black gel pen ink were analyzed using HPLC-Tandem/MS (Table 23). The MVB and CV dyes in sample 1, 2, 3, 4, 5, 6,

and 7 were significantly decreased by UV light in a time-dependent manner. After one hour UV of light treatment, MLB dye detected 6.476 µg/kg at sample 1, 3.85 µg/kg at sample 2, 4.461 µg/kg at sample 3, 7.113 µg/kg at sample 4 and 10.547 µg/kg at sample 5. After seven hours UV light treatment, MLB dye detected 2.924 µg/kg at sample 1, 2.149 µg/kg at sample 2, 2.601 µg/kg at sample 3, 4.855 µg/kg at sample 4 and 3.652 µg/kg at sample 5. After one hour UV of treatment, CV dye detected 3.572 µg/kg at sample 1, 3.51 µg/kg at sample 2, 2.488 µg/kg at sample 3, 1.794 µg/kg at sample 4 and 2.479 µg/kg at sample 5. After seven hours of UV treatment, CV dye detected 2.803 µg/kg at sample 1, 1.15 µg/kg at sample 2, 1.224 µg/kg at sample 3, 1.09 µg/kg at sample 4, and 0.915 µg/kg at sample 5. The increased detection of several dyes following the weathering test might be caused by the degradation of some dyes into shared components or could be due to the sample pretreatment process for the HPLC-Tandem/MS trace-level analysis.

In this report, it was established an HPLC-Tandem/MS method for simultaneous determination of the dye components in black gel pen ink, and showed that black gel pen inks produced from three different countries contained common as well as unique dyes. It was also demonstrated that MVB and CV dye contents were significantly reduced by UV light. Based on the data described here, it may be possible to classify the manufacturing origin of black gel pens based on the ink dye components and provide a scientific foundation for dating of documents written with ink from black gel pens.

Question Document, Black Gel Pen Ink, HPLC-Tandem/MS

J3 Studies in Ink Analysis and Line Crossing

Gary H. Naisbitt, PhD, Elizabeth Purser, and Logan Bodily, Utah Valley University, Forensic Science Program, 800 West University Parkway, Orem, UT 84058*

After attending this presentation, attendees will be presented with an example of creating and validating a new analytical capability in their laboratory.

This presentation will impact the forensic science community by presenting an example on determining the suitability of different techniques for ink analysis and line crossing; and validating that analytical capability in their laboratory.

Ink identification and the order of ink layer deposition when lines cross are important determinations confronting questioned document examiners. Before performing case work, individual laboratories need to determine their own capability with the instrumentation on hand, validate analytical protocols, and write standard operating procedures. The results of this study will be used as a guideline for ink analysis in Utah Valley University lab.

A selection of conventional ballpoint and gel pens were purchased from office supply stores. In general, the analytical approach of these experiments is to characterize each line by determining the visible and infrared spectra of each line using a microspectrophotometer, a FTIR microscope, and a Raman microscope. Thin layer chromatography (TLC) was used to visualize the dyes and/or pigments, and examiner impressions of visible microscopic examination of ink deposition at the point of crossing are included. Because not every ink lent itself to unique identification by every analytical technique, a rubrics is used to report the findings of useful application.

Inks of the same color are often made of different combinations of dyes and /or pigments. Although TLC destroys the sample it is useful to answer if two lines were made with the same ink. But it not useful to determine which ink is the top layer when lines cross.

Because gel inks are more fluid, they tend to penetrate paper where ballpoint inks tend to create layers on the paper's surface. Visually, gel inks produce more uniform coverage with little or no raw paper showing, whereas a significant area of uncolored raw paper remains after a line with a ballpoint pen has been written. When a ballpoint line crosses on top of a gel ink line, only a small amount of randomly deposited ballpoint ink is deposited, resulting in a ballpoint line that lacks uniformity and edge definition. However, when the underlying line is made with a ballpoint pen, its line remains distinct and uniform when a gel ink is written over it. Although a gel ink will penetrate and color the raw paper left by the ballpoint ink, it will not disturb the underlying ballpoint ink. Spectral analysis in the visible region of ballpoint inks at the point of line crossing usually is the spectrum of the overlying ink. Inks at the point of crossing were evaluated with visual microscopy, FTIR, and Raman microscopy.

Because not every technique is meaningful with every sample type or situation, a rubric was created to guide appropriate analysis based on the evidence to be examined. Analytical accuracy was determined by comparing analytical results of known sample against the known expectation and the error rate is 100% – analytical accuracy. Robustness was measured by compiling the accuracy of the analytical results of several examiners who each analyze the same samples.

Ink Analysis, Microspectrophotometry, Raman Microspectrometry

J4 Differentiation of Document Paper Based on Elemental Profiles Using Inductively Coupled Plasma-Mass Spectrometry, Inductively Coupled Plasma-Optical Emission Spectroscopy, and Multivariate Statistical Procedures

Emily G. Riddell, BS, 560 Baker Hall, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand how trace elements can be used to differentiate different types of document paper, such as copy paper and recycled paper. Inductively coupled plasma-mass spectrometry (ICP-MS) and inductively coupled plasma-optical emission spectroscopy (ICP-OES) are used to generate element profiles for different paper types from the same manufacturer. A combination of statistical procedures, including analysis of variance (ANOVA) and principal components analysis (PCA), are then used to differentiate the paper by type based on the trace elements present.

This presentation will impact the forensic science community by generating element profiles for different paper types. These profiles potentially offer greater discriminatory information than the physical and chemical methods currently used in paper analysis. Demonstration of the statistical procedures will provide an objective method that can be implemented in forensic laboratories for the analysis of questioned documents.

Paper analysis typically relies on comparing physical characteristics of the paper such as color, thickness, and brightness. However, due to improvements in the production process, these physical characteristics do not necessarily allow differentiation of paper. As a result, alternative methods for analyzing and comparing paper samples are necessary.

Trace elements present in paper originate from impurities in the raw materials, as well as from processes used during paper production. These elements may provide greater discrimination of paper by both type and production plant. However, due to the low levels of these elements, sensitive instrumental techniques are necessary for the analysis.

Preliminary research conducted demonstrated the potential of differentiating two different paper types based on element profiles generated using ICP-MS. However, the instrumentation is very expensive and analysis using this technique involves high running costs. Inductively coupled plasma-optical emission spectroscopy (ICP-OES) may be a viable alternative to ICP-MS for this purpose. In this research, element profiles for a larger number of different paper types will be obtained using both ICP-MS and ICP-OES and multivariate statistical procedures will be used to

assess discrimination of paper according to type based on the elements present. Results will be used to assess the potential of ICP-OES compared to ICP-MS for this purpose.

In this research, two reams each of five different types of paper produced by the same manufacturer were purchased. Paper samples were microwave-digested using nitric acid and hydrogen peroxide prior to instrumental analysis. A subset of samples, representative of all paper types, was initially analyzed using ICP-MS in full scan mode to identify potentially characteristic elements for each paper type. Such elements were those that: (1) were present at levels above the instrument limit of detection; (2) were not present at significant levels in the procedural blank; and, (3) did not vary significantly in concentration within a ream of paper. The full sample set was then analyzed by ICP-MS using the selected ion monitoring mode and quantifying the elements of interest. Samples were then analyzed by ICP-OES, quantifying the same elements.

The resulting element concentrations were normalized according to the initial mass of paper digested, and separated into two data sets: the first contained element concentrations determined by ICP-MS and the second contained element concentrations determined by ICP-OES. Analysis of variance (ANOVA) was performed on each data set separately to assess variation of each element within a ream, between reams of the same paper type, and between reams of different paper types.

Each data set was then subjected to principal components analysis (PCA), which is a multivariate statistical procedure used to identify sources of variance within a data set. The PCA scores plot is a scatter plot in which chemically similar samples are grouped, with distinction from samples that are chemically different. The PCA loadings plots can be used to identify the variables contributing most to the variance in the data set. In this research, the scores plots were used to assess association of reams of the same paper type, with discrimination of different types, based on the element profiles. The loadings plots were used to identify those elements that were responsible for the association and discrimination observed. Both scores plots were also assessed to determine if one technique, ICP-MS or ICP-OES, offered improved discrimination of the paper types based on elemental profiles.

Questioned Documents, Trace Elements, Spectroscopic Techniques

J5 The Examination of Suspected Artificially Aged Paper

Gerald M. LaPorte, MSFS, National Institute of Justice, Investigation & Forensic Science Division, 810 Seventh Street, NW, Washington, DC 20531; and Kirsten A. Singer, MFS*, Department of Veterans Affairs, Office of Investigation, 51L, 801 Eye Street, NW, Washington, DC 20001*

After attending this presentation, attendees will be able to provide information regarding the application of commonly used methods to artificially age paper and apply physical, optical, and chemical techniques that may be used to distinguish the differences.

This presentation will impact the forensic science community by informing examiners of some of the characteristics that indicate that paper has been artificially aged. This kind of examination may be infrequent for some laboratories; therefore, this presentation will provide visual examples, methods to apply in an examination, and suggested conclusions.

The artificial aging of paper is a popular activity among hobbyists and specialty paper-makers who seek to reproduce the appearance of genuinely antiqued paper, and the plethora of craft books and websites that provide methods that can be easily applied at home attest to its popularity. These same, easy-to-use methods; however, are also employed by those who seek to create fraudulent documents that appear to have been produced from another time.

Determining the purported age of a questioned document is among the myriad examinations that can be conducted by a forensic document examiner. These examinations include establishing the introduction dates of various writing inks and machine printing processes, such as ball point pen, typewriting and inkjet printing that may be present on the document in question, and whether the introduction dates comport with the alleged date of the document's production. Other dating determinations can be made by examining the actual paper for coded watermarks or whether the constituents of the paper's composition were available on its purported date. Numerous forensic texts and published articles have described many of these kinds of examinations for decades. Understanding the natural causes of paper aging and deterioration, and how to better preserve paper and books, has been an ongoing topic of study by conservationists for years. The focus of this study; however, is on a less-studied, specific aspect of dating determination - the appearance of the paper itself and the more common, widely-available methods that are used to artificially age paper for fraudulent purposes.

The natural paper aging process tends to produce observable, readily identifiable characteristics that significantly differ from the effects created through artificial paper aging. The current study employed some of the most common methods used to artificially age paper, such as soaking paper in coffee or tea, or applying lemon juice or milk prior to baking the paper in an oven. Other methods used may include intentional burn marks or man-made holes added to paper to simulate other artifacts of natural paper aging. Naturally-aged paper that is at least 60-years-old was compared to paper that has been artificially aged for purposes of this study, as well as paper that was suspected of artificial aging for fraudulent purposes from actual cases. Appropriate physical, optical, and chemical techniques that may be used to distinguish the differences between genuine and artificial aging features, such as paper texture, discoloration patterns, and ultraviolet properties will be described.

Following a comparison of the paper properties of genuine and artificial aging, recommendations will be provided regarding which physical properties a forensic document examiner can recognize or identify that would lead to definitive conclusions versus which features can be combined, or may be less reliable for aging purposes, but may nevertheless indicate that artificial aging has been attempted. The possibility for making errors in conclusions, and misinterpreting observations will also be discussed.

The findings of other research projects that address the long-term natural paper aging and accelerated paper aging studies, such as the American Standards and Testing Materials (ASTM) Paper Aging Research Program, as well as studies conducted by the Library of Congress will also be included.

Artificial, Paper, Aging

J6 The Challenges of Examining Liquid Soaked Documents

Carl R. McClary, BA, 2600 Century Parkway, Suite 410, Atlanta, GA 30345*

After attending this presentation, attendees will be aware of the challenges when handling, examining, and preserving documents that have been liquid soaked or previously liquid soaked.

This presentation will impact the forensic science community by providing useful information on the challenges in handling liquid soaked documents or rehydrating liquid soaked documents that have dried in an unusable state.

There are numerous conditions in which a disputed document may be found and the impact that these may have on an examination requires that they each must be dealt with individually. This presentation will offer a glimpse into the limitations, but ultimate success, of one case in which a previously soaked document was reconstructed and examined. Liquid soaked documents for the purposes of this presentation are not only those that are still in a wet or in a damp condition, but are also those that have been previously wetted and then dried. In either case, the document examiner must be knowledgeable of how to properly preserve and record the evidence for an optimal examination.

In this particular case, the document in question was originally an 8.5"

X 11" ruled paper bearing hand printing and drawings. It was folded numerous times and then left out in a harsh Northern environment for approximately a year. Upon initial examination it was thought that unfolding and reconstruction of the evidence might not be successful due to the number of folds and its extremely dry condition. At best, it was thought that only portions might be reconstructed. The current ASTM standard, Standard Guide for the Preservation of Liquid Soaked Documents, ASTM E2711-11, advocates the use of submersion, using an appropriate liquid. Among other equipment, atomizers, trays, and pliable screening are also suggested. As is also the case with charred documents, other publications in the field have advised the application of a glycerin and water mixture to the evidence to facilitate the preservation process. In this instance, a 10% glycerin and water mixture was prepared and an atomizing process was begun. After placing the item in a glass dish, the mixture was slowly and lightly applied to both sides of the folded mass. The examiner then allowed the mixture to fully soak into the document before attempting any sheet separation. A plastic wrap was placed over the dish to prevent drying and approximately an hour later the unfolding process began. Using tweezers, each layer was carefully unfolded, taking care to visualize paper edges and avoid tearing at folds. With a multifold document, this process was challenging, but with a repeat of the atomizing process over several days, the document was successfully recreated, save for two portions in the middle section.

The permanent conservation of the final product is crucial in these types of cases and the proper assessment of the item at hand and the appropriate use of an atomized mixture and drying substrate is important to this process. To finalize the examination, glass plates provide the necessary viewing and yet firm substrate for the rest of the forensic and legal processes to follow. In order to prevent the plates from slipping and causing possible damaging movement of the document, the edges are taped. Attendees will learn how to successfully approach and perform these stages of preservation and also to apply them in similar types of cases to include charred evidence.

Liquid Soaked Documents, Questioned Documents, Preservation

J7 Current Bank Check Scanning Practices

Jane A. Lewis, MFS, 544 East Ogden Avenue, Suite 700-289, Milwaukee, WI 53202*

After attending this presentation, attendees will learn about the history of the law regarding check clearing for the Twenty-First Century, also known as Check 21. The examination of images of checks with current bank check scanning practices will be described. Implications of scanned low resolution versus higher resolution images of checks as they relate to forensic document examination will be presented.

This presentation will impact the forensic science community by presenting information about the existing bank check scanning practices. Attendees will be made aware of the resolution and image types used by banks to scan and save images of checks.

According to ASTM Standard Guide for Examination of Handwritten Items – E2290-07a, 7.5.1, *if the original is not submitted, evaluate the quality of the best available reproduction to determine whether the significant details of the writing have been reproduced with sufficient clarity for comparison purposes and proceed to the extent possible. If the writing has not been reproduced with sufficient clarity for comparison purposes, discontinue these procedures and report accordingly.*

Low resolution (200dpi or less) images do not reproduce significant details necessary for a proper examination by a forensic document examiner. ASTM E2290-07a describes the potential significant handwriting features considered by forensic document examiners. *Note 6 - Amoung the features to be considered are elements of the writing such as abbreviation; alignment; arrangement; formatting; and positioning; capitalization; connectedness; and disconnectedness. Cross strokes and dots, diacritics and punctuation; direction of strokes; disguise; embellishments; formation; freedom of execution; handedness; legibility; line quality; method of production; pen hold and pen position; overall pressure and patterns of pressure emphasis; proportion; simplification; size; skill; slant or slope; spacing; speed; initial, connecting, and terminal strokes; system; tremor; type of writing; and range of variation are other forms of handwriting features considered by forensic document examiners.*

Forensic document examiners in the United States, Canada, Australia, and Europe were asked to contact their banks to ask five questions:

1. What resolution are checks scanned at your bank?
2. Is the image type black and white or grayscale?
3. Are the images saved as jpegs or tiffs?
4. What is the make and model of the scanner?
5. What is the name of your bank?

Results were analyzed to determine the current bank practices for scanning checks since implementation of Check 21 in 2004.

The most common scanning resolution in the banking industry is 200 dpi. Banks most often save images in black and white rather than grayscale. Files of check images were saved as either jpeg or tiff formats.

A case study example of a sample check scanned at 100 dpi, 200 dpi, 300 dpi, and 800 dpi will be presented. Forensic document examiners benefit from the best quality images of questioned checks. The better the resolution, the more handwriting details are available for examination. Images with resolution of 300dpi are superior to the current bank scanning resolution of 200 dpi.

It is recommended that the banking industry consider adopting a standard of scanning checks at 300 dpi or higher resolution. Forensic document will appreciate the current state of bank check scanning practices in the United States and internationally.

Document Examination, Scanning, Checks

J8 Determining Reliability and Frequency of Trough Pattern in Gel Ink Pens

Kesha T. White, BS, Florida Department of Law Enforcement, 1301 North Palafox Street, Pensacola, FL 32501*

After attending this presentation, attendees will understand the frequency of trough patterns in blue and black gel ink pens, their reliability, and value as a physical characteristic when influenced by various substrates.

This presentation will impact the forensic science community by providing further knowledge to the Forensic Document Examiner (FDE), by enhancing their non-destructive examination techniques in casework where the determination and differentiation of a writing instrument is vital.

To become a FDE, a two year minimum training program must be completed under the tutelage of a trained FDE. The training program includes a multitude of tasks that must be successfully mastered. One of those tasks is the ability to classify the type of writing instrument used in the preparation of a document; for example, a ball point pen from a roller ball pen or a roller ball pen from a gel ink pen.

When examining the earliest gel pen lines, an acceptable assumption (at initial inspection) was that a visible trough in the ink line was indicative of a gel pen being used. The term "trough" is described as a "long narrow or shallow channel" according to the dictionary. Over the course of numerous examinations, it was discovered that this visual identification is not always reliable. Some gel ink pens do not demonstrate a trough pattern. Consequently, research had to be conducted to determine the reliability and frequency of trough patterns produced by gel ink pens.

In forensic document examination, both destructive and non-destructive techniques can be used to determine and differentiate writing instruments and inks. For the purpose of this research, only non-destructive techniques were utilized. Eighteen gel ink samples were handwritten on three types of substrates using multiple brands of blue and black gel pens. After careful examination of the samples, the trough observations were documented and divided into four categories based on trough presence.

These categories were: no trough observed, trough observed some of the time, trough observed most of the time, and trough observed all of the time. The observations from all three substrates were used to calculate the trough frequencies. In addition to observing how the substrate may have influenced the trough pattern, the gel pen brand and ink color were considered and the frequency was calculated as well.

An analysis of the results determined that the substrate influenced the presence of a trough pattern, and that a trough pattern was unreliable as the only physical feature to differentiate gel ink pens from other types of writing instruments. Therefore, it is recommended that trough patterns, only in conjunction with other physical characteristics, be used to successfully classify gel ink pens.

Frequency, Trough, Gel

J9 Hidden Data: A Barcode Primer With Casework Examples

Elaine Wooton, MFS, Office of Investigations Forensic Document Laboratory, Stop 5116, 8000 Westpark Drive, Suite 200, McLean, VA 20598-5116; and Jordan C. Brough, MFS*, 5501 Seminary Road, Apartment 208, Falls Church, VA 22041*

After attending this presentation, attendees will be able to understand the history, use, and examination of 1D and 2D barcodes, and will have a foundation upon which to develop their competency in assessing and deciphering barcodes.

This presentation will impact the forensic science community by providing a broader, updated understanding of the current usage of barcodes in which examiners may encounter.

Upon initial consideration, the barcode (in its various forms) is a printed element used for automatic identification and data capture (AIDC). It would be perfectly natural for a Questioned Document Examiner (QDE) to shy away from all but a perfunctory comparison of size and format. Unfortunately, there is no technical profession that specializes in deciphering barcodes. That the task will fall to the QDE is evident in the incorporation of barcode reading software in the newest versions of equipment marketed to forensic labs. A certain level of competence regarding barcodes will be necessary for an examiner to properly assess, document, and present the physical features and data of a barcode. That competence must include an understanding of the history of barcodes, the types of barcodes and their various applications, technical limitations in their assessment, and an understanding of the types of data that may be revealed.

The history of the barcode is a long one. The first documented consideration was in the late 1940s. Their first use was in tracking train cars (clearly a limited application). However, it was not until the mid-1970s that the grocery industry began to see the possible cost savings of scanning products and put out a request for proposals to a variety of technology companies. As late as 1980, the implementation of "UPC" barcodes for food stores was seen as a failure. Albeit at a crawl, the technology moved into more and more stores, and then eventually spread to other industries. The military began to require that all purchases contain a barcode ("Code 39"). The U.S. passport application system generates a barcode that summarizes the form data, as do some medical records. The creation of the tech-savvy Japanese marketplace, the "QR code" is now seen on coupons and products throughout the U.S.

Today, there is a great variety of barcodes. The simple "1D" barcodes hold a small amount of data in a simple to read format; for experienced users, some can be deciphered at a glance. These barcodes may be used to impart only a small amount of information, or they can be used to access information in a centralized system. The more advanced "2D" barcodes can hold far, far more information. The most common of these, the PDF-417, is based on an international standard and a correctly encoded PDF-417 can be read by any standard reader (or by a scan/software solution). Efforts to encrypt the PDF-417 for identification documents have had limited success because this solution requires that all verifiers obtain equipment for decryption.

The QDE may encounter barcodes on a variety of documents: state driver licenses, state insurance documents, applications (the information is summarized in a barcode), passports, commercial and industrial products, and countless others. Both the simple and more advanced barcodes typically hold data. While some barcodes serve as pointers to information in a central system, the majority hold the actual data. In the case of travel and identity documents, and certainly medical records and other forms, comparing the data in the barcode to the text on the document immediately reveals if there is a difference.

The first limitation a QDE may encounter with a barcode is access to equipment to decipher the entire barcode. The "readers" used for point of sale (POS) acceptance of documents and by some law enforcement entities extracts the "important data" and presents it in a summary form. More data is often present and may be revealed (and made useful) given the use of a decoding system. The assessment of barcodes is also limited by the lack of information regarding methods for incorporating non-encryption based enhancements and/or security elements. This limitation must be addressed on a case-by-case basis through contact with the issuing authorities for the genuine documents. Unfortunately, there is often a very small group of individuals who have this information and they are difficult to find.

At the FDL, it was determined that counterfeiters are making readable barcodes and including them on counterfeit documents. This is unfortunate because at POS locations, clerks often rely on the scan to verify the document, and never actually look for any of the security features. The barcodes produced by the counterfeiters include the name/address/date of birth in readable form. Fortunately, they also contain data that can help lead investigators to their source. To date, there have been a limited number of cases at the FDL in which barcodes played a significant role. A summary of those cases will be presented.

Although barcodes are not new, their role in the examination of documents is. Given the potential for identifying altered or wholly fabricated information on a document, passing them off as a "data element" and hoping that another technically-trained individual will handle them is no longer appropriate.

Currently, most questioned document examiners are not assessing barcodes when they are present on suspect documents. Both the physical features and the deciphered data of a barcode must be considered in order to provide a full assessment of a document. By developing competence regarding barcodes, QDEs will be better able to identify evidence of alterations, counterfeiting and unauthorized production.

Questioned Documents, Barcodes, Data

J10 Frequency of Occurrence in Handwriting and Hand Printing Characteristics — Research Methodology

Thomas W. Vastrick, BS, 380 South State Road 434, Suite 1004-132, Altamonte Springs, FL 32714-3866*

After attending this presentation, attendees will have a better understanding of how to apply various scientific principles to research so as to achieve maximum validation of any research efforts.

This presentation will impact the forensic science community by instructing and enforcing the need for the use of proper research methods.

Research is the backbone of any science. People often hear the word "exact science" thrown around in courts and elsewhere, but the cold, hard, fact is there is no such thing as an exact science, as that would necessitate a body of knowledge that never changes or advances. For any science to maintain their integrity and legitimacy, the profession must proactively seek to advance – whether through use of new technologies, new methods, or the

reconsideration of established practices under the beneficial eyes of further experience.

Leading the way are those of the profession that take the time to conduct research. One can look at any journal, scientific magazine, or various organizational websites to see that there are countless meetings in every corner of the world providing presentations of work from professionals.

But how much of this work is truly research that will impact the advancement of the science? Yes, there is room for "I had a case," and "Let me show you a really neat new gadget," but advancement requires committed time and study into areas and thoughts that may be new and unexplored. It can require imagination that is out of the ordinary. One thing is for sure: effective research requires proper planning as to the methodology used. Is the method a valid method? Is the method the most valid method? What are the weaknesses and strengths of the method? Can the limitations be quantified in any way? Are there experts in other areas, such as statisticians, that can help in the validation process?

In January 2011, a large-scale, two-year research project was initiated. One of the goals of this study was to utilize the most valid methods. In so doing, subject matter experts were utilized in order to insure that proper methods were indeed being used. It is the purpose of this presentation to walk attendees through the development of the methods used in this study. One of the first issues was determining how many specimens would be needed to provide an adequate sampling of the population in the United States. Numerous questions arose in dealing with this issue. For example, what criteria were used to determine adequate numbers? Should a random selection process be used or some other method? Is there more than one method that would be considered statistically valid? Is there a good-better-best of the valid methods? What are the criteria that needs to be addressed in order to obtain the best sampling, if not random? What authorities and standards apply to this problem?

Another issue addressed was what features within handwriting would be utilized in the study. Again there were numerous concerns that affected the product of this portion of the study. One of the concerns was whether the cataloguing of each characteristic would be reproducible. To deal with this problem, features were initially listed that were thought to be objective in nature. For example, whether a certain stroke curved clockwise, curved counterclockwise, or was relatively straight would be used. Whether a stroke was long or short was not used, as it was thought that this kind of feature was too subjective. Next the selected features were put through a pilot test by having attendees at the 2011 ASQDE meeting categorize one set of specimens in order to determine whether any of the characteristics displayed an unacceptable level of non-reproducibility. These were but a few of the issues that had to be addressed in order to maximize the value and integrity of this study. The presentation will detail these issues and how they were addressed.

Research, Statistics, Principles

J11 Portable Document Format (PDF) Technology in 2011

Joseph L. Parker, MSA, 518 Pinegate Road, Peachtree City, GA 30269*

After attending this presentation, attendees will have a greater understanding of "Portable Document Format" (PDF) digital file technology in 2011, to include PDF history, basic PDF file structure, PDF technical applications, PDF file security, worldwide PDF use, and PDF technical features that forensic document examiner should consider when examining many contemporary questioned documents, particularly when related PDF files exist.

This presentation will impact the forensic science community by providing additional knowledge of contemporary PDF technology, specifically the potential application of PDF technology software features in determining the origin(s) and production method(s) used to create PDF-related questioned documents. The increased knowledge should enhance the thoroughness, accuracy, and overall efficacy of forensic document examiner during examinations of documents and materiel involving PDF technology.

Forensic document examinations most often involve disputes concerning the origin and genuineness of questioned documents. The proliferation of "Portable Document Format" (PDF) digital file technology documents today, particularly the expansion of PDF use in digital document archiving, suggests forensic document examiners will increasingly examine questioned documents that involve PDF technology. A review of PDF technology literature was performed and a summary of this information is provided. The summary includes an overview of PDF technology and related historical highpoints; a description of fundamental PDF file structure and the development of specialized PDF file subsets; developments up to the present concerning PDF document file security and related considerations; and

Adobe® Systems Inc., introduced the initial PDF technology in 1993. A chronology is given of the PDF technology significant points of evolution that followed through to today; of great significance was the adoption of PDF as an ISO standard by the International Organization for Standardization in July 2008. Also discussed are the specialized subsets of PDF files that were developed to meet the distinctive needs of respective customer groups: (1) PDF/X (2001) supports Graphic Designer/Print Professionals and Creative professionals; (2) PDF/A (since 2005) supports records managers, compliance managers, and archivists; (3) PDF/E (since 2008) supports architects, engineers, and the construction and manufacturing fields; (4) PDF/VT (since 2010) supports variable data/transactional printing (i.e., bank statements); (5) PDF/UA (begun in 2011) supports government and industry to meet disabled user needs; (6) PDF/H (since 2008) not a standard, but a best practices guide for Healthcare; (7) PAdES –standard for PDF digital signature security to meet European standards; and, (8) U3D—PDF technology supporting embedded 3D files for interactive and other 3D data. Finally, a summarization of PDF technology security considerations is related, including the recent warnings projected on an international level. Experimentation was conducted to identify PDF technology features having particular value to forensic document examiners for the examination of PDF-related questioned documents and their associated PDF files.

The initial experimentation tested whether PDF text and imaging materials could be accessed and acquired on the Internet. This initial experimentation confirmed the ease and simplicity involved in acquiring PDF materials from the Internet and further demonstrated the ease with which these items could be used to create fictitious documents. The fictitious PDF documents created, and other PDF materiels, were then tested to identify what types of information could be derived from PDF files by forensic document examiners using PDF software features readily available. The testing of these controlled/known PDF materiel identified features that forensic document examiners may employ during examinations of known/suspected PDF document files to determine the time(s), date(s) of PDF creation, and editing; method(s) employed in creating PDF documents, i.e., scanning printed documents versus software conversion of text or text and image combination files directly into PDF files; identification of various software programs used in the creation of PDF documents and sub-components; and the possibility of identifying individuals involved in creating and editing/altering PDF files and related documents. Experimentation confirmed that existing PDF software tools can be used productively for questioned document examinations by forensic document examiners operating at a "software user" level, and that it is not essential for forensic document examiners to transcend this somewhat "elementary" level of expertise in understanding PDF technology, to a deeper level of technical understanding, such as comprehending computer programming code.

PDF Files, PDF Archives, PDF Documents

J12 A Case Study of a Specialized Gang Alphabet and the Transfer of Characteristics From That Alphabet Into the Normal Daily Writing Habits of a Gang Member

Pamela Zilly, BS, and Sarah Zarnick, MSFS*, Nebraska State Patrol Crime Laboratory, 1233 Arapahoe Street, Lincoln, NE 68502*

After attending this presentation, attendees will become familiar with a specialized alphabet used in the writings of a gang claiming affiliation with the Almighty Latin Kings. Attendees will gain some background information about the Almighty Latin Kings and see examples of a transfer of habits between the gang alphabet writing and a member's normal daily writing.

This presentation will impact the forensic science community by raising awareness of forensic document examiners of a specialized alphabet and how remnants of the specialized alphabet can be displayed in the normal habitual writing of a person that often uses that alphabet.

In September 2002, three gunmen entered a Nebraska bank and, in a botched robbery attempt, shot and killed four bank employees and one customer. Four individuals were later apprehended, three suspected of being the gunmen and one suspected of being the lookout and planned getaway driver. What followed was a costly and extensive investigation and series of trials, resulting in three of the defendants being sentenced to death and the lookout receiving five life sentences.

During the investigation, it was discovered that the four individuals arrested all claimed affiliation to the Almighty Latin Kings gang. Over the course of a number of months, investigators seized numerous handwritten documents that were submitted to the Nebraska State Patrol Crime Laboratory. Among them were several that were written in an alphabet previously unseen by the document examiner working on the case. The complex letters of the alphabet were written fluidly and naturally and the writings were extensive. The alphabet was deciphered and the texts decoded; the documents were found to contain the bi-laws and various rules of the gang. Of additional interest, the document examiner observed within the extensive known writing of the lead gang member a number of natural, fluid embellishments resembling those seen in the specialized alphabet. Over the course of the investigation and trial preparation, a number of handwritten letters were sent to various witnesses, the media, and family and friends of the defendants, sent from various correctional facilities. Examination and comparison to known writing from the defendants identified many of the letters as having been written by three of the four defendants.

Although the bulk of the letters were written by three of the defendants, one letter that alluded to an additional murder taking place before the botched robbery was only partially written by one of the gunmen. That letter contained an insertion written by a different person. The insertion was the critical text about the previous murder.

This case contained a number of interesting elements including a specialized alphabet, transfer of characteristics between the specialized alphabet and the natural writing of one gang member, information about the culture and rules that controlled the gang, and a critical insertion in an incriminating letter. Some of these elements will be shared during the course of this presentation.

Specialized Alphabet, Gang Writing, Writing Characteristics

J13 Dynamics of Stroke Direction in Genuine and Simulated Signatures

Linton Mohammed, MFS, Rile, Hicks, & Mohammed, 100 Oceangate, Suite 670, Long Beach, CA 90802; Bryan Found, PhD, La Trobe University, School of Human Biosciences, Bundoora, Melbourne, Victoria 3086, AUSTRALIA; Michael Caligiuri, PhD, University of California, San Diego, Department of Psychiatry, 9500 Gilman Drive (0603), San Diego, CA 92093; and Doug Rogers, PhD, La Trobe University, Bundoora Campus, Melbourne, 3086, AUSTRALIA*

After attending this presentation, attendees will learn empirical data about the dynamics of stroke direction.

This presentation will impact the forensic science community by providing Forensic Document Examiners (FDEs) with information that can be used in real casework.

A handwriting pattern is a sequence of ballistic strokes comprised of a series of upstrokes and down strokes, which may or may not be concatenated. Forensic Document Examiners (FDEs) consider the movement, shape, and formation of upstrokes and down strokes when determining the authenticity of handwriting. Osborn (1929) noted that upward connecting strokes were significant for the comparison of movement impulses and the relative smoothness of downward strokes was indicative of genuine or fraudulent writing.

In this study, each of 60 writers provided ten genuine signatures and 15 simulations of three model signatures. The model signatures were in three styles – text-based (where all the allographs are legible); mixed-style (where two or more allographs are legible); and stylized (where no more than one allograph is legible). The signatures were collected on specimen checks, which lay on a digitizing tablet that was connected to a laptop computer running MovAlyzeR® software. The resulting database comprised 600 genuine signatures and 1350 simulations in hard copy form and in electronic form with dynamic data.

The data were processed to extract five parameters from each pen stroke: stroke duration; stroke length; stroke velocity; normalized jerk; and, average pen pressure. Kinematic data for the upstrokes and down strokes were coded on the basis of the direction of the velocity trace for a given stroke. For each writer, the average value of each of the five kinematic scores was calculated for upstrokes and down strokes for the genuine and simulated signatures yielding 240 scores for each kinematic parameter.

A mixed model analysis of variance (ANOVA) was used to test main effects of writer style (text-based, mixed, stylized) and condition (genuine and simulated). Upstroke-down stroke difference scores were calculated and t-tests were used to evaluate differences between genuine and simulated conditions for each writer group.

Results supported previous findings showing differences between upstrokes and down strokes for genuine signatures along several kinematic parameters including stroke length (19% longer for upstrokes), stroke velocity (15% higher for upstrokes), and pen pressure (14% lower for upstrokes) across writer styles. The study revealed new findings on differentiating simulated from genuine signatures based on analysis of upstroke/down stroke ratios. Specifically, it was found that the ratio for stroke length was significantly greater in simulated than genuine signatures for stylized writers, but lower in simulated signatures for text-based or mixed writers. For stroke velocity an increase was observed in the ratio (from 18% to 31% greater velocity for upstrokes) from genuine to simulated signatures for stylized writers. Lastly, it was found that stylized writers exhibited lower pen pressures for upstrokes than down strokes (11%) for simulated signatures, which was not observed for genuine signatures. For all other writer groups, consistently lower pen pressures for upstrokes than down strokes were observed for both genuine and simulated signatures. Using existing tools, FDEs can evaluate stroke length and pen pressure from known and questioned historical documents for judgments of authenticity. These findings suggest that accurate measures of stroke length and calculating the upstroke/downstroke ratio or difference can increase the scientific rigor of judgments of authenticity.

Handwriting, Dynamics, Strokes

J14 An Elemental Approach to Forensic Document Examination

Fary L. Lee, MS, Foster & Freeman, USA Incorporated, Summit Forensic Document Laboratory, PO Box 207, Eden, UT 84310; and David Tobin, Owen Lang, MFS, and Michael Zontini, BA, Foster & Freeman, USA Incorporated, 46030 Manekin Plaza, Sterling, VA 20166*

After attending this presentation, attendees will learn about the use of the Elemental Composition Comparator (ECCO) that may be applied to forensic document examination. Introduced is the theory and application of the ECCO that employs Laser Induced Breakdown Spectroscopy (LIBS) for the elemental examination of paper, banknotes, inks, metallic foils, and coins. The results of this research will be presented.

This presentation will impact the forensic science community by enhancing the understanding of the discriminating power of this methodology, as it relates to the examination of questioned documents.

The substitution of a page within a multiple page document such as a will or contract, counterfeiting of paper banknotes and coins, and associating ransom or extortion notes, have all been the focus of forensic document examination. The comparison of the elemental composition of questioned documents, determined by LIBS, can further assist the forensic document examiner in the examination of questioned documents. LIBS, also known as Laser Induced Plasma Spectroscopy (LIPS) is basically an emission spectroscopy technique where atoms and ions are primarily formed in their excited states as a result of interaction between a tightly focused laser beam and the material sample that can be used to quickly determine the elemental composition profiles of a gas, liquid, and solid samples with minimal sample preparation. This technique is based on the analysis of spectra emitted by atomic species and the excitation of those elements by creating a plasma using a low energy laser source. This technique is based on Atomic Emission Spectroscopy (AES) which can be used to determine the elemental composition of a substance. Described simply, AES is achieved by measuring the light emitted from an electronically excited atom as it drops from a high energy state to a lower energy state. LIBS has evolved quickly over the past twenty years and is experiencing exponential growth in interest and finds today a growing number of applications. The advantages of LIBS are that the technique is relatively non-destructive, requires very little sample preparation, and the spectra can be obtained instantaneously. The disadvantages of LIBS are that the limit of detection is presently only 4-10 parts per million (ppm) and the percent composition of trace elements cannot be determined to the level of accuracy required for forensic analysis. However, LIBS can be used as a quick test when specific elements can be used to identify a sample.

ECCO uses this analytical technique called LIBS. LIBS, as previously stated is an atomic emission technique that determines which elements are present in the target sample. This means that the record of a spectrum is based on the breakdown of a sample that was created by a laser. This will then allow a comparison of the elemental composition of sample materials based on the spectra that they give. ECCO uses a high power pulsed infra-red laser that is focused onto a sample raising the temperature by up to 15,000°C which produces a micro-plasma of the sample. The micro-plasma contains excited atoms and ions of the elements within the sample. The plasma then emits ultra-violet and visible colored light, which is collected by the spectrometer. The peaks seen on the spectra are called atomic emission lines. Each element has its own signature or pattern of atomic emission lines of both wavelength and intensity. Therefore, it is possible for elements to be identified from the peaks that are present. The atomic spectrum of the constituent elements of the target sample provides a material "fingerprint".

ECCO using LIBS offers significant advantages in speed, sensitivity and cost effectiveness over other processes such as x-ray fluorescence, scanning electron microscope, and mass spectroscopy. Examinations conducted with the ECCO are not only fast and simple to perform, but require minimal sample preparation, gives an immediate spectra of the elements down to low parts per million, and the examination process is only minimally destructive. This presentation will show the varied applications of ECCO in the elemental analysis of questioned documents such as security paper, office paper, envelopes, differentiating between genuine and counterfeit banknotes and coins, pencil leads and toners.

Elemental Composition Comparator, Laser Induced Breakdown Spectroscopy, Forensic Document Examination

J15 Kinematic Evidence of Parkinsonism in the Handwriting of Patients With Alzheimer's Disease

Michael P. Caligiuri, PhD, University of California, San Diego, Department of Psychiatry, 9500 Gilman Drive (0603), San Diego, CA 92093; and Linton A. Mohammed, MFS, Rile, Hicks, & Mohammed, 100 Oceangate, Suite 670, Long Beach, CA 90802*

After attending this presentation, attendees will understand why some individuals with Alzheimer's Disease (AD) exhibit handwriting characteristics that resemble Parkinson's disease.

This presentation will impact the forensic science community by providing: (1) a neurobiological understanding of why signatures change in Alzheimer's disease; and, (2) an empirical support for a difference in handwriting and signatures between two forms of dementia.

The principle handwriting impairment in early Alzheimer's disease (AD) has a cognitive-linguistic basis comprised of lexical or semantic errors, word selection, and phonological substitutions. The literature on handwriting among patients with mild or early AD generally suggests little or no graphic motor impairment. Later in the course of the disease writing samples can show more graphic motor disturbances. While there have been numerous published works characterizing the linguistic aspects of handwriting impairment in AD, debate remains as to whether the decline in handwriting in AD reflects the pathological change in frontal cortical integrity, giving rise to cognitive and psychomotor deficits or pathological change in sub-cortical basal ganglia integrity, giving rise to Parkinsonian features. This distinction has relevance to forensic document examiners charged with the task of authenticating signatures and handwriting from older individuals with suspected dementia.

A study was conducted of handwriting kinematics in AD. AD patients were sub-grouped according to scores on a standard clinical assessment that suggested either the presence or absence of Parkinsonian neuropathology. Patients with clinical signs of Parkinsonism comprise a subtype of AD known as Dementia with Lewy Bodies or DLB. The study goals were to determine whether kinematic analyses of handwriting movements support previous literature that handwriting is preserved in AD and to identify kinematic parameters in signatures and handwriting that might distinguish AD from DLB. A standard laboratory assessment of handwriting was employed. Briefly, subjects were instructed to draw concentric circles, write series of the letter 'l' and alternating "lleelle", write a standard sentence, and sign their signature five times using an inkless pen on a digitizer tablet. MovAlyzeR® software was used to acquire and process multiple kinematic variables from each pen stroke.

Results indicated that as a group, AD writers exhibited longer stroke durations, lower stroke velocities, and greater number of acceleration peaks (inversions) per stroke. Overall, these features were not significantly different from those of healthy writers. However, AD patients were more variable as a group than healthy writers suggesting that some AD patients may have significantly impaired handwriting. One likely source of this variation could be the presence of motor impairment consistent with the provisional diagnosis of DLB. Further analyses of signature and handwriting movements in DLB patients showed slower movement velocities, longer stroke durations, decreased stroke length, and an increased number of acceleration inversions versus non-DLB AD patients. The present findings indicate that motor aspects of handwriting may be

impaired in AD patients, particularly those who met clinical criteria for DLB, and that the nature of this impairment may not have a solely cognitive or linguistic basis.

Alzheimer's Disease, Handwriting Kinematics, Parkinsonism

J16 Basics of Typography for the Forensic Document Examiner

Peter V. Tytell, BA, Forensic Research, 116 Fulton Street, Suite 2W, New York, NY 10038-2712*

After attending this presentation even the experienced forensic document examiner should have an increased level of familiarity with systems used internationally for type measurement, typestyle classification, as well as with the nomenclature used to describe the classifying features of type designs, and how these fundamentals of typography can ultimately be used in practical applications for forensic examinations requiring the differentiation of similar designs. This introductory presentation should provide awareness of some areas for the kind of further education, training, and experience needed to achieve the knowledge, skills, and abilities of the domain-specific expertise required in actual case work.

This presentation will impact the forensic science community by providing an historical perspective on typographic development over the half-millennium plus since the Guttenberg Bible (ca. 1454) as well their calligraphic and inscriptional underpinnings. Socio-economic and aesthetic trends as well as technological advances will be considered.

This presentation will seek to provide forensic document examiners and other attendees with an overview of forensically relevant technical and design aspects of typography. In an age when the overwhelming majority of documents submitted for examination are produced on computer printers using adapted or evolved versions of traditional printers' type styles, the forensic document examiner needs a basic knowledge of typography.

The domain-specific terminology developed by typographers and printers over the centuries will be emphasized because of the role of language in comparison type examinations in facilitation of the perception and labeling of significant features and patterns, both the similarities and the differences. The use of correct and specific terminology should also increase effectiveness in note taking, report writing, and demonstrative presentations.

Aspects of various typographic classification systems will be considered. Traditional classification systems have been historically based, such as the Association Typographique Internationale (ATypI) system based on the work of Maximilien Vox, and the similar, but more restrictive, British Standards Classification of Typefaces (BS 2961). Such systems are subject to criticism as inadequate in an age of computer-aided revivals, hybrids, and combinations of type designs and other material from diverse centuries and sources. The various versions of the PANOSE system, originating from the work of Benjamin Bauermeister, are largely measurement based with minimal subjective decisions or typographic background required. The system devised by Catherine Dixon from England considers the various design sources along with a series of formal attributes, factors that can combine in the patterns of commonly seen groups of type styles.

A variety of criteria have been used for these various classification systems, and their relevance to forensic document examination is that they provide the examiner with strategies of comparative measurements and an extensive starting list of selected characteristics for focused attention in the analysis and comparison of type. Covering both the major elements as well as fine and subtle features of the designs, these classifying characteristics include: overall style, posture, treatment of terminals, including presence and style of serifs, weight, proportion, degree of contrast and axis of contrast or stress, stroke variation, midline placement and x-height, as well as features of certain key characters.

Some information on typewriter type styles will also be provided because of the prolific use of these machines in creating documents in the last century that still need to be examined in this century, and also the ongoing use of this technology in certain areas. Accordingly, the presentation will also address classification systems developed by Ordway Hilton, David A. Crown, Joseph Haas, and Interpol for monotone typewriter type styles, as well as the overall style classifications developed by Gerry de la Durantaye and Philip D. Bouffard.

Typography, Classification, Differentiation

K1 Hair Analysis of Amphetamine Using SPE and LC/MS/MS

Jeffery Hackett, PhD, United Chemical Technologies Incorporated, 2731 Bartram Road, Bristol, PA 19007; Albert A. Elian, MS*, Kerrie Donovan, MS, Massachusetts State Police Crime Laboratory, 59 Horse Pond Road, Sudbury, MA 01776; and Michael J. Telepchak, MBA, United Chemical Technologies Incorporated, 2731 Bartram Road, Bristol, PA 19007*

After attending this presentation, attendees will learn about the extraction of amphetamine (and related compounds) in hair using readily available solid phase extraction (SPE) cartridges and tandem mass spectrometry. Use of this SPE method will permit analysts to provide data on these compounds in hair samples.

This presentation will impact the forensic science community by offering analysts in forensic facilities a method that permits small samples of hair to be analyzed in a clean format with minimal matrix effects and excellent analytical characteristics in terms of both LC/MS/MS and solid phase extraction.

Method: Extraction (SPE) was performed on mixed mode column (C8/SCX) conditioned with methanol, deionized water, and pH 6 buffer (3mL, 3mL and 1mL, respectively) prior to sample loading. Samples of decontaminated hair (10mg) were digested in 1M NaOH (containing deuterated analogues) for one hour at 70°C. The samples were cooled and glacial acetic acid (100µL) was added. Each solution was adjusted to pH 6 with 0.1M phosphate buffer (4mL) and applied to a conditioned SPE column. After loading the sample, the sorbent was washed with deionized water, acetic acid (0.1M), and methanol (3mL of each, respectively). Each SPE column was dried and eluted with 3mL of a solvent consisting of methylene chloride/isopropanol/ ammonium hydroxide (78:20:2). After elution, 200µL of mobile phase was added to the collection tube. The samples were then evaporated to the mobile phase for analysis by LC/MS/MS in positive multiple reaction monitoring (MRM) mode. Data is presented for MRM's of amphetamine, methamphetamine, MDA, and MDMA (and deuterated analogues), respectively.

Liquid chromatography was performed in gradient mode employing a 50 x 2.1 mm biphenyl analytical column and a mobile phase consisting of acetonitrile and 0.1% aqueous formic acid. The gradient was programmed to run from 5% to 30% acetonitrile in four minutes and then back to 5% for re-injection. The total run time for each analysis was less than five minutes. In this presentation, representative chromatograms are shown to illustrate the efficiency of the chromatography and analysis of amphetamine related compounds.

Results: The limits of detection/quantification for this method were determined to be 0.05ng/ mg and 0.1ng/mg, respectively for amphetamine (and other analogues). The method was found to be linear from 0.1ng/mg to 10 ng/mg (r2>0.999). Data is presented to show that recoveries of amphetamine were found to be greater than 95% for all the amphetamine analogues. Interday and Intraday analysis of the amphetamine analogues were found to < 8% and < 12%, respectively. Matrix effects were determined to be < 6% for the amphetamine analogues. Concentrations of amphetamine in real samples of hair were found to range from 1.2ng/mg to 1.3ng/mg. Other amphetamine analogues (methamphetamine, MDA, and MDMA) were not found to be present in the hair samples.

Conclusion: The use of this new procedure for the analysis of amphetamine and related compounds will be of great use to analysts in the field of forensic hair analysis as it demonstrates the use of SPE/LC/MS/MS to provide data from small amounts of hair sample.

Hair, LC/MS/MS, SPE

K2 Evaluation of the Immunalysis Tapentadol Enzyme Immunoassay Kit

Kayla N. Ellefsen, BSc, 3123 7th Line, Innisfil, ON L9S 4G8, CANADA; MacKenzie L. Willis, BS, 1202 NW 15th Street, Andrews, TX 79714; Ayodele A. Collins, MSc, and James A. Bourland, PhD, Ameritox Limited, 9930 West Highway 80, Midland, TX 79706; and Ronald C. Backer, PhD, 502 Solomon Lane, Midland, TX 79705*

After attending the presentation, attendees will understand the performance of a new tapentadol enzyme immunoassay (EIA) screening kit, using a chemistry immune analyzer with a UPLC-TQD for confirmation of all urine samples.

This presentation will impact the forensic science community by demonstrating the applicability of the Immunalysis Tapentadol EIA screening kit for the consistent detection of tapentadol in urine samples.

Tapentadol (Nucynta®) is a schedule II synthetic opiate that is often used as an analgesic for moderate to severe pain. It is excreted in urine as unchanged drug (3%) and as metabolites: N-desmethyltapentadol (13%), tapentadol glucuronide (55%) and tapentadol sulfate (15%).[1] Urine drug testing of pain patients plays a significant role in monitoring their prescribed medication. Tapentadol's availability as a prescription drug in the United States and its potential for abuse similar to other opioid agonists has lead to the development of a homogenous enzyme immunoassay to screen for this drug in urine.[2] Currently, Immunalysis has developed an immunoassay kit for tapentadol. This study aims to evaluate and validate the Immunalysis Tapentadol EIA screening kit, at a cutoff concentration of 200 ng/mL.

The Tapentadol EIA was validated by determining the linearity, precision, accuracy and carryover of tapentadol standards and controls using an chemistry immune analyzer. Linearity was assessed in the range of 200-20,000 ng/mL (n=5). The precision and accuracy of the screening kit were evaluated at the proposed cutoff concentration (200 ng/mL) and at 25% above and below cut-off concentrations (250 ng/mL and 150 ng/mL, respectively) for tapentadol. Controls (n=10) were tested on three separate runs on three consecutive days. Carryover was assessed by screening certified negative urine (n=5) following the injection of urine fortified with tapentadol up to a concentration of 40,000 ng/mL. For the parallel study, de-identified urine specimens (n=300) from pain management patients that were previously confirmed positive or negative for tapentadol were obtained. All 300 patient samples were tested with the Immunalysis Tapentadol EIA kit at the cut-off concentration for tapentadol. All urine samples were then analyzed on a Waters Acquity UPLC-TQD for tapentadol and its metabolites (N-Desmethyltapentadol, Tapentadol Glucuronide and Tapentadol Sulfate) at a confirmation cut-off concentration of 100 ng/mL.

The immunoassay kit was found to be linear up to 1,000 ng/mL. The inter-assay and intra-assay precision of the Immunalysis Tapentadol EIA screening did not exceed a coefficient of variation of 10%. Accuracy was determined to be within ± 25% of each target concentration tested. No carryover was observed in the negative urine samples preceded by 40000 ng/mL of tapentadol. A total of 125 true positives and 167 true negatives were confirmed, by UPLC-MS/MS, based on free tapentadol concentrations only. No false negatives were demonstrated in the parallel study and only eight samples produced a false positive result. The immunoassay exhibits a cross reactivity with N-Desmethyltapentadol (2%) and tapentadol glucuronide (25%).[2] Similarly, it was found that the Tapentadol EIA was also cross reactive with tapentadol sulfate at 25%. The accuracy of the kit improved when examining total tapentadol

concentrations versus free tapentadol (128 true positives, 167 true negatives, 0 false negatives, 5 false positives). The sensitivity and specificity results obtained for the parallel study (sensitivity=100% and specificity = 95.4%) compare to the expectations per the package insert.[2]

The results of this study demonstrated that the specificity of the tapentadol immunoassay kit is based off of not only tapentadol, but its metabolites as well. The assay demonstrated good agreement with the UPLC-TQD confirmation results (97.3%). The Immunalysis tapentadol EIA appears to be a reliable homogenous enzyme immunoassay for the detection of tapentadol in urine.

Tapentadol, Homogeneous Enzyme Immunoassay, Validation

K3 Validation of Liver Oxymorphone Analysis Using LC/MS/MS: Comparison With Associated Blood Concentrations in Fatal Intoxications

Erin D. Crum, BS, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; and David J. Clay, BA, Kristen M. Bailey, MS, Myron A. Gebhardt, MS, and James C. Kraner, PhD, West Virginia Office of Chief Medical Examiner, 619 Virginia Street West, Charleston, WV 25302*

The goal of this presentation is to present a validated method for the detection and quantification of oxymorphone in liver tissue.

This presentation will impact the forensic science community by demonstrating an assay which provides reproducible quantification of oxymorphone in liver tissue. The assay has application in forensic and postmortem toxicology laboratories.

Oxymorphone, a semi-synthetic opioid analgesic derived from thebaine, is a μ-opioid receptor agonist and indicated for the relief of moderate to severe pain. It is also an active metabolite of oxycodone and has about six to eight times the analgesic potency of morphine. With the introduction of oral formulations in 2006, oxymorphone has become widely abused. The West Virginia Office of the Chief Medical Examiner has seen a dramatic increase in incidence of accidental deaths related to oxymorphone. Most quantification methods focus on the analysis of oxymorphone in blood or urine. The objective of this study was to develop and validate a reliable method for the quantification in a common supplemental specimen, liver tissue.

Oxymorphone standards ranging from 0.5 – 500 μg /kg and four control samples ranging from 6 – 300 μg /kg were prepared in drug and ethanol negative liver homogenate. Internal standard, d3-oxymorphone, was added prior to extraction. Solid phase extraction utilizing Trace-B columns was employed to process the calibrators and controls. Dried eluents were reconstituted in 100 μL of a mixture of water/acetonitrile/formic acid (99:1:0.1) and transferred to high recovery autosampler vials for LC-MS/MS analysis. All chromatography was performed using a ultra-performance liquid chromatography (UPLC) system with separation achieved on an UPLC HSS T3 2.1 x 100 mm (1.8 μm) column. For each analysis, column temperature was maintained at 40°C. All chromatographic runs were performed using linear gradients where mobile phase A was water with 0.1% formic acid and mobile phase B consisted of acetonitrile with 0.1% formic acid. Initial conditions of mobile phase A/B (99:1) were maintained for 0.5 minutes. Mobile phase B was then increased to 30% over 1.5 minutes. It was then increased to 100% over 1.0 minute and maintained for 1.0 minute. The system was then returned to initial starting conditions and held for 0.9 minutes until the subsequent injection. Total run time for each injection was 5.0 minutes. Tandem MS analysis was carried out using a TQ Detector with ionization in electrospray positive mode. Oxymorphone and d3-oxymorphone were analyzed using multiple reaction monitoring (MRM) with argon as the collision gas. The source temperature was set at 150°C and desolvation temperature was 400°C. Desolvation gas was maintained at 800 L/h and cone gas was set to 11 L/h. One quantification and two target transitions were monitored for both oxymorphone (302->284, 302->227, 302->242) and the deuterated internal standard (305->230, 305->245, 305->287).

As part of the validation, studies to determine potential interference, ion suppression/enhancement and carryover were conducted. The calibration model, limit of detection, lower limit of quantitation, linear range, precision and accuracy were established from calibrators and controls prepared and analyzed on five different days with four replicates each day. The linear range was shown to be 5 to 500 μg/kg for oxymorphone in liver homogenate. The limit of detection (LOD) and lower limit of quantitation (LLOQ) were determined to be 5 μg/kg.

Liver specimens from thirty-three cases were analyzed using this validated method. For each, 3.0 g of water was added to 1.0 g of liver tissue. Samples were homogenized, extracted and analyzed. The oxymorphone concentrations ranged from 39 to 1740 μg/kg for liver and 5 to 546 μg/L for blood. A comparison of blood and liver oxymorphone data in fatal intoxications will also be presented.

Oxymorphone, Validation, Liver

K4 Driving Under Impairment With Hydrocodone, Carisoprodol, Topiramate, and Phenytoin

Yuanwei Gao, BS, 555 Bowers Boulevard, #1528B, Huntsville, TX 77340; and Andre A. Salazar, BS, and Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be familiar with the driving under impairment with prescription drugs, hydrocodone, carisoprodol, topiramate, and phenytoin in one case.

This presentation will impact the forensic science community by providing understanding of the effects and interactions of hydrocodone, carisoprodol, topiramate, and phenytoin. These drugs are common prescription drugs in United States and the combination of them will definitely impair the driver's performance.

A 38-year-old female was charged with DWI following a mid-morning traffic accident. Breath alcohol levels were negligible; however, she did not perform well in the Standardized Field Sobriety Tests (SFST) such as the one-leg stand (OLS) and the horizontal gaze nystagmus (HGN). In fact, the driver failed all tests administered at the scene: she could not walk in a straight line, balance on one foot, and underestimated elapsed times. In the HGN test nystagmus appeared at 40 degrees and her eyes lacked both smooth pursuit and convergence. Additionally body and eyelid tremors were noted. Substantial miosis of the driver's pupils (2.0mm) was recorded. Because of the driver's refusal to submit to having a blood sample taken, no further testing was performed; however, the driver volunteered that she had taken hydrocodone, carisoprodol, topiramate, and phenytoin pills at 6:30 a.m. the morning of the incident. Her stated medical problems included a herniated disk, hypertension, and epilepsy.

Based upon the drugs the driver claimed to ingest, her poor performance in the SFSTs is readily rationalized. Carisoprodol and hydrocodone play a very important role for the noted impairment. Carisoprodol use may result in side effects that include drowsiness, analgesia, euphoria, sedation, dizziness, muscle relaxation, anxiolysis, and somnolence. Meprobamate, a metabolite of Carisoprodol, produces impaired perception, sluggish reaction time, confusion, inattentiveness,

slurred or thick speech, lack of balance and coordination, unsteadiness, and difficulty standing, walking, or exiting vehicles have also been noted in persons taking carisiprodol.

Hydrocodone is a narcotic analgesic and its effects on motor skills are well documented. These effects include: dizziness; lightheadedness; stupor; nausea; sweating; drowsiness; constipation; vomiting; and, euphoria. Topiramate and phenytoin are anticonvulsants used to treat patients suffering from epilepsy. The effects of topiramate include sedation, dizziness, ataxia, speech difficulty, and nystagmus. Overdose of topiramate can cause confusion and sluggishness. Additionally, phenytoin can cause horizontal gaze nystagmus (HGN), indicating that the result for the HGN test may produce false positives for patients taking phenytoin. Some common side effects such as dizziness, lethargy, and drowsiness might impair driving; however, most patients can tolerate them quite well.

Based upon on a Drug Recognition Expert's (DRE) opinion, she was under the influence of a central nervous system (CNS) depressant and a narcotic analgesic therefore impairing her ability to operate a motor vehicle. A jury convicted the defendant of driving while impaired with prescription drugs: hydrocodone, carisoprodol, topiramate, and phenytoin.

Driving While Impaired (DWI), Prescription Medicine, DRE

K5 Validation and Comparison of the Microgenics and Immunalysis Buprenorphine EIA Kits

MacKenzie L. Willis, BS, 1202 NW 15th Street, Andrews, TX 79714; Kayla N. Ellefsen, BSc, 3123 7th Line, Innisfil, ON L9S 4G8, CANADA; Ayodele A. Collins, MSc, and James A. Bourland, PhD, Ameritox Limited, 9930 West Highway 80, Midland, TX 79706; and Ronald C. Backer, PhD, 502 Solomon Lane, Midland, TX 79705*

After attending this presentation, attendees will gain knowledge of the validation and performance comparison of two buprenorphine EIA screening kits, at a cut-off of 5ng/ml using a chemistry immune analyzer and a UPLC-TQD for confirmation.

This presentation will impact the forensic science community by demonstrating the applicability and performance of the Microgenics and Immunalysis buprenorphine screening kits using a cut-off of 5ng/mL in authentic urine samples.

Buprenorphine is a semi-synthetic opioid that is closely related to morphine. It has recently been prescribed for treating opioid-dependence.[1] Around 10-30% is excreted in the urine primarily as conjugated metabolites. There is a need for specific assays with low detection limits.[1] A sensitive and rapid immunoassay is critical for drug screening situations. This study aims to validate and compare two buprenorphine EIA kits at a cut-off of 5ng/mL.

Both kits were validated based on linearity, precision, accuracy and carryover. The linearity study was completed by running five replicates at nine concentrations ranging from 5-500 ng/mL. Precision and accuracy were tested on controls at concentrations of 3.75, 5 (cut-off) and 6.25 ng/mL. Ten replicates of each were tested on three separate runs on three separate days. The carryover study was performed by injecting certified negative urine (n=3) following the injection of urine fortified with buprenorphine up to 1000 ng/mL and observing the response of the samples. For the parallel study, de-identified patient urine specimens (n=400) that were previously confirmed positive or negative were obtained. Each sample was screened by both kits. All 400 samples were confirmed on a UPLC-TQD for buprenorphine, buprenorphine-glucuronide, norbuprenorphine and norbuprenorphine-glucuronide.

The Microgenics kit displayed linearity up to 100ng/mL, while the Immunalysis kit was linear up to 15ng/mL. Inter-assay and intra-assay precision for the Immunalysis kit demonstrated a lower coefficient of variation (<8%) for all concentrations compared to the Microgenics kit (<13%). The inter-assay and intra-assay accuracy was determined to be within ± 25% for Microgenics and ± 20% for Immunalysis from the target concentrations. No carryover was observed for either kit. The 200 previously confirmed positive samples all screened positive with the exception of one negative by the Immunalysis kit. From the 200 previously confirmed negative samples, five screened positive by Immunalysis and 16 by Microgenics. The confirmation results demonstrated the accuracy of both kits. A total of 203 true positives, 193 true negatives, one false positive, and three false negatives were observed for Immunalysis. Microgenics displayed the following results: 205 true positives, 183 true negatives, 11 false positives and one false negative. The sensitivity and specificity results obtained for the parallel study were 98.5% and 99.5%, respectively for Immunalysis and 99.5% and 94.3%, respectively for Microgenics. Both sets of sensitivity and specificity results compared well with the predictions of the respective package inserts.

The results of this study imply that both kits are reliable yet vary in screening ability due to cross reactivity with certain metabolites. Microgenics and Immunalysis were both in good agreement with the confirmation results at 97% and 99% respectively. Norbuprenorphine was present by UPLC-TQD confirmation in 201 of the confirmed positive samples out of 206 total positives by Immunalysis and Microgenics. The Immunalysis kit, that has significant cross reactivity with this metabolite, is likely to display a more ideal performance when norbuprenorphine is present. The Immunalysis kit proved to be more specific yielding less false positives while the Microgenics kit proved slightly more sensitive with less false negatives.

Buprenorphine, Enzyme Immunoassay, Validation

K6 Conversion of Codeine to Dihydrocodine During Toxicological Analysis of Urine

Martha Wood, BS, 292 East Ridge Drive, Boone, NC 28607-4414; Jillian Yeakel, MSFS, Fredric Rieders Family Renaissance Foundation, 2300 Stratford Avenue, Willow Grove, PA 19090; and Barry K. Logan, PhD, G. John DiGregorio, MD, PhD, and Edward J. Barbieri, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be aware of the risk for conversion of codeine to dihydrocodeine in toxicological samples as an artifact of the sample preparation.

This presentation will impact the forensic science community by presenting suggestions to minimize this conversion in laboratory settings and to prevent misinterpretation of results obtained after analyzing for total opiates.

Codeine is the most frequently prescribed oral opiate and is also commonly found in combination with multiple other drugs such as acetaminophen and aspirin. It is available over the counter in Canada and Asia. Codeine, like other opiates, is conjugated with glucuronic acid in the liver as one pathway of metabolism allowing codeine to be excreted by the kidney. This is important when urine samples are tested in forensic laboratories because the glucuronide must be hydrolyzed before the opiates can be analyzed using gas chromatography/ mass spectrometry (GC/MS).

The procedure implemented to hydrolyze, extract, derivatize, and analyze codeine found in urine samples has been demonstrated to cause a small percentage of the codeine to convert into dihydrocodeine, which is visualized by analysis on the GC/MS. The procedure involved enzyme hydrolysis using β-glucuronidase followed by derivatization of keto-opiates (such as hydrocodone, hydromorphone, oxycodone, etc.) with

hydroxylamine, to allow their separation from codeine during analysis on GC/MS. Codeine should not react with the hydroxylamine. Both the enzymatic hydrolysis and the derivatization with hydroxylamine require incubation at high temperatures. An acetate buffer (pH 6) is used to prepare the sample for hydrolysis and a phosphate buffer (pH 5.5) is used to ionize the drug for solid phase extraction. A mixed bed column is used to clean the sample and a mixed elution solvent of methylene chloride, isopropanol, and ammonium hydroxide is used for elution. The sample is then dried down and derivatized with BSTFA before being analyzed on the GC/MS.

Continued investigation of the conversion determined that approximately 0.2% of the codeine was converted to dihydrocodeine using this procedure. It is forensically important to determine how this conversion is occurring and determine if it is possible to prevent. The steps in the procedure preceding SPE were assessed to determine the likely cause for the conversion. In the standard procedure 0.5mL of β-glucuronidase and 0.5mL of pH 5.5 acetate buffer is used to hydrolyze the glucuronide and 0.1mL of hydroxylamine is used to derivatize keto-opiates. Both of these steps also involve an incubation period, two hours for β-glucuronidase and 20 minutes for hydroxylamine. Reagent volumes and incubation times were varied to determine the effects on the extent of conversion. Incubation times of one hour and two hours were tested for both compounds while the β-glucuronidase incubation was also lengthened to three hours. For each of these times the incubation temperature was tested at the original 50°C and at 24°C. The pH of the acetate and phosphate buffers were varied between four and six, and volumes of 0mL, 0.5mL, 1mL and 2mL were added to the sample.

Both the glucuronidase hydrolysis and the hydroxylamine conversion were evaluated to determine which step was responsible for the formation of dihydrocodeine. Initially, the volume, length of incubation and temperature of the glucuronidase incubation were investigated and appeared to have no effect on the extent of formation of dihydrocodeine. The conditions for the conversion of the formation of the keto-opiates were investigated. These conditions include the volume, length of incubation and temperature of the incubation. Less codeine converted to dihydrocodeine when a lesser concentration of hydroxylamine was added and when the samples were incubated for a longer period.

Hydroxylamine is a reducing agent, which may be the reason for the conversion of codeine to dihydrocodeine. Further research will investigate the use of other derivatizing agents to determine an alternate method for the separation of keto-opiates for analysis on GC/MS.

Forensic Science, Codeine, Dihydrocodeine

K7 Differential Mobility Spectrometry as a Tool to Improve Mass Spectral Library Searching Scores by Removal of Isobaric Interferences

Adrian M. Taylor, PhD, and Yves Le Blanc, PhD, ABSciex, 71 Four Valley Drive, Concord, ON L4K 4V8, CANADA*

After attending this presentation, attendees will understand how differential mobility spectrometry (DMS) can be used advantageously to pre-separate isobaric compounds and therefore allow the removal of interfering peaks in generated MS/MS spectra that are used in library searching; improving the purity scores obtained for the library hit.

This presentation will impact the forensic science community by enabling a more confident confirmation of the identification of drug compounds in urine.

Rapid and reliable screening methods for drugs of abuse are required for the detection of xenobiotics in forensic intoxication cases. Multi-targeted screening by LC/MS/MS uses MRM triggered Information Dependent Acquisition (IDA) MS/MS spectra, which are used to confirm the identity of detected drugs based on mass spectral library searching.

Matching MS/MS spectra generated from real samples to library spectra can be impeded by the presence of interfering isobaric compounds in the sample matrix. These isobaric interferences having similar m/z to the analyte will fragment producing extra peaks in the sample spectrum not present in the library spectrum. This results in a reduced score and reduced confidence rating.

DMS separates ions on the basis of the difference in their migration rates under high versus low electric fields and requires the application of an intense asymmetric electric field known as the DMS separation field, typically in the megahertz frequency range. Ion filters based on planar DMS can be integrated with the inlet configuration of most mass spectrometers and are able to enhance the quality of mass analysis by reducing chemical noise and pre-separating ions of similar mass. Using this technology, we have shown the separation of isobaric interferences that, in the absence of the device, would have been transmitted into the mass spectrometer and fragmented at the same time as the analyte.

Data was obtained using a linear ion trap system coupled with an LC system. The ion source region of the mass spectrometer was modified for incorporation of various DMS analyzers. The standard ceramic orifice plate was replaced with a modified ceramic plate that included provisions for sealing a DMS cell. The mass spectrometer analysis consisted of an MRM detection using scheduled MRM algorithm and product ion dependent scans using the linear ion trap, automatically triggered to collect full scan MS/MS fragmentation spectra. The MS/MS data were collected using low, medium, and high energy fragment ions. A 1250 compound Forensic Drug Library was searched to provide identification and confirmation.

Comparisons of IDA triggered product ion spectra generated from urine samples both with and without the use of the DMS were made. An improvement in the MS/MS spectrum generated with the use of DMS was seen for amphetamine detected in urine, by removal of the interfering ions at m/z 77, 107, and 109. This improved the quality of the spectrum for searching against the forensic drug library, producing 100% purity score for an amphetamine match when compared to only 40% when performing the same experiment, on the same sample but without the use of the DMS device. Other examples where improvements in MS/MS spectra were gained by the use of the DMS device, compared to without using the device, included product ion spectra triggered for m/z ions that corresponded to lidocaine, indomethacin, and fentanyl. Library match purity scores for these compounds improved from 79 to 90%, 14 to 78% and 32 to 89% respectively, allowing for a higher confidence in the identification of these compounds. Comparisons of product ion spectra generated from urine samples both with and without the use of the DMS show that fragment ions are detected and falsely represented in the resulting product ion spectrum in those experiments performed without the use of the DMS. The DMS, therefore, removes these isobaric interferences, improving the mass spectral library searching scores.

Differential Mobility Spectrometry, Drug Screening, LC/MS/MS

K8 Incidence of Fetal Drug Exposure in Alabama: 2004-2011

Jack R. Kalin, PhD, Alabama Department of Forensic Sciences, 2026 Valleydale Road, Hoover, AL 35244-2095*

After attending this presentation, attendees will learn the incidence of fetal drug exposure in Alabama from 2004 through June of 2011 and by extension, the extent of maternal drug use proximate to the delivery of stillborn fetuses and/or newborn infants.

This presentation will impact the forensic science community by pointing out how maternal drug use during pregnancy manifests in fetal drug exposure and represents a significant public health problem. This presentation describes toxicological findings in specimens collected from stillborn fetuses and newborn infants as a measure of the extent of drug exposure in utero and, by extension, of maternal drug use proximate to delivery. In some instances, maternal blood was also available for analysis and findings were compared to the stillborn fetuses. This differs from the

more common practice of conducting toxicological examinations with meconium.

The Alabama Department of Forensic Sciences (ADFS) provides forensic laboratory services to the law enforcement community in Alabama (pop. 4.66 million), which includes approximately 600 state, county and local police, sheriff departments, district attorneys, coroners, and medical examiners. Laboratory records from cases submitted to ADFS were reviewed for instances of fetal demise, regardless of cause, for the period 2004 through June of 2011. Cases were selected where blood and/or tissue specimens were available for toxicological examination, the purpose being to identify instances of in utero drug exposure. Thirty-two cases were identified statewide, excluding Jefferson County (pop. 700,000).

Toxicological examinations included headspace analyses for ethanol and related volatiles, immunoassays for common drugs of abuse and both liquid-liquid and solid-phase extractions followed by analysis with GC/MS and/or LC/MS/MS. Where significant, quantitative analyses were conducted.

Twenty-one cases were positive for one or more drugs and/or metabolites; autopsies were conducted in 18 of 21. Five full-term live births were followed by death due to drowning, asphyxiation (2x), acute drug intoxication (within minutes), and/or delayed drug intoxication while in the hospital (after 24 hours). One case involved fetal death due to the mother sustaining blunt-force injuries in a traffic incident.

Six drugs and/or metabolites were identified in one case; four were identified in two cases and one – three were identified in the remainder. Cocaine and/or benzoylecgonine (BE) were the most prevalent substances identified followed by methamphetamine and amphetamine. Levamisole, a common adulterant present in street cocaine, was identified in some cases where cocaine was present. In one case, cocaine and/or metabolites, methamphetamine, and amphetamine were all identified. A summary of drug incidence is provided herein. This presentation will include toxicological findings, causes, and manners of death, and body weights for each individual case.

Analyte	Incidence	Analyte	Incidence
Cocaine/metabolites	10	Chlordiazepoxide	1
Methamphetamine/amphetamine	6	Chlorpheniramine	1
Levamisole	3	Clonazepam/7-aminoclonazepam	1
Citalopram/Escitalopram/Desmethyl-	2	Etomidate	1
Dextromethorphan	2	Meperidine	1
Diazepam/nordiazepam	2	Meprobamate	1
Diphenhydramine	2	Methadone/EDDP	1
Hydrocodone	2	Oxycodone	1
Lidocaine	2	Promethazine	1
Acetaminophen	1	Pseudoephedrine	1
Bupivacaine	1		

In two cases, maternal blood was also available for examination. Results are provided herein.

CaseNo(s)	Fetal Blood	Maternal Blood
******101/102	Methamphetamine, 650 ng/mL Amphetamine, 250 ng/mL	Methamphetamine, 220 ng/mL Amphetamine, 100 ng/mL
******680/048	Acetaminophen Cocaine, 210 ng/mL Benzoylecgonine, 480 ng/mL Levamisole	Cocaine, 65 ng/mL, <10 ng/mL (+24h) Benzoylecgonine, 1700 ng/mL, 59 ng/mL (+24h) Methylecgonine Meperidine Normeperidine

Fetal Drugs, Drugs *in Utero*, Drugs During Pregnancy

K9 A Comparison of Alprazolam Levels in Blood and Urine

Danielle A. Dela Cruz, BS, 507 Oak Lake, Lake Dallas, TX 75065; Chris Heartsill, BS, Dallas Coutny Institute of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX 75235; and Jorn C.C. Yu, PhD, Box 2525, College of Criminal Justice, Sam Houston State University, Huntsville, TX 77341*

The goal of this presentation is to understand that there is an apparent correlation between the concentration levels of alprazolam in blood and urine specimen.

This presentation will impact the forensic science community by showing that there is an apparent correlation between urine and blood levels of Alprazolam that may assist the toxicologist in determining the possible intoxication.

It is generally accepted that blood levels of drugs are better indicators of impairment and urine concentrations cannot be correlated to levels of impairment; however, in many cases urine may be the only specimen received by the laboratory. Any correlation between urine and blood levels would assist the toxicologist in determining the possible level of intoxication.

Alprazolam is a common benzodiazepine that is used for the treatment of depression, anxiety disorders and panic attacks. Common side effects of the drug include drowsiness, confusion, hypotension, and tachycardia. Typical blood concentrations in persons using the drug therapeutically range from 0.005 - 0.05 mg/L; however, in cases of abuse or over dosage the levels may range between 0.1-0.4 mg/L. Alprazolam is commonly seen in cases related to intoxicated driving where urine may be the only specimen available. Labs typically use blood to determine the concentration of drugs that are present; however, in the case of alprazolam, urine specimens may work just as well. The goal of this study is to show that there is an apparent correlation between the levels of alprazolam in the blood and urine that is not typically seen with other drugs.

A total of 55 cases, from 2011, from the Southwest Institute of Forensic Science in Dallas, Texas were used for the study, all of which had previously had alprazolam quantitated in the blood specimen. The corresponding urine specimens were extracted for comparison using a liquid-liquid extraction method with two control standards, alphaprodine for an internal standard and cholestane for an external standard. The drug was first extracted into n-butyl chloride, followed by a back extraction into 1 N hydrochloric acid. Finally, the samples were concentrated into a chloroform layer and 2.5 µL of the chloroform layer, containing the extracted drug, was injected onto a gas chromatogram-flame ionization detector. The instrument uses a split injection and contains two different columns, a 100% Dimethylpolysiloxane (DB-1) and a (5%-Phenyl)-methylpolysiloxane (DB-5) column; quantitation of the drug occurs on the DB-1 column but the concentration on the DB-5 column should be consistent. Alprazolam was measured at its respective retention time, approximately 20 minutes, and a concentration was generated based on a previously defined curve. The results indicate that approximately 76% of the urine specimen contained alprazolam levels that were within ± 0.05 mg/L of their corresponding blood level concentration. When therapeutic levels and abuse levels were categorized and evaluated, the results remained consistent. The urine and blood level concentrations for alprazolam do have an apparent correlation unlike most other drugs. In the absence of a blood specimen, a urine specimen could be quantitated for alprazolam and potentially be used to determine the approximate value of the blood concentration. Further studies will be done to broaden the scope of these initial findings.

Alprazolam, Urine, Concentration

K10 Distribution of Methadone and Its Metabolites in Plasma and Blood Cell

Ray H. Liu, PhD, 3786 Upland Drive, Marietta, GA 30066; and Ya-Ching Hsu, BS, Fooyin University, 151 Ching-Hsueh Road, Ta-Liao District, Kaohsiung, 83102, TAIWAN, ROC*

After attending this presentation, attendees will learn that data derived from the analysis of plasma do not represent the concentration of methadone in whole blood.

This presentation will impact the forensic science community by illustrating that methadone, perhaps most other drugs and their metabolites, is distributed between plasma and blood cell. Therefore, whether plasma or whole blood should selected as the test specimen depends on the test objective.

Methadone has long been adopted as the primary substitution drug for "treating" heroin addicts elsewhere and recently in Taiwan. Accurate determination of this compound and its metabolites in patients' blood provides valuable information helpful to safe and effective implementation of the substitution therapy policy.

Simulated samples (drug-free whole blood spiked with the analytes of interest) were first separated into plasma and blood cells portions. Resulting whole blood, plasma, and blood cell samples were used for developing effective sample preparation approaches to determine the distribution characteristics of the analytes of interest in plasma and blood cell portions. Clinical samples collected from patients under treatment were then analyzed to: (a) validate the findings derived from simulated samples; and, (b) study factors — e.g., treatment dosage, time lapse between drug intake and sample collection, and genetic variations, such as ABCB1 (C1236T, C3435T, and G2677T/A) and CYP2C19 (G681A and C990T) — that may affect the distributions. Typical sample preparation steps included: (a) addition of internal standards (MTD-d9 and EDDP-d3); (b) deproteinization twice by acetonitrile; and, (c) extraction with isopropanol/hexane (1:8, v/v) at pH 10.2 (carbonate buffer). Extracts were dried, then reconstituted with ethyl acetate for analysis. GC-MS was used as the primary analytical method, while a significant number of samples were also analyzed by LC/MS/MS (triple quadrupole configuration) to confirm the accuracy of data derived from GC-MS analysis. Since the concentrations of the commonly monitored metabolites, 2-ethylidene-1,5-dimethyl-3,3-diphenylpyrrolidine (EDDP) and 2-ethyl-5-methyl-3,3-diphenyl-1-pyrrolidine (EMDP), in most clinical specimens were below the GC-MS quantification limits, MTD data were more fully evaluated.

The validity of a set of analytical data was examined by comparing the compatibilities of: (a) finding of the whole blood sample and the sum of the findings of the plasma and the blood cell samples; and, (b) the analytical findings derived from the GC-MS and LC-MSMS for those clinical specimens that have been analyzed by both methods. Data derived from simulated samples indicated: (a) 80% (standard deviation = 0.52%; n = 5) of MTD and 77% (standard deviation = 0.95%; n = 5) of EDDP in whole blood were found in plasma; and, (b) portions of MTD and EDDP (especially MTD) on the blood cells can be removed by washing the blood cell with phosphate buffer (pH 7.4). Data derived from GC-MS and LC-MSMS methods for the analysis of clinical specimens were found compatible. Among the 26 clinical specimens studied, the amount of MTD found in the plasma portion ranged from 70 to 86%. Specimens were re-collected from a small group of patients (n = 5). Data derived from the follow-up analysis of these specimens appeared to indicate the observed inter-patient variations (in MTD distribution) was unlikely caused by differences in treatment dosage or the time lapse between drug intake and specimen collection. It is currently being examined.

Methadone, Distribution, Blood

K11 Alcohol Intoxication

Dilek Salkim Islek, MSc, and Sharon S. Ramadanoglu, MSc, Istanbul University, Institute of Forensic Sciences and Medicine, Cerrahpasa Kampusu, Fatih, Istanbul, 34303, TURKEY; and Salih Cengiz, PhD, Istanbul Universitesi, Adli Bilimler Enstitüsü, Cerrahpasa Tip Fakultesi, Istanbul, 34300, TURKEY*

After attending this presentation, attendees will be informed about HS-GC/MS analysis of alcohols with specific toxicity and case reports.

This presentation will impact the forensic science community by providing details on the analysis and validation alcohol intoxications demonstrating a multi-disciplinarily approach to the toxicity evaluation process.

Methanol, also known as methyl alcohol, wood alcohol, wood naphtha, or wood spirits, is a chemical with the formula CH3OH (often abbreviated MeOH). It is the simplest alcohol, and is a light, volatile, colorless, flammable liquid with a distinctive odor very similar to, but slightly sweeter than, ethanol (drinking alcohol). Methanol, is a commonly used organic solvent, the ingestion of which has severe potential ramifications. It is a constituent in many commercially available industrial solvents and in poorly adulterated alcoholic beverages. Toxicity usually occurs from intentional overdose or accidental ingestion and results in metabolic acidosis, neurological sequelae, and even death. Methanol toxicity remains a common problem in many parts of the developing world, especially among members of lower socioeconomic classes.

The pathological effects of methanol are attributed to the accumulation of the toxic metabolites formaldehyde and formic acid. Thus, symptoms of methanol poisoning may be delayed by 12 hours or more from the time of ingestion and may be accompanied by a severe metabolic acidosis. The early non-specific symptoms of nausea, headache, abdominal discomfort, generalized weakness, and deteriorating conscious level can be accompanied by visual impairment. This picture can then proceed to blindness, coma, and death in association with a profound metabolic acidosis. Recommended management aims to delay methanol metabolism by using intravenous ethanol infusion; to reduce methanol levels with hemodialysis; to control metabolic acidosis; and to support cardiorespiratory function.

A case is presented involving a transient loss of consciousness resulting from self-administered denaturated alcohol (methylated alcohol). A 60-year-old woman was found unconscious at home, with a needle mark on her leg. A bottle of purple liquid was found next to the body. The compound was identified and quantified by headspace gas chromatography coupled to mass spectrometry. Headspace Gas Chromatography Coupled to Mass Spectrometry (HS-GC-MS) is one of the most commonly used techniques for the analysis of volatile compounds. At the intensive care unit, specimens of whole blood and centrifuged blood serum were collected at arrival to the emergency clinic. Post-dialysis serum sample from the second day and whole blood samples from the third day were collected for toxicological analysis, and stored at 4°C until analysis. A sample of the purple liquid from the bottle found near the patient was also collected. A sample of whole blood was collected at the clinic a week after the incident and was sent for toxicological analysis for the control and confirmation of the treatment.

The purple liquid found in the bottle was diluted 100 times and tested for ethanol and methanol using the headspace-GC/MS method. The whole blood sample collected at the arrival was found to be un-fit for the analysis due to clotting and low volume, the centrifuged blood serum was preferred instead. Remaining specimens were also tested for methanol and ethanol, respectively.

Methanol, a volatile compound that was identified by the following ions, m/z 29 and 31 after chromatography on a HP5-MS capillary. A headspace gas chromatographic-mass spectrometric (HS-GC-MS) method was developed for detection of ethanol and methanol in blood and quality control and validation was performed. The linearity ranges of the method were 0-2g/L for ethanol and methanol. The limit of detection was 0.03g/L

for ethanol and methanol. The limit of quantitation was 0.05g/L for ethanol and methanol. The range of recoveries was between 94%-120% for both ethanol and methanol.

A similar case that was studied involved alcohol intoxication which included a child who was abused and toxicated continuously with anti-freeze. The case was brought due to nausea, dizziness, and fainting of the child and was suspected of a case of intoxication. After, using the same method mentioned above, it was clear by the qualitative analysis carried out that the child was toxicated with methanol and ethylene glycol.

Another interesting case of alcohol intoxication was also studied using this method. The analysis was carried out on blood samples sent by the military. The person was found unconscious near an anti-freeze storage unit. The method was used for qualitative analysis and iso-propyl alcohol was detected.

Alcohols, Headspace, Intoxication

K12 The Optimization of a Sol Solution for Its Use With Molecular Imprinting for the Extraction of Illicit Drugs

Michelle Cerreta, BS, Florida International University, International Forensic Research Institute, Department of Chemistry and Biochemistry, 11200 SW 8th Street-CP344, Miami, FL 33199; Abuzar Kabir, PhD, Florida International University, 11200 SW 8th Street, ECS 445, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will learn the solidification process of a sol gel along with factors affecting gel solidification and network strength. The process surrounding the molecular imprinting of sol gels will also be shown, with preliminary data on the imprinted sol gel's uptake of the target drug molecule.

This presentation will impact the forensic science community by demonstrating how the use of a novel sol gel can be molecularly imprinted with illicit drugs to enhance the selectivity and extraction efficiency in comparison to current techniques due to its high stability, retention capacity, and affinity for the imprinted target molecule.

According to the 2009 National Survey on Drug Use and Health (NSDUH), over 20 million Americans, aged 12 and older, were said to be current users of illicit substances, an increase from 2008. With the rise in drug abuse, the frequency of forensic drug testing is becoming more prevalent. Drug testing can be performed on variety of biological specimens, such as urine, to determine the presence of any residual illicit substances and to conclude if the presence of such substances were the cause of criminal behavior. When testing for the presence of drugs, samples must undergo an extensive sample preparation process in order to pre-concentrate the analyte, as well as to minimize the detrimental effects of sample matrix interferences. Such procedures can prove to be a challenging task for many forensic toxicologists due to the complexity of biological specimens.

Solid phase extraction (SPE) is the most common technique for drug extraction and preparation, yielding high recoveries and clean extracts of the target drugs; however, SPE offers only generic selectivity, often extracting other matrix interferences, complicating instrumental identification and quantification. In order to improve extraction selectivity, molecularly imprinted polymers (MIPs) have been developed. Recently, studies have shown that the use of molecular imprinting for the extraction of illicit drugs yields better recoveries than SPE, as they display higher molecular recognition for the template molecule. It was also found that MIP provides an enhanced sensitivity with a more superior limit of detection than that of SPE. Furthermore, MIP has a higher ability for matrix reduction, removing a larger amount of background and interferences existing from biological matrices.

The polymer chosen to be molecularly imprinted for this research is a sol gel. Through the sol gel process, a silica based network is created which can and has been utilized for the production of ceramic or glass particles, surface bound coatings, and SPE cartridges. Sol gel chemistry has received an increased amount of attention in recent years due to its high thermal stability and increased intermolecular interactions between target analytes and itself. Another advantage is its high and adjustable porosity, which allows for high retention capacity of the extracted drug. Furthermore, sol gels are also very easy to prepare and can solidify at ambient temperatures. Other polymers that have been experimented with for the purpose of molecular imprinting produced swelling which causes a distortion of the cavities that are left behind after imprinting the target drug molecule. On the other hand, using a sol gel with molecular imprinting, allows for a higher selectivity than imprinting on other polymers because of the negligible swelling that sol gels produce.

An optimal sol gel was created by varying the various key ingredients. The ideal molar ratio of the participating ingredients was determined and the sol gel's ability to maintain its shape during supercritical fluid extraction (SFE) demonstrated strength and stability of the network. A scanning electron microscope (SEM) was used to view the gel's homogeneity and its porosity. This new optimal sol gel has a high porosity allowing for the enhancement of the gel's surface area, and thus, its retention capacity. Preliminary data will be provided demonstrating the molecular imprinting capability of the novel sol gel, as well as factors affecting gel solidification and network strength. This newly developed sol gel is highly stable and highly porous, making this an ideal candidate for molecular imprinting, and thus, a providing a promising future for the capability of drug extractions.

Sol Gel, Molecular Imprinting, Toxicology

K13 Evaluation of Lin-Zhi International EDDP Enzyme Immunoassay for the Determination of Methadone Metabolite in Urine

Ashley M. Goldstein, MS, Virginia Commonwealth University, Department of Forensic Science, PO Box 843079, Richmond, VA 23284-3079; Justin L. Poklis, BS, Virginia Commonwealth University Department of Pharmacology and Toxicology, 410 North 12th Street, Room 746, PO Box 980613, Richmond, VA 23219-0613; Carl E. Wolf, PhD, Medical College of Virginia, PO Box 98-165, Richmond, VA 23298-0165; and Alphonse Poklis, PhD, Medical College of Virginia, Box 98-165, VCU/MCVH Station, Richmond, VA 23298*

The goal of this presentation is to inform attendees of the performance of the Lin-Zhi International EDDP [2-Ethylidene-1, 5-dimethyl-3, 3-diphenylpyrrolidine] Enzyme Immunoassay for the detection of this methadone metabolite in urine.

This presentation will impact the forensic science community by providing an evaluation of the performance of the Lin-Zhi International EDDP Enzyme Immunoassay offering the field of toxicology alternative choices for the rapid detection of methadone metabolite in urine.

In this presentation, an evaluation of a new EDDP [2-Ethylidene-1, 5-dimethyl-3, 3-diphenylpyrrolidine] Enzyme Immunoassay [EDDPI] for the detection of this methadone metabolite in urine is presented. The Lin-Zhi assay is based on competitive antibody binding between EDDP in urine and glucose-6-phosphate dehydrogenase labeled EDDP. When EDDP is present in urine, active unbound enzyme reduces the co-enzyme NAD to NADH resulting in an increase of measured absorbance at 340 nm.

The EDDPI was evaluated by testing 362 urine specimens collected from pain management clients and substance abuse treatment patients. All specimens were tested with the assay in a chemistry system auto-analyzer using two different calibrator sets. One calibration set contained 0 and 150ng/ml (cut-off calibrator) of EDDP and the other set contained 0 and 300ng/ml of EDDP. Controls containing 0ng/ml of EDDP, and -25% (negative control) and +25% (positive control) of the 150ng/ml and

300ng/ml cut-off calibrators (Lin-Zhi) were analyzed with each batch of specimens. All urine specimens were then analyzed by HPLC/MS/MS for EDDP with a 25ng/ml LOQ.

Approximately 42% (151) of the 362 specimens yielded positive results by the EDDPI at 150ng/ml and/or 300ng/ml cut-off values. Of these specimens, HPLC/MS/MS confirmed the presence of EDDP above 25ng/ml in 151 specimens; however, at the 300ng/mL EDDPI cut-off, nine specimens yielded positive results when EDDP was present at <300ng/mL as determined by HPLC/MS/MS. Similarly, at the 150ng/mL EDDPI cut-off, three of the nine specimens also yielded positive results when EDDP was present at <150ng/mL by HPLC/MS/MS. These three specimens contained 121, 68, and 29ng/mL EDDP. No specimen yielding a negative EDDPI result contained EDDP above 25ng/ml by HPLC/MS/MS. Therefore, when applying a 150ng/ml cut-off, the EDDPI demonstrated a sensitivity of 1.00, a specificity of 0.986, and an overall agreement with HPLC/MS/MS results ≥150ng/ml of >99%. When applying a 300ng/ml cut-off, the EDDPI demonstrated a sensitivity of 1.00, a specificity of 0.959, and an overall agreement with HPLC/MS/MS results ≥300ng/ml of 97.5%. The intra-run precision of EDDPI as determined from the absorbance rates of the negative and positive controls yielded CVs of ≤ 2% (n=8); while inter-run precision of the controls yielded CVs of ≤ 6% (n=21). EDDPI demonstrated no cross reactivity with drugs of abuse or popular prescription drugs added to urine at 100mg/ml. The Lin-Zhi EDDPI provides a precise, reliable method for the routine detection of methadone metabolite in urine specimens.

Enzyme Immunoassay, EDDP, HPLC/MS/MS

K14 Deaths Involving Methylenedioxypyrovalerone (MDPV) in Upper East Tennessee

Trista H. Wright, BS, and Karen Cline-Parhamovich, DO, East Tennessee State University, Jenkins Forensic Center, PO Box 70425, Johnson City, TN 37614-1707; Dawn R. Lajoie, MD, William L. Jenkings Forensic Center, Johnson City, TN ; Laura Parsons, BS, East Tennessee State University Pathology, PO Box 70425, Johnson City, TN 37614; Mark Dunn, HS, William L. Jenkins Forensic Center, Forensic Pathology, Box 70425, Johnson City, TN 37614; and Kenneth E. Ferslew, PhD, East Tennessee State University, Section of Toxicology, Box 70422, Johnson City, TN 37614*

After attending this presentation, attendees will learn about the abuse of MDPV and the significance of blood and urine MDPV concentrations in actual postmortem cases.

This presentation will impact the forensic science community by providing actual case studies of deaths involving recreational MDPV abuse and the respective MDPV concentrations in postmortem blood and urine.

Two deaths involving the drug 3,4-methylenedioxypyrovalerone (MDPV) are reported from the Upper East Tennessee region. MDPV is a synthetic stimulant that affects the central nervous and cardiovascular systems. MDPV is one of the constituents commonly found in "bath salts," the other being mephedrone (4-methylmethcathinone). Bath salts are legal, cheap, and readily available in the Upper East Tennessee region and the effects have been compared to those of methamphetamine. To date no postmortem MDPV biological concentrations have been reported in the literature. A qualitative and quantitative analysis for MDPV was performed by gas chromatography-mass spectrometry and liquid chromatography-mass spectrometry on two postmortem cases.

A 46-year-old white male was found dead on the floor by his partner after injecting and smoking baths salts in the days prior to his death. He was reportedly nauseous, weak, and vomiting for several days but refused medical attention. The decedent had a history of diabetes mellitus and his blood sugar was elevated days prior to his death. He had a history of known drug abuse including opiates, heroin, and methamphetamine; however, the weekend before his death was the first time he tried bath salts. Ten vials of bath salts labeled Drone IV were collected from the scene, analyzed, and found to contain the bath salt constituent, MDPV. Analysis of the femoral venous blood and urine revealed MDPV concentrations of 39ng/mL and 760ng/mL. Metoclopramide was also present in the femoral blood at a concentration of 490ng/mL. No mephedrone was detected in the Drone IV vials, blood, or urine. At this time no cause of death has been established.

The second fatality was a 40-year-old white male found dead who had a history of drug and bath salt abuse. The deceased was alleged to have been smoking and/or snorting bath salts prior to death. He was HIV positive and undergoing hormone therapy treatment for gender reassignment. Analysis of the femoral venous blood revealed a MDPV concentration of 130ng/mL, dextromethorphan of 250ng/mL, and a butalbital concentration of 5.1µg/mL. The urine MDPV concentration was 3800ng/mL. Dextromethorphan, guaifenesin, bupropion, diphenhydramine, phenothiazine metabolites, barbiturates, and caffeine were also present in the urine. No mephedrone was detected in the blood or urine. At this time no cause of death has been established.

Toxic or lethal ranges for MDPV have not been established in the literature. A study by Ojanoerä monitoring opioid-dependent patients undergoing opioid substitution treatment screened each subject's urine for MDPV.[1] The median MDPV concentration from nine positive urines was 160ng/mL with a range of 40 to 3900ng/mL. Urine MDPV concentrations from our postmortem cases are within their documented recreational abuse range. The other drugs and/or combination of the drugs present do not solely explain the causes of death in these two cases. Preliminary pathological findings indicate other contributing factors for their causes of death.

Postmortem blood and urine MDPV concentrations in cases with bath salt abuse is presented. Literature and preliminary autopsy findings suggest that the deceased were recreational abusers and that other factors contributed to their deaths.

Methylenedioxypyrovalerone (MDPV), Bath Salts, Postmortem Blood and Urine Concentrations

K15 Fatal Intoxication With Amiodarone: Report of Two Cases

Anne Marie Andersen, MD, Iana Lesnikova, MD, and Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgårdsvej 100, 8200 Aarhus N, DK-8000, DENMARK*

The goal of this presentation is to describe and discuss a case of fatal intoxication with amiodarone.

This presentation will impact the forensic science community by increasing awareness of toxicity of this widely used drug and its potential hazardous effect.

Amiodarone has become a widely used class III antiarrhythmic drug and is effective in treating both supraventricular and ventricular arrthythmias. It has been found to be more effective than other antiarrhythmic drugs in maintaining sinus rhythm, but because of its serious and potentially life threatening side effects, it is not the drug of first choice. Common side effects of amiodarone treatment are bradycardia, pneumonitis, liver function disturbances, hyperthyroidism, hypothyroidism, photosensitivity, cornea deposits, etc. Torsades de pointes and AV conduction disturbances are seldomly seen.

When amiodarone has been absorbed, it is metabolized in the liver to produce the active metabolite desethylamiodarone. Due to its lipophilic nature, it has strong tissue affinity and a large volume of distribution. In chronic users, high concentrations are found in fatty tissue, liver and lung and lower concentrations in kidneys, heart, skeletal muscle, thyroid gland and brain. The distribution to these tissues is relatively slow, and therefore

a steady state of tissue concentration is reached only after two months. The relation between serum concentration and clinical effect is not very clear. The therapeutic concentrations of amiodarone in serum are 1-2.5 mg/l and serum concentrations > 2.5 mg/l have been associated with an increased risk of toxicity. The most commonly used oral dose is 200 mg per day. In Denmark due to potential risk of toxicity, only cardiologists are allowed to prescribe amiodarone.

Case 1: A 69-year-old woman was found dead at home in her bed. She had been prescribed amiodarone for atrial fibrillation. Three days earlier she was discharged from the hospital, where she was subjected to a catheter ablation in the left atrium. Previously, she complained of chest pain and a shortness of breath, and twice she was seen by the doctor from the emergency unit, who thought she was all right. At autopsy there were two small holes in the foramen ovale and discoloration in the septum and back wall as follows from the operation. Histology examination showed that the SA-node, the AV-node, and the bundle of His was normal. Routine drug testing was performed on the peripheral blood, and it revealed the concentration of amiodarone was 2.8 mg/kg. The medical examiner concluded that the cause of death was heart rate disturbances likely related to amiodarone intoxication.

Case 2: A 48-year-old woman was found dead at home. She was taking amiodarone for atrial fibrillation, and had gone through a catheter ablation in the left atrium two weeks earlier. Two days before her death, she was administered an electrical cardioversion at the hospital, and was discharged the next day. In the evening she called the hospital, because she had a feeling, her heart was not beating correctly. She was told to contact her general practitioner in the morning. The autopsy revealed a slight enlargement of the left atrium with discoloration of the wall, and arteriosclerosis of the left coronary artery and stenosis of the LAD. Histology examination revealed a normal SA-node, AV-node, and the bundle of His. Drug testing was performed on the peripheral blood, and the concentration of amiodarone of 4.0 mg/kg was found. The cause of death was established to be heart rate disturbances probably in relation to amiodarone intoxication.

Discussion: These two cases illustrated deaths due to unintended intoxication with amiodarone. The cases show how doctors need to keep the possibility of intoxication with amiodarone in mind when prescribing amiodarone to patients with persistent atrial fibrillation. Despite amiodane's long history and current widespread use, there are no broadly accepted evidence-based monitoring recommendations. Since the serum concentration has little relation to the clinical effect, measuring it usually is of limited use. However, in such cases the measurement of concentration of amiodarone in serum can be considered in order to prevent the intoxication and death.

Amiodarone, Intoxication, Death

K16 Extraction of Methamphetamine From Postmortem Blood Samples by Molecularly Imprinted Polymers for Selective Solid Phase Extraction

Nicole M. Harre, MS, 701 West Jefferson Street, Phoenix, AZ 85007; Ashley J. Pipkin, BS, 8511 Easton Lane, Apartment 211, Fort Worth, TX 76120-2743; Jorn C.C. Yu, PhD, Box 2525, College of Criminal Justice, Sam Houston State University, Huntsville, TX 77341; and Colin C. Anderson, MS, Office of the Medical Examiner, 701 West Jefferson Street, Phoenix, AZ 85007*

After attending this presentation, attendees will have the opportunity to learn a new way to extract methamphetamine from a complex matrix involving putrefactive amines.

This presentation will impact the forensic science community by presenting information on a new extraction method called MIP-SPE. The imprinting technique creates high affinity binding sites in MIP. The selectivity of MIP-SPE towards target molecules will be reported in this presentation.

Methamphetamine, a sympathomimetic amine, is a commonly encountered controlled substance in the forensic science community. When postmortem samples are analyzed, particularly blood and tissue, false positives may occur on the enzyme-linked immunosorbent assay (ELISA) screen, or the enzyme-multiplied immunoassay technique (EMIT), which are well known screening tests used by many forensic science laboratories. The false positive from the screen is confirmed with gas chromatography/mass spectrometry (GC/MS). One of the explanations for the occurrence of false positives is the appearance of putrefactive amines in postmortem samples, which may produce cross reactions with the ELISA test. Putrefactive amines, including 1-phenethylamine, 2-phenethylamine, putrescine, tryptamine, and tyramine, have similar chemical and physical properties as methamphetamine and are produced during putrefaction, a step in decomposition in which microorganisms breakdown proteins. Therefore, putrefactive amines have the potential to interfere with the interpretation of ELISA test results of methamphetamine. In this research, methamphetamine was extracted from known ELISA positive blood samples, some that have been treated with known putrefactive amines, putrefactive amines and methamphetamine, and methamphetamine only. The two extraction methods include a liquid-liquid extraction and a molecular imprinted polymer cartridge for solid phase extraction (MIP-SPE), which is designed to be specific towards amphetamines. Liquid-liquid extraction is a well known method for drug extractions but can be less selective and has the potential to use a large quantity of solvents. The liquid-liquid extraction of choice involves multiple washes and a back extraction, which further cleans the extract. The extracts were analyzed by GC-MS in order to determine which extraction method has a more significant specificity towards methamphetamine, which was determined through the absence or the decreased number of putrefactive amines. After attending this presentation, the attendee will know if the MIP-SPE is a more specific extraction method for postmortem blood sample. After method validation, actual postmortem samples will be collected at various postmortem intervals and evaluated with the new validated MIP-SPE method to further confirm the conclusions found in the earlier research. The removal of putrefactive amines from an analysis could reduce the potential for misinterpretation or interference when evaluating methamphetamine results from postmortem samples.

Putrefactive amines are potential interferences when methamphetamine is analyzed from postmortem samples in forensic toxicology. This research will evaluate the application of MIP-SPE for selective extraction of methamphetamine from postmortem samples. The objective is to see if MIP-SPE can successfully eliminate putrefactive amines from postmortem blood samples.

MIP-SPE is a new extraction method. The imprinting technique creates high affinity binding sites in MIP. The selectivity of MIP-SPE towards target molecules will be reported in this presentation.

Methamphetamine, MIP-SPE, Putrefactive Amines

K17 Capillary Electrophoresis and Capillary Electrochromatography Mass Spectrometry for Chiral Drug Detection

Hanzhuo Fu, BS, Department of Chemistry, Florida International University, E36, Miami, FL 33199; and Bruce R. McCord, PhD, Department of Chemistry, Florida International University, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand some principles of how chiral drugs can be separated and detected using capillary electrochromatography – time-of-flight mass spectrometry (CEC-TOF-MS).

This presentation will impact the forensic science community by discussing one of the novel chiral separation techniques called capillary electrochromatography mass spectrometry (CEC-MS).

Worldwide issues with poisoning and death from clandestine drug manufacturing make it important to develop methods that can not only detect low levels of drugs but also determine their chirality. In this way, law enforcement can better track users and victims of these products. In addition, the field of chiral toxicology has become increasing important as researchers and practitioners recognize the importance of defining the precise role structure – reactivity relationships play in drug activity. As a result, a large amount of research has been conducted in the analysis of chiral drugs. The goal of this project is to develop methods to detect these drugs using Capillary Electrophoresis (CE) and Capillary Electrophoresis Mass Spectrometry (CE-MS) techniques.

Trace detection of pharmaceutical compounds typically employs several analytical techniques, including gas chromatography-mass spectrometry (GC-MS), and liquid chromatography-mass spectrometry (LC-MS). For chiral separations, these techniques may utilize specific stationary phases or may require derivation to diastereisomers. Capillary electrophoresis can be a powerful alternative for the separation of neutral and chiral drugs through the use of guest-host reactions and micellar-solute interactions. It is proposed that CE-MS with an electrospray ionization (ESI) source would be a useful technique for separating and analyzing this class of drugs. Capillary electrophoresis-mass spectrometry has a number of important advantages for toxicological analysis including low sample consumption and the potential for highly efficient chiral analysis. Generally electrophoretic techniques are restricted to the analysis of charged molecules. However, in the past 20 years, a variety of electrophoresis techniques have been developed which are suitable for the detection of neutral and chiral drugs including micellar electrokinetic capillary electrophoresis (MEKC) and capillary electrochromatography (CEC).

Proper identification of unknown drugs is a critical issue in forensic drug analysis. While capillary electrophoresis with UV, electrochemical or fluorescence detection can be used to presumptively determine the presence of a particular compound, for absolute identity of trace levels of these compounds, mass spectrometry coupled to chromatography is necessary. While a number of useful procedures have been developed for the detection and screening of compounds by capillary electrophoresis/mass spectrometry, to date applications involving neutral or chiral drug detection by MEKC procedures have been problematic. These samples require separation via a detergent or cyclodextrin based pseudo-stationary phase that can be incompatible with electrospray ionization methods that require volatility. One potential solution for this issue is to operate the CE-MS system in a partial filling mode to avoid spraying the reagent into the spectrometer. However, the issues of timing of the capillary filling and the potential instability of a bimodal buffer make this a difficult technique.

Alternatively, capillary electrochromatography (CEC) can be used. This procedure is a novel technique which permits the detection of neutral compounds by combining the high efficiency of CE with outstanding selectivity of HPLC. In CEC, the capillary column is packed with an HPLC type stationary phase. Separation occurs via sample partitioning between the packed stationary phase and an electrodriven mobile phase. An efficient way to produce this stationary phase is through in-situ polymerization into a so called polymer monolith2. When coupled to mass spectrometry, the procedure has been shown to provide efficient and sensitive detection of drugs and their metabolites in biological fluids.

In this study, monolithic CEC-MS will be developed and compared with partial filling MEKC for the application of chiral drug detection in complex matrices. The CEC stationary phase will be developed by bonding chiral selectors onto the silica inner wall of a capillary or through attachment of these selectors to carbon chains on acrylate monomers. In this way CEC-MS can be developed as a powerful technique for chiral toxicology as well as other applications in pharmacological analysis.

Capillary Electrochromatography, Mass Spectrometry, Chiral Drug Detection

K18 A Spectroscopic Investigation of the Binding of Benzodiazepines to Human Serum Albumin

Marianne E. Staretz, PhD, Cedar Crest College, Department of Chemical & Physical Science, 100 College Drive, Allentown, PA 18104; and Kristina M. McNerney, BS, Cedar Crest College, 100 College Drive, Box 281, Allentown, PA 18104*

After attending this presentation, attendees will understand how fluorescence spectrophotometry can be used to study the interactions of different benzodiazepine derivatives with human serum albumin. Attendees will become aware of the varying binding affinities of different benzodiazepines for human serum albumin and some important parameters used to characterize the binding.

This presentation will impact the forensic science community by providing further pharmacological and toxicological information on benzodiazepines, a class of drug that is commonly used therapeutically and is increasingly being abused in social settings.

Benzodiazepines are commonly prescribed central nervous system depressants which are found in a wide variety of different medications from sedatives, hypnotics, to amnesiatics, and anticonvulsants. Benzodiazepines are increasingly being used as recreational drugs often in combination with other drugs such as opiates and alcohol. Human serum albumin is the most abundant plasma protein in humans. Many drugs, including benzodiazepines, bind reversibly to albumin with albumin then acting as a carrier for the drug. This binding can increase the apparent solubility of the drug in the plasma and can influence the distribution, metabolism, and excretion of the drugs. Quenching of albumin fluorescence can be used to study the interactions of these drugs with albumin and was the method utilized in the current research to study the interaction of different benzodiazepines with human serum albumin. The quenching of albumin fluorescence by nine benzodiazepines were analyzed at three different temperatures, 24°C, 30°C, and 37°C. The nine benzodiazepines used in this study were alprazolam, bromazepam, diazepam, flunitrazepam, flurazepam, lorazepam, oxazepam, temazepam, and triazolam. Varying concentrations of each benzodiazepine were incubated with a 2.42µM solution of human serum albumin. The albumin solution was prepared in a 0.05M Tris buffer at a pH of 7.4. Benzodiazepines were tested at each temperature at concentrations ranging from 19.82 µM to 198.2 µM. Each concentration was analyzed five times. A fluorescence spectrophotometer with thermostated cell holder was used to measure fluorescence. The excitation wavelength was set at 290nm and the emission wavelength range was set at 300-500nm.

Quenching mechanisms associated with the binding between a quencher and a macromolecule can be static or dynamic. Stern-Volmer analysis of the data was used to characterize the quenching mechanism. Comparison of the nine benzodiazepine derivatives established that all derivatives exhibited a quenching rate constant of >> 2x1010L mol-1 s-1, indicating that static quenching was present. Static quenching as opposed to dynamic quenching signifies that a relatively stable complex is being formed between the benzodiazepines and the human serum albumin. Analysis of the fluorescence quenching using double log plots allowed the determination of the number of binding sites (n) and binding constants (Kb). The benzodiazepines that showed significant variation in binding affinity were diazepam and flurazepam. Diazepam, for example had a binding constant of 114.1 at 37°C whereas flurazepam had a binding constant of 1.808x106 at the same temperature. Diazepam had an "n" value close to one whereas flurazepam had an n value closer to two, possibly indicating the existence of more than one binding site. Van't Hoff analysis of the data was also used to calculate the thermodynamic parameters of binding and provided evidence of spontaneous binding and information on the involvement of hydrogen bonding and hydrophobic interactions in the binding of these drugs to albumin. The eventual goal is to use this information to determine if the affinity of these drugs for albumin can

influence the analysis of these drugs in blood/plasma using current methods of sample preparation and analysis.

Forensic Science, Benzodiazepines, Fluorescence Spectrophotometry

K19 Multi-Analytical Measurement of Drugs of Abuse in Vitreous Humor With Evidence Biochip Arrays

Allen J.M. Huxley, PhD, and S. Peter Fitzgerald, PhD, Randox Laboratories Limited, 55 Diamond Road, Crumlin, BT29 4QY, UNITED KINGDOM; and Duncan W.S. Stephen, PhD, Department of Clinical Biochemistry, Link Building, Aberdeen Royal Infirmary, Foresterhill, Aberdeen, AB25 2ZD, SCOTLAND*

After attending this presentation, attendees will be able to see the application of biochip technology to the screening of common drugs of abuse compounds in small amounts of vitreous humor.

This presentation will impact the forensic science community by introducing cutting-edge technology for screening very small quantities of vitreous humor for drugs of abuse. This is pertinent in cases where no blood or urine is available and for screening for drugs in small children.

Introduction: To accommodate the demand for tests and the appearance of new drug classes, new analytical methods are required for clinical, regulatory, toxicological, and forensic applications. The use of screening methods enabling the rapid and simultaneous detection of multiple drugs of abuse facilitates the application to regulatory control as only positive results require confirmation. Evidence biochip array technology provides a flexible platform for the simultaneous determination of multiple analytes from a single sample across a number of matrices including vitreous humor.

Methods: The Drugs of Abuse I blood array was used to analyze the vitreous humor from 81 subjects that had gone through postmortem examination in the NHS Grampian region and the results compared against confirmatory GC/MS and LCMS/MS methods. The Drugs of Abuse I blood array facilitates the simultaneous detection of the following drug classes using 20µL of vitreous humor – methamphetamine, amphetamine, barbiturates, generic benzodiazepines, lorazepam, methadone, PCP, opiates, cocaine metabolite, and THC. Cut-off's were chosen by evaluation of a set of standards manufactured by spiking across a calibration range (5-200ng/mL) of the drug/metabolite of interest into bovine vitreous humor.

Results: The biochip screening method showed a high degree of agreement with the confirmatory methods with an overall average of 92% of results being in concordance with those generated from confirmation. Of the various drug classes: six agreed with confirmation in over 96% of cases (amphetamine, barbiturates, benzodiazepines, cocaine metabolite, methadone, and PCP); two others agreed with confirmation in over 90% of cases (lorazepam and methamphetamine). The opiates test was correct in 82% of the cases with THC correct in 67% of the cases. The lower specificity of the THC detection in vitreous may be on account of the proportion of THC and THCCOOH distributed in the vitreous humor compared to blood. Discrepant results were both falsely negative and falsely positive in relation to the chosen cut-offs for these two drug classes.

Conclusion: The data from this small pilot study indicate that the biochip drugs of abuse blood arrays can potentially be modified to allow for the drugs screening of vitreous humor. This is potentially very useful in cases where postmortem blood and/or urine may not be available, for example in victims of traumatic injury. Further investigations may improve the agreement for opiates and THC either by a different choice of cut-off concentration or possibly by performing a quick sample extraction procedure. This technology enables the generation of quantitative abused drug profiles and represents a useful tool for application in forensic and postmortem toxicological settings.

Biochip Array, Vitreous Humor, Drugs of Abuse

K20 Pharmacokinetic Postmortem Evaluation Reveals Death of a Toddler From Carbamazepine to be Accidental Rather Than Criminal

Fran Gengo, PharmD, Meghan Rowcliffe, PharmD, and Michelle Rainka, PharmD, DENT Neurologic Institute, 3980 Sheridan Drive, Amherst, NY 14226*

After attending this presentation, attendees will understand principles of clinical pharmacokinetics regarding the concentrations of carbamazepine that would be expected in its treatment of epilepsy. These include the effect of dosage changes, interactions with drugs that induce carbamazepine metabolism, and drugs that inhibit carbamazepine metabolism. Knowledge of dosage changes and drug interactions provide critical insight for interpretation of toxic concentrations measured at time of autopsy.

The presentation will impact the forensic science community by providing an understanding of how pharmacokinetic variables can affect relationships between dose and concentrations can provide insights for interpretation of toxic concentrations

Carbamazepine and phenytoin are two antiepileptic drugs that are prescribed for both partial seizures and generalized tonic clonic seizures.[1] These two drugs require therapeutic drug monitoring during treatment to ensure efficacy and prevent undesired adverse effects. When administered concomitantly, there is potential for a pharmacokinetic drug-drug interaction to occur. Rare cases of toxicity due to concomitant administration have been reported in the literature. Described herein are the circumstances and autopsy findings of a 23-month old child with a history of epilepsy whose death was caused by acute carbamazepine intoxication. This child suffered from seizure disorder since the age of one. Because of an intolerability to phenobarbital and mephobarbital (two other antiepileptics), he was placed on carbamazepine and phenytoin. The child died five months later and the cause of death was determined to be carbamazepine toxicity. The postmortem serum concentration of carbamazepine was 23.7mcg/ml, which is significantly higher than targeted therapeutic levels of 5-12mcg/ml.[1] The toddler's caregiver was then alleged to have intentionally overdosed the child causing acute toxicity, but events leading up to the death of this child included a myriad of dosing changes including discontinuation of phenytoin two weeks prior to the time of death.

Carbamazepine is converted to an active metabolite, carbamazepine 10,11-epoxide, through oxidation which is then metabolized to carbamazepine diol, the inactive metabolite.[2] Phenytoin is a potent inducer of the liver enzyme CYP3A4, which predominantly metabolizes carbamazepine, causing higher carbamazepine epoxide/carbamazepine and carbamazepine diol/carbamazepine ratios in children receiving both drugs.[2-3] A decrease in plasma concentrations of carbamazepine is correlated with the dosage of phenytoin being administered.[4-5] Also, because carbamazepine has a unique property of auto-induction, the dose is increased gradually based on serum levels drawn every two to four weeks after initiation of therapy.[1] Average steady state concentrations of carbamazepine decrease by 50% after three weeks of administration.[6] A study conducted by Duncan et al. observed the effects of phenytoin discontinuation on concomitant carbamazepine therapy. It was found that upon discontinuation, total carbamazepine concentrations increased by a mean of 48% after four weeks of phenytoin removal and the ratio of carbamazepine epoxide/carbamazepine decreased.[7]

During the five months prior to death, the child's carbamazepine dose was increased from 150mg/day to 500mg/day. Over this same period of time the child was also treated with medications that can alter the pharmacokinetic disposition of carbamazepine. Pharmacokinetic modeling was used to estimate expected carbamazepine serum levels based on carbamazepine dosing orders from the time carbamazepine was started, the known effects of concomitant drugs on the pharmacokinetic disposition of carbamazepine and the timing of the addition and/or removal of these other

drugs. Estimates of carbamazepine concentrations from the pharmacokinetic model were compared to actual measured concentration. Estimated concentrations correlated well with measured concentrations. This demonstrated that carbamazepine concentrations measured at autopsy were the concentrations expected based on the dosing history and timing of the addition and removal of other drugs known to effect the pharmacokinetics of carbamazepine. The concentrations of carbamazepine measured at autopsy were concentrations were expected concentrations based on the prescribed doses as predicted by the pharmacokinetic model. Deliberate overdosing of carbamazepine was ruled out and with this insight the child's caregiver was exonerated.

This case underscores the importance of understanding the pharmacokinetic history of drugs with narrow therapeutic indices in the interpretation of toxic drug concentrations measured at autopsy.

Carbamazepine, Toxicity, Postmortem Drug Levels

K21 Analysis of Synthetic Cannabinoids by Mass Spectrometric Methods Coupled With Accurate Mass Determination

Dima Sbenaty, 1507 Buckingham Drive, Murfreesboro, TN 37129; and Vanessa Hobbs, MS, and Ngee-Sing Chong, PhD, Middle Tennessee State University, PO Box 68, Chemistry Department, Murfreesboro, TN 37132*

After attending this presentation, attendees will learn about the role of accurate mass determination in gas chromatography-mass spectrometry (GC/MS) and liquid chromatography-mass spectrometry (LC/MS) methods for analyzing synthetic cannabinoid products. The synthetic cannabinoid compounds of herbal products along with the full range of organic compounds present in the gas and particulate phases of smoke samples of the herbal products will be discussed. The findings and methodologies will contribute to future development of a protocol for analyzing banned synthetic cannabinoid substances and assessing their toxicological effects.

This presentation will impact the forensic science community by emphasizing the advantages of accurate mass determination in mass spectrometric analysis of illegal drugs and how it will be beneficial to the drug enforcement and forensic communities by providing rapid and reliable analysis of synthetic cannabinoid substances. Sound analytical methods based on mass spectrometry for characterizing products seized in police raids and assessing the levels of the related drug compounds in the urine and smoke samples will contribute to effectiveness in drug enforcement and toxicological studies of the synthetic cannabinoid products, respectively.

The use of illegal synthetic cannabinoids has become increasingly popular over the past several years. These drugs have been successful in providing a "high" just like marijuana and yet these drugs and their metabolites can circumvent detection by most standard drug testing methods for natural cannabinoids. As a result, herbal products containing the synthetic cannabinoids such as JWH-018 and JWH-073 have become more appealing to drug users. These synthetic cannabinoids have shown harmful health effects in the human body and may even cause death from high concentrations of toxic compounds accumulated via extended drug abuse or accidental overdoses through haphazard manufacturing practices involved in these illegal products. It is therefore critical for these drugs and their metabolites to be identified and quantitatively determined by law enforcement and clinical laboratories. The study aims to develop an efficient and reliable method that will identify the synthetic cannabinoids in a forensic testing laboratory.

Forensic analysis of illegal compounds usually involves methods that could provide unequivocal evidence in a court of law. Most current methods involve GC/MS and LC/MS for analyzing commonly abused drugs like cocaine, heroine, and methamphetamine. Although both GC/MS and LC/MS have been reported for determining synthetic cannabinoids in the herbal products and urine samples,[1-3] there has not been any study of cannabinoid distribution in the gas and particulate phases of the smoke inhaled by the users. In this study, the smoke of the herbal products containing synthetic cannabinoids is studied in order to estimate the range of doses of the active ingredients in commonly available products. The GC/MS method developed in this project also relies on accurate mass determination to provide greater confidence in MS analysis based on quadrupole mass analyzers. The goal of developing such a method is that the analytical chemist can either bypass the GC analysis or use a short GC column to achieve rapid analysis to cope with the sample throughput issue in most forensic laboratories. Furthermore, the possibility of a portable mass spectrometer with accurate mass analysis can be conducive toward the development of mobile laboratory testing of illegal drugs for the law enforcement community. GC/MS instrumentation is fairly bulky and is too cumbersome for crime scene analysis. Therefore, it is beneficial to develop "GC-less" MS methods for onsite analysis in order to exclude possible contamination when crime scene samples are collected and brought back to the laboratory for GC/MS analysis. Also, accurate mass analysis is more efficient in unequivocal identification of target compounds relative to GC that is prone to chromatographic co-elution. Preliminary analysis of this study has shown that software-based accurate mass determination using quadrupole mass data allow highly specific and accurate mass-to-charge analysis to the third decimal places for the parent and fragment ions of commonly abused drugs, thus allowing reliable determination these banned substances.

There is great variability in the drug concentrations found in different herbal blends of synthetic cannabinoids. The amount of JWH-018 ranged from 4.09±0.04 mg/g herbal blend in K2 Blond to the highest concentration in Ultra Cloud 10 of 41.80±0.62 mg/g of herbal blend. The amount of JWH-073 ranged from 6.11±0.27 mg/g of herbal blend in K2 Blond to the highest concentration in Ultra Cloud 10 of 13.20±0.24 mg/g of herbal blend. Low concentrations of JWH-018 in K2 Blonde are likely compensated by the presence of JWH-250, a compound not found in the other 4 herbal blends studied. When the smoke samples were analyzed, it was found that the synthetic cannabinoids were not detectable in the gas phase but were detected in the particulate phase collected using a cascade impactor. This indicates that JWH-018, JWH-073, and other synthetic cannabinoids are inhaled in the particulate phase with a particle size fraction of less than 0.25 μm. The analysis also revealed that most of the flavor or scent additives for the herbal products were detected in the particulate phase. Further analysis using LC/MS with a time-of-flight mass spectrometer and ion mobility instrumentation allows the complete characterization of the synthetic cannabinoids and their related metabolites

and by-products in the mainstream smoke samples.

Illegal Synthetic Cannabinoids, Accurate Mass Determination, Mass Spectrometric Analysis

K22 Analysis of Volatile Organic Compounds Emitted During Aerobic Decomposition of Various Swine Tissues

Ngee-Sing Chong, PhD, Middle Tennessee State University, PO Box 68, Chemistry, Murfreesboro, TN 37132; and Samantha T. Keene, BS, Middle Tennessee State University Department of Chemistry, 1301 East Main Street, Murfreesboro, TN 37132*

After attending this presentation, attendees will learn about the analytical methods for the analysis of analytes released from decomposing animal tissues and organs. Cryogenic and sorbent preconcentration of ultratrace analytes are used in conjunction with gas chromatography-mass spectrometry (GC/MS) and pre-evacuated bottle or canisters for sample collection. The identity of the volatile organic compounds (VOCs) discovered and their relationship to the decomposition process will be discussed. The findings and methodologies will have important implications in understanding the chemistry of decomposition and the postmortem interval (PMI) in addition to improving the efficiency in search and recovery of dead human or animal remains.

This presentation will impact the forensic science community by providing important information on the profile of chemical compounds emitted from various tissues of animal carcasses, correlating the specific parts of the carcass with unique identities of compounds released, and their relationship to the different stages of the decomposition process. Knowledge related to the decomposition process could also improve the search and recovery of victims as well as provide crucial evidence for convicting or acquitting suspects in murder trials.

In a recent trial case, emitted volatile organic compounds (VOCs) found in the trunk of the car used by the accused for transporting human remains was introduced as evidence for the first time. However, just like with any new evidence, lawyers were able to discredit this evidence due to lack of knowledge and the need for further research. The goal of this research is to elucidate the decomposition mechanisms of animal carcasses that might yield forensic clues in the investigation of human remains.

Variable environmental conditions, the presence of microorganisms and the disposal mode of the animal or human remains, as well as the amount of time elapsed once the decomposition process has taken place greatly influence the emission profile of the VOCs. Statheroproulos et al.[1] and Vass et al.[2] independently measured more than 100 VOCs that were released during the decomposition of human remains. However, these studies involve the presence of body bags or other burial conditions including the soil matrix, insects, and microorganisms that are typically associated with decomposition. In this study, the influence of environmental media (e.g., soil, sand, water) in the decomposition process was minimized by conducting the study of decomposing tissues in glass vessels that are configured with a leak-proof design for efficient collection of compounds emitted from the degradation of tissues. Samples were collected approximately three times a week over a period of ten weeks using pre-evacuated bottles or canister that were analyzed by gas chromatography-mass spectrometry (GC/MS) with analyte enrichment on a 3-trap preconcentrator.

The predominant classes of compounds found in decomposing tissues include sulfur-containing compounds, esters, and aldehydes. The data shows that aldehydes are formed more readily in organs and in general, aldehydes with five or six carbons, i.e., petanal, hexanal, and 3-methyl butanal were found at the highest concentrations. Several ketones and esters were found in the muscle and skin samples whereas 1,1-difluoroethane was found to be characteristic in bone decomposition. The presence of sulfur-containing compounds such as carbon disulfide, methanethiol, dimethylsulfide, dimethyldisulfide, and dimethyltrisulfide could be linked to the biochemical degradation of sulfur-containing amino acids like methionine, cystine, and cysteine that constitute the swine tissues or organs. The presence of dimethyldisulfide and dimethyltrisulfide may be linked to cystine, which is due to the dimerization of two cysteine units and is commonly found in collagen (e.g., connective tissue) and keratin (hooves and hair).

The cryofocusing GC/MS technique based on a 60-meter column with dimethylsiloxane stationary phase was able to detect alkanes with carbon numbers ranging from 3 to 14 as well as aliphatic alcohols with 2-8 carbons. The detection limits of the compounds released from the decomposition of porcine tissues are generally in the 0.1 to 20 parts per billion levels. With the current study of tissue-specific or organ-specific decomposition studies, valuable information will be gleaned for strengthening the credibility of evidence involving odor analysis pertaining to human decomposition in court.

VOC Analysis, Decomposition Chemistry, Animal Carcass

K23 Is Your Urine Really Dilute? An Analysis of Normal Urine Creatinine Measured by HPLC-UV Below the Cutoff Limit of 20 Mg/Dl

Brad T. Holden, BS, Heather L. Workman, BA, and Erica A. Guice, MS, Western Slope Laboratory, 1197 Rochester Road, Suite K, Troy, MI 48083*

After attending this presentation, attendees will understand a simple method for the detection of creatinine in urine samples, how creatinine concentrations is used in clinical medicine to determine adulteration of samples, factors effecting creatinine concentration in urine, and hear a proposal to change the cutoff limit of adulterated urine samples.

This presentation will impact the forensic science community by addressing concerns of the Substance Abuse and Mental Health Services Administration (SAMHSA) guidelines for urine adulteration by reviewing the creatinine concentration of a population of unknown advanced toxicology urine samples.

In clinical and forensic toxicology laboratories there is a need to establish criteria for identifying a random urine sample submitted for drug testing as being adulterated by using creatinine analysis. According to SAMHSA, the cutoff value mandated for workplace drug testing is 20mg/dL; however, there are many factors that independently influence the concentration of creatinine in a urine sample. These factors include but are not limited to: gender, muscle mass, diet, fluid consumption, and several clinical conditions such as polyuria. With so many factors influencing the concentration of creatinine in the urine it is possible that many samples may

be determined to be dilute or substituted when, in fact, a value of less than 20mg/dL is normal for that donor. This presentation will discuss the use of creatinine concentration data from the aforementioned population of samples to address the issue of the 20mg/dL SAMHSA cutoff being too high as well as predispose the samples to falsely high level of positive diluted urine samples.

A simple method for the detection of creatinine in urine samples was used in this study to determine the creatinine concentration in 4,600 advanced toxicology urine samples. This method uses cation-paring high pressure liquid chromatography with a ultra-violet detector (HPLC-UV). This HPLC-UV method allows for simple sample preparation and the automation of sample analysis. Using this method also allows for a large linear range of quantitation in the physiologically relevant range of 0.1-500 mg/dL and a limit of detection as low as 0.05mg/dL. For this study, 4,595 samples were tested for creatinine using the method described above. Out of these samples, 160 (3.48%) tested for a creatinine concentration of less than 20mg/dL. From these samples determined to be dilute or substituted, 140 (87.5%) samples were confirmed positive for one or more drugs. Altogether, 70% of the dilute samples were from women and 30% were from men. The average value for the dilute samples was 12.3 and the median value was 14. Twenty-one of these low creatinine samples were tested for pH, specific gravity and creatinine using urine drug adulteration test strips. Out of these 21 samples, 20 of them were suspected of adulteration based off the results of creatinine or specific gravity.

In conclusion, this presentation addresses the concerns of the SAMHSA guidelines for urine adulteration by reviewing the creatinine concentration of a population of unknown advanced toxicology urine samples and noting potential issues with the current cutoff limit. As many factors can influence the creatinine concentration this newly proposed value will help reflect this and help to reduce the number of samples reported to be falsely diluted.

Creatinine, Adulteration, Toxicology

K24 Method Development and Validation for the Detection of Cannabinoids in Blood Using LC/MS/MS

Eduardo Padilla, BS, Texas Department of Public Safety Crime Laboratory, 5806 Guadalupe Street, Austin, TX 78752; and Sarah E. Martin, BS, 2435 Montgomery Road, Apartment 133, Huntsville, TX 77340*

After attending this presentation, attendees will understand how a method was developed and validated for Texas Department of Public Safety (DPS) Crime Laboratory to detect cannabinoids, specifically, Δ^9-THC and carboxy- Δ^9-THC, in blood using LC/MS/MS.

This presentation will impact the forensic science community by allowing for the detection of cannabinoids, Δ^9-THC and carboxy- Δ^9-THC, in blood samples submitted to the DPS Crime Laboratory.

The objective of this research was to develop and validate a method for the detection of cannabinoids in blood using LC/MS/MS.[1] This project is beneficial to the toxicological field in that the compounds of interest, Δ^9-THC and carboxy- Δ^9-THC, would be able to be detected in blood, which is the biological sample that is most often submitted to the Texas DPS Austin Crime Laboratory. Using LC/MS/MS, the cannabinoids would not need to be derivatized, while GC/MS requires it, saving time and therefore money. Methods were developed for detection of cannabinoids in blood on the LC/MS/MS by other agencies and manufacturers, but a cannabinoid method for the DPS laboratory will benefit the entire state by being free of charge to law enforcement agencies. The developed method for DPS was similar to the Dallas County Institute of Forensic Sciences method, but also took into account the methods in published scientific articles. This project required testing the different procedures obtained, and evaluating and optimizing each step performed, including the extraction technique, LLE or SPE. Based on the results, a method for the DPS Crime Laboratory was created.

This method was validated through different parameters that tested selectivity, recovery, linearity, limit of detection, limit of quantitation, carryover, reproducibility, stability, and competency. The method showed no carryover at concentrations four times the highest calibers, 100 ng/mL for Δ^9-THC and 250ng/mL for carboxy- Δ^9-THC, was only selective for Δ^9-THC and carboxy- Δ^9- THC, and showed that both Δ^9-THC and carboxy- Δ^9- THC are stable reconstituted after twenty-four hours. The recovery efficiency for Δ^9-THC was found to be 68.1% for the low concentration, 2ng/mL, and 56.8% for a mid concentration, 25 ng/mL. The recovery efficiency for carboxy- Δ^9-THC was 23.7% for the low concentration, 2 ng/mL, and 18.6% for a mid concentration, 25ng/mL. These results are comparable to other agencies' results. It was also determined that the LOQ for Δ^9-THC was ¼ of the low caliber (0.5 ng/mL) and the LOQ for carboxy- Δ^9- THC was ½ of the low caliber (2.5 ng/mL). The LOD for Δ^9-THC was 1/32 of the low caliber (0.0625ng/mL) while the LOD for carboxy- Δ^9- THC was ¼ of the low caliber (1.25ng/mL). Regarding linearity, both Δ^9-THC and carboxy- Δ^9- THC produced an acceptable curve with a quadratic inverse squared plot. The outside controls were all reproducible and fell well below +/- 20% bias and precision. Therefore, this method can now be used for Texas DPS casework in the future to test for the presence and the concentration of Δ^9-THC and carboxy- Δ^9- THC.

Δ^9-Tetrahydrocannabinol, Carboxy-Δ^9-Tetrahydrocannabinol, Liquid Chromatography Tandem Mass Spectrometry

K25 An LC/MS/MS Analytical Method for Mephedrone and Naphyrone Metabolite Analysis in Urine

Cicely Berg, BS, Brent Dawson, PhD, and Hua-Fen Liu, PhD, AB Sciex, 353 Hatch Drive, Foster City, CA 94404*

The goal of this presentation is to show a strategy for detecting metabolites of mephedrone and naphyrone in a urine matrix with tandem MS technology. Attendees will learn the identity of some of the prominent metabolites and their characteristic ions.

This presentation will impact the forensic science community by showing how mephedrone and naphyrone and their metabolites can be detected with tandem mass spectroscopy. Additionally the work will give forensic scientists confidence in the analysis of such compounds with qualifying and quantifying ion transitions.

Designer drug chemistry has been dominated by substituted phenylethylamines and tryptamines. The production, availability, and use of cathinone as a framework drug have been perceived as the next big thing. They include the beta-keto version of amphetamines which includes mephedrone. In 2010, mephedrone was made illegal in many countries. Naphyrone (also known as NRG-1, Energy-1, or O-2482) is a cathinone derivative that emerged in late 2010 as a new legal high in the UK after the banning of mephedrone. Naphyrone is a new designer drug and stimulant with many cases of abuse reported in the UK.

Until July 2010, naphyrone was not controlled by the misuse of Drug Act 1971 and was therefore not illegal for someone to possess. Since the Medicines Act prevented naphyrone for being sold for human consumption, it was often sold as a "pond cleaner." Currently very little safety or toxicity data are available for naphyrone, but its high potency by comparison with previous cathinones or MDMA (ecstasy) suggests that its use is likely to be associated with a higher risk of accidental overdose.

LC/MS/MS analysis can provide a fast analysis time as well as accurate, precise, and reproducible results. Here we present a method for the analysis of mephedrone and naphyrone metabolites in urine using a triple-quadrupole-ion trap mass spectrometer.

The method development process evaluated different sample preparation procedures, calibration curve construction, column selection, mobile phase selection, and ion suppression.

This analysis was performed on a reversed phase column analyzed by LC/MS/MS with a run time under five minutes. The mass spectrometer was operated in multiple reaction monitoring mode (MRM) in positive ion mode. The assay was shown to be accurate and precise with %CV and % accuracy within ±15% of nominal across the full linear range.

K26 Screening for K2: Monitoring JWH-018, 073, 081, and 250 and Some Prominent Metabolites by HPLC-MS/MS

Cicely Berg, BS, AB Sciex, Brent Dawson, PhD, Alexandre Wang, MS, and Hua-Fen Liu, PhD, AB Sciex, 353 Hatch Drive, Foster City, CA 94404*

The goal of this presentation is to show a strategy for detecting synthetic cannabinoids in a urine matrix with quadrupole-linear ion trap technology. Attendees will learn the identity of the some of the prominent metabolites and their characteristic ions.

This presentation will impact the forensic science community by showing how synthetic cannabinoids and their metabolites can be detected with a hybrid quadrupole-linear ion trap mass spectrometer even in the absence of standards. Additionally, the work will give forensic scientists confidence in the analysis of such compounds with mass spectral library search techniques.

Objectives: To expand K2/spice screening method to include JWH-81 and JWH-250 metabolites using a quadrupole-linear ion trap, to identify the metabolites and generate a spectral library. Human liver microsomes and hepatocytes were incubated with the parent drugs (JWH-018, 073, 081, 250) to generate phase I and phase II metabolites. After predicting the precursor and product ions using a metabolite identification software package the incubated samples were analyzed using the multiple reaction monitoring to trigger acquisition of product ion spectra. Spectral comparison of the metabolite spectra to those of the parent drugs allowed for the identification of the metabolites. The objective of the work was to produce a highly sensitive screening method for JWH-81 and JWH-250 metabolites and parent drugs to augment our current method that screens for JWH-73 and JWH-18 metabolites and parent drugs.

Materials and Methods: A state of the art quadrupole linear ion trap and High Performance Liquid Chromatography (HPLC) were used to acquire the metabolite mass spectra. The initial multiple reaction-monitoring list was generated from a metabolite identification software package. Samples were analyzed on a biphenyl hplc column using an acetonitrile gradient with 0.1% formic acid to aid ionization. Standards were prepared in synthetic urine matrix and samples were prepared by diluting them with acetonitrile prior to centrifugation at 21,000 rcf. When the multiple reactions monitoring transition generated a signal above a set threshold, the linear ion trap obtained the product ion spectrum on the metabolite precursor. Once the metabolite identification was confirmed through spectral analysis, the product ion spectra were added to a spectral library.

Result: Multiple metabolites of each parent drug were found including alkyl chain hydroxylations, demethylations, indole ring hydroxylations, carboxylations and hydrogenations. The glucuronide conjugates of these phase I metabolites were identified in the hepatocyte incubation of JWH-250. The mass spectral analysis allowed for the identification of the prominent metabolites as hydroxylations on the aromatic rings or the aliphatic chain portions of the molecules. The addition of 17 daltons to the recorded m/z values for the metabolite parent ion and the fragment ions versus those of the drug as well as the absence of other changes in the m/z values led to this conclusion. Representative product ion spectra were added to a compound database against which spectra from physiological samples could be searched using mass spectral software. Using dilute and shoot sample preparation allowed for rapid and sensitive sample analysis with good purity scores on spectral matches though sensitivity could be increased with enzyme hydrolysis of the glucuronide metabolites. When the microsome incubation solutions were spiked into urine samples, metabolites of JWH-018, JWH-73, JWH-081, and JWH-250 could be uniquely identified through a library search algorithm.

Conclusion: Many common metabolites of JWH-250 and JWH-081 were identified using the quadrupole linear ion trap. A spectral library of the most common metabolites was generated, and this library was used in a screening method to detect metabolites in urine samples. The method provides for the high sensitivity screening of physiological samples for JWH-018, JWH-073, JWH-081, and JWH-250 metabolites as well as the parent drugs.

K2, Spice, Mass Spectrometry

K27 Drug Screening Using a High Resolution Accurate Mass System

Cicely Berg, BS, Alexandre Wang, MS, Brent Dawson, PhD, and Hua-Fen Liu, PhD, AB Sciex, 353 Hatch Drive, Foster City, CA 94404*

The goal of this presentation is to show the use of fast, high resolution, accurate mass system capable of generating TOF-MS data with up to 20 product ion spectra in under a second.

This presentation will impact the forensic science community by giving attendees a great option for generating high resolution, accurate mass data for use in forensics and toxicology.

Objectives: This research evaluates the use of a fast, high resolution, accurate mass system capable of generating TOF-MS data with information dependent acquisition (IDA) of up to 20 TOF-MS/MS in one second for drug screening purposes. Initial drug identification was accomplished by accurate mass MS and confirmation by accurate mass product ion spectrum which was searched against a library. The use of an existing product ion spectra library generated on a hybrid triple quadrupole ion trap system with the data generated from high resolution, accurate mass system is also evaluated.

Methods and Sample Preparation: Blood samples (250µL) were precipitated with the addition of 750µL of acetonitrile. Samples were then vortexed, centrifuged and the supernatant evaporated, before reconstitution with 500µL of 10/90 acetonitrile/water. Urine samples were diluted with five volumes of 10/90 acetonitrile/water.

Chromatography: The separation was carried out on a PFP Propyl 50mm x 2.1mm x 5µ column. Mobile phase A consisted of 0.2% formic acid and 2mM ammonium formate in water and mobile phase B consisted of 0.2% formic acid and 2mM ammonium formate in acetonitrile. A linear gradient starting at 10% organic and ending at 90% organic was used with a total flow rate of 0.7mL/min and a total run time of 17.5 min.

Mass Spectrometer: The drug screening method consisted of a full range TOF-MS survey scan with IDA-triggering of up to 20 accurate mass product ion scans. Total cycle time for the TOF-MS – IDA – TOF-MS/MS (20) was approximately one second. The product ions were automatically searched against an existing library containing spectra for over 1200 compounds. The library was previously generated on a hybrid triple quadruple ion trap system and was evaluated for compatibility with the accurate mass system.

Results and Conclusion: Positive blood and urine samples, as well as spiked matrix samples, were used for the evaluation of the drug screening method and the library search tool along with the library previously generated on a different mass spectrometer. All compounds in the spiked

matrix samples were correctly identified and confirmed. High concentrations of antidepressants, pain medications, or drugs of abuse were observed in the positive samples. The method allows for the positive identification of over 1,200 drugs and metabolites by using accurate mass along with MS2 confirmation. With the fast, high resolution, accurate mass system, TOF-MS along with 20 product ion scans were collected in about one second allowing for more analytes to be confirmed even with multiple co-eluting analytes. TOF-MS scan allowed for identification of analytes by exact mass with mass error less than 5ppm. Confirmation was accomplished by searching all generated product ion scans against a library with more than 1,200 compounds generated on the hybrid triple quadruple ion trap system. Library search scores ranged between 75% and 98% showing that even though the library was generated on a different mass spectrometer, the spectra can be used since similar fragmentation patterns are obtained in both instruments.

Accurate Mass, Mass Spectrometry, TOF-MS

K28 Two Fatalities, Survival Driver, and Topiramate

Nicolas Yim, BS, Texas Southern University - College of Pharmacy, 3100 Cleburne Street, Houston, TX 77004; and Michael Chen, PhD, Jeffrey P. Walterscheid, PhD, and Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will have greater awareness of how the misuse of prescription drugs can result in cognitive impairment and judgment which could lead to serious motor vehicle accidents and possible death due to overdosing.

This presentation will impact the forensic science community by informing attendees of a potential problem with prescription drug abuse such as topiramate without any street drug or alcohol.

Topiramate (Topamax®) is FDA approved for initial monotherapy or adjunct treatment for partial, generalized tonic-clonic seizures, Lennox-Gastaut syndrome, and as a migraine prophylaxis. The common side effects seen with topiramate include ataxia, reduced concentration, confusion, dizziness, fatigue, impaired psychomotor performance, memory impairment, somnolence, and speech difficulty. Topiramate is categorized in the sugar sulfamate family and is available in a capsule, sprinkle, and tablet forms in varying dosage strengths.

A 28-year-old man was reported driving on the freeway at a high rate of speed and weaving in and out of traffic when he struck another vehicle on the back quarter of the vehicle. The rear ended vehicle lost control and rolled over several times and landing in a grassy area along the right side of the freeway. The passenger of the rolled over vehicle was ejected out of passenger front window. He was rushed to a nearby hospital where he was pronounced dead by major head trauma, collapsed lungs, and open fractures on both lower legs. The driver was properly restrained but died at the scene because the roof of his vehicle collapsed on top of him.

The man that caused the accident was not injured. The suspect was given a field sobriety test at the scene but failed. The suspect was then transported to a local hospital where he voluntarily gave a blood sample for DUI toxicology testing the shows topiramate was the sole drug identified and confirmed in the blood at a concentration of 13mg/L. A reported blood toxic concentration range is 8 to 17mg/L. The therapeutic concentration levels are recognized at a mean of 5 mg/L.

Prescription drug abuse for the purpose of "getting high" is emerging today because of the ease of access to this prescription drugs. The side effects of topiramate further highlight the dangers of potential drug abuse; however, this case of topiramate toxicity that lead to two motor vehicle related deaths was unusual in that no other drugs or alcohol were detected and that topiramate was contributory to impaired human performance in operating a motor vehicle.

Topiramate, DUI, Prescription Drug

K29 Development of a New Gas Chromatographic Column Set for the Analysis of Blood Alcohol Concentration

Frank Dorman, PhD, Penn State University, 107 Whitmore Labs, University Park, PA 16802; Gary Stidsen, MS, Richard Morehead, BS, Jarl Snider, BS, Restek Corporation, 110 Benner Circle, Bellefonte, PA 16823; and Jessica Westland, MPS, Penn State University, 107 Whitmore Laboratories, University Park, PA 16802*

After attending this presentation, attendees will understand the importance of GC column chemistry in the resulting separation, and how this may be optimized.

The presentation will impact the forensic science community by making attendees aware of improved methodology available for BAC analysis.

Blood alcohol concentration (BAC) analysis may be the most common analytical test performed by laboratories involved in forensic and medical testing. This analysis typically uses static headspace sampling, followed by dual-column gas chromatography (GC) separation followed by flame ionization detection (FID). Chromatographic separation of the target analytes, as well as the possible interfering compounds, is critical for this analysis, especially given that the FID is not selective. Incomplete chromatographic separation will cause a quantification bias, and possibly invalidate the results of the test. This condition makes a number of demands on laboratories performing this work. Laboratories are also under time pressure, and must continually balance the need for separation with fast sample turnaround and short analysis times.

The most important chromatographic variable in this separation is the selectivity of the GC stationary phase; however, most GC column stationary phases were not designed with a particular separation in mind. This may lead to compromises in either the separation, or the analytical run-time of the analysis. By using a GC stationary phase and column dimensions which are specifically tuned for a separation will result in analytical improvements relative to the use of columns and dimensions that are not optimized.

The methodology of how this optimization is performed will be covered in this presentation. In brief, the use of thermodynamic modeling has been demonstrated as successful for both the development of new stationary phase materials and also for the optimization of GC conditions using commercial software without the need for lengthy experimental work in the laboratory. While these technologies have been proven successful, most laboratory personnel do not consider them in their method development work, and therefore most GC methods are actually operated far from optimal conditions.

This presentation will address the theory and development of two GC columns that are specifically optimized for the BAC separation using current analytical instrumentation. Through the use of thermodynamic modeling two new GC columns have been developed which allow for improved separation of the target analytes. Known interfering compounds have also been addressed in this approach, so as to maintain complete separation between the blood alcohols and possible coeluting compounds which may also be present in these samples. Finally, total analysis time has been minimized so that the complete separation occurs in less than three minutes, allowing for greater laboratory throughput as compared to most laboratories current operating conditions. Modeling accuracy will be demonstrated by comparison of theoretical results to those obtained in the laboratory. Also, comparison to existing column chemistries used for these separations will be shown to demonstrate the improvements possible using this approach.

The impact of this work to the forensic community is improvement in data quality for this very common analysis. Through the use of optimized GC column dimensions and stationary phase chemistry this analysis will have improved chromatographic resolution in shorter analysis times than what is common in current laboratories. This will enable laboratories to

have greater sample throughput without sacrificing analytical quality, and will likely improve analytical quality for most testing laboratories performing BAC analysis.

Blood Alcohols, GC-FID, Ethanol

K30 Clinical Pharmacologic Factors in Interpretation of Serum Benzodiazepine or Opiate Concentrations in Automobile Drivers

Fran Gengo, PharmD, Michelle Rainka, PharmD, James R. Miller, and Horacio Capote, MD, DENT Neurologic Institute, 3980 Sheridan Drive, Amherst, NY 14226*

After attending this presentation, attendees will understand some principles of clinical pharmacology that influence the expected effects of benzodiazepines and opiates in individual drivers. Factors such as medical use versus recreational use, the medical condition being treated, the specific benzodiazepine, the duration of treatment, and the time since drug administration will markedly influence the likely effects produced by these drugs in individual drivers.

The presentation will impact the forensic science community by providing insight into important factors that can influence the effects produced by concentrations of benzodiazepines or opiates

Following automobile crashes, in the absence of measurable ethanol concentrations, law enforcement officers often require drivers to submit blood samples for determination of the presence and concentration of drugs. However, millions of drivers use opiates and benzodiazepines for legitimate medical indications. Published literature suggests that 2.4% of drivers are currently taking benzodiazepines, and 11.1% of drivers are taking opiates.

A review of published literature reveals that in patients using these medications chronically, measures of impairment are often no different from placebo. Much data reporting an increase in odds ratio for motor vehicle accidents in drivers taking opiates or benzodiazepines occur within the first one to two weeks of drug exposure, or in drivers using these drugs recreationally.

A review of the literature reveals the following published results. The effects of alprazolam 2mg per day was examined using the Hopkins verbal learning test and by measuring benzodiazepine receptor density using SPECT scans. Subjects treated for 24 days showed a steady decrease in impairment scores, with day 24 effects proving no different than placebo. This indication of tolerance correlated with steady decreases in benzodiazepine receptor density. A similar study, measuring psychomotor performance and memory in subjects treated with alprazolam (.25-2mg) daily for three weeks, showed that after two to three weeks of daily administration, no significant impairment remained. Another double-blind placebo controlled crossover trial in 16 normal male volunteers confirmed that sedative and psychomotor effects, following chronic alprazolam administration, were no different from placebo after ten and four days respectively. The effects of diazepam (.2mg/kg for 15 days followed by .3mg/kg for seven days) and oxazepam (.8mg/kg for 15 days followed by 1.2mg/kg for seven days) were also studied using a battery of psychometric tests in healthy subjects. Following the first dose there was marked impairment; however by the end of 15 days performance was similar to testing prior to drug administration. When the dose was then increased for the final week of treatment no further impairment was measured. Even when examining only the acute effects of benzodiazepines there are marked differences between agents. A study compared the skills related to driving after a single administration of diazepam 10mg and lorazepam 2.5mg. Lorazepam impaired all measured skills for 12 hours while diazepam impaired only perceptual speed and coordinative skills for five to seven hours. Nonetheless, there were measurable plasma concentrations of both drugs for at least 24 hours.

Much like benzodiazepines, there is an intuitive presumption that all individuals with measurable blood concentrations of an opiate will be impaired. However, a substantial amount of literature suggests impairment from chronic therapeutic opiate use is no different from placebo. A study in Texas compared the driving records of 104 former heroin users during one year while they were maintained on methadone. No significant difference was found in convictions for accidents, negligent collisions, or other moving violations compared to the entire pool of Texas licensed drivers. Another study, which examined various forms of cognitive function in 17 opiate-dependent subjects, demonstrated an improvement two months after methadone maintenance when compared to baseline. Likewise, six patients with severe non-malignant pain demonstrated positive behavioral and neurophysiological changes after instituting a sustained daily morphine dosage. Patients' mood and clinical pain were rated on visual analog scales, while their reaction time was measured using a standard auditory task. The non-impairment of patients' reaction time and evaluation of mood both failed to indicate a sedative effect. Neurophysiologic measures such as late auditory evoked potentials (AEP) and a P300 component were used to measure vigilance and cognitive performance. Auditory P2 and P300 amplitude actually increased under morphine use showing improved vigilance

These and other studies by various authors which have appeared in peer reviewed publications and their own clinical experience from a pharmacokinetic and pharmacodynamic perspective will be discussed. In addition, there will be discussions about those patients treated with opiates or benzodiazepines whose medical diagnosis can produce symptoms easily misinterpreted as drug impairment. Examples include cancer pain treated with opiates and spasticity treated with benzodiazepines, both which can produce outward signs that can be confused with drug intoxication.

In summary, the impairing effects produced by specific concentrations of opiates or benzodiazepines will vary depending on whether these medications are being used to treat chronic medical conditions, being used acutely, or being used recreationally.

Benzodiazepines, Opiates, Automobile Drivers

K31 Comparison of Ethanol Elimination Rate of Human Females and Body-Paired Males

Michael R. Corbett, PhD, and Andy Huang, BSc, University of Ontario Institute of Technology, Faculty of Science, 7309 Sandhurst Drive, Mississauga, ON L5N 7G8, CANADA*

After attending this presentation, attendees will learn about the importance of the formulation of ethanol elimination rate and human gender difference.

This presentation will impact the forensic science community by revealing the prevalence of higher ethanol elimination rates in forensic (driver) female subjects that were investigated.

Subjects consumed commercial alcoholic beverages (beer, wine, liquor, coolers, and/or liqueur) up to 2.2g of ethanol per kg body mass (median=1.1g/kg) in up to 290 min. (median=151 min). Thereafter, they provided suitable breath samples into two different breath alcohol testing instruments about 20 minutes apart. Instrument calibration was confirmed using forensic ethanol standards from different manufacturers with differing concentrations and simulators. The ethanol elimination rate was the post-absorption/distribution linear decrease of alcohol with time.

Ethanol elimination rates for 102 females were paired with varied body criteria of ultimately 207 males from a larger database (109 females, 702 males) of post-offense forensic toxicology casework. Data from females were first paired with males of identical age (yrs), and then varied body criteria of: (i) body mass index (BMI) (±3, n=98); (ii) body mass (BM) (±4.5 kg, n=70); (iii) estimated total body water (ETBW) (±10 L, n=83); and, (iv) estimated liver weight (ELW) (±300 g, n=84). ETBW was calculated from equations derived by Watson[1] and ELW from Chouker.[2] Ethanol elimination rates were formulated in concentration per time (mg/210 L/hr), mass per time (g/hr), and mass per body mass per time (g/kg/hr). No significant differences (albeit less paired subjects) were

found for smaller ranges of body criteria (e.g., BMI ±2, ±1; BM ±2.3kg, ±0.9kg; ETBW ±5L, ±2L; ELW ±200g, ±100g).

Breath ethanol elimination rates in concentration per time were significantly higher ($p<0.01$) in females than males for all body criteria considered (e.g., median of 20.3 vs. 17.1mg/210 L/hr for BMI ±3; 20.5 vs. 17.2 for BM ±4.5kg; 20.6 vs. 17.4 for ETBW ±10L; 20.2 vs. 17.4 for ELW ± 300g). Females had a wider and higher range in elimination rate (concentration per time) for all body criteria considered (e.g., 13.7 to 29.0mg/210 L/hr vs. 11.9 to 23.1mg/210 L/hr for BMI ±3; 13.6 to 29.0 vs. 11.9 to 24.3 for BM ±4.5kg; 13.6 to 29.0 vs. 11.9 to 24.3 for ETBW ± 10L; 13.6 to 29.0 vs. 11.9 to 24.3 for ELW ±300g).

Breath ethanol elimination rates in mass of ethanol per time (g/hr) were statistically lower ($p<0.01$) in females than males when paired for BMI (e.g., median of 7.60 g/hr vs. 8.92g/hr for BMI ±3), but were not statistically different for other body criteria (e.g., median of 7.90 g/hr vs. 8.51g/hr for BM ±4.5kg); median of 7.86g/hr vs. 7.77g/hr for ETBW ±10 L; median of 7.80g/hr vs. 8.26 g/hr for ELW ±300g)

Elimination rates in mass of ethanol per body mass per time (g/kg/hr) were not significantly different between gender for all body criteria (e.g., median of 0.119 vs. 0.119g/kg/hr for BMI ±3; 0.112 vs. 0.119g/kg/hr for BM ±4.5kg; 0.116 vs. 0.119g/kg/hr for ETBW ±10L; 0.114 vs. 0.120g/kg/hr for ELW ±300g).

A higher proportion of females had elimination rates (concentration per time) greater than 20.0 mg/210 L/hr than males for all body criteria (e.g., 54.1% vs. 9.2% for BMI ±3; 57.1% vs. 18.6% for BM ±4.5 kg; 57.8% vs. 18.1% for ETBW ±10L; 53.6% vs. 16.7% for ELW ±300g).

Dettling et al. (2007) reported that different liver masses as calculated in relation to the distribution volume account for the differing ethanol elimination rates between men and women.[3] Dettling et al. (2008) reported that gender differences in the pharmacokinetics of ethanol can partly, but not completely, be explained by progesterone levels.[4] Dettling et al. (2009) reported the difference in average ethanol elimination rate between gender of 0.012 g/kg/h was statistically significant ($p<0.0001$).[5] We found the ethanol elimination rate is higher in human females than males when formulated in concentration per time, but no significant difference in concentration per body mass per time.

Ethanol, Elimination, Female

K32 Improved Blood Alcohol Concentration Analysis Utilizing Two Novel Chromatographic Stationary Phases

Jessica Westland, MPS, and Frank Dorman, PhD, Penn State University, 107 Whitmore Labs, University Park, PA 16802*

Headspace gas chromatographic analysis of blood alcohol concentration is a routine analysis carried out in forensic laboratories. After attending this presentation, attendees will understand the principles of blood alcohol headspace analysis and why the forensic community is focused on optimizing this methodology.

This presentation will impact the forensic science community by providing an improved methodology for the analysis of blood alcohol concentration. The improvement focuses on the modification of the protocol, the automation of the analysis, and the separation and resolution of the alcohols.

In the United States, alcohol abuse is associated with automobile fatalities, industrial accidents, and numerous other incidents such as alcohol poisoning and drug facilitated sexual assault. Due to its enormous impact on society, a rapid and precise methodology for the determination of blood alcohol concentration is desired.

Blood alcohol concentration reflects the amount of ethyl alcohol in the body. The most significant blood alcohol compound is ethanol. After ethanol is absorbed through the stomach and small intestine, it is eliminated from the body via metabolism and excretion. To accurately determine a subject's blood alcohol concentration, numerous factors must be taken into account, including the qualitative and quantitative analysis of the alcohols and their metabolites. There are a number of other compounds present such as methanol, isopropanol, and acetone that can interfere with the identification and quantitation of ethanol. A common interference observed with these other alcohols is their possible co-elution with ethanol. By use of the application specific columns, an improved baseline resolution of ethanol from all other potential components can be achieved.

The presentation will focus on the improvement of the established methods for blood alcohol analysis. Current methods include both direct gas headspace and solid-phase microextraction (SPME) under either static or dynamic conditions. The direct injection methodology does not have optimal standards due to its sample introduction of biological samples onto the gas chromatographic column. This frequently leads to column contamination and decreases performance. The integration of head space sampling into the method prevents the buildup of non-volatile contaminates in the injector and on the column. It also helps to maintain consistent performance and extends the lifetime of the column.

The selected instrumental technique is gas chromatography combined with either a mass spectrometer (GC–MS) or a flame ionization detector (GC–FID). The main element of this improved methodology is the use of two new gas chromatographic column stationary phases. These stationary phases, which are application specific, show an improvement in the separation and resolution of the studied alcohols.

These two capillary column stationary phases were developed specifically for blood alcohol analysis. The new stationary phases focus on the same analysis, but will improve the baseline resolution of all low molecular weight alcohols and their metabolites in minimum needed analysis time.

The presented method includes the evaluation of blood alcohol concentration by both direct gas headspace and SPME. An investigation of the method detection limits (MDLs) was also conducted in order to report with greater confidence the degree of uncertainty than previous methods (0.025 – 0.100 %). The instrumental technique utilized was GC–FID. The technique was chosen because of its accessibility in forensic labs, low operating costs, reliability, as well as its specificity in analyzing these volatile compounds.

Blood Alcohol Concentration, Head-Space Analysis, SPME

K33 New Criteria for Accepting Breath Alcohol Test Results Using Exhalation Profile Data

Brian M. Lutmer, BS, Missouri Department of Health and Senior Services, 2875 James Boulevard, Poplar Bluff, MO 63901*

After attending this presentation, attendees will understand new criteria for accepting breath alcohol concentration (BrAC) test results using exhalation data to determine breath alcohol sample irregularities.

This presentation will impact the forensic science community by providing changes to BrAC testing, through new parameters for sample acceptance, utilizing exhalation profile Phase III slope data.

A breath alcohol exhalation profile is the plot of BrAC as a function of time or volume during sample submission into a breath alcohol instrument utilizing infrared spectrometry for analysis. Breath alcohol exhalation profiles normally have three distinct phases.[1] Phase I is the initial emptying of the residual air from the instrument. Phase II is the rapid increase in BrAC as breath from the upper bronchial passages is analyzed. The nonlinear phase transitions into Phase III, with a linear increase of BrAC over time and volume of soluble gas exchange beginning with approximately 1.2 liters of lung air volume until expiration has ceased.

Older breath alcohol equipment do not retain all exhalation profile data and use moving point averages to minimize noise to detect mouth alcohol for a determination of BrAC. Recent breath alcohol instruments preserve all BrAC and flow rate data. This data may be used to redefine sample acceptance through additional criteria.

BrAC as a function of Phase III volume slope is a consideration. Phase III slope should correlate to the BrAC sample at a fixed volume under normal breathing conditions. In addition, subjects undergoing hypoventilation prior to breath alcohol testing achieve significantly higher BrAC test results and exhibit distinctive exhalation profiles.[2] Hypoventilation samples are characterized by a rapid Phase II rise in BrAC coupled with a lower Phase III slope. BrAC Phase III slope correlation redefines sample validity and identifies abnormal samples including hypoventilations.

The Missouri breath alcohol program conducted a small exhalation profile study between April 2009 and October 2010. It consisted of twenty-four subjects (20 men, 4 women) selected during law enforcement training programs. Each subject was dosed with ethyl-alcohol to achieve varying BrACs ranging from 0.03 to 0.15 g/210 L, mean and median 0.084 g/210 L. The subjects provided 69 breath samples including 10 hypoventilations. Samples were collected using a DataMaster DMT manufactured by National Patent Analytical Systems, Inc.(DMT).[3] The DMT was selected for retention of concentration data, mass flow rate at 0.25 second intervals per sample and ease of data exportation. Microsoft Excel® was used for data analysis.

A correlation between the Phase III linear slope as a function of volume and the BrAC at a fixed delivered volume (1.5 liters) was observed, although it exhibited inter-subject variability ($R2 = 0.70$). The ratio of the BrAC at 1.5 liters over the Phase III slope (BrAC/Phase III slope) was calculated for each sample (median 11.2 liters, s.d. 2.2 liters). No outliers appeared when the normal three standard deviation rule was applied; however, 8 of 10 hypoventilation tests were outliers using the normal sample data ratios as the standard.

Between October 2010, and May 2011, the BrAC/Phase III slope ratio was calculated for breath exhalation data collected from 504 DWI suspects using 27 DMTs. The DWI subject data was randomly selected from 11,834 breath samples and 152 instruments.[4] Subject BrACs ranged from 0.015 – 0.345 g/210 L, mean and median 0.14 g/210 L. The BrAC/Phase III slope ratios were significantly different than laboratory results (mean 13.5, median 13.2, s.d 3.1, $p<0.0001$). The basis for this difference is unclear. The same ±3 SD test was applied to the DWI subject data, and 17 of the 504 samples (3.4%) were determined to be statistical outliers. The outlying samples were plotted to assess causation and difference. The 17 samples yielded five hypoventilations with 12 samples exhibiting breath alcohol sample characteristics inconsistent with current exhalation profile models.[1]

Application of BrAC/Phase III slope ratios to breath alcohol exhalation data functions as a method to identify hypoventilation and other anomalies during subject exhalation. Other approaches to BrAC data interpretation including computation of the averaging value, Fourier transforms and integration for area under the curve, may increase quality control and reduce uncertainty for BrAC testing. Redefining parameters for sample validity through the exhalation profile is warranted. Additional criteria for sample acceptance and reporting should be incorporated in breath alcohol instrumentation for reliability of results.

Breath Alcohol, Quality Control, Data Interpretation

K34 Tools, Techniques, and Findings for the Qualitative Analysis of Delta-9-Tetrahydrocannabinol (THC) in Oral Fluids

Alexander L. Maggitti, BS, Barry K. Logan, PhD, and Matthew M. McMullin, MS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will gain insight into scientific methods, applications, and technologies used to test oral fluids for drugs of abuse, particularly exposure to cannabinoids.

This presentation will impact the forensic science community by providing methods and data associated with the development and validation of THC in oral fluids for two separate collection devices.

Devices and techniques used for oral fluid collection and drug screening provide both advantages and new challenges to the field of forensic toxicology. When compared to conventional biological matrices, oral fluids are easier to collect, less prone to adulteration, offer on-site specimen screening, and reflect more recent drug use often associated with impairment.

For each device, the sample collection process involves placing an adsorbent pad in one's mouth until saturated with oral fluid. Following saturation the pad is placed into a pre-packaged tube filled with a diluent buffer, which helps preserve the matrix and prevent adsorption of THC to the pad. Next, the specimen can be analyzed on-site using an immuno-assay, which identifies positive samples based on drug class. If an oral fluid specimen is found to be positive the collection process is repeated and the device will be sent for more a selective confirmation analysis.

The primary goals of this research consisted of developing and validating a more selective and sensitive confirmatory method complimenting immuno-assay field findings for the detection of cannabinoids in oral fluid. Challenges met during development included; the need to detect low concentrations with a cut-off concentration of 0.50 ng/mL (in oral fluid + diluent buffer), complexity and variability of the matrix and limited specimen volume for testing. To overcome such obstacles sample preparation involves acidic dilution of the specimen followed by a solid phase extraction (SPE) and derivatization. The derivatized extracts are then analyzed for THC by multi-dimensional GC/MS.

Validation studies involved matrix matching of synthetic oral fluid to human oral fluid, as well as, between the two collection device's diluent buffers. Each matrix was tested for and showed comparable recovery and precision and accuracy around the cutoff. All batches consisted of three spiked cutoff calibrators, three spiked positive controls (125% cutoff concentration), and three negative controls to be used for evaluating precision, accuracy, and reproducibility of the method. Stability and recovery of THC was performed by spiking positive control pools at three concentrations into each of the two collection devices containing the absorbent pad. Enough devices were spiked to compare and evaluate three concentrations, in triplicate, at nine time intervals over 21 days. Sensitivity and specificity of the assay was performed by analyzing a minimum of 40 blind controls at concentrations ranging from 0% - 1000% over four analytical batches. Testing for interfering substances involved spiking commonly encountered drugs, as well as, three possible adulterants including mouthwash, toothpaste, and denture adhesive into blank matrix for analysis.

Validation results and findings all met acceptance criteria provided by the standard operating procedure for qualitative method validation The limit of detection was calculated to be approximately 0.01ng/mL using the signal to noise ratio of a cutoff calibrator. For precision data negative controls, cutoff calibrators and positive controls were evaluated in triplicate over ten batches. All negative controls were found to be negative and the %CV values for the cutoff calibrators and positive controls were 10.2% and 6.9% respectively. Due to no false positive or false negative findings both sensitivity and specificity were calculated to be 100%. Stability studies showed a decrease in THC values over time when positive controls (125% cutoff) were prepared in bulk and frozen. To accommodate for loss of THC over time, positive controls were hand spiked with each batch. Stability studies also showed one of the collection devices to be superior regarding recovery of THC. Although interference studies showed no interferences, certain toothpaste and mouthwash brands spiked into synthetic oral fluid did show a peak very close to the retention time of THC, with ion ratios being just outside that of the acceptable range. Further investigation determined the possible identity of the interfering peak and showed that the introduction of a "disqualifier" ion to the method clearly distinguished the peak from THC without affecting sensitivity. Also, human oral fluid collected following use of the toothpaste and/or mouthwash containing the interferent lacked concentrations required to impact qualitative results.

THC, Oral Fluids, Multi-Dimensional GC/MS

K35 A Rapid and Comprehensive Analysis of HFAA Derivatized "Bath Salts," Synthetic Cathinones, and Amphetamines in Postmortem Blood by Supported Liquid Extraction (SLE) With Gas Chromatography-Mass Spectrometry Detection

Krista M. Gubanich, MS, and Eric S. Lavins, BS, Cuyahoga County Medical Examiners Office, 11001 Cedar Avenue, Cleveland, Ohio 44139; John F. Wyman, PhD, Cuyahoga County Regional Forensics, Toxicology Section, 11001 Cedar Avenue, Cleveland, OH 44106; and Thomas P. Gilson, MD, Cuyahoga County Medical Examiner's Office, 11001 Cedar Avenue, Cleveland, OH 44106*

After attending this presentation, attendees will understand new trends in "Bath Salts," synthetic cathinones, and amphetamine abuse. Attendees will learn a unique approach to utilizing Supported Liquid Extraction (SLE), the challenges of derivatizing with Heptafluorobutyric Acid Anhydride (HFAA), and techniques to overcome analytical column contamination due to byproducts caused from HFAA derivitization.

This presentation will impact the forensic science and law enforcement communities by highlighting the abuse patterns for new designer drugs. Abuse of synthetic cathinones and amphetamines, particularly in our youth, is on the rise. A comprehensive approach to extraction, detection, and quantification of "Baths Salts," synthetic cathinones, and amphetamines is required to fully assess the extent of this problem. Challenges related to identifying these compounds, including compound volatility and derivitzation, will be discussed. The method presented suggests one possible approach that may be utilized to reliably characterize and identify these new compounds. Efficient testing procedures are a necessary first step in a comprehensive surveillance program.

3,4-Methylenedioxypyrovalerone (MDPV), is a new "designer" drug with observed toxicities including tachycardia, hypertension (vasoconstriction), insomnia, hyperthermia, mydriasis, panic attack seizures, and aggressive behavior. MDPV is a psychoactive, synthetic analog of the CNS stimulants cathinone and pyrovalerone. Because of their appearance, MDPV is often referred to as "bath salts."

A new procedure to facilitate a rapid, comprehensive, and simultaneous detection and analysis of amphetamine, phentermine, methamphetamine, amantadine, nicotine, pseudoephedrine, methylenedioxyamphetamine (MDA), methylenedioxymethamphetamine (MDMA), phenylpropanolamine (PPA), MDPV, mephedrone, and 3,4-Methylenedioxy-N-ethylamphetamine (MDEA) was developed using Supported Liquid Extraction (SLE). Beta-Phenethylamine was also analyzed as it is a common byproduct which is often observed in postmortem blood specimens.

Ten postmortem samples that tested positive for the amphetamine drug class via ELISA screen were further evaluated using this new method. Extraction is rapid, utilizing a small sample volume and involving two steps. The two step sample preparation and extraction utilizes an ISOLUTE SLE cartridge (Biotage, Charlotte, NC) combined with a positive-pressure manifold. The SLE cartridge composition contains Diatomaceous earth, a porous structure. Using SLE, the aqueous sample solution that has been pH adjusted with alkali or NH4OH will penetrate into the pore of the Diatomaceous earth. When eluted with a hydrophobic solvent, an extraction interface occurs between the two liquid phases. The high surface area of the Diatomaceous earth provides for enhanced extraction efficiency while alleviating much of the technical expertise associated with traditional Liquid-Liquid Extraction (LLE). SLE is able to minimize the impact from hemolyzed specimens, a common concern when dealing with postmortem blood samples. In addition, costly disposal of organic waste is not required because of minimal extraction volumes. This extraction is followed by derivitization with HFAA and Gas Chromatography-Mass Spectrometry (GC/MS) detection. This method was challenged by analytical column contamination from the HFAA which was overcome by incorporating a post conversion/derivitzation clean up procedure that uses a phosphate buffer. This clean up procedure helped to maintain chromatographic quality without adding a labor intensive step.

With this methodology, a single analytical protocol can be used to conduct the confirmation test for a comprehensive panel of sympathimometic amines on postmortem blood samples that preliminarily tested positive by immunoassay for amphetamines. Criteria for method validation which include accuracy, inter-assay precision, intra-assay precision, and analytical measurement range studies will be reported. In comparison with traditional LLE, this method offers considerable savings in sample volume, extraction time, solvent usage, waste production and disposal.

Bath Salts, Postmortem, Supported Liquid Extraction (SLE)

K36 Chromatographic Analysis of Synthetic Amphetamine Street Samples

Amanda Leffler, BS, 445 Waupelani Drive, Apartment M22, State College, PA 16801; and Frank Dorman, PhD, Penn State University, 107 Whitmore Labs, University Park, PA 16802*

After attending this presentation, attendees will learn what to look for when analyzing synthetic amphetamine street samples. This presentation will discuss the development of the extraction of the drug compounds from various commercial media, followed by separation using gas chromatography with mass spectrometric detection (GC/MS). Quantification of the active compounds based on the use of appropriate internal standards will also be addressed

This presentation will impact the forensic science community by providing an efficient method for analyzing street amphetamine samples and hence increasing the amount of evidence that analysts can process in a given time. Identification of the active components and added constituents in the samples can be made. Additionally, if an individual is in a possible overdose situation, rapid analytical methodology is also important.

The production and marketing of synthetic amphetamines is an ever-increasing threat to society. In 2007 a new line of "legal highs," labeled as bath salts, plant food, and jewelry cleaner, have flooded the streets of the United States, as well as other countries. Three years later in 2011, over one thousand calls were made to poison control centers across the country in response to these drugs.[1] Most of these products are cathinone analogs that are currently popular due to their amphetamine-like effects and their ease of access online and in "headshops" across the country.

Cathinone and its derivatives are extracted from the khat plant and can cause rapid heart rate, chest pains, insomnia, depression, suicidal thoughts, or seizures. The analogs used vary from sample to sample, as well as their concentrations, and when used in conjunction with other drugs can prove to be fatal.[2] Pyrovalerone is a Schedule V stimulant originally synthesized in 1964 to suppress appetite or treat chronic fatigue and MDPV, or 3,4-methylenedioxypyrovalerone, is the methylenedioxy analog of pyrovalerone that is not currently scheduled in the United States. Both of these compounds have been found previously in "legal highs" along with cathinone analogs such as methylone and methymethcathinone (mephedrone). Plant feeder has also been found to contain 3-fluoromethcathinone and other isomers of the drug, and has become popular due to methcathinone's simple synthesis from ephedrone.[3]

The Drug and Chemical Evaluation Section is a section of the DEA Office of Diversion Control (ODE) that is gathering information on the abuse of synthetic amphetamines to support their possible scheduling. Such information includes identification to establish prevalence and trends.[1] Therefore, the analysis of such designer drugs and the determination of their individual compounds may help ban their production and illegalize their use. This study presents the development of a sample preparation and chromatographic method for the chemical characterization of selected synthetic amphetamine samples for the purpose of identification of the active components and added constituents.

Synthetic amphetamines are entering the drug market faster than they can be restricted. A quick and efficient extraction method will allow for a more efficient analysis of such compounds. In regards to the forensic community, crime labs already have a large workload. Thus creating a more efficient methodology will benefit analysts by increasing the amount of evidence that they can process in a given time. Additionally, if an individual presents a possible overdose situation, rapid analytical methodology is also important. This presentation will discuss the development of the extraction of the drug compounds from various commercial media, followed by separation using gas chromatography with mass spectrometric detection (GC/MS). Quantification of the active compounds based on the use of appropriate internal standards will also be addressed.

The developed chromatographic method provides qualitative and quantitative analysis of synthetic amphetamines in samples seized on the illegal drug market and in the compounds referred to as "legal highs." Potentially, this method could reduce the time a new drug is on the market. Future studies will also involve diluents used in the processing of these "legal highs."

Bath Salts, Chromatography, Amphetamines

K37 A Novel LC/MS/MS Method for the Detection and Quantitation of GHB

Jaclyn Vincent, BS, Cedar Crest College, 900 Mickley Road, Apartment IT-3, Whitehall, PA 18052; and Marianne E. Staretz, PhD, Department of Chemical & Physical Science, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will be introduced to a new LC/MS/MS method that can be used for the detection of gamma-hydroxybutyric acid (GHB) using Hydrophilic Interaction Liquid Chromatography (HILIC).

This presentation will impact the forensic science community by supplying an effective method of GHB analysis that is time efficient, involves very little sample preparation, and does not require sample derivatization.

GHB is a common Schedule I central nervous system depressant that is often implicated in the commission of many drug-facilitated sexual assaults because it leaves the victim confused, unable to resist, incapacitated, and promotes memory loss. GHB is also clinically used for the treatment of cataplexy. HILIC is a newer technology, and although there has not been extensive research done on this particular chromatography, it has been shown to be useful for the analysis and separation of polar compounds. Due to this property, it has been speculated that it would work very well for GHB, but has yet to be applied to biological samples, such as urine. HILIC works by applying a water-miscible mobile phase across a strongly hydrophilic stationary phase. This current research focused on the development of a new LC/MS/MS method that can be used in conjunction with HILIC to identify and quantify GHB in urine samples. This method included a Zwitterion Chromatography (ZIC^{O}) HILIC column (3.5mm, 100 x 2.1mm) from SeQuant. The mobile phase consisted of 10mM ammonium formate in water, pH 6.38, for Solvent A, and 100% acetonitrile for Solvent B. The following gradient was employed: 90% organic to 40% organic in 20 minutes (~2.5% per minute), then back up to 90% organic at 10% per minute, maintaining a flow rate of 0.2 mL/min for the duration of the run. The gradient allowed sufficient time for the compound to come off the column, and also for the column to re-equilibrate, which is important due to the sensitivity of the column. Additionally, the gradient provided a wash step to clean the column of any impurities that had the potential to be carried over into subsequent samples. LC/MS/MS was performed using electrospray ionization with negative ion mode monitoring. Ions were examined in MRM mode, and the 103 to 85 and 103 to 101 transitions were used. GHB-d6 was used as the internal standard, and the 109 to 90 transition was used. A linear range of GHB standards were observed from 0.01ug/mL to 10 g/mL. GHB was also detected in synthetic urine in concentrations as low as 0.04mg/mL. It was found that injecting straight synthetic urine did result in some ion suppression; however, when the samples were diluted by 75% with acetonitrile, there was not as much ion suppression. Potential interferences, such as gamma-butyrolactone (GBL) and 1,4-butanediol, will also be tested to ensure that drugs with similar structures to GHB will not provide any interference with the results on this particular column. Blind studies will

also be performed.

GHB is often difficult to detect due to its increased rate of metabolism and excretion in the body; this new method will provide a simple, quick method for the detection of the drug in urine without extensive extraction or derivatization procedures using ZICÒ-HILIC and LC/MS/MS.

LC/MS/MS, ZIC-HILIC, GHB

K38 Maternal Death in a Young, Irish Primigravida (in the Seventh Month of Pregnancy) With Positive Postmortem Toxicological Analysis for Pentobarbital

Khalid Jaber, MD, Firebrigade Training Centre, Malahide Road, Marino, Dublin 3, IRELAND*

After attending this presentation, attendees will understand a unique case of a maternal death in a pregnant young female, whose postmortem toxicology analysis revealed pentobarbital. The decedent was a mature student enrolled in third-level education, with a history of bipolar disorder and previous episodes of self-harm.

This presentation will impact the forensic science community by presenting a case of a death of pregnant female identified with pentobarbital in her blood and urine at a level just outside the therapeutic range, and almost borderline toxic level. It is certainly the first such case in Ireland, and possibly the first case reported in English literature of a suspected suicidal death by the ingestion of pentobarbital by a pregnant female.

Maternal death is a rare phenomenon in Ireland and in other developed countries. This is the case of a young, unmarried, Irish primigravida found dead in her seventh month of pregnancy. She lived with her mother and her step-father in a middle class neighborhood. She was a mature student in a third level education. She was known to be a non-drug abuser, and an advocate for curtailing the abuse of drug culture. She first attended antenatal clinic in her second trimester. Her pregnancy was progressing well with no identifiable antenatal abnormality. According to her family, she was excited about her pregnancy and was looking forward to motherhood and the baby.

Prior to this pregnancy, she was diagnosed with bipolar disorder for which she was not taking medication. Episodes of self harm were documented, that never materialized into life threatening or incapacitating injuries. She was found by her step-father in a kneeling-like position in her tidy bedroom. She was placed into supine position on the bedroom floor. She was found holding a pen in her left hand. Her face and upper torso revealed diffuse marked, purple, postural hypostasis *(livor mortis)* discoloration. Prominent, bilateral, petechial hemorrhages were noted on the eyelids and conjunctiva. Mucosal surfaces of the lips revealed similar petechiae. Larger, punctate (ecchymotic) hemorrhagic spots were noted on the upper torso.

Non-indented, pale, neck-markings were seen on the anterior and posterior aspects of the neck. Internal hemorrhages were identified in the soft tissues of the neck and involving focally some of the neurovascular structures. The lungs were mildly congested and mildly to moderately oedematous. The heart was mildly dilated, but not scarred. The coronary arteries were free of acute thrombi. The external genitalia revealed no evidence of external trauma. The vaginal canal contained a small amount of pinkish-white discolored fluid. The cervix appeared purple, but not associated with bleeding or mucosal disruption. There was no evidence of DIC or TTP. The rest of the maternal examination was unremarkable; especially as there was no evidence of unusual allergic skin manifestations. The placenta was posterior and fundal. There was no evidence of placental abruption or infarction. The placental surfaces appeared unremarkable.

The fetal membranes were intact. The amniotic fluid was of normal and not meconium stained. The fetus was well developed for his gestational age. There were no congenital abnormalities (externally or internally). Re-examination of the scene two days later recovered two capped brown glass bottles, with Spanish language labels, bearing a canine picture and designation for veterinary medicine usage. Analysis of these bottles confirmed the presence of pentobarbital. This drug was identified in the postmortem blood and urine and the amniotic fluid. Phenobarbital level was 11ug/ml (therapeutic range is 2-10ug/ml, toxic levels start at 12ug/ml while lethal levels are much higher).

This drug is used in euthanasia in veterinary practices. In humans it has limited, therapeutic, medically-approved applications: treating intractable epilepsy, induction of neurological coma to protect the brain during certain procedures, and in the control of intra-cranial hypertension. It is likely the bottles were sourced out of country, possibly via the internet. A partially illegible short suicidal note recovered from the scene included, "I cannot continue anymore."

This drug is known be a direct CNS and myocardial depressant. The decedent stomach contained evidence of a recently digested food and this drug is known to impair gastrointestinal motility and increases hepatic microsomal activity. It causes a decrease in sympathetic activity and thus increases venous capacitance.

In the United States, Andrew Grant DeYoung recently died in a Jackson prison following a three-drug protocol that included pentobarbital. Also executions in Alabama and Georgia, using pentobarbital, have raised concerns among human rights activists and opponents of the death penalty on the merit of employing this drug in inmate sanctioned executions. Roy Blankenship and Eddie Duval Powell, are inmates who apparently have exhibited signs indicating they might have been conscious or in pain during this chemical death process.

The literature review of suicidal maternal deaths in association with drug(s) overdose, especially barbiturates is discussed. Pertinent scene and autopsy photographs are presented to highlight the described circumstantial and anatomical findings.

Maternal, Death, Pentobarbital

K39 A Klimaxic Head Trip

Veronica Hargrove, MS, Randall Frost, MD, Kimberley Molina, MD, and Michael Neerman, PhD, Bexar County Medical Examiner's Office, 7337 Louis Pasteur Drive, San Antonio, TX 78229*

After attending this presentation, attendees will better understand synthetic cannabinoids; discussing its pharmacology and toxicity.

This presentation will impact the forensic science community by increasing awareness and understanding of the possible toxicity of synthetic cannabinoids. Synthetic cannabinoids are relatively new drugs in the United States and it is important to make this information known to any and all parties that may be impacted by its use and/or abuse. Therefore, this information can potentially be used to educate forensic toxicologists and medical examiners as well as the lay public as to the dangers of synthetic cannabinoid use.

Synthetic cannabinoids were originally produced as research tools in order to create drugs that could potentially be used in the treatment of nausea, glaucoma, and appetite stimulation. These compounds were designed to mimic marijuana by binding to the same cannabinoid receptors that THC, the active ingredient in marijuana, bind to in the brain. There are hundreds of these compounds available, all with varying potency and varying affinity to the cannabinoid receptors. Most of these compounds are much more potent than THC and have been shown to cause increased heart rate, increased blood pressure, agitation, hallucinations, and seizures. Emergency departments and poison control centers are both seeing a rise in visits and calls from people using these compounds. The American Association of Poison Control Centers estimates 2,915 calls about synthetic cannabinoids in 2010 and as of June 30, 2011, approximately 3,094 calls have so far been received. In November 2010, the Drug Enforcement Agency (DEA) moved to designate five of these synthetic cannabinoid compounds as Schedule I drugs. In this one-year period the DEA as well as the United States Department of Health and Human Services will study

these drugs further in order to evaluate whether it is necessary to permanently control these substances.

Three cases in which synthetic cannabinoids were found in blood will be discussed. Two of these cases are medical examiner cases and one is a driving while intoxicated case. A 58-year-old male with a history of heart disease, Parkinson's disease, and hypertension bought some synthetic marijuana, called "Head Trip," at a convenience store. After smoking the Head Trip, he began to complain of not feeling well. He was found unresponsive about an hour later by family members and taken to the hospital where he later died. A 29-year-old healthy female with no medical history or disease was discovered unresponsive in a hotel room by her boyfriend. The boyfriend called 911 and she was pronounced dead upon emergency personnel arrival. Possible marijuana and synthetic marijuana called "Klimax" were found in the room. A 23-year-old male driver was pulled over for drifting in and out of his lane. He was arrested for DWI after appearing intoxicated to the officer and during a search of his car two bags of "Head Trip" were found. Blood was sent to the Medical Examiner's office for testing. Results and implications of use of synthetic cannabinoids for all three of the previously described cases will be discussed.

Synthetic Cannabinoid, Pharmacology, Toxicity

K40 A Systematic Study of the Cellular Toxicity of Common Amphetamine and Ring-Substituted Drugs

Mya Fekry, MSc, Anglia Ruskin University, Mel 210, ARU, East Road, Cambridge, CB1 1PT, UNITED KINGDOM; Michael D. Cole, PhD, Anglia Ruskin University, East Road, Cambridge, CB6 2UD, UNITED KINGDOM; and Beverley R. Vaughan, PhD*, Anglia Ruskin University, East Road, Cambridge, Cambridgeshire CB1 1PT, UNITED KINGDOM*

After attending this presentation, attendees will have an understanding of the effects and comparative toxicity levels between a number of amphetamine type stimulant compounds and the need for such systematic studies

This presentation will impact the forensic science community by informing health care professionals, law enforcement agencies, and those involved in drug administration about the potential dangers of toxicity of a number of established and new stimulant drugs that are increasing in popularity. It will allow attendees to make an informed choice in drug administration and treatment of drug users.

There are now a wide range of amphetamine and 3,4-methylenedioxyamphetamine (MDA) drugs available in the illegal drug market. While amphetamine and methamphetamine were originally used within this context as stimulants, the fact that some users experienced unpleasant side effects let to the development of the ring substituted 3,4-methylenedioxy compounds. These latter compounds, in addition to stimulant effects, are entactogens and facilitate inter-personal communication.

The majority of amphetamine-type-stimulants currently found "on the street" contain one or more of these drugs. MDMA (3,4-methylenedixymethamphetamine), a.k.a. ecstasy, remains a popular contender on the party scene. Globally, there are distinct differences in the usage between countries. In the United Kingdom, the incidence of ecstasy usage has fallen in recent years whilst there has been an explosion of use across Northern America. Its usage is concentrated in younger adults, and in Europe is more commonly abused in males with approximately 2.5 million people using ecstasy in 2009.[1] MDMA is now tightly controlled across the globe but other analogues, including MDA and 3,4-methylenedioxy-N-ethylamphetamine (MDEA) have also been growing in popularity. The legislative control of these compounds, under the Misuse of Drugs Act and their related laws and legislations abroad, often leads to the synthesis of uncontrolled analogues and derivatives of the initial substance in search of similar desired effects.

The mixture of synthetic analogues commonly found in tablets sold as "ecstasy" frequently includes MDMA, MDA, and MDEA. Profiling and analysis of street ecstasy samples via chromatographic methods has often been used to illustrate complexity of the mixture of stimulant compounds present as well as the multiple chemical impurities produced in the synthesis of street samples.[2]

While evidence of the toxicity of these compounds has often been seen in patients admitted to hospital emergency departments, the effects of these compounds and their related analogues on vital organs at a cellular level, is not well defined. Damage to organs involved in the metabolism and excretion of these compounds and their by-products has been reported however, the extent to which toxicity occurs and the mechanisms of action by which this damage is induced are still poorly understood.[3]

Cells were exposed to the drugs at concentrations ranging from 1.1mg/ml to 11mg/ml, after which they were incubated and then assessed morphologically for evidence of cell death in the form of either programmed cell death (apoptosis), uncontrolled cell death (necrosis). Further assessment of cell death was carried out using Annexin V assays in which the presence of apoptosis and propidium iodide (PI) provided evidence of general cell membrane disruption. Samples were analyzed using a flow cytometer, after which results were given according to the expression of annexin V and PI labelling. Results were expressed as the percentage increase in the presence of non-viable cells (Annexin V +/PI +) after correcting for background cell death. This data was confirmed using fluorescent microscopy and immunolabelling of the Annexin V in-situ. The most toxic of the compounds to the liver was amphetamine, with an LD50 of 1.5mg/ml, whilst the least toxic was methamphetamine with an LD50 value of 2.9mg/ml. Conversely in the kidney, amphetamine appeared to be the least toxic compound, while methamphetamine was more toxic. Respective LD50 values were calculated at 4.9mg/ml and 3.9mg/ml.

MDA showed higher levels of toxicity in both the liver and the kidney than both MDMA and MA. LD50 values for this compound were calculated at 2.1mg/ml and 3.7mg/ml respectively, while values for MDMA were 2.5mg/ml and 3.8mg/ml. The effects of all compounds supported both dose and time dependant increases in toxicity. In the process of data analysis, comparisons between amphetamine and MA, and MDMA and MDA were made due to the related nature of their structures.

The data supports published literature that MA and amphetamine become rapidly toxic to the kidney, whilst MDMA and its metabolite MDA are more toxic to the liver. This may be due to rapid accumulation of amphetamine and MA in the kidney as previously described in studies of the pharmacokinetics and distribution of amphetamines in the human body.[4] MDMA is cleared by hepatic metabolism, but with dose dependant increases this rapidly leads to saturation of hepatic clearance and biological toxicity. The profile of ecstasy users however, is all too frequently one of poly-drug abuse, dosing repeatedly in a recreational environment. Therefore, it is essential to perform systematic studies and poly-drug investigations to understand the profile of the patient presenting to the doctor, and the cold case to the forensic pathologist.

K41 Forensic Toxicology Fellowship Training Model

Anna Kelly, PhD, and Ashraf Mozayani, PhD, PharmD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be informed about a forensic toxicology fellowship program and how the more widespread implementation of such a program would benefit the forensic toxicology community.

This presentation will impact the forensic science community by drawing attention to the lack of comprehensive on-the-job training in the field of forensic toxicology and the advantages of providing a formal training program.

Programs in which a broad exposure to the various aspects of forensic toxicology in a lab holding American Board of Forensic Toxicology (ABFT) as well as ISO/IEC 17025 accreditation is provided to recent graduates are few and far between. By developing a formal training program for emerging forensic toxicologists, trainees will develop a strong foundation in the application of the fundamental principles of toxicology to actual casework.

A recent chemistry doctoral graduate was hired and given hands-on experience in the forensic toxicology laboratory, from the acquisition and processing of samples to the analysis and reporting of analytical findings for medicolegal (ML), driving under the influence (DUI), and drug facilitated sexual assault (DFSA) cases. The fellow was exposed to techniques including gas chromatography/mass spectrometry (GC/MS), enzyme-linked immunoassay (ELISA), and liquid chromatography/mass spectrometry (LC/MS). In addition to learning procedures already in place, the fellow was involved in the development and validation of methods, providing invaluable exposure to the method development process as it applies to the field of forensic toxicology. The HCIFS Forensic Toxicology Fellow developed a method for the detection of helium in postmortem specimens.

The fellow attended daily medical examiner briefings in which the medical examiners and representatives from the toxicology, anthropology, and investigation departments discuss cases that have come into the office, providing information regarding scene investigation and the circumstances of the death. Autopsies performed the previous day are also discussed. In attending these meetings, the fellow was able to see how the testing in the laboratory helps in determining cause and manner of death. Additional continuing education courses and observation of court testimony provided the fellow with exposure to a variety of areas, including medical examiner law and jurisdiction, medicolegal death scene response, determination of cause and manner of death, pathological and anthropological findings and how they contribute to determining cause and manner of death, and the role of the crime laboratory in death investigations. Being able to learn how each of the forensic disciplines work together with medical examiners in order to formulate the whole story in determining the cause and manner of death, and how toxicology analysis helps these investigations provided the fellow with a strong foundation from which to start her career.

It is encouraged that a fellowship program for toxicologists be implemented in order to provide recent graduates with a strong background which will help them establish a career in the field of forensic toxicology.

Toxicology, Training, Fellowship

K42 Drug Overdose Fatality Due to an Herbal Blend Containing Mitragynine and O-Desmethyltramadol

Vinita Magoon, DO, JD, MBA, Texas A&M, Scott and White Hospital, 2401 South 31st Street, Temple, TX 76508; and Brad J. Hall, PhD, and Vickie Willoughby, DO, 1213 Sabine Street, PO Box 1748, Austin, TX 78767*

After attending this presentation, attendees will understand the effects of an herbal blend containing Kratom.

This presentation will impact the forensic science community by becoming aware of the Kratom herbal drug mixture that is available over the internet and contains mitragynine, a Kratom alkaloid, as well as O-desmethyltramadol, and has been implicated in a drug overdose fatality.

A 19-year-old college student was found unresponsive in his bed by his roommate. The prior evening, the decedent was at a party drinking alcohol. After arriving to his residence, he reportedly consumed a mixture of a Kratom tincture with soda and went to bed intoxicated. There were two vials at the scene. One was labeled "Full Spectrum Tincture 10mL Not for Human Consumption" and the other vial was unlabeled. A receipt for "Full Spectrum Alkaloid Tincture 300 mg" from Speciosa Specialist, Chicago, IL was present. Duloxetine and citalopram, which were prescribed to the decedent, were also collected from the scene.

The femoral blood was subject to routine volatiles, acid/neutral, alkaline, and ELISA screening. Ethanol levels were 0.07g/dL and 0.09g/dL within the femoral blood and vitreous, respectively. 9-carboxy-tetrahydrocannabinol was confirmed in the urine by GC/MS. The only other finding per initial screening was O-desmethyltramadol in the alkaline drug screen. Ingestion of tramadol would typically result in the presence of tramadol, N-desmethyltramadol, and O-desmethyltramadol; the presence of only O-desmethyltramadol makes this an unusual finding. In the decedent's femoral blood, duloxetine (0.21mg/L) and O-desmethyltramadol (0.81mg/L) were identified by LC/MS/MS. Due to lack of an authentic standard and reference laboratory test, quantification of Kratom alkaloids was not pursued. However, the presence of Kratom alkaloids including mitragynine or its diastereomers in the urine of the decedent and the two vials collected at the scene was confirmed by full scan LC/MS/MS and comparison to the specific mass spectrometric fragmentation pattern of mitragynine. O-desmethyltramadol was confirmed in the two vials qualitatively by GC/MS.

There is an increasing popularity of "legal highs" which can be purchased over the internet and are not regulated by the Food and Drug Administration (FDA). Therefore, the contents of the products are not always known to the consumers. In this case, a product called "Full Spectrum Alkaloid Tincture" was bought over the internet from Speciosa Specialist. The product description on the website states that it has alkaloids from Kratom that have been "isolated, purified to the highest level, and captured ..."[1] Products on this website are specified as not intended for human consumption. The vials collected at the scene; however, not only contained mitragynine, an alkaloid from Kratom, but O-desmethyltramadol was present as well.

Mitragynine is the alkaloid found in highest concentration in Kratom, which is a leaf native to Southeast Asia and has traditionally been used for medicinal purposes. Kratom was used by the workers as a stimulant and more recently, has been used for pain management and opioid withdrawal. However, it is now considered a controlled dangerous substance in Thailand, Bhutan, Australia, Finland, Denmark, Poland, Lithuania, Malaysia, and Myanmar. There is no medicinal use for Kratom in the United States and it has not been approved by the FDA for any use; however, it is not classified as a controlled dangerous substance in the United States.[2]

At low doses, mitragynine binds to delta-opioid receptors, but as the dosage increases, it binds the mu-opioid receptors. This receptor binding profile corresponds to the physiologic effects of mitragynine, where it is a

stimulant at low doses and has sedative effects at high doses. Mitragynine appears to be a drug with abuse potential with rare toxic effects. No cases of death solely due to mitragynine have been reported in the U.S.; however, over the last six years, mitragynine has been combined with another drug, O-desmethyltramadol, to create a more potent herbal mixture that is often referred to as Krypton. Krypton is available through the internet and has been associated with fatalities as reported in Sweden.[3] O-desmethyltramadol is a metabolite of tramadol, which is an opioid agonist use to treat moderate to severe pain. Tramadol acts as a mu-opioid receptor agonist and is a synthetic analog to codeine.

With the growing popularity of Kratom and other opioids that can easily be purchased over the internet, the forensic community should be aware of these drugs. The contents of the herbal extracts are not necessarily listed or known to the consumer since these products are not regulated by the FDA. In this case, the O-desmethyltramadol was incidentally found within the Kratom tincture. Since mitragynine and O-desmethyltramadol are mu-opioid agonists, the combined use of the drugs especially with other drugs and ethanol can lead to sedation and respiratory depression, and can be fatal, as was in this case.

K43 The Hidden Dangers of Clandestine Methamphetamine: Synthesis to Cellular Toxicity

Mya Fekry, MSc, and Agnieszka Biedron, BSc, Anglia Ruskin University, East Road, Cambridge, CB1 1PT, UNITED KINGDOM; Michael D. Cole, PhD, Anglia Ruskin University, East Road, Cambridge, CB6 2UD, UNITED KINGDOM; and Beverley R. Vaughan, PhD, Anglia Ruskin University, East Road, Cambridge, Cambrdigeshire CB1 1PT, UNITED KINGDOM*

After attending this presentation, attendees will have an understanding of the origins and occurrence of chemical impurities in methamphetamine and appreciation of the potential toxicity of these compounds in a street drug, both alone and in combination.

This presentation will impact the forensic science community by informing health care professionals, law enforcement agencies, and those involved in drug administration about the potential dangers of toxicity of pure stimulant drugs and common impurities. This will allow attendees to make an informed choice in drug administration and treatment of drug users.

Methamphetamine (MA) is a widely abused stimulant, which may be manufactured using a variety of different routes. While amphetamine is the most commonly occurring phenethlyamine of choice in Europe, methamphetamine is more prevalent in North America and the Far East.[1] New data from the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) shows that the geographic concentration and availability of these compounds is responsible for shifts in global user trends.[2] Given the global popularity and accessibility of the Internet, synthetic routes were chosen from this medium for methamphetamine synthesis. One of the most popular and straight-forward routes of synthesis is the reductive amination of benzylmethylketone (BMK), which is commonly employed in Europe.[2] This route involves the reaction of methylamine with BMK in the presence of mercuric chloride and aluminium followed by purification of the crude drug base and subsequent crystallisation of the hydrochloride salt.

Routes such as this lead to complex mixtures of reaction by-products and a significant number of impurities. These compounds may contribute to the toxicity profile of street samples of methamphetamine. To date there had been no systematic study of the drug or its impurities. The aim of such a study was to determine whether these impurities contributed to the overall toxicity of the street methamphetamine samples. Alongside MA's addictive properties, it produces widespread organ toxicity. The most commonly occurring impurities identified in the mixtures, including benzylaldehyde, pheylacetone, 1-phenyl-2-propanol and the related compound ephedrine were subjected to cytotoxicity testing against immortalized human kidney (CAKI-2) and liver (HepG2) cell-line models.

According to the pharmacokinetics of MA, a dosing strategy was developed from the reported distribution of the compound in the body and the recently reported levels of purity in street samples. We focused on vital organs that are involved in the metabolism and excretion of the compound and its by-products. Given that, respectively, 22% and 7% of the ingested compounds are expected to reach the liver and the kidneys, it was possible to assess the cytotoxicity of each individual chemical based on their purity within the sample.[3]

Cells were exposed to the drugs for one hour at concentrations ranges from 1.1mg/ml-11mg/ml, following which they were assessed morphologically for evidence of cell death, either programmed cell death (apoptosis), uncontrolled cell death (necrosis) or no effect at all. To assess for cell death, cells were then labelled with annexin V to evidence the presence of apoptosis and propidium iodide (PI) for evidence of general cell membrane disruption. These samples were then analyzed using a flow cytometer. Results were given according to the expression of annexin V and PI labelling. Results were expressed as the percentage of viable cells (Annexin V -/PI -) veruses the percentage of non-viable cells (Annexin V +/PI +). This data was confirmed using fluorescent microscopy and immunolabelling of the annexin V in- situ.

The most toxic of the compounds was MA, with an LD50 of 3.9mg/ml to the kidney and 8.2mg/ml to the liver. 1-phenyl-2-propanol conversely, produced minimal toxicity with respective LD50 values of 37.1mg/ml to the liver and 111.9mg/ml to the kidney. All other compounds displayed significant toxicity with LD50 values of less than 10mg/ml. Effects of the compounds supported both dose and time dependant increases in toxicity. By flow cytometry, it can be deduced that apoptosis and necrosis are both activated following exposure to these compounds. For further mechanistic confirmation, changes in expression levels of genes associated with these pathways are investigated. This will include Bax (an apoptosis related gene), Beclin (autophagy related) and the Caspase family (apoptosis) on both exposure to impurities and in both dose and time dependant assays.

These data provide evidence of the cellular cytotoxicity of MA and related impurities at the sites of biological purification and excretion. Overall, the liver is more sensitive to these compounds than the kidney, with MA exhibiting the most significant toxicity. This supports published research that there is a complex and highly damaging cellular response to MA and that this drug continues to pose a significant risk to those who fall in its path.

Methamphetamine, Impurities, Cellular Toxicity

K44 Metaxalone Related Deaths in North Carolina (2002-2010)

Ruth E. Winecker, PhD, North Carolina Office of the Chief Medical Examiner, Campus Box 7580, Chapel Hill, NC 27599-7580; and Sandra Bishop-Freeman, PhD, North Carolina Office of the Chief Medical Examiner, 1001 Brinkhous Bullitt Building, Campus Box 7580, Chapel Hill, NC 27599-7580*

After attending this presentation, attendees will be able to describe the types of postmortem casework associated with metaxalone at various concentrations.

This presentation will impact the forensic science community by providing information regarding metaxalone as it relates to cause and manner of death determinations.

Metaxalone (Skelaxin®) is a central nervous system (CNS) depressant indicated for the treatment of acute, chronic, traumatic, and inflammatory musculoskeletal disorders. It is typically prescribed in doses ranging from 800 to 3,200 mg daily. Approved by the Food and Drug Administration in 1962, metaxalone given orally at a therapeutic doses typically produces peak plasma concentrations ≤4.0mg/L. Adverse reactions associated with metaxalone are generally related to CNS depression including drowsiness, dizziness, headaches, as well as nausea and vomiting. Limited information has been published on metaxalone toxicity. A review of the literature indicates that there are presently five reported deaths in which the causative agents included metaxalone.

At the North Carolina Office of the Chief Medical Examiner, cases suspicious for toxicological cause or with essentially negative autopsy findings are routinely screened for common over-the-counter, prescription and illegal drugs via various laboratory techniques. This presentation will detail 44 cases where metaxalone was detected during routine postmortem drug screening in support of cause and manner of death determination. The laboratory methods used to detect and quantify metaxalone in this laboratory have been previously described.[1]

Decedents were divided into three groups according to manner of death for the purposes of studying metaxalone concentrations in overdose and non-overdose situations (Table). The accidental and suicidal overdoses were subsequently divided into subgroups for further study: those where metaxalone was determined to contribute to the cause of death (attributed) and those where it was not (unattributed). The deaths in which metaxalone was determined to contribute to the cause of death were further divided into those where metaxalone additively combined with other drugs to cause the death and those where the drug was present in sufficient amounts to have caused the death regardless of other drugs and their concentrations.

Manner	N	Mean (median)	Range
Natural (n=4)		5.4	1.2-8.6
Accidental (n=24)			
Unattributed	13	N/A	<2.0-6.9
Attributed	11	15.4 (10)	4.4-50
Suicical (n=16)			
Unattributed	4	N/A	<2.0-5.0
Attributed	12	25(24)	8.4-63

N/A - not calculated due to the number of concentrations reported as less than the lower limit of quantification.

Total, there were nine cases (seven suicides, two accidents) where the pathologist ruled that metaxalone was present at sufficient concentrations to cause death had it been the only drug detected. The mean (median) concentration of metaxalone in these cases was 34 (32)mg/L and concentrations ranged from 23 to 63mg/L. Of these nine cases there was only one in which metaxalone was the only drug detected (suicide, 63 mg/L) and the remaining eight were ruled multiple drug intoxications. Co-intoxicants included antidepressants (five of eight), antihistamines (three of eight), and miscellaneous CNS depressants (four of eight). Notable was the absence of opiates/opioids in this sub-group. This was not the case in deaths where metaxalone was ruled as an additive agent in the death (nine accidents, five suicides). In these cases, metaxalone mean, median and range were 10.8, 9.5 and 4.4-18, respectively. Opiates/opioids were ruled as contributing to death in 86% (12 of 14) of these cases.

In conclusion, of the 44 cases studied, 21 (47.7%) metaxalone was ruled noncontributory to death, 22 (50%) were ruled multiple drug intoxication and 1 (2%) single agent intoxication. Concentrations of metaxalone in these groups were <2.0-8.6, 4.4-50 and 63 mg/L, respectively.

Metaxalone, Death Investigation, Toxicology

K45 The Methylecgonine to Cocaine Ratio in Blood Samples and the Effectiveness of Preservation With Sodium Fluoride

Ingrid J. Bosman, PhD, and Klaas J. Lusthof, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague, 2497 GB, NETHERLANDS*

After attending this presentation, attendees will understand the use of the methylecgonine to cocaine concentration ratio in blood samples as an indicator of enzymatic cocaine hydrolysis and effectiveness of preservation with sodium fluoride.

This presentation will impact the forensic science community by providing data on the methylecgonine to cocaine concentration ratio in blood samples as an indicator of enzymatic hydrolysis and effectiveness of preservation with sodium fluoride.

The limited stability of cocaine in forensic samples has been a problem for several decades. In unpreserved whole blood, cocaine (COC) will hydrolyze to methylecgonine (ME) by the action of cholinesterase and to benzoylecgonine (BE) by pH-dependent chemical hydrolysis. ME and BE are further converted into ecgonine (ECG). Fluoride inhibits plasma cholinesterase and as a result the conversions of COC to ME and of BE to ECG are reduced. The conversions of COC to BE and ME to ECG can be inhibited by acidification. Moreover, cooling slows all conversions. Addition of fluoride is generally recommended to prevent cocaine hydrolysis. In postmortem blood, acidification may occur, which makes the conversions of COC to BE and ME to ECG less important. However, enzymatic conversions continue after death. As a result, a large part of ME measured in postmortem blood may originate from postmortem hydrolysis of cocaine.

In the Netherlands, whole blood samples in cases of driving under the influence (DUI) of alcohol and/or drugs are collected in glass tubes containing sodium heparin and sodium fluoride (NaF). The samples are then sent to the Netherlands Forensic Institute (NFI) by regular mail, which generally takes one to two days, without cooling. After receipt at the NFI, blood samples are kept at 4ºC for a maximum of two weeks and at -18ºC thereafter. In autopsy cases, the interval between the finding of the body and the autopsy is generally one to two days. Preservation of (femoral) blood samples takes place after the autopsy, by using the same tubes as in DUI cases and by freezing at -18ºC. Until the end of 2005, blood tubes contained 0.8% NaF and 700 IU/mL sodium heparin. From 2006 until mid-2007, these tubes were gradually replaced by tubes containing 0.4% NaF and 143 IU/mL sodium heparin, for commercial reasons.

In this paper, the ME/COC and BE/COC concentration ratios in whole blood samples of DUI cases with 0.8% NaF, DUI cases with 0.4% NaF, and autopsy cases were compared. The goal of this study was to obtain more

insight in the role of NaF as preservative and to investigate if the ME/COC or the BE/COC concentration ratio is indicative for hydrolysis of cocaine.

Electronic data files of the NFI were searched for concentrations of COC, BE and ME in blood samples from 1999 through 2010. The ME/COC ratios and BE/COC were calculated and statistically evaluated. Cases of DUI as well as autopsy cases were investigated. COC, BE, and ME were analyzed by using GC-MS, after solid phase extraction and derivatization, or by LC/MS/MS, after protein precipitation.

The results show that the median ME/COC concentration ratio increased over the years after 2006 in cases of DUI. This increase coincided with a gradual change from blood tubes containing 0.8% NaF to tubes containing 0.4% NaF from 2006 until mid-2007. A trend was not observed in the BE/COC concentration ratios or in autopsy cases over the years. The median ME/COC concentration ratios (and 95% range) were respectively 0.8 (0-2.1) for cases of DUI (0.8% NaF), 1.5 (0-4.6) for cases of DUI (0.4% NaF), and 1.9 (0-5.5) for autopsy cases. The observed increase in ME/COC concentration ratio is in line with the order of decreasing preservation in DUI cases. In autopsy cases, the median BE/COC concentration ratio was significantly lower than in DUI cases.

In conclusion, the results show that the ME/COC concentration ratio is probably a useful indicator of enzymatic cocaine hydrolysis in cases of DUI as well as in autopsy cases. A ME/COC ratio greater than 2.1 is indicative of (enzymatic) cocaine hydrolysis. This information will improve the interpretation of forensic results. Furthermore, the data show that a concentration of 0.4% NaF was insufficient to prevent decomposition of cocaine in blood during more than one or two days under the practical circumstances in DUI cases in the Netherlands. The relatively low BE/COC ratio in autopsy cases points to the protective role of postmortem acidification in the chemical hydrolysis of cocaine.

Cocaine, Hydrolysis, Sodium Fluoride

K46 Postmortem Pediatric Toxicology

Robert A. Middleberg, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Nikolas P. Lemos, PhD, Nikolas Lemos, PO Box 77332, San Francisco, CA 94107; Marina Stajic, PhD, New York City, Chief Medical Examiner's Office, 520 1st Avenue, New York, NY 10016; Jack R. Kalin, PhD*, Alabama Department of Forensic Sciences, 2026 Valleydale Road, Hoover, AL 35244-2095; David M. Benjamin, PhD*, 77 Florence Street, Suite 107N, Chestnut Hill, MA 02467-1918; and Michael Heninger, MD*, Fulton County Medical Examiner's Office, 430 Pryor Street, Atlanta, GA 30312*

After attending this presentation, attendees will gain an appreciation for the challenges unique to toxicological findings in postmortem pediatric cases. Attendees will learn interpretive guidelines for pediatric cases involving forensic toxicology in both a general and case-specific sense.

This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in the pediatric population.

In this 13th Annual Special Session within the Toxicology Section, pediatric cases involving toxicological findings are discussed. As a relative dearth exists of interpretive information involving toxicological findings in the pediatric population, this session is a forum to help elucidate and clarify such issues. The format is a short case presentation including pharmaco-toxicokinetic data and other relevant ancillary information followed by audience participation to provide interpretive clarity around the case-specific impact of the toxicological findings. This presentations allows for various perspectives of case issues that lead to integrative consensus, or differing opinions, as to cause of death in children.

Dr. Jack Kalin will review data related to toxicological findings in stillbirths. This specific population is somewhat unique given its direct dependence on the mother, her exposures and the pharmacokinetic and toxicokinetic changes that occur during pregnancy. These changes include altered maternal hepatic biotransformation, increased gastric emptying, decreased gastric motility and altered renal blood flow. As an additional factor, placental transfer, biotransformation, etc. affect the fetal insult due to maternal exposure to potentially harmful agents. Coupled with maternal changes are the developing characteristics of the fetus, its metabolic capabilities, and the toxicodynamics effects of specific agents.

Dr. Marina Stajic will present a case involving lithium. Lithium, a classic antipsychotic agent, is a potentially teratogenic substance and is one of the few agents that can result in hypercalcemia in children. Pharmacokinetics of lithium in children varies from that in adults with a shorter half-life and faster renal clearance. Classically, lithium has a narrow therapeutic index leading to potential severe toxicity at low doses. There is debate as to the clinical utility of lithium in younger children.

Dr. David Benjamin will address an extremely difficult interpretation of clonidine and other toxicological findings in a suspected filicide. Clonidine, a centrally-acting alpha-2 receptor agonist used to control blood pressure in adults, is used in children to help control attention deficit hyperactivity disorder (ADHD) and other behavioral deficits. The use of this drug in children can induce sedation and a hypertensive crisis upon abrupt withdrawal.

Dr. Michael Heninger will discuss findings involving methadone and fentanyl and the problems associated such agents in children. Most childhood exposures to these compounds are either accidental or intentional for purposes of sedation, but not homicidal. Both compounds are classified pharmacologically as opioids and have the associated sequelae of these agents, including CNS-depression capable of producing death. Methadone has recently been tagged as a compound capable of producing death even with therapeutic use based on adverse cardiovascular events. Fentanyl on the other hand, has strict black box warnings due to potency (80-100 times that of morphine).

The case studies presented reflect current day findings in medicolegal investigations of childhood deaths. In years past, discussions of these type cases have been educational and demonstrative of the issues in this special population. Only through these continued case studies and audience participation can there be shared perspectives on the meaning of the toxicological findings.

Pediatric, Toxicology, Postmortem

LW1 Two Congressmen, Two Killings, and a Cannonball

Patrick Zickler, BA, 5520 MacArthur Boulevard, Washington, DC 20016-2536*

After attending this presentation, attendees will understand the facts associated with the deadly shooting in 1856 by California Congressman Philemon Herbert of a waiter who did not satisfactorily serve breakfast; the subsequent failure prosecutor Philip Barton Key to gain a conviction; Key's death by gunshot at the hands of cuckolded New York Congressman Daniel Sickles; the first (and successful) use of a temporary insanity defense against murder charges; and the ironic circumstances on the Gettysburg battlefield that transformed Sickles' right leg into a popular museum exhibit.

This presentation will impact the forensic science community by providing an entertaining summary of facts involving mid-19th century elected officials, murder, and maiming by firearms.

The history of the U.S. Congress includes criminals of a vast and fascinating variety. In the mid-19th century two particularly colorful Representatives used handguns in killings — one in a swank Washington dining room, the other in Lafayette Park adjacent to the White House — both of which resulted in murder trials. Neither Congressman was convicted, but their stories are linked by the prosecutor who failed to convict one and was killed by the other. On May 8, 1856, Representative Philemon T. Herbert, a California Democrat, walked into the dining room of Washington D.C.'s Willard Hotel. It was late morning — close to the hotel's 11:00 a.m. deadline for breakfast. Perhaps Herbert was late, perhaps he was drunk. Witnesses disagreed. When waiter Thomas Keating refused to speed up his service, Herbert complained in an argument that escalated until Hebert took a pistol from his pocket and shot Keating in the chest. Herbert was charged with murder. Prosecutor Philip Barton Key, son of Francis Scott Key, was unsuccessful in persuading the Dutch Minister — the most credible witness — to testify, and the jury could not reach a verdict. Key also prosecuted a second trial, which ended in Herbert's outright acquittal. Unlucky at law, Key was apparently lucky at love, of a sort. Soon after the Herbert trials, Key met Teresa, the wife of Representative Daniel Sickles, a Democratic Representative from New York and powerhouse member of the Tammany Hall political machine. In 1859, Sickles lay in wait in Lafayette Park, confronted and killed Key, then walked to the home of the Attorney General and confessed the murder. At trial, Sickles' defense team, led by lawyer Edwin Stanton (later the Secretary of War for Abraham Lincoln), proposed a defense never before entered in a U.S. court: Sickles, Stanton claimed, was driven mad with rage at his wife's flagrant infidelity and was innocent because the killing was an uncontrollable manifestation of temporary insanity. It worked. Sickles was acquitted, announced that he and Teresa had reconciled, and withdrew from public life without resigning his seat in Congress. When the Civil War began Sickles used his Tammany Hall connections to be commissioned as a colonel under another political clout-wielder, Major General Joseph Hooker, whose headquarters was compared to a frontier saloon and brothel. At the battle of Gettysburg, Union commander George Meade ordered Sickles to take his troops to a defensive position on Cemetery Ridge. Sickles thought otherwise and positioned his men more than a mile away. The insubordinate maneuver likely would have earned Sickles a court-martial had he not garnered sympathetic forgiveness as a result of his right leg being shattered by a cannonball while Confederate troops smashed through Meade's ill-positioned corps. The limb was amputated within the hour and Sickles ceremoniously donated the splintered bones — delivered in a small coffin — to the Army's Surgeon General, who had announced interest in establishing a collection of "specimens of morbid anatomy." Sickles was said to have tried to visit his leg each year on the anniversary of their separation. Most of Daniel Sickles is now buried in Arlington National Cemetery; his leg sits in a glass display case at the National Museum of Health and Medicine.

Murder, Insanity Defense, Adultery

LW2 Ötzi the Iceman – Austrian, Italian, or Other?

Matteo Borrini, PhD, Via del Mattone 17, Cadimare, La Spezia 19131, ITALY; and Helmut G. Brosz, BASc*, Brosz Forensic Services, Inc., 64 Bullock Drive, Markham, ON L3P 3P2, CANADA*

After attending this presentation, attendees will better understand how the Copper Age influenced the Modern Age and what scientific methods can be used in that effort.

This presentation will impact the forensic science community by describing the use of various scientific methods in understanding the world's most studied 5,300-year-old mummy. This presentation will shed a contrarian light on the discovery of Ötiz the Iceman by using the archaeological, medical, toxicological, and engineering sciences which, when combined, lead to astounding opinions. This presentation will also shed light on early tattooing practices and artifacts as they might relate to today.

A German husband and wife, hiking along the Tisenjoch border between Austria and South Tyrol, Italy on September 19, 1991, near the Ötztal Valley, discovered a body sticking out of the ice – hence named Ötzi the Iceman – along with his equipment and clothing. No form of ID, such as credit cards, hunting license, passport, bar bill receipt, etc., was found upon his partially clothed body. At first, the body was believed to have been a hiker who inexplicably perished not long before the discovery. Others believed the body to have been only 500-years-old. For these reasons, the recovery was performed with great care.

Amateur recovery attempts to free the mummified, dried, jerky-like body, half frozen in ice, involved ski poles, picks, and hair dryers which caused some damage to the body and artifacts.

The artifacts found give us a fascinating picture of life in the late Neolithic period or the beginning of the Copper Age and represent the unique features of the discovery of the Iceman, Ötzi.

The tool artifacts claimed to have been associated with "Ötzi" include a copper axe, half-finished bow and arrows, quiver flint bladed "dagger" and sheath, retouching tool of stag antler, marble stone with leather cord, einkorn wheat kernel, hophornbeam tree pollen, flint drills, birch fire container, and bone needle fire starter. All of his belongings have undergone meticulous examination.

Associated with the body, the fragments of restorable clothing artifacts include goat skin leggings, belt pouch, hide coat, bear skin hat, deer skin shoes, backpack, and a grass mat overcoat.

Ötzi has been studied, analyzed, x-rayed and has had his personal space, innards and orifices invaded by over 100 scientists and researchers. It is now known that his spine, ankle, hip, and knee joints were strained and his teeth worn down. Other medical conditions discovered included a hardened aorta, a broken nasal bone, parasitic worms, and cysts. The oldest tattoos ever seen have been documented on his body. From Ötzi's preserved stomach, intestinal contents and fingernails have been analyzed. "Ötzi hurried through a forest he knew well, wincing from the pain in his injured right hand and pausing occasionally to listen for sounds that he was being pursued..." as Stephen S. Hall writes for National Geographic magazine.

Ötzi's origins, destination, and who he was have been debated. Ötzi's current resting place is in Bolzano, Italy. After almost 20 years of international analysis and speculation by others, it is time for forensic experts to enter the debate and present the possible politically correct or incorrect opinions and fan the contrarian notions as to Ötzi being Italian, Austrian, or other; and his effect on today's society.

Iceman, Ötzi, Anthropology

LW3 More Than a Cold Case: The Frozen Murder of Iceman — A Heinous or a Merciful Crime Scene?

Matteo Borrini, PhD, Via del Mattone 17, Cadimare, La Spezia 19131, ITALY*

After attending this presentation, attendees will understand how it is possible to investigate an ancient death scene with a criminalist's point of view to reconstruct historical and cultural events.

This presentation will impact the forensic science community by suggesting that the area where the Iceman mummy was found can be interpreted differently from what has been done so far.

In September 1991 in the Ötztal Alps, on the border between Austria and Italy, a natural mummy radiocarbon dated to the Calcolithic Age (about 3300 BC) and consequently named Ötzi or Iceman, was found.

A CT scan and forensic light examination of the corpse pointed to the cause of death: an arrow point in the left shoulder, which cut the subclavian artery. Other pieces of evidence such as peri-mortem facial trauma and a deep defense cut on the right hand as a result of hand-to-hand fighting indicates a double assault. It is clear that the Iceman was killed, though some doubts may be raised looking at the recovery scene.

The body was found with a complete set of clothes: a coat and a cloak made of woven grass, a bearskin cap, a belt, a pair of goat skin leggings, a loincloth, and shoes. If one can reasonably explain a dressed man killed during a fight, it is much more difficult to explain the large number of artifacts and tools found with the body. Iceman was found, in fact, with a copper axe, a flint-bladed knife, a quiver of 14 arrows, an unfinished yew longbow, a wood backpack, two birch bark baskets, some small stone, and bone tools.

The first inconsistency with the primary crime scene are the numerous materials found with the body; hard to carry for a fugitive especially if he has a deep bleeding wound and if his unfinished bow is 72 inches long and his body statue only being 5 feet, 5 inches tall.

Other evidence is the absence of the shaft of the killer arrow. No "chipping" around the wound seems to indicate that Iceman did not extract the arrow. The aggressor may have taken the arrow to reuse it, but it is strange that he did not steal the complete quiver of the victim as this kind of object was very important. The same consideration should be given in regards the copper axe, a very expensive status symbol that was left with the corpse.

Iceman was quite old for his time and sick, as demonstrated by the Beau's lines on the fingernail and CT analysis. He was also a man of high social standing in his group as indicated by the axe. Peri-mortem lesions may indicate a fight for the village leadership; failing the competition, Ötzi would have demonstrated that he was not able to defend himself anymore or to be able to care of his village. In ancient communities, a leader must be dead tin order to be replaced. The entrance angle of the arrow in the back of Iceman indicates that he was killed from behind as was the ancient ritual of expiation, where the victim is shot while he is running away from the village.

After the death, Ötzi's corpse was prepared for burial — the arrow was pulled out, he was dressed with all his clothes, and laid with all his objects surrounding him.

Some characteristics of the clothing and the location of the recovery scene can justify this conclusion. First of all, the weapons found with Ötzi are ineffective because they are unfinished. It is not likely that a fugitive would run away with a lot of useless stuff. Typically in protohistoric graves, broken or fake weapons were usually buried to connect with the soul of the deceased and to prevent the ghost he fought against in the living to return back from the afterlife.

Further contradictory evidence is the improbability that Iceman would have chosen a snow-clad and a very difficult route for his escape, especially if wounded. The high location of the burial in a mountain pass is very similar to other contemporaneous graves generally interpreted as a spatial signal used by ancient transhumance communities.

In addition to this consideration, at the slopes of the mountain where Ötzi was found in recent centuries, a stele or monument, engraved with a bowman striking the back of another man with an arrow was discovered indicating a possible memorial of the ritual sacrifice of an important village chief.

How the recovery scene of Iceman believed to be the crime scene of an inexplicable murder can be reinterpreted as the burial site of a sacrifice victim will be presented.

Crime Scene, Cold Case, Iceman

LW4 The Execution of a Pregnant Murderess: Global Views

James E. Starrs, LLM, 8602 Clydesdale Road, Springfield, VA 22151*

After attending this presentation, attendees will gain insights into the correctional difficulties encountered by pregnant inmates.

This presentation will impact the forensic science community by studying the problems of pregnancy during imprisonment.

Bathsheba Spooner, 32, lived with her husband, Joshua Spooner, and her three pre-teen children in Brookfield, Massachusetts on March 1, 1778. Bathsheba Spooner was well named – for like her biblical namesake – death followed in her wake. It is indisputable that both the Bathsheba of the Bible and the Bathsheba of the 18th Century Massachusetts were femme fatales. Like King David, 17-year-old Ezra Ross, a private in the Revolutionary Army of George Washington, looked with covetous eyes on Bathsheba Spooner with whom he and two escapees from General Burgoyne's failed Saratoga campaign, hatched a plan to murder Joshua Spooner. The three soldiers were prevailed upon by Bathsheba Spooner to waylay and kill her husband as he returned from a visit to Cooley's tavern on the Old Boston Post Road on the night of March 1, 1778. The murder occurred as planned with Joshua Spooner having been assaulted by the three male perpetrators who, according the death warrant, "did strike, beat, and kick" the victim with the body being dumped into a well fronting on the Spooner property in Brookfield. While the murder was in progress and the disposal of the remains was under way, Bathsheba was in her home performing housekeeping chores in the kitchen and not participating directly in her husband's murder nor giving any sign of being distressed by what was going on outdoors. The murder was ill-concealed and quickly discovered with Mr. Spooner's body being removed from the well and laid out in the sitting room of his home, as per the custom in those days. The Brookfield coroner, Thomas Gilbert, was summoned and arrived at the Spooner's house where Bathsheba was seen reluctant to place her hand on her deceased husband's forehead while saying "Poor Little Man." This touching was pursuant to the then prevailing medical myth called the "ordeal by touch." According to this old wives' tale, the skin of a murder victim would display color when touched by the murderer. Bathsheba's touching the forehead of the deceased left no imprint and had no discernible effect. At the Worcester Superior Court on April 24, 1778, the four murder conspirators, with Mrs. Spooner charged as an accessory before the fact, were tried, convicted, and sentenced to be hanged on June 4, 1778. Mrs. Spooner was represented by attorney Levi Lincoln who pleaded insanity on her behalf but the execution of the four was delayed until July 2, 1778 by a petition filed with the Massachusetts Council by Bathsheba in which she claimed to be some five months pregnant and requesting a delay of her

execution until the birth of her child. In the intervening wrangling over whether she was "quick with child" or not, it was first said by the male and female "experts" summoned on the question that she was not pregnant but even though a later opinion found her to be quick with child, her seeking a postponement of her hanging was denied. On July 2, 1778 all four of the conspirators were hanged with Bathsheba Spooner continuing to maintain that she was pregnant and requesting a post-hanging dissection to prove it. She was granted that request and a five month old male child was found to have died with its mother's execution. This outcome reflects the first time in the United States that a state-sanctioned execution resulted in the death of an innocent child In other countries than the United States, as well as under contemporary law in Federal and State jurisdictions, in today's world the execution of a pregnant woman would be treated differently from the manner of its processing in Massachusetts in 1778. The alternative approaches taken in foreign countries will be recounted and discussed.

Pregnancy, Execution, Penology

LW5 Hoarders: A Postmortem Analysis

Sheila E. Dennis, MS, New York City, Medical Examiner's Office, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016; and Benjamin J. Figura, PhD*, New York City, Medical Examiner's Office, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will learn about cases of deceased hoarders brought before the Identification Review Committee of the New York City Office of Chief Medical Examiner and the processes involved in their identification.

The presentation will impact the forensic science community by giving insight into the complications and methods of identification even when it appears that a wealth of information is at their disposal.

The Identification Review Committee within the New York City Office of Chief Medical Examiner (NYC OCME) is a group assembled to discuss not-so straight forward cases for the identification of decedents within the five boroughs of New York City. The group is comprised of the collaborative effort of the disciplines that assist with identification: forensic anthropology, forensic biology (DNA), fingerprints, forensic odontology, x-ray, identification unit, and the medical examiner assigned the case. The Committee meets once a month and each discipline with information contributing to supporting or refuting the present identification results of their discipline's testing or any additional scene and/or family information. Identification is not purely visual and relies heavily upon the combination of scene information, family, and science.

With the success of the reality TV series Hoarders™, the Identification Review Committee at the NYC OCME has also been witness to the reality of the many cases involving hoarders. Hoarding, also known as compulsive hoarding, is the excessive acquisition of possessions and the inability to dispose of them. The possessions may be of little or no value (i.e., trash) but the hoarder cannot bear to part with it. Unfortunately unlike the show where there is usually an intervention, massive house cleaning, reveal, and follow-up, the intervention on NYC OCME's part is to an individual who has perished as a direct result of their hoarding habit. The additional challenge is that the individual is usually found long after they have died and is not visually recognizable due to advanced decomposition or skeletonization.

Forensic anthropological analysis is routinely performed on cases of decomposed and/or skeletonized individuals in addition to when the medical examiner requests assistance with aging and trauma analysis such blunt force or toolmark analysis. The forensic anthropology report is extremely valuable in providing sex, age, race/ancestry, stature, trauma, and pathological and general observations. Ironically, despite the amount of debris and mail which provides a timeline and possible identification, many of these decedents are still difficult to identify because no antemortem medical or dental records can be found. Many of the deceased hoarders are older individuals who have led hermit lifestyles. Medical records and insurance cards provide some veracity to the name of the deceased individual found in the locked home but many times that individual has not seen a doctor in years and their medical records have been purged or destroyed.

Due to their isolated lifestyle, many have not had contact with their immediate families and only distant relatives are alive. If any family is located, many of them haven't seen their potential relative in years to be able to do a visual identification even if it were an option. DNA testing in these cases does not add additional information as the relative is not only separated by distance but also by generations. Many relatives of deceased hoarders are nieces and nephews or even great nieces and nephews. If other desirable relatives for DNA testing are located, usually only one is found (such as a sibling) or only one cooperates and gives a DNA sample.

This presentation will touch upon the disease of hoarding and give an overview of just a few of the many cases of hoarding from the NYC OCME. These cases will be discussed in detail from their unusual causes of death such as "asphyxia due to fallen bookshelf" to the complicated process of identifying the individual even when investigators are literally wading through abundant amounts of information from within the home.

Hoarding, Identification, Postmortem

FINANCIAL DISCLOSURE

ATLANTA 2012

As a sponsor of continuing education, the American Academy of Forensic Sciences must ensure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty participating in a sponsoring activity are expected to disclose to the activity audience any significant financial interest or other relationship: (1) with the manufacturer(s) of any commercial product(s) and/or provider(s) of commercial services discussed in an educational presentation, and (2) with any commercial supporters of the activity. (Significant financial interest or other relationship can include such things as grants or research support, employee, consultant, major stockholder, member of speaker's bureaus, etc.) The intent of this disclosure is not to prevent a speaker with a significant financial or other relationship from making a presentation, but rather to provide listeners with information on which they can make their own judgments. It remains for the audience to determine whether the speaker's interests or relationships may influence the presentation with regard to the exposition or conclusion. The executed Financial Disclosure Forms are on file in the AAFS Office.

To serve on the 2011/2012 Program Committees, it is required that relevant AAFS staff members, program committee members, and/or reviewers complete a Financial Disclosure form before they were provided access to review submissions for the program. For continuing education accreditation purposes, the disclosed relationships are published below so that learners are aware of the nature of any relationships that may impact the selection of presentations for the program. If a committee member failed to provide complete disclosure of a relevant financial interest or relationship, the committee member or reviewer was not allowed to serve.

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have as related to the contents of their presentation(s). The existence of commercial or financial interests of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s); however, disclosure should help participants form their own judgments.

If an author failed to provide a complete disclosure of the discussion of commercial products, a relationship with the manufacturer including an employee/employer relationship, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted.

PRESENTING AUTHOR INDEX

ATLANTA 2012

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2012 AAFS Annual Scientific Meeting. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Criminalistics	J	Questioned Documents
B	Digital & Multimedia Sciences	K	Toxicology
C	Engineering Sciences	LW	Last Word Society
D	General	BS	Breakfast Seminar
E	Jurisprudence	ES	Evening Session
F	Odontology	L	Luncheon
G	Pathology/Biology	S	Special Session
H	Physical Anthropology	W	Workshop
I	Psychiatry & Behavioral Science
