Forensic art is a discipline that requires specialized training, above and beyond advanced drawing skills. Applications relate closely with those of other disciplines of the forensic sciences, especially forensic anthropology, forensic odontology and forensic psychology.

E24 Introduction to the Science Behind Trace Evidence Examination

Cara A. Plese, MS, Antonio Scatena, BS*, and David L. Exline, MSFS, Gateway Analytical, 5316 William Flynn Hwy, Ste 303, Gibsonia, PA 15044*

After attending this presentation, attendees will gain a general introduction to the scientific method employed in the analysis of trace evidence, as well as the conclusions that can be expected from the various types of trace evidence examinations. Evidence included in the trace evidence category, such as animal and human hairs, natural and synthetic fibers, condom lubricants, gunshot residue, and paint will be discussed along with the different analysis methods used to examine those evidence types. Regarding the analysis methods used to examine trace evidence, a general but informative overview will be given on several analytical methods including optical and Polarized Light Microscopy (PLM), Scanning Electron Microscopy–Energy Dispersive Spectroscopy (SEM-EDS), Fourier transform infrared spectroscopy (FTIR), Raman spectroscopy, and Gas Chromatography – Mass Spectroscopy (GC-MS). The objective of discussing the analytical techniques is to expose the attendees to general types of evidence each method would be appropriate for, as well as what results that can be expected from each.

This presentation will impact the forensic science community by explaining the analytical methods used for analysis of trace evidence, along with the importance in the process of finding, interpreting, and properly testifying about the evidence. Even though trace evidence is usually circumstantial, and often cannot be used to identify an individual, it still plays an important role in forensic science. In addition to the direct comparison of questioned and known samples, trace evidence is vital in the evaluation of physical evidence to provide investigative leads to investigators in a variety of criminal investigations.

Trace evidence may be left behind at the crime scene, found on victims, and also taken with the perpetrators of crimes. The exchange of these traces often occurs without the knowledge of the perpetrator and is sometimes crucial in establishing a connection between the crime scene, the victim, and the suspect. DNA examination has evolved into a significant type of forensic evidence; however, trace evidence may be particularly important in establishing these connections in situations where suspect DNA is not recovered from a victim or the perpetrator's DNA profile is not listed in databases which law enforcement would use to make an identification of an unknown suspect. To give a better understanding of the occurrence of trace evidence, the authors will discuss the Locard Exchange Principle and different methods of transfer which can result in the depositing of various types of trace evidence.

This presentation will also discuss the strengths and weaknesses of the different trace evidence examinations, as well as what conclusions can be reached and how forensic scientists reach their conclusions and utilize trace evidence. As trace evidence is most commonly used as associative evidence as opposed to evidence that yields an identification of a suspect, the realistic strength of trace evidence analysis conclusions will be discussed, as well as some effective questions that can be asked in the courtroom to best portray to the jury the gravity of the results. Several case studies will be presented in which trace evidence played a crucial role in investigations and trials. Trace evidence is a valuable tool for forensic investigations as well a providing a solid scientific foundation to the trier of fact when determining the possible associations present in forensic casework.

Trace Evidence, Scientific Method, Evidence Transfer

E25 Effective Use of an Expert in a Premises Liability Case

Donn N. Peterson, PE, Peterson Engineering, Inc, PO Box 664, Brainerd, MN 56401-0664*

After attending this presentation, attendees will: (1) learn the elements involved in a premises liability case; (2) understand how a forensic engineering science expert can help evaluate the merits of a slip/trip/miss and fall incident; and, (3) be able to participate in preparing the case.

This presentation will impact the forensic science community by informing those involved in civil litigation related to slip/trip/miss and fall incidents, discussing the strengths and pitfalls of actual cases.

When pedestrians unexpectedly encounter a sudden change in a walkway surface, they might not adjust their gait sufficiently to prevent loss of balance and avoid a fall. The sudden stop of their body at the end of the fall may result in injuries severe enough to merit a claim for damages. Slip/trip/miss and fall accidents as premises liability cases are usually subjects of civil litigation.

Slip and fall cases usually involve a sudden decrease in available friction between the walkway and footwear contact surfaces. The unsuspecting pedestrian typically loses traction on the bottom of the leading foot when it meets the slipperier surface. The leading foot slides forward out from under his/her body and he/she falls onto or toward the side of the leading foot. Injuries to the trailing leg and/or knee are also possible. Less common is slippage of the trailing foot typically resulting in a fall onto the knee or leg of the trailing foot.

Trip and fall cases usually involve a sudden increase in elevation along the walkway. The unsuspecting pedestrian typically fails to lift the leading foot high enough to clear the transition to the elevated surface and instead catches it on the rise or edge of the transition. The leading foot does not support the pedestrian and he/she falls forward onto or toward the side of the leading foot. Less common is tripping when encountering a sudden increase in surface friction resulting in the leading foot not sliding as in preceding paces.

Miss and fall cases usually involve a sudden decrease in elevation along the walkway. The unsuspecting pedestrian typically fails to extend the leading foot downward far enough to meet the lower surface, stumbles, and falls forward onto or toward the side of the leading foot.

The forensic engineering science expert investigation typically begins with evaluating a description of how and where the pedestrian fall occurred. Appropriate hypotheses and alternatives for the slip/trip/miss and fall incident are developed. The incident site is evaluated for surface variations or irregularities that are consistent with the hypotheses and may have contributed to the incident. Determinations are made as to whether sudden changes in walkway surface existed at the time of the incident. If so, then evaluations are made to establish whether they are related to design, construction, or maintenance. Reviews of codes, standards, and statutes are made for applicability and for possible violations relative to the incident. Design and construction defects probably have statutory time limits for recovery of damages. (e.g., Minnesota has a limit of 10 years for design and construction defect claims.)

Indoor incident sites are usually subject to building codes and standards. Interior walkway features addressed by them include, but are not necessarily limited to, stairways, landings, ramps, handrails, guard rails, doors, dimensions, and illumination. Occasionally, design and construction features will be encountered that are not explicitly addressed in the written codes and standards and broad interpretations are evaluated for applicability.

Most exterior incident sites are not directly covered by building codes. The codes might be used as a guide for good practice but not be legally enforceable.

Exterior walkways are usually exposed to conditions of rain water and winter snow and ice. Thus, weather data for the hours and days immediately preceding the incident are often significant when evaluating causation. Drainage from overhead roof structures and along walkway surfaces can be a significant factor. Surface debris, color pattern, and illumination can also be significant factors.

A slip/trip/miss and fall incident involves contact or lack thereof between the walkway surface and the footwear contact surface. Thus, the footwear should be evaluated for possible contribution to causation.

Pedestrian conduct might be a contributing factor. If so, then the question of whether or not that conduct is reasonably foreseeable to an alleged negligent party must be addressed.

Pedestrian, Falls, Walkways

E26 A Criminal Case Can Turn on a Maggot

Christine M. Haskell, JD, 128 North Cullen St, Rensselaer, IN 47978*

After attending this presentation, attendees will understand the importance of collecting forensic entomological evidence in criminal investigations, its impact to cases due to the lack of the forensic entomological evidence, and how to ensure that forensic entomological evidence is collected.

This presentation will impact the forensic science community by providing case examples of the importance of collecting insect evidence by law enforcement officers for use in prosecuting criminal offenses.

The prosecution of criminal cases involves proving the various elements of criminal statutes. Law enforcement officers are the initial responders to criminal activity and are responsible for the amount and quality of evidence that is collected from the crime scene. In some jurisdictions, prosecuting attorneys are regularly consulted by the law enforcement officers during the processing of the crime scene. This consultation can facilitate the proper collection of necessary evidence, the legality of evidentiary issues, and certain additional avenues of investigation that need to be pursued.

Unfortunately, when communication between law enforcement officers and prosecuting attorneys is lacking, crucial evidence can potentially be lost, thus causing future proof issues at trial. This is especially true with forensic entomological evidence. Forensic entomological evidence, in the form of blow fly eggs, larvae, and adults, is usually only found and available for collection at the initial crime scene and/or autopsy. Insect evidence can provide law enforcement officers and prosecuting attorneys valuable information on time of death, location of death, length of insect infestation, and in some cases identification of the perpetrator. If police officers fail to collect this insect evidence during the first response to the crime scene, the evidence is unlikely to be present days, weeks, or months later. Without this entomological evidence, important elements of the crime may not be established, such as time or location of death in murder cases or time of insect infestation in abuse cases.

There are several reasons why the necessary entomological evidence is not collected. First, individuals in law enforcement may not be aware of the importance of insect evidence and lack the knowledge regarding proper collection techniques for the preservation of specimens. In addition, law enforcement officers and crime scene technicians may not want to take the additional time necessary to collect the “bug” evidence or wait for a forensic entomologist to arrive to assist them in recovery. Finally, those collecting the evidence may feel that the entomological evidence is not important because they have other evidence that will determine the time frame.

In order to ensure proper collection of forensic entomological evidence, police, as well as coroners and medical examiners, need to be informed of the importance of collecting this evidence. Prosecuting attorneys need to be familiar with the information that this evidence can provide for their cases. By being familiar with the answers that can be provided by forensic entomology, law enforcement and prosecuting attorneys can ensure that these answers are not lost by failure to collect and retain the necessary evidence.

Prosecuting attorneys need to be familiar with the elements of a crime that entomological evidence can determine and be able to communicate with law enforcement officers, coroners, and medical examiners to make sure that this important evidence is not lost. Proper collection of essential evidence ensures that the guilty are convicted and the innocent are exonerated.

Criminal Justice, Forensic Entomology, Evidence Collection

E27 Search Warrant Language for Cloud Computing

Josiah Dykstra, MS, Univ of MD - Baltimore County, Baltimore, MD 21144*

After attending this presentation, attendees will be able to understand and create search warrants for data in cloud-computing environments. Attendees also will be able to enumerate potential challenges facing the production of cloud-based evidence.

This presentation will impact the forensic science community by arming the legal and digital forensic communities with language for cloud-specific search warrants, an example warrant based on a case study, and a list of potentially relevant cloud-based forensic artifacts.

Cases involving evidence from cloud computing environments will soon dominate criminal and civil litigation and the legal community must be armed with the knowledge about how to execute e-discovery of cloud evidence. Companies are embracing cloud technology to offload some of the cost, upkeep, and growth of equipment that they would otherwise have purchased themselves. The general public is increasingly storing their data in clouds, sometimes unknowingly. Cloud infrastructure – with exceptional bandwidth, storage, and computing power – offers an attractive prize for hackers. Where the people, the data, and the money go, so too does crime. While many people have lamented how the users of the cloud and their data are protected, few of these discussions have considered the difficulty of responding to security breaches, including forensics and criminal prosecution.

This presentation gives the first public discussion of search warrant language that could be used to compel cloud-based data from a cloud provider. Law enforcement and legal professionals may be unfamiliar with this new technology, and therefore unsure what electronic evidence may exist and what to seize in a warrant. Many audience members will be familiar with e-discovery of online webmail and social media, but cloud computing differs in important ways that make acquisition of data different. This presentation will rely on technical expertise of cloud computing to suggest possible language for use in a search warrant. In particular, friendly definitions of technical cloud terms, and a list of potentially relevant data to ask for in a warrant will be presented. This work builds on discussions with cloud providers about the forensic data they collect, and incorporates prior work from legal scholars about the legal challenges associated with cloud-based data.

A hypothetical case study of child pornography being hosted in the cloud will be used to illustrate suggested wording and phrases to use in a search warrant. While fictional, it describes a common computer crime where the cloud is an accessory to a crime. This sample language is useful for agents and prosecutors who wish to obtain a warrant authorizing the search and seizure of data from cloud computing environments. In particular, this example is tailored to Amazon Web Services, the largest and most popular public cloud service provider.

Following the discussion of warrant language, several potential shortcomings of cloud-based e-discovery in general will be enumerated. The defense could use the deficiencies identified to challenge and discredit the process and product of cloud-based evidence. Such issues include the untrustworthiness of cloud data, extreme complexity of the cloud environment, and likely failure of the *Daubert* test.

Now is an exciting time for cloud computing as innovative new product offerings emerge. The legal community is also at the threshold of a wave of cloud-related litigation. The first public cases involving cloud-based ESI are likely to appear soon, and the people involved in

those cases have a unique opportunity to set new legal precedent. This exploration of seizing electronic evidence from cloud computing provides a foundation to forensic investigators and legal professionals as they investigate and prosecute cloud-based crimes.

Cloud Computing, Digital Forensics, E-Discovery

E28 Visualization of Mobile Evidence: Timelines, Maps, and Social Graphs

John J. Carney, JD, 1442 Osceola Ave, St. Paul, MN 55105; and James C. Austad, JD*, 816 W St Germain St, Ste 410, St. Cloud, MN 56301*

After attending this presentation, attendees will understand the advantages of using software to visualize forensics data and "see" patterns and relationships in the digital contents of mobile devices. In doing so, data is elevated into information, or even knowledge, that attorneys can use with their clients for decision making, for strategy formulation, and for taking meaningful action in a legal, investigative, or corporate context. The presentation will include technical information on software bridges that span leading mobile forensic examination tools and popular timeline, mapping, and investigative software packages used by attorneys and investigators today. Evidence visualizations created by this technology will be briefly demonstrated for the audience.

This presentation will impact the forensic community by proposing new evidence visualization techniques available to both criminal justice attorneys and civil litigators that have the potential to contribute greatly to just legal outcomes in and out of the courtroom. Many trials today, whether in federal or state court, involve showings of complex factual information produced as digital evidence. But how can justice be served if the trier of fact cannot understand the evidence and the story it can tell? Therefore, it is imperative that complex digital evidence be presented in such a way as to be relatively straightforward for the judge or jury to understand. The visualization of digital evidence is one technique to provide that understanding cost effectively.

Digital evidence is usually presented today as narrative and numbers accompanied by a stream of bits and bytes in computer forensic reports that are at best sorted into buckets of similar items. For example, mobile phone evidence is presented such that call logs appear in one section split into inbound, outbound, and missed calls. Text messages appear elsewhere split into inbound and outbound messages. The phone's address book appears yet somewhere else. This primitive and fragmented approach at production hides or makes opaque the evidence story that attorneys desperately need to develop a theory of the case for presentation to juries to win at trial. Technically, forensics data is made available to attorneys and their clients, but often this evidence is so difficult to interpret and understand that they derive little, if any, value from it. Why? Because many digital forensic examiners report their findings one-dimensionally and out of context. Unfortunately, legal professionals, who are not technologists, cannot relate to it. They miss the substance and the importance of the evidence's meaning and its ability to tell the story of the case.

The hypothesis or proposition of this presentation is that forensic information must be visual in order to be optimally useful and valuable to attorneys and the clients they serve. It puts forward the idea of using software to visualize forensics data and "see" patterns and relationships in the digital contents of mobile devices. In so doing data is elevated into information, or even knowledge, that attorneys can use with their clients for decision making, for strategy formulation, and for taking meaningful action in a legal, investigative, or corporate context. Attorneys, investigators, forensic accountants, and others most effectively perform their work with timelines and maps, not data streams. They map and chart factual information like events, actions, incidents, messages, calls, and so forth.

This presentation will show how digital forensic examiners can put meaningful evidence to use with attorneys, opposing counsel, judges, juries, and their own legal teams. The focus is on how meaning can be mined from forensics data cost effectively using software automation. It will include technical information on software bridges that span leading mobile forensic examination tools and popular timeline, mapping, and investigative software packages used by attorneys and investigators today. Evidence visualizations created by this technology will be briefly demonstrated for the audience.

Furthermore, visualization capabilities have as much evidentiary value earlier in the legal process as they do at trial in the courtroom. Depositions, motion practice, and pre-trial hearings present excellent opportunities for sharing and communicating the meaning of forensic data. So do settlement conferences. Why? Today so few cases actually go to trial. The legal community knows that less than 10% of cases at the federal level are tried. Many are subject to decision by plea bargains, settlement conferences, arbitration, and even mediation. Yes, the majority of cases today are settled on or before the courthouse steps. Modern evidence visualization techniques can tell the story of the case and contribute great value to justice in and out of the courtroom.

Visualization, Mobile, Evidence

E29 Comparison of the Current Italian Legislation Regarding Assisted Reproduction With the Other European Union Countries: What's New?

Francesco P. Busardo, MD, Via del vespro, 129, Palermo, ITALY; Paola Mancarella, PhD*, Viale Regina Elena 336, Roma, ITALY; Matteo Gulino, JD, 336, Viale Regina Margherita, 00161, 5, Viale Bruno Buozzi, 00197, Rome, ITALY; Raffaele La Russa, MD, and Arianna Giovannetti, MD, 336, Viale Regina Elena 00161, Rome, ITALY; and Paola Frati, PhD, Univ of Rome, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, ITALY*

After attending this presentation, attendees will learn about a comparative legislative analysis regarding assisted reproduction in European Union (EU) countries.

This presentation will impact the forensic science community by discussing important regulatory and legal differences among EU nations in the provision of assisted reproduction, taking into account peculiar aspects concerning the handling of embryos, use of donors, surrogates, and embryo research.

This report reviews the 2012 legislation concerning Assisted Reproduction (AR) in 27 EU Member States, trying to compare the Italian legislation with the other European countries. The collection of data was completed on January 31, 2012.

In 2004, a broad range of legislative quality and safety requirements for the donation, procurement, testing, processing, preservation, storage, and distribution of tissues and cells was introduced by the European Parliament and the Council with the launch of the Directive 2004/23/EC1. Taking into account the wide coverage of the Directive in comparison to the very specific nature of AR treatments, all EU Member States except Belgium have implemented the EU Tissue and Cells Directive.

Nineteen EU Member States (FI, SE, UK, DK, NL, DE, BE, FR ES, PT, IT, AT, SI, CZ, SK, HU, BG, GR, EE) have reported the existence of AR specific legislation in their own countries, whereas 8 countries (CY, IE, LT, LU, MT, PL, RO, LV) have reported not having AR specific legislation but general legislation covering AR procedures. For Romania, although no AR specific legislation is in place, there exists a general law based on Tissues and Cells Directive for all kinds of cell and tissue transplants (Law n° 95/2006 and law guidelines/25.10.2006 with all later amendments) which covers AR treatments.

In Italy, in May 2009, the Italian Constitutional Court modified the law regulating assisted reproduction technology (ART) which had been approved in February 2004 by the Italian Parliament, eliminating most of the limitations. The 2004 law had led to considerable reproductive migration as it imposed so many limitations on infertile Italian couples: e.g. no more than three oocytes could be fertilized at any one time during IVF or ICSI treatment; all embryos had to be transferred into the uterus; it was forbidden to freeze embryos or screen them for genetic or

chromosomal successful pregnancy and oocyte and sperm donations were prohibited. The application of the Law was regulated by governmental guidelines.

In recent years, in EU Countries, ethical debates about the scope of medical services available to enhance a couple's ability to procreate have resulted in laws that curb access to certain procedures. These laws, derive from different origins ranging from an extremely prohibitive approach in IT, DE, and AT, versus a cautious regulatory approach in DK, SE and FR and the liberal regulatory approach in the UK, ES, and NL.

There are important regulatory and legal differences among EU Nations in the provision of AR services, including divergence on key issues such as the handling of embryos, use of donors and surrogates, embryo research, and PGD treatment.

Assisted Reproduction Law, Italian Law N° 40/04, Ethics and Law

E30 The Scientific Question vs. the Legal Burden: How Much DNA Testing Is Enough?

Ted R. Hunt, JD, Jackson County Courthouse, 415 E 12th St, Fl 7M, Kansas City, MO 64106*

After attending this presentation, attendees will better understand the differences between the scientific question posed to DNA analysts and the legal burden faced by prosecuting attorneys, as these distinct concepts relate to different levels of proof required in forensic science and law.

This presentation will impact the forensic community by enhancing interdisciplinary understanding of the important distinction between these two concepts. This presentation will also facilitate a greater appreciation of the necessarily dynamic, rather than static nature of the "scientific question" posed to analysts by prosecutors who must respond to a moving target—an ever-evolving theory of defense—while attempting to satisfy the legal burden of proving the defendant's guilt beyond a reasonable doubt.

Typically, the "scientific question" is initially posed to a DNA analyst by law enforcement. Answering that question consists of determining whether, to a reasonable degree of scientific certainty, a known biological standard can be associated with questioned crime scene stain—and if so, what amount of weight that conclusion deserves. In many cases, the scientific question is asked and answered before an arrest is made and provides the basis for the prosecutor's decision to file charges.

However, an incriminating answer to this evidence specific question does not conclusively establish the prosecution's theory. Rather, it supports an inference in favor of that theory. Accordingly, analysts must remember that a single, ostensibly strong DNA association to a criminal defendant is not necessarily sufficient to satisfy the prosecutor's burden of proof in court. As the case proceeds toward trial and the defense begins to take shape, the original scientific question may evolve, may be reframed, or it may be necessary to answer altogether new scientific questions. Thus, additional DNA analysis may be necessary to shore up a case for prosecution, to rebut a defense attack, or respond to newly-developed facts and/or fluctuating legal theories.

From the analyst's perspective, a prosecutor's request for supplemental DNA analysis of one or more additional *probative* evidence stains may seem pointless, redundant, and unnecessary. This belief may stem from the analyst's lack of intimate familiarity with the factual context of the originally tested evidence, and/or the litigants shifting legal issues and theories relative to that evidence. It may also arise from the analyst's unfamiliarity with the prosecutor's task—qualitatively different than answering the scientific question—of proving the case beyond a reasonable doubt to a unanimous 12 member jury. The potentially different perspectives of prosecutors and analysts regarding the need for supplemental DNA testing highlight the distinction between the "scientific question" and the "legal burden."

The "legal burden" shouldered by American prosecutors is to prove each element of a criminal offense beyond a reasonable doubt. The prosecutor's theory is informed by the credible facts in the case and the admissible incriminating evidence. In many cases, the single most incriminating fact may be the DNA test results offered by the prosecution's expert witness.

However, it must be remembered that the defendant also has a theory of the case. Furthermore, the defense is never legally obligated to disclose or declare its theory to the prosecution. That theory may ultimately be that the prosecutor has failed to meet his or her burden of proof, may incorporate and utilize different and additional facts and evidence, or may call for a contrary and competing interpretation of the same facts.

The ability of the defense to constantly update its theory in response to the government's case results from legally recognized distinctions between the parties. Unlike the prosecution, the defense has no burden of proof; must *never* declare his/her trial strategy at any point in time; is entitled to categorical acquisition, review, and use of the prosecution's discovery; and may largely ignore the same discovery rules and deadlines that the prosecutor is obligated to follow. In some cases, the result will be a defense that resembles a moving target—constantly evolving and updating in reaction to the prosecution's case. In this way, the defense will attempt to accommodate, avoid, or refute the prosecution's DNA evidence with whatever strategy counsel deems most plausible at *any* given point in time.

Because of this legal asymmetry between the parties, corroborative (sometimes called convergent) evidence is essential to any prosecution. Corroborative evidence may be defined as that which is supplementary to evidence already given and that tends to strengthen or confirm it.[1] In those cases in which DNA provides the sole or primary link between a suspect and a crime, supplemental DNA analysis of one or more available *probative* evidence samples may provide essential corroboration for the prosecution's existing DNA evidence. Such testing can also simultaneously diffuse defense attacks against the contextual significance of the evidence, its chain of custody, the analyst's skills and experience, the lab's evidence handling procedures, testing protocols, and the interpretation of the results. In sum, targeted supplemental DNA analysis can serve to greatly diminish the courtroom plausibility of various defense attacks against a single incriminating DNA result, while simultaneously increasing the chances of a just and successful prosecution.

It is recognized that laboratories may fear that the prosecution's need for corroborative DNA evidence will present a number of practical and logistical challenges. Among these are unpredictable rush jobs, disrupted work flow, increased pressure placed on already limited resources, and greater risk of error due to artificially imposed deadlines. These fears, however, should not cause labs to refuse to test supplemental *probative* samples that may corroborate existing incriminating DNA results.

One solution to this problem – either wholly absent or extremely rare in many jurisdictions is the consistent interdisciplinary communication and collaboration between prosecutors, law enforcement, and laboratory officials. Forensic case coordination, or "triage" meetings, should take place between representatives of these agencies before or immediately after criminal charges are filed in cases whose success will heavily depend upon DNA testing and analysis. The main purpose of these interdisciplinary meetings should be to collectively discuss the facts of the case, potential legal issues, various possible theories of the prosecution and defense, and to make informed decisions about which *probative* items of evidence should be tested. Such meetings also provide a forum for prosecutors and lab officials to share their potentially different perspectives on the need for supplemental DNA testing, and allow them to justify and defend their positions at a point in time in which such testing remains a realistic possibility.

In addition, follow-up interdisciplinary case meetings or communications should take place as needed. During these meetings, the prosecutor should update laboratory officials on the current status of legal issues and evolving theories of both the prosecution and defense. Participating officials should also collectively decide whether any additional remaining *probative* items of evidence should be analyzed to further strengthen the prosecution's case, or to rebut a potential attack

from an unfolding defense theory. In this way, the "scientific question" will remain relevant by frequent updating and refinement based on the current legal and factual exigencies of each case.

Scientific Question, Legal Burden, DNA Analysis

E31 DNA in the Courtroom: Top Ten Tips From the Bench

Arlene Perkkio, JD, Dakota Co District Court, 1560 Highway 55, Hastings, MN 55033*

After attending this presentation, attendees will understand ten concrete practicing tips on how to present DNA in a courtroom. The tips are drawn from in court experiences of a state court trial judge.

This presentation will impact the forensic science community by explaining how scientific evidence is a growing issue in court cases and showing the importance for lawyers and judges to explain DNA evidence in a user-friendly language.

Attendees will understand ten concrete practicing tips to assist in improving understanding and communication with others of the importance and value of DNA evidence. These practicing tips will focus predominately on how to present DNA evidence in a courtroom. The ten concrete practicing tips are drawn from actual in court experiences of a state court trial judge.

This presentation will impact the forensic science community by providing an explanation from the perspective of a state court trial judge, of how scientific evidence is a growing issue in court cases and courtrooms across the country. This presentation will also impact the forensic science community by showing why it is important for lawyers, judges and scientists to explain DNA evidence in simple, easy, understandable, user-friendly language.

Judges serve as the "gatekeeper" to the admissibility of forensic science evidence. Yet many lack scientific training and must rely upon the lawyers coming before them to explain how DNA evidence is or is not relevant and should or should not be admissible. The central issues addressed in this presentation are: how do lawyers, with little or no scientific background, explain DNA evidence to other lawyers and judges, with little or no scientific background? How do lawyers and judges insure jurors, with little or no scientific background, understand DNA evidence? How do scientists insure lawyers, judges and jurors understand scientific evidence?

Understanding and then explaining scientific evidence is a growing issue in court cases and courtrooms throughout the country. Attorneys and judges have a tendency to scan over scientific evidence, getting to the end result, the findings, and then disregarding the underlying data. This presentation will show the importance of understanding the DNA evidence, its significance as related to the facts in the instant case, and common sense application of this information. If the analysis says the DNA matches, most attorneys look no further; this presentation will stress why this should be a starting point, the beginning, not the end of the analysis.

Lawyers who are able to effectively understand and then break down scientific issues into understandable language get their desired results. Lawyers, who can explain the science in simple and understandable language, understand the science. The ten concrete practicing tips will: (1) focus on what lawyers and judges can do to educate themselves about the science of DNA; (2) demonstrate how to explain the forensic scientific information; and, (3) will explain what scientists can do to help lawyers, judges, and jurors understand DNA evidence.

Data from DNA court cases, compiled over an 18-month period, gathered by the author will be reviewed. This presentation seeks to offer practitioners, judges, and scientists information about best and worst practices in the courtroom for DNA court cases. Lawyers and judges have taken different approaches to understanding, handling, and presenting DNA evidence. This presentation will provide a composite which will educate the lawyers, judges, and scientists.

This presentation seeks to inform attorneys, both prosecution and defense, and scientists as to what should be considered when attacking the very real problem of addressing the "gatekeeper," the judge, about DNA evidence. The ten concrete practicing tips will focus on what scientists and lawyers can do to explain the science of DNA in court cases to judges with no science background.

DNA, Courtroom, Lawyer

E32 Preventing DNA Wrongful Convictions: Legal and Judicial Responsibilities

Brian C. Zubel, JD, PO Box 70, Fenton, MI 48430*

After attending this presentation, attendees will recognize that the bench and bar have important responsibilities to provide not only legal analysis in criminal cases, but also an independent review of forensic testing results and interpretations. By accepting reported results of forensic testing at face value, attorneys and judges run the risk of overlooking important exculpatory evidence, errors, and misinterpretations.

This presentation will impact the forensic science community by demonstrating how forensic DNA methods and their interpretation can be highly subjective. In order to prevent wrongful charges and convictions, both judges and attorneys must develop an independent capacity to scrutinize the conclusions claimed by laboratory personnel.

Forensic DNA results are susceptible to a wide range of interpretation, particularly where DNA mixtures are concerned. Studies such as NIST MIX05 have demonstrated that differences in the interpretational guidelines used by different laboratories can influence the conclusions claimed in DNA mixture cases. Even DNA analysts from the same lab and using the same interpretational guidelines have reached very different results when examining the exact same data. Given the range of inter- and intra-laboratory interpretational variation, it falls upon the legal profession to provide additional tiers of meaningful review.

In 2009, a homeowner returned to find his house burglarized and a number of firearms stolen from his gun cabinet. The homeowner saw that the cabinet had been pried open and that one of his kitchen knives, the blade bent into a curve, was lying at the foot of the cabinet. Police investigators collected the knife as evidence; both it and a swabbing taken from the handle were submitted for forensic DNA typing.

Employing AmpFℓSTR® Profiler Plus® and COfiler® amplification kits, the laboratory obtained a male profile across the thirteen CODIS DNA loci. Additional alleles were also detected, but these fell below the laboratory's validated reporting threshold of 150 rfu. Lacking any suspect at that time, the unknown male profile was entered into CODIS.

More than a year later, police investigators arrested a suspect they found in possession of firearms which had been stolen in other burglaries in the area. They obtained a search warrant for buccal swabs and submitted these reference samples to the laboratory for comparison. As it turned out, the suspect's buccal swabs were processed by a different DNA analyst than the one who had processed the knife handle swab.

The second analyst never processed any evidence obtained from the knife; relying entirely on the data generated by his colleague a year earlier. Looking at the exact same electropherograms, the second analyst reached an entirely different conclusion. Instead of agreeing with the first analyst that the knife handle represented DNA from an unknown male, the second analyst concluded it was instead a mixture of types from at least two individuals ***and that the suspect could not be excluded as a possible contributor to the mixture***.

These two conclusions are obviously irreconcilable. The first analyst had correctly reported the unknown male profile to CODIS. When the suspect's known profile is compared to the CODIS profile, the suspect is ***excluded*** at eight of the thirteen DNA loci tested. The second analyst had improperly concluded that the sample was a mixture, taking into consideration allelic activity that was clearly below the laboratory's validated interpretational threshold.

The government laboratory in question employed internal procedures for the administrative review of reports, yet the obvious error

in this case was not spotted. Nor was it detected by the police investigator who submitted the matter to the prosecutor for a warrant, or by the prosecutor who issued charges. Fortunately for the suspect, the defense team was able to bring the mistake to the prosecutor's attention. All charges were dismissed on the day scheduled for preliminary examination.

While this case might constitute anecdotal evidence of "analyst bias," it also provides a sobering reminder of how easily the criminal justice system can fail. If DNA wrongful convictions are to be prevented, lawyers and judges must have the technical ability to scrutinize claims made by forensic scientists.

DNA, Wrongful Convictions, Mixed Samples

E33 Death Row Defense: Investigating and Evaluating Forensic Issues in Post-Conviction

Matilde Carbia, JD, 3050 Grand Rt St John, New Orleans, LA 70119; and Gary Eldredge, JD, 205 S Scott St, New Orleans, LA 70119*

After attending this presentation, attendees will understand the role that guilt and mitigation investigations, and the forensic issues commonly developed through such investigations, play in the representation of death row inmates in the state post-conviction stage of appeals. The importance of post-conviction investigation in preventing the execution of wrongfully convicted defendants will be underscored, as will intellectually disabled defendants who are constitutionally barred from receiving the death penalty.

This presentation will impact the forensic science community by educating attendees about the variety of forensic issues encountered in death penalty defense, and the ways in which a legal team identifies and develops these issues in post-conviction. The forensic community will also gain insight into how the work of capital defense organizations and innocence projects have proven that wrongful convictions are far too common to be acceptable in our criminal justice system.

Over 130 people have been exonerated from death rows around the United States since 1973.[1] Between 1973 and 1999 there were an average of three exonerations per year.[2] From 2000 through 2011 there have been an average of five exonerations per year.[3] In a 2001 study that looked at the cases of eighty-six wrongfully convicted death row inmates dating back to 1973, the three leading causes of wrongful convictions were faulty eyewitness identifications, government misconduct, and the testimony of jailhouse informants.[4] However, mishandled or unpreserved evidence or the use of unqualified experts was a contributing factor in almost ten percent of the wrongful convictions.[5]

In post-conviction, capital defense organizations systematically review client's cases for evidence of innocence, prosecutorial misconduct, and other indicia of wrongful conviction. Representing capital clients in post-conviction requires that an attorney become knowledgeable in multiple forensic disciplines in order to spot potential forensic issues, successfully develop them through investigation and expert involvement, and cogently present them to a judge in the form of legal claims. During the guilt phase and mitigation phase investigations that take place in post-conviction, forensic issues are frequently encountered and must be fully explored.

A guilt investigation focuses on the development of forensic issues related to the crime and the physical evidence, while a mitigation investigation focuses on trauma and mental illness in a client's family history.

Several steps of a guilt investigation involve the forensic sciences:

- Careful preliminary review of the prosecution's forensic evidence, including lab reports, the crime scene, and lay and expert testimony;
- Finding, examining, and evaluating the physical and scientific evidence collected and developed during pre-trial law enforcement investigation; and
- Consulting with experts and considering independent defense scientific testing and analysis.

Steps in a mitigation investigation that involve the forensic sciences include:

- Making preliminary assessments of a client and his family members for potential mental health or intellectual functioning issues; and
- Consulting with forensic mental health experts to fully develop a history of mental illness and/or brain damage that was not presented at trial.

Hypothetical case examples will be presented in order to illustrate a sampling of issues that are frequently encountered in the course of guilt and mitigation investigations in capital post-conviction.

Capital Defense, Fact Investigation, Wrongful Conviction

E34 Girls Rule, Perps Drool: How an 84 Pound Teenager Made Her Attacker Bleed All Over the Evidence

Melissa Mourges, JD, and Martha Bashford, JD*, NY County DA Office, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will understand how to use a "John Doe" indictment to preserve jurisdiction against the statute of limitations, focusing on an attempted murder/sexual assault case in which a teenage girl fought her attacker so fiercely she drew blood, but the perpetrator's forensic profile had no match in CODIS.

This presentation will impact the forensic science community by providing an insight into what kinds of cases make good candidates for "John Doe" indictments and how to proceed when a match finally occurs in CODIS.

It was just two days after her 15th birthday when Jessica Reyes, measuring 4′8″ and weighing only 84 lbs, entered the lobby of her building in a huge housing complex in upper Manhattan. She got into an elevator, intent on her cell phone, and as she was about to exit, she was grabbed from behind by a man who put her in a stranglehold and threw her onto the floor. He choked her to unconsciousness and pulled her off the elevator on the top floor, 34 stories above the ground. Surveillance video captured this blitz attack.

When Jessica came to, he had her in the stairwell, alternately choking and punching her in the face. Hoping to avoid something worse, Jessica gave him her only possessions, a student subway metrocard and a single dollar bill. He threw her to the floor and they tumbled down three flights of stairs, fighting and clawing at each other. The assailant tore off her pants and underpants. When he took his hands off her to pull down his zipper, she fled to her own apartment. She was bleeding profusely, with blackened eyes, a torn lip, a broken nose and bruises all over her body.

The stairwell looked like a charnel house. Crime scene photos show clots and smears of blood where Jessica's head repeatedly bounced off the stairs. Crime scene investigators recovered a pair of men's eyeglasses and the blood-stained metrocard from the stairwell. DNA analysis developed the same male profile from each item and the profile was uploaded to CODIS. No match was found.

Fearing that the statute of limitations would run out, in 2007 the Cold Case Unit of the Manhattan District Attorney's Office obtained a

"John Doe" indictment. "John Doe with a Particular DNA Profile" was charged with attempted murder, attempted rape and other crimes to stop the clock. Because New York is a grand jury state, that means the victim had to testify in person, knowing her assailant may never be caught.

Finally, a CODIS "hit" matching to a man named Steven Carter. As a result of a conviction for a home invasion against an elderly man with Parkinson's disease, Carter's DNA entered CODIS on September 10, 2010. The match occurred on September 13, 2010. It took CODIS three days to solve a crime that had lingered unsolved for almost seven years. Carter pleaded guilty on the eve of trial. Jessica Reyes became the public face of the power of DNA as she crisscrossed New York state encouraging legislators to pass an "All Crimes" DNA Databank expansion law, requiring offenders convicted of all misdemeanors and felonies to go into CODIS. Her efforts paid off; that law was signed into effect this past May.

Sex Crimes, John Doe Indictment, CODIS

E35 Collecting DNA From Arrestees: An Examination of Policies, Practices, and Implications

Julie Samuels, MPP, Elizabeth H. Davies, BS, and Dwight B.N. Pope, BA*, Urban Institute, 2100 M St NW, Washington, DC 20037*

After attending this presentation, attendees will understand the variations in these laws and how key provisions in laws (e.g., the scope of the qualifying offenses for which samples are collected, the point in a case at which samples are obtained or analyzed, the policy for expunging DNA profile records) have been translated into practice, all of which impact the operations and infrastructures of state crime laboratories and law enforcement agencies. Special attention will be paid to the workload implications of these provisions for state crime laboratories and law enforcement agencies, as well as the impact these provisions have on CODIS.

This presentation will impact the forensic science community by highlighting implementation lessons generated from the experiences of other states and helping states understand the implications of such an expansion on agencies responsible for implementation. Further, the presentation will not only address how such laws impact CODIS, but also how criminal justice stakeholders can begin to measure the effectiveness of collecting DNA at arrest or charging.

As of July 2012, more than half the states and the federal government have enacted laws authorizing DNA collection not only from individuals who are convicted, but also from individuals who are arrested for or charged with certain qualifying offenses. The Urban Institute's Justice Policy Center, with support from the National Institute of Justice has studied the investigative utility of these laws and how they impact the law enforcement agencies and state crime laboratories responsible for their implementation. The study team conducted a thorough review of relevant state laws, interviewed state crime laboratory representatives and various key stakeholders, and collected summary laboratory workload and CODIS data.

While the scope of qualifying offenses varies across states, about half the states collect for all felony offenses. The rest of the states authorize collection from a subset of felony or misdemeanor offenses. The scope of collection not only impacts the volume of samples crime laboratories receive and subsequently analyze (e.g., laboratories, for instance, may need to hire additional personnel), but it also impacts the administrative workload of both law enforcement agencies responsible for collection and laboratories. Further, while laws authorizing the collection of DNA prior to conviction have been referred to as "arrestee" DNA laws, the point at which collection occurs varies widely across states. Most states that have such laws collect DNA as part of the booking procedure. However, others have set additional requirements for collection. In some states collection is not legally authorized until an individual has been formally charged or arraigned, or a judicial determination of probable cause has been issued. Last, the process for initiating the removal – or expungement – of DNA profiles from CODIS upon acquittal or case dismissal varies among states. In general, few laws require the states to automatically carry out an expungement if an individual is eligible, while most laws require that the individual initiate the process.

Because of case attrition from arrest to conviction, the collection of DNA *prior* to conviction typically means that law enforcement is drawing from a larger universe of individuals than if collection only occurred upon conviction. Indeed, based on data collected from states, the total number of samples laboratories have received since implementation typically surpass the volume of samples received annually prior to implementation. However, this growth may be limited in states that bear the burden of expunging profiles. While the number of matches – or hits – between known and forensic profiles have increased over the years as the number of profiles have increased, the attribution of the growth in hits to the laws' expansion is challenging to substantiate.

DNA, CODIS, Arrestee

E36 Low Copy Number Y-STR Evidence: Will "Junk" DNA Dilute the Power of the Phrase "DNA Match" and Debase the "Gold Standard?"

Scott M. Kozicki, JD, Law Office of Cook Co Public Defender, 69 W Washington, Chicago, IL 60602*

After attending this presentation, attendees will become aware of the emerging issues surrounding low copy number Y-STR evidence in criminal trials and the concerns of prosecuting and defending these types of cases.

This presentation will impact the forensic science community by challenging participants to debate about the wisdom of prosecuting cases using low copy number Y-STR DNA evidence, and whether new guidelines are needed to maintain the integrity of forensic DNA technology.

The phrase "DNA match" carries terrific power. It derives from the notion that the DNA associated with a crime is essentially unique; it can virtually and statistically single out the accused as the source of the DNA evidence. What happens when laboratories and prosecutors begin calling "DNA matches" with one-in-four probabilities, when the DNA evidence might actually match three members of the jury? Will that "DNA match" claim sometimes be wrong, associating some accused individuals as included when they might be excluded? Will subjectivity and bias increase? Will powerful science be mixed with junk science? Will the meaning of the phrase "DNA match" become diluted?

These concerns are increasing in the forensic courtroom setting, especially in Y-marker cases. The Y-chromosome short tandem repeat (Y-STR) markers have been used in criminal investigations to help detect low levels of DNA where other kits have failed, targeting only the male contribution in the evidentiary sample. As DNA science and technology advances, forensic labs are now able to get test results from smaller quantities of DNA, even when these test results yield incomplete and partial DNA. In some instances, these Y-results are reported as "DNA matches" even when the profile is derived from only one loci detected. In fact, lab analysts have reported such test results, defended them in court, and have been supported by their management teams.

The use of low copy, Y-STR DNA results leads to differing mixture interpretations. Typically, Y-STR loci produce single alleles at each of the ten (out of the eleven loci available in the kit) loci in single source samples of male DNA. As a result, lab analysts interpret these Y-STR results as single source samples. When forensic analysts observe multiple peaks at any one of these ten loci, they commonly report that more than one male contributor is present in the tested sample. Absent from this forensic analysis is when a particularly challenging problem arises: while many individuals have only one allele at each of these ten loci on the Y-chromosome, some individuals have two or even three alleles at some loci. Accordingly, a laboratory report interpreting the Y-result as a mixture of at least two contributors and "matching" the defendant's DNA haplotype could likewise be interpreted as a DNA

exclusion. The use of this low copy, Y-STR DNA evidence at a criminal trial could ultimately result in the most egregious failure in the criminal justice system: the conviction of the innocent, while allowing perpetrators to walk free.

This presentation will show examples of this emerging issue from actual casework and trials. Attendees will learn about the challenges presented by this new issue, and be challenged to engage in a debate within the forensic science community about the wisdom of such practices, and whether new guidelines are needed to maintain the integrity of forensic DNA technology.

Y-STR, DNA, Mixtures

E37 Minnesota Trial Team: Public Defenses' Responses to State-Sponsored Forensic Science

Keith S. Belfry, JD, 1400 Alworth Bldg, Duluth, MN 55802*

After attending this presentation, attendees will recognize that, within the national criminal justice system, the forensic education of lawyers in public defense is generally behind that of their counterparts in law enforcement and prosecution. Attendees will also recognize that because of this realized gap in forensic education, Minnesota's public defense system embarked on a rather novel approach in dealing with its unique lack of forensic knowledge and education of its public defense lawyers.

This presentation will impact the forensic science community by showing that the development of a concept, such as Minnesota's Trial Team, can significantly "level the playing field" for indigent criminal defendants when there is a state prosecution that contains significant forensic evidence generated by state-sponsored forensic laboratories. The forensic community will further understand that, with the creation of such entities, it enables the public defense lawyer to challenge the forensic scientist's testing methods, the results, the interpretations and, in some instances, even the very validity of certain forensic evidence being brought forth in today's criminal courts. The forensic community will ultimately understand that the criminal justice system is best served by both the state and defense having the ability to intelligently present, and question, significant forensic evidence presented at a trial.

In the years leading up to 2006, the Minnesota State Public Defender recognized that major felony trials in Minnesota were becoming increasingly involved with complex forensic issues and evidence. This was not only occurring within the major metropolitan area of Minneapolis and St. Paul, but more importantly in rural, Greater Minnesota. The Minnesota Public Defender system in greater Minnesota is manned by part-time personal that also have private practices. At the time, county attorneys representing small counties would routinely seek assistance from the Minnesota Attorney General's Criminal Division, and the accompanying forensic labs, for assistance in these complex, forensic cases. The part-time public defender did not have any like resource, nor experience, to draw upon concerning forensic trial issues.

In order to address this need, the State Public Defender created the "Trial Team." The Trial Team is comprised of five lawyers that have an over-all mission of providing high-quality, cost-effective assistance for trial representation in major felony cases that involved forensic evidence as well as to train other assistant public defenders in the understanding and use of forensic evidence. These lawyers are all trained in the science of DNA, and continue to update that training through the Minnesota Public Defender Advanced DNA Institute. They have also selected other forensic areas in which to become well versed in order to further their basic mission. These additional areas include arson, gunshot residue, psychiatry, pediatric forensics, fingerprints, ballistics, eyewitness identification, blood spatter and digital/electronic evidence.

With the advent of the National Academy of Sciences Report in 2009, the Trial Team's mission of statewide forensic education, support and assistance to local public defenders became more critical in order to adequately represent indigent clients. When requested by local co-counsel, this has meant that, with support of the Trial Team, local public defenders are now looking closer at the forensic evidence produced by local police and other state sponsored forensic laboratories on a pre-trial level. The Trial Team provides its specialized forensic knowledge, and litigation support as co-counsel, to local public defenders for the purpose of litigating those *Frye-Mack* challenges to questionable forensic evidence once considered above such challenges (fingerprints, handwriting analysis, ballistics, gunshot residue and shaken baby syndrome to name a few), to file other similar motions and to assist in the client's trial.

The National Academy of Sciences Report of 2009, the ongoing *Frye-Mack* challenges supported by the Trial Team and those public defenders trained or co-counseled by Trial Team members have led, in part, to the Minnesota Supreme Court advising the State District Courts that *Frye-Mack* challenges should be allowed in all cases with forensic evidence, even forensic evidence long-permitted by Minnesota Courts[1]

Trial Team, Forensic Evidence, DNA

E38 Learning a Forensic Science Discipline Can Make You a Better Attorney

Julie A. Maxwell, JD, 510 15th St NW, Rochester, MN 55901*

After attending this presentation, attendees will understand how learning one aspect of forensic science contributes to increased proficiency in all areas of forensic science and improves trial skills for attorneys. The successes of participants in the Minnesota Public Defender Advanced DNA Institute will be used as examples of how investment in an in-depth forensic science program can increase forensic skills for attorneys. Successful incidents from actual cases will be described.

This presentation will impact the forensic science community by showing how in-depth DNA training for attorneys can improve litigation skills in this complex area. This training can also prompt attorneys to gain additional knowledge and skills in other forensic fields that can lead to better courtroom litigation skills.

The National Academy of Sciences (NAS) Report found that lawyers "often lack the scientific expertise necessary to comprehend and evaluate forensic evidence." In response, the Minnesota State Public Defender, working with a small group of attorneys, developed a year long training program to teach thirty assistant public defenders DNA typing litigation skills, using a combination of intensive lecture, small group discussion, and one-on-one tutoring. Each attorney applied this advance training to one of their own actual, pending cases. Prior to this training, a lot of attorneys just accepted the reports submitted by the forensic laboratory for their face value. Now, following the training, nothing is taken at face value. These lawyers increased confidence in their ability to spot issues and then to work with experts on complex forensic issues.

This presentation will explore what has occurred in the Minnesota Public Defender System since this program's training component was completed in 2011. Since this time, many of the attorneys originally involved in this program have demonstrated an increased interest in a variety of areas of forensic sciences. Using the structure put in place during the formal training period, lawyers have continued to collaborate with each other on cases using both a listserve and monthly group meetings. They have also returned to their own jurisdictions throughout Minnesota and worked with lawyers who were not involved in the Institute to improve the overall ability of lawyers throughout the public defender system to spot issues and litigate relevant subject matter. The ongoing work of these lawyers collectively as a group and individually, has led to the increased interest in other areas of forensics such as toxicology and digital forensics that impact on their practice of law.

Examples of cases that will be discussed include: challenges to the State's requests to obtain DNA samples from defendants before the known samples have been tested in criminal sexual conduct, assault,

and burglary cases, thus preserving clients' constitutional rights of privacy; dealing with a complex mixture in a criminal sexual conduct case; recovery of crucial evidence by retrieval of text messages from a broken cellphone which the expert has called "the smoking gun" evidence in a burglary and assault with a dangerous weapons case; and the probe into the policies and practices of the City of St. Paul Police Department Crime Lab.

This presentation will give a detailed explanation of how advanced training in forensics can lead to improved performance in the courtroom.

In-Depth Training, Improvement, Litigation Skills

E39 Investigating a Serial Killer: Jeffrey Dahmer, 20 Years Later

Jeffrey M. Jentzen, MD, PhD, Univ of Michigan, 5226 Med Sci I, 1301 Catherine, Ann Arbor, MI 48109-5602*

After attending this presentation, attendees will gain an understanding of the specific roles of forensic pathologists, investigators, and criminalists investigating serial killers.

This presentation will impact the forensic science community by informing jurists and investigators on the contributions of forensic pathologists, investigators, law enforcement, and criminalists in the documentation, evaluation, and case preparation of a serial killer. By analyzing the the investigation of the Jeffrey Dahmer case, participants will experience the step-by-step sequence of scene, autopsy, and interview techniques, as well as the necessary collaborative environment and interactions required in a high profile death investigation.

On July 23, 1991, personnel from the Milwaukee County Medical Examiner Office and Milwaukee Police Department responded to an apartment where partially skeletonized remains of eleven individuals had been detected. Law enforcement had initiated the investigation of the premises after responding to a naked man, who while handcuffed, was running down a city street. The assailant, Jeffrey Dahmer, was quickly taken into custody. In this unique situation, Dahmer freely discussed his role in the killings with investigators and provided a valuable resource for the collaboration of the scene and autopsy findings to pathologists and law enforcement personal during the investigation. Medical examiner personnel recovered seven human skulls, three of which were painted; four human heads, and one postcranial skeleton from a portable freezer; and three skeletonized bodies from a 55-gallon plastic storage drum. The partially dissected bodies, skulls, and numerous photographic journals were transported to the medical examiner's office. Scene investigation, anthropological analysis, and autopsy details of the bodies provided prosecutors with valuable evidence of the methods of death, motives of the killer, and psychological state of Dahmer during the course of a death spree that lasted nine months.

The evaluation of the scene allowed investigators to establish methods, motives of death, begin the preliminary identification process, and to demonstrate the mental capacity of the assailant. Forensic pathologists assisted with the identification, established the cause of death, and documented injuries that allowed investigators to question Dahmer on various injuries he inflicted upon victims. Of the eleven victims recovered from the scene, all were identified on the basis of antemortem dental comparison by a forensic odontologist. The skeletons were easily identified due to characteristic dissection levels of the spine and extremities. Fingerprints were recovered from four victims. The anthropological and odontological examination assisted with the identification and also resulted in the establishment of victim profiles. Dahmer was diagnosed as having a mixed personality disorder with sadistic, obsessive, fetishistic, antisocial, necrophilic features typical of what has been described as organized, nonsocial, lust murderer.

This presentation will discuss investigation of the Jeffrey Dahmer Case from scene to the courtroom. It will discuss the physicial and pathological evidence used to convict Jeffrey Dahmer. It will also discuss the pitfalls in the investigative process using the lessons learned in the Dahmer case.

Serial Killer, Jeffrey Dahmer, High-Profile Case

E40 The DUI HGN Test: A Forensic Look at the NHTSA's HGN Robustness Study

Jay Zager, 10638 NW 69 St, Parkland, FL 33076; and Lance A. Platt, PhD, 4301 Carter Creek Pkwy, Ste 201, Bryan, TX 77802*

After attending this presentation, attendees will understand the importance of conducting a proper Horizontal Gaze Nystagmus (HGN) test in Driving Under the Influence (DUI) investigative cases.

This presentation will impact the forensic science community by reinforcing the necessity of conducting a proper DUI HGN test in the prescribed standardized manner to avoid false positive results.

The HGN test is a pre-arrest exam utilized by law enforcement in the United States of America. It is a component of a three battery testing procedure also including a nine step walk and turn test and a one leg stand test. These three components are collectively referred to as the "Standardized Field Sobriety Tests" or SFST.[1]

The SFST's are taught to law enforcement officers nationwide as a means to "standardize" the investigation of those motorists who are suspected of have having driven an automobile with an unlawful BAC.

The SFST's were developed in the Southern California Research Institute over 30 years ago with periodic updates published by the United States Department of Transportation's National Highway Traffic Safety Administration (NHTSA).[2]

The HGN test is described to law enforcement as "the involuntary jerking of the eyes" as they move from side to side and are further taught that if the HGN test is performed correctly revealing four or more clues that HGN is 77% accurate in predicting that a motorist's blood alcohol concentration is over 0.10%. A stimulus (often a pen or finger) is held between twelve to fifteen inches from the face at slightly above eye level.

The standardized procedures for the administration of the HGN test begins with screening the motorist for certain pathological disorders that include brain damage or diseases of the middle ear by looking for equal pupil size, resting nystagmus, and equal tracking (eyes following an object together).

The HGN test is then scored for a total of three clues per eye for a total of six clues.

The first component is checking the eyes for "the lack of smooth pursuit" by moving the stimulus two seconds out and two seconds back for each eye and then repeating the sequence to determine if the motorist's eyes are able to pursue the stimulus smoothly.

Next the motorists eyes are checked for "distinct and sustained nystagmus are maximum deviation" by holding the stimulus all the way across the motorist's face and holding that position a minimum of four seconds to observe the eye for distinct and sustained nystagmus. Both eyes are to be checked twice.

The third HGN test step requires the officer to check for "onset of nystagmus prior to forty-five degrees" by moving the stimulus at a speed of approximately four seconds to reach the edge of the motorist's shoulder. When HGN is observed the officer is told to stop and verify that the jerking continues. Again, both eyes are checked twice.

The NHTSA training manual emphasizes that the validation of the SFST's applies only when: "The tests are administered in the prescribed standardized manner."

A study of officers performing HGN tests on motorists being investigated for DUI revealed that in only one out of fifty two occurrences the HGN test was performed correctly.[3] The statistical evaluation of NHTSA's 1998 report "Validation of the Standardized Field Sobriety Test Battery at BAC's Below 0.10%" concluded that, "The accuracy is substantially less for individuals with lower alcohol levels."[4]

An improperly administrated HGN test creates a conflict between forensic science, law and public policy. When the HGN test has been compromised the government often endeavors to still justify the test results. Too often law enforcement or the prosecution attempts to minimize the flawed HGN test by extolling the statistics of the approved standardized test.

The NHTSA report, "*The Robustness of the Horizontal Gaze Nystagmus Test*" states that, "HGN as used by law enforcement is a robust procedure. The study findings provide no basis for concluding that the validity of the HGN is compromised by minor procedural variations."[5]

An evaluation of the "HGN Robustness Study" as applied to potential motorists .080% BAC or below will be presented. This evaluation reveals a high false positive result per the NHTSA SFST training received by police officers in relation to an arrest decision at 0.08% based on four or more ovserved HGN test clues.

E41 EPA, GLP, and USP vs. Forensic Science: Where is the Commutability? Why Are There no Standardized Methods Across All of Forensic Science?

Justin J. McShane, JD, 4807 Jonestown Rd, Ste 148, Harrisburg, PA 17109; and Josh D. Lee, JD*, Ward, Lee & Coats, PLC, PO Box 352, Vinita, OK 74301*

After attending the presentation, attendees will appreciate the difference between the highly regulated world of analytical chemistry in the Good Laboratory Practices (GLP) and the Environmental Protection Agency (EPA) regulated environment, as well as USP guidelines versus the largely unregulated world in forensic science where there is no overarching oversight.

This presentation will impact the forensic science community by bringing into focus the discussion on the need for validated, standardized methods in forensic science with the prize not simply being proper metrology, but instead commutability.

Commutability is the hallmark of all measurement science and is particularly important in analytical chemistry at large. Commutability is the feature of being comparable across borders and universal over all time. It's goal is to set up a scheme so that a test of an unknown results in the same qualitative identification and a quantitative estimation regardless of where the testing happens (geographically and environmentally) and through all of time (this year, next year or 100 years later). Using appropriate and traceable standards/reference materials during calibration combined with using validated and standardized methods provides for commutability.

Since the mid 1980s, the Environmental Protection Agency (EPA) has pushed the forefront of standardizing assays and methods in testing then delivering validated and standardized methods for all laboratories to us throughout the United States and in the world. Shortly thereafter, the Food and Drug Administration (FDA) developed GLP whereby a method has to be proven as valid, standardized, and then is accepted and used throughout industry for a particular purpose. The United States Pharmacopeia (USP) has published a stringent set of guidelines that govern the validation and standardization of methods. These validation procedures include testing to determine:

1. Accuracy (Bias)
2. Precision (Calibration)
3. Specificity (Degree of Selectivity)
4. Limit of detection
5. Limit of quantitation
6. Linearity and range
7. Ruggedness
8. Robustness

Put basically and simply, a validated method means that there has been some sort of rigorous method of testing of the instructions of the assay and its calibration procedure to produce data that shows and proves that the method is suitable for its intended purpose.

A true validation study much like the ones found in GLP and EPA regulated environments are consistently missing in the world of forensics. Therefore, the true commutability of any measurement reported in the forensic world can be questioned. There is a high degree of variability in the world of forensics. Not so in GLP and EPA worlds.

Contrast this with the world of forensics. For example, blood ethanol analysis by way of Headspace Gas Chromatography using a Flame Ionization Detector (HS-GC-FID) is a routine method of analysis and perhaps the most frequently run forensic assay in the US today. Yet, unlike EPA, GLP, or USP methods, there are no standardized methods, instrumentation or assays developed and implemented in the testing world. Some laboratories conduct ethanol determinations by enzymatic assay, others use direct liquid injection on packed columns by way of GC-FID. Still others use single column GC-FID. One laboratory runs GC-FID with MS. Not all laboratories use dual column HS-GC-FID. Those that do run dual column HS-GC-FID some consciously decide not to quantitate on two columns. What constitutes a batch as well as what constitutes proper quality control is never uniform among laboratories. Acceptance criteria vary in a seemly arbitrary way. Should there be blanks between unknowns? Should inorganic salt be used? How much dilution should be performed by way of ISTD? And the list goes on and on showing a great amount of variance between and among laboratories to the point that the core question remains: where is the commutability of the number generated USP, VIM 3, and TAM sense of the word.

GLP, EPA, Commutability

E42 The Misleading Nature of Unconfirmed Single Column Headspace Gas Chromatography Flame Ionization Detection Blood Ethanol Reports

Jeremy C. Brehmer, JD, and; Richard O. Middlebrook, JD*, Middlebrook & Brehmer, LLP, 5201 California Ave, Ste 450, Bakersfield, CA 93309*

After attending the presentation, attendees will appreciate the need for confirmation testing of forensic blood ethanol samples consistent with the published Society of Forensic Toxicologists and American Academy of Forensic Sciences (SOFT/AAFS) Forensic Toxicology Laboratory Guidelines – 2006 and the various gas chromatograph column manufacturer guidelines. The need for confirmatory testing will be evidenced by real life examples of unjust consequences that occur when these critical guidelines are not followed.

This presentation will impact the forensic science community by furthering the discussion that just because a blood ethanol report has the appearance of reliability does not unequivocally mean the results are an unquestionable true value.

For the past several decades forensic toxicology reporting of blood ethanol levels by crime laboratories have been relied upon by attorneys, juries, and judges largely without scrutiny to the qualification of the subject analyte, quantification of the reported blood ethanol level, or reporting of any uncertainty in the measurement. The 2006 SOFT/AAFS Guidelines dedicate a section to Confirmatory Tests. The Guidelines specifically provide that *"…confirmation using a second analytical system is encouraged…Confirmation using a second GC column is acceptable IF the second results in significant changes in retention time AND change in elution order of at least some of the common volatiles."* One major column manufacturer publishes, *"Don't forget: Blood alcohol analysis requires dual column confirmation when using GC/FID."* Yet many crime laboratories fail to adhere to either the 2006 Guidelines or the gas chromatograph column manufacturer's published warnings/instructions. Instead, these crime laboratories report blood ethanol results from only a single column.

The admissibility of blood ethanol reports and other forensic evidence have now been addressed in multiple recent United States Supreme Court decisions. These issues are now at the forefront of our country's high court and forensic community. Despite the guidance from the high court, state courts are slow and even reluctant to require a proper foundation prior to the introduction of blood ethanol reports which do not comply with SOFT/AAFS and gas chromatograph column manufacturer guidelines and warnings. State courts routinely allow unconfirmed blood ethanol results into evidence. Often times judges are persuaded to believe that the blood ethanol reports, inclusive of quantitation, should be published to the jury and admitted into evidence without being subjected to pretrial in-limine motions. Some state courts have ruled that the jury may determine what weight to give the blood ethanol reports without any substantial foundational showing. Judges are also faced with the challenge to determine what expert testimony regarding the blood ethanol report is required. These "weight versus admissibility" rulings appear more prevalently in states where the well known *Frye* "general acceptance" test is used and not the *Daubert* or federal standard which requires both a preliminary assessment of whether the methodology underlying the blood ethanol report is scientifically valid and whether that methodology properly can be applied.

Jurors rely upon the blood ethanol reports to convict defendants based on partial information, educated guesses, and the belief that the judge as the gate keeper would not allow the reports into evidence unless they were accurate, precise, and reliable.

Single Column GC, Unconfirmed Results, AAFS/SOFT Guidelines

E43 Legal Implications of Bitemark Evidence, Post-NAS Report: Is There a Problem?

Christopher J. Plourd, JD, Imperial County California, 939 Main St, El Centro, CA 92243*

The goal of this presentation is to review the legal implications related to innocent people who have been shown to have been wrongfully convicted based upon erroneous bitemark identification evidence. Bitemark case false convictions have been a serious concern for the forensic science community and the criminal justice system for well over a decade. The educational objective of this presentation is to identify legal system errors and/or omissions made in bitemark cases were factual innocence has been demonstrated and propose solutions for improving the adjudication of cases were bitemark evidence is proffered. The attendee will understand the need for attorneys and trial judges to exercise caution in litigation of cases involving identity based in part or solely upon a bitemark comparison.

This presentation will impact the forensic science community by focusing on judges and attorneys who deal with cases involving bitemark experts to better understand issues related to bitemark evidence reliability.

DNA identity testing continues to exonerate innocent people who's cases involved bitemark comparison evidence. The problem of innocent people being convicted and unjustly imprisoned for crimes they did not commit became a significant concern to the forensic odontology community for the past decade and efforts to establish the science of a bitemark comparison have been and are being vigorously pursued. Two recent bitemark exoneration cases will be discussed. In a case from Wisconsin, Robert Lee Stinson, served 23 years of a life sentence for the 1984 murder of Lone Cychosz. Ms. Cychosz had been a neighbor of Mr. Stinson and her body was bitten a number of times in the course of a brutal assault that killed her. In 1986 Stinson's direct appeal of his first degree murder conviction was denied.[1] After DNA testing, the State of Wisconsin on February of 2008 agreed that Robert Lee Stinson should be granted a new trial. Mr. Stinson consistently maintained his innocence. In July of 2009, the State of Wisconsin dismissed the murder charge against Robert Lee Stinson. Thereafter in 2010, DNA evidence identified the actual killer of Ms. Cychosz. In a second case, Kennedy Brewer was accused by the State of Mississippi of the 1991 murder of Christine Jackson, the three-year-old daughter of his girlfriend. Kennedy Brewer was initially convicted of raping and strangling Jackson to death in 1995. He was sentenced to death and spent 12 years on Mississippi death row. In February of 2008, Kennedy Brewer's case was dismissed by the State of Mississippi after another person identified by DNA evidence confessed to killing the three-year-old girl. Both Stinson and Brewer were convicted due to bitemark evidence. In both the Robert Lee Stinson and Kennedy Brewer cases, the dental bitemark experts were board certified by the American Board of Forensic Odontology (ABFO). The Stinson and Brewer cases are examples of a number of cases where bitemark evidence has been shown to be erroneous. Many legal experts now claim that bitemark identification evidence should be held to be a junk science. Now, defense attorneys faced with bitemark evidence in a case routinely are filing legal challenges against the admission of bitemark evidence. The challenges contend that there is effectively no valid documented scientific data to support the hypothesis that bitemarks are demonstrably unique. Additionally, it is argued that there is no documented scientific data to support the hypothesis that a bitemark is a true and accurate reflection of this uniqueness. To the contrary, scientific evidence that does exist supports the conclusion that crime related bitemarks are grossly distorted, inaccurate, and therefore unreliable as a method of identification. A published study of the National Research Council entitled Strengthening Forensic Science in the United States: A Path Forward, in the specific section on forensic odontology, the NAS Study found that bitemark comparison was the most controversial area of forensic odontology and that there *"is continuing dispute over the value and scientific validity of comparing and identifying bitemarks."*[2] In its criticism of bitemark comparisons, the NAS Study stated:

> *"There is no science on the reproducibility of the different methods of analysis that lead to conclusions about the probability of a match." Even when using the American Board of Forensic Odontology guidelines, different experts provide widely differing results and a high percentage of false positive matches of bitemarks using controlled comparison studies."*

If bitemark evidence is to remain as viable evidence of identification in our judicial system specific measures must be taken to guard against any circumstance where a miscarriage of Justice could occur. One lesson learned from bitemark exoneration cases is that errors occur when an expert overstates the validity or certainty of a bitemark identification. Also, exoneration cases show the need to develop a minimum threshold of objective criteria for the suitability of a suspected bitemark before a comparison is ever attempted.

The investigation of bitemark cases by forensic dentists are evolving as the result of deficiencies uncovered after convictions which relied on bitemark evidence were overturned by DNA evidence. As a direct result of past bitemark case mistakes, there should be a better understanding by attorneys and judges within the legal system to recognize problems with bitemark evidence and put in place safeguards to protect against wrongful convictions. Courts should accept the reality that there is no scientific basis to allow a bitemark expert opinion that a person is a "positive match" to a suspected bitemark. The path forward: One approach would be to simply not allow bitemark evidence in any court case until a firm scientific basis is established. Another approach would be to limit the manner bitemark evidence could be used by a trier of fact in cases where a person is identified by a bitemark. For example, to assure that an innocent person is not wrongfully confined based upon bitemark evidence; a jury instruction could be tailored to limit the use of bitemark evidence. Specific jury instructions will be discussed.

Bitemark, Wrongful Conviction, Reliability

E44 Bitemark Analysis: Foundation, Lessons From the Past, and Paradigm Shift to the Present and the Future

Franklin D. Wright, DMD, 1055 Nimitzview Dr, Cincinnati, OH 45230*

After attending this presentation, attendees will better understand the scientific methodology of bitemark analysis, the evidentiary strengths of bitemark analysis, the roles of the bitemark analyst and bias, past cases of "bitemark analysis-gone-wrong," comments on the National Academy of Sciences Report, *"Strengthening Forensic Science in the United States: A Path Forward"* (2009), and the evolving future of bitemark analysis.

This presentation will impact the forensic science community by demonstrating the evidentiary value of the appropriate use of bitemark analysis. Despite a recent past that has included innocent persons to lose liberty and freedom as a result of expert testimony involving faulty bitemark analysis, there have been exponentially more cases where the use of bitemark analysis has resulted in protecting individuals and society from violent predators as well as interventions that have saved countless lives.

Bitemark analysis as a scientific investigation meets all the criteria for the definition of *science* with one notable exception, the ability to create and study bitemarks in living human skin. It is not currently possible to experimentally create and study biting patterns in living human skin. All other aspects of the application of scientific methodology in bitemark analysis are valid, accurate, and scientifically sound.

When a bitemark injury is considered to be of high evidentiary quality, the presence of semi-circular opposing arch forms depicting the maxillary and mandibular teeth, each with distinctive markings representing the individual teeth in the associated semi-circular patterns, and a closed population of suspected biters is identified - each with distinctly differing arrangements of teeth - bitemark analysis can be done to reliably identify or exclude given biters in the suspected biter population. These bitemark cases are best exemplified with infant abuse victims where only a small number of known caregivers had contact with and access to the infant when the abusive attack occurred or in sexual assault cases where the sexual assailant was known to the victim. Supporting DNA evidence from swabbings of the bitemark in any given case can further aid in establishing biter identity or exclusion.

Historically, there are two issues in bitemark analysis that have led to the problem bitemark cases; operator bias and analyst error. Operator bias is a well known problem in many scientific investigations. It is incumbent on the operator to be able to know where bias can be introduced in a given case and what steps to take to avoid the introduction of bias, including the use of an independent case review by another qualified analyst.

The problems with incompetency of the analysts have been of far greater concern. Using poor quality bitemark evidence, poor methodology as well as the introduction of the extraneous issues of bias in the investigation, opinions have been rendered in bitemark cases that are not scientifically supported. It has been these cases by a small number of analysts that represent the majority of past wrongful convictions based, in part or completely, on bitemark analysis. Contemporary bitemark analysis includes processes to avoid errors by the analyst before preparing the final bitemark case report.

The 2009 National Academy of Sciences Report, "*Strengthening Forensic Science in the United States: A Path Forward"* correctly identified the problems of bias and analyst error and made further comments on where they felt the process of bitemark analysis should improve. However the report completely neglected to mention where bitemark analysis was an appropriate methodology in criminal investigations, where properly applied bitemark analysis had contributed to successful criminal prosecutions in assault and abuse cases and how to strengthen those aspects of bitemark analysis on "…the path forward."

The evolving future of bitemark analysis will include competency testing for bitemark experts, improved guidelines and standards, research in areas of pattern creation and analysis as well as the relationship between the biter's dentition and the patterns created by those teeth when biting living skin.

Bitemark Analysis, Bias, NAS Report 2009

E45 Review of the Scientific Basis of Bitemark Comparison: Pre-NAS Report

Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, S Campus, Buffalo, NY 14214; Raymond G. Miller, DDS, 122 Covington Rd, Buffalo, NY 14216; H. David Sheets, PhD, Dept of Physics, 2001 Main St, Buffalo, NY 14208; and Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main St, Buffalo, NY 14214*

The goal of this presentation is to review the scientific background of bitemark analysis that existed prior to the 2009 National Academy of Sciences (NAS) Report.

This presentation will impact the forensic science community by providing a historical summary of the peer-reviewed literature for this forensic discipline.

The precedent for bitemark admissibility was mainly set in the 1970's with two landmark cases: The first was *People vs. Marx*. In this case, the methodology used in the comparison process was deemed *not novel*. That methodology consisted of the use of dental X-rays, models, and photography. In the second case, *People vs. Milone*, dental individuality, based on the process of victim ID, was incorrectly extrapolated to bitemarks.

The foundation of bitemark analysis rests on the ability to distinguish between dentitions; that is, there are features that make each persons set of teeth different. There is far more information with which to make a comparison in victim identification than in bitemark analysis, as this post-mortem identification involves examination of possible combinations of 32 decayed, missing and restored teeth, including root morphology, trabecular bone patterns and sinus morphology.

With bitemark analysis, typically only the biting surfaces of the six anterior, or front teeth of each arch impress the tissue, severely limiting the amount of information available to claim one dentition is distinct compared to another.

Furthermore, bitemark analysis is often accomplished by evaluating a wound or injury pattern in human skin and comparison of that pattern to representations of the dentition. Human skin is a notoriously poor recording medium, and prone to highly variable distortion. Given the loss of resolution of the resulting pattern due to these properties, the ability to distinguish between individuals is further compromised.

A survey of the peer-reviewed literature concerning bitemarks since the 1960's reveals interesting patterns. There are very few empirical studies that substantiate any scientific basis of bitemark analysis, or that investigate the core premises of dental individuality and transfer of the dental pattern to skin. Most of the publications consist of case reports, review papers, and technique reports on procedural issues and evidence collection.

With regard to the dental aspect of bitemark analysis; that of individuality of the dentition, there have been very few studies in six decades that have attempted to address this issue. Unfortunately, these studies suffered from inappropriate use of statistics, lack of statistics altogether, or had too small of a sample size from which to make a conclusion. With regard to properties of the skin, there have been even fewer studies in the forensic odontology literature.

With such limited scientific basis, it is valid to question how bitemark comparison has reached the level of acceptance that it has, with the serious consequence of determining the life or liberty of an individual. This question has been brought to the fore by the number of recent exonerations of those incarcerated or convicted on bitemark evidence.

Bitemarks, Bitemark Research, History

E46 Review of the Scientific Basis of Bitemark Comparison: Post-NAS Report

Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main St, Buffalo, NY 14214; Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, S Campus, Buffalo, NY 14214; Raymond G. Miller, DDS, 122 Covington Rd, Buffalo, NY 14216; and H. David Sheets, PhD*, Dept of Physics, 2001 Main St, Buffalo, NY 14208*

The goal of this presentation is to explore basic research in bitemark analysis published since the release of the 2009 National Academy of Sciences (NAS) Report.

This presentation will impact the forensic science community by providing a summary of the current status of the scientific basis for this forensic discipline.

The 2009 NAS Report was critical in its assessment of bitemark comparison. Lack of research supporting the basic tenets of this technique was noted. The tenets are that the human dentition is unique and that the unique features transfer to the skin; however, at time of publication of the NAS Report, systematic studies supporting these basic suppositions were conspicuously lacking. As per the NAS Report, "the uniqueness of the human dentition has not been established, the ability of the features of the dentition to transfer to the skin has not been established, and the scope or extent of distortion has not been demonstrated."

Admittance of a technique into the courtroom when there are few systematic studies to support its validity can have negative consequences, as exemplified by a number of exoneration cases. When life and liberty are at stake, there is a responsibility to base testimony on substantiated techniques with a clear understanding of the limitations of the approaches used. When testimony is not grounded in systematic scientific studies, interpretation can become subjective rather than objective.

Given the concerns stressed in the NAS Report, and the serious consequences seen in the courtroom, it would stand to reason that research is warranted to evaluate the basis of bitemark analysis. Current research is exploring these questions and the results are pointing to a cautionary view of bitemark analysis as a means of identification. Those results indicate that there is a large degree of distortion possible in human skin and that relatively small collections of human anterior dentitions contain multiple dentitions with differences below achievable measurement resolution. The inability to distinguish between these dentitions creates questions about the notion of uniqueness within this class of forensic data.

Many of the details that make the dentition as a whole distinct for victim identification are not present in a bitemark, creating further limitations on the ability to individuate in this circumstance. As such, it may be more appropriate to consider the extent to which distortion would include similar suspect dentitions in a bitemark, given the loss of resolution encountered in skin, and whether it is still possible to make distinctions in small, closed populations.

It is inevitable that a degree of distortion will be seen in a bitemark. Human skin is a poor recording medium as it exhibits a visco-elastic, anisotropic response to stress. Skin tension lines dictate the extent to which skin can stretch. These tension lines vary across the body and can be altered depending on body movement. Given this property of skin, it should not be surprising to see a large range of distortion. Results demonstrated that the maxillary and mandibular arches distort independently as impressed in a bitemark, meaning that the distortion in one arch is not reflective of the distortion seen in the other. Furthermore, it has been observed that multiple bites, all made with the same dentition will vary widely in the pattern seen, and that other dentitions, which did not inflict the bite, may be a better candidate than the biter.

Bitemark analysis has a long history in the legal system and it is inarguable that mistakes have been made, resulting in incarceration of innocent people. The new level of scrutiny of forensic evidence will demand fresh examination of the scientific basis and admissibility of bitemark comparison.

Bitemarks, Bitemark Research, NAS Report

E47 Report on a Recent *Frye* Challenge of Bitemark Evidence in New York

Chris Fabricant, JD, The Innocence Project, 40 Worth St, Ste 701, New York, NY 10013*

The goal of this presentation is to discuss a recent bitemark case and through that discussion offer broader strategies for challenging the admissibility of bitemark evidence. More specifically, the presentation will discuss in detail a recent *Frye* challenge to the admissibility of bitemark evidence, focusing on the defense and prosecution litigation strategies in the wake of the National Academy of Sciences (NAS) Report, "*Strengthening Forensic Science in the United States: A Path Forward*."

This presentation will impact the forensic science community by demonstrating how the exonerations of numerous innocent defendants convicted in part based on bitemark evidence and the release of the NAS Report highlights that forensic odontology has not been validated, as well as the danger of admitting into evidence unvalidated disciplines where life and liberty are at stake. The ability of forensic dentists to consistently and with any degree of accuracy associate an individual's dentition with a bitemark recorded on human skin has never been scientifically validated. Recent research has further eroded the scientific community's confidence in bite comparison as a forensic discipline.

The NAS Report was critical of nearly all pattern and impression evidence, but was particularly critical of bitemark evidence, concluding that there is "no evidence of an existing scientific basis for identifying an individual to the exclusion of all others" by using bitemark comparisons, because there is "a lack of valid evidence to support many of the assumptions made by forensic dentists during bitemark comparisons."[1] The fundamental assumptions – that human skin is a reliable registration material for bitemarks and that the human dentition is unique – have been challenged in research published since the NAS Report.

The pre-trial litigation in a homicide case in New York City presents a unique learning opportunity for judges, prosecutors and lawyers who may be presented with bitemark comparison evidence in a criminal case. Although the defendant was excluded from a DNA swab taken from the bitemark at issue, the opinion of the initial prosecution witness, in his forensic report and evaluation prior to the DNA analysis, was that the bitemark was "caused by the dentition of [the accused]." The prosecution expert in the pre-trial hearing (a different expert), whose testimony related only to the general admissibility of bitemark evidence, concluded that the NAS Report "cherry picked" the research it relied upon and that well-trained forensic odontologists are capable of accurately and reliably associating a known dentition with a bitemark injury. In contrast, the defense witness testimony relied on the results of scientific studies published in peer reviewed journals. These studies, the first post-NAS Report efforts to determine whether or not bitemark associations can be validated as a scientific discipline, have cast more doubt about its validity.

The Innocence Project is actively litigating several cases involving bitemark evidence and the newly created Strategic Litigation Unit is focused on, among other forensic disciplines, forensic odontology. This presentation will be an opportunity to learn and discuss best practices for challenging such evidence.

Senn, DDS*; UTHSCSA, 7703 Floyd Curl Dr, San Antonio, TX 78229-3900; and Thomas J. David, DDS*, 1000 Johnson Ferry Rd, Bldg H, Marietta, GA 30068*

After attending this presentation, attendees will be educated on the latest scientific basis and legal admissability status of bitemark evidence.

This presentation will impact the forensic science community by bringing together the most knowlegable experts in the field to debate a subject that is of significant importance to the American criminal justice system.

The question posed to the bitemark subject experts is, "Does bitemark evidence meet or exceed threshold legal admissibility standards?" This presentation will answer questions related to bitemark reliability from the audience.

The admissibility of bitemark evidence historically has been based on courtroom precedence and a half-century acceptance in the underlying fundamental principles of the technique. Over the past decade wrongful convictions based on bitemark evidence have called into question the fundamental scientific basis of bitemark identification methods.

The standard for admission of scientific expert testimony differs from court to court and from state to state. Generally courts are guided by Rule 702 of the Federal Rules of Evidence and two main cases, *Frye v. United States* and *Daubert v. Merrell Dow Pharmaceuticals, Inc.* The *Frye* test for admissibility requires the scientific principle being proffered as evidence "to have gained general acceptance in the particular field in which it belongs." If the trial court determines that a technique has gained general acceptance in its field, then the technique is deemed reliable enough to be admitted at trial. In 1993, the United States Supreme court in the *Daubert* case held that Rule 702 of the Federal Rules of Evidence changed the *Frye* test. Rule 702 states in part, "*If scientific, technical, or other specialized knowledge will assist the trier of fact to understand the evidence or to determine a fact in issue, a witness qualified as an expert by knowledge, skill, experience, training, or education, may testify thereto in the form of an opinion or otherwise . . . ." Daubert* retained *Frye*'s general acceptance principle for admission, it also stated that scientific evidence must be both relevant and reliable. The *Daubert* court went on to outline factors relevant to the admissibility of scientific expert testimony to aid trial court judges, including: (1) the theory or technique must be able to be, and have been, tested; (2) it must have been "subjected to peer review and publication;" (3) the known or possible error rate of the scientific technique must be taken into consideration; (4) the court should take into account the "relevant scientific community" and a determination of the degree to which the theory or technique in question is accepted in that community; and (5) the focus is on the principles and methodology behind the technique, not necessarily on the conclusions generated.

The guidelines of the American Board of Forensic Odontology (ABFO) permit an expert member to render conclusions expressing near certainty – they could conclude that a bitemark matches a criminal defendant to a "reasonable medical certainty" and "high degree of certainty" and/or "a reasonable medical and dental certainty, did inflict the injury." This language appears to mean, in certain cases, a virtual certainty; no reasonable or practical possibility that someone else did it. Does science exist for what observations and analysis could permit an expert to draw such conclusions? The guidelines added that experts may not convey "unconditional certainty;" however, they may express "reasonable medical certainty," and noted that it was acceptable to state that there is "no doubt in my mind" or "in my opinion, the suspect is the biter" when such statements are prompted in testimony. Many expert conclusions that go beyond the ABFO guildline are still allowed, such as that a person "beyond a reasonable doubt" or "99 percent certainty" the suspect made the bite.

Are the ABFO guidelines faulty? Is the underlying method of this discipline reliable?

Bitemark, Frye, *Daubert*

E49 The Amanda Knox Case: Scientific Investigation and Criminal Trial in Italy

Luciano Garofano, PhD, Via G. D'Annunzio n.9, Parma, ITALY; and Michele Vaira, JD*, V. le I Maggio 27, Foggia, ITALY*

After attending this presentation, attendees will understand the scientific and judicial issues that have characterized the criminal trial held in Italy against Amanda Knox, accused to be the murderer of Meredith Kercher. This presentation will explain the peculiarities of the Italian trial system, the differences with the U.S. trial system focusing on the admission and evaluation of scientific evidence, as well as the role of the so called "independent expert."

This presentation will impact the forensic science community by highlighting the need to improve forensic science performance using good science. This is particularly relevant, as in the case to be discussed, when the trial judge, as the gatekeeper of the judicial system, is facing controversial conclusions from the defendant and the prosecution side that may condition or affect his decision. Thus, the judge needs to appoint a board of highly qualified and independent experts in order to establish which hypothesis is correct and reliable.

This case refers to the murder of Meredith Kercher, a young British student, who was found dead in her apartment in Perugia on November 2, 2007. According to the prosecutor's investigation, the murder was committed by Amanda Knox, Raffaele Sollecito, and Rudy Guede. Knox and Sollecito were indicted on murder charges on October 28, 2008. Guede is found guilty of murder in his fast track trial and sentenced to 30 years. The evidence offered by the prosecution is of circumstantial value. No witnesses were present at the time of the crime. Among the evidence, the most damaging piecies of evidence found during the scientific investigation that pointed to the guilt of Knox and Sollecito, was a hook of the victim's bra and a knife found at Raffaele's house. The first of these two elements (the hook of the bra) is found during the first crime search made by the police the day after the murder, but inexplicably it gets lost and will be found and collected only 46 days after the crime, during new technical activities at the crime site.

According to the prosecution theory based on the DNA analyses made by the forensic science lab of the national police, the hook shows genetic material that matches Sollecito, hence his presence at the crime scene during the murder.

According to the defense theory, the DNA found on the hook is due to contamination occurring within the technical activities made at the scene of crime during those 46 days. The second element (the knife) shows DNA on the blade (that matches the victim) and on the handle (that matches Amanda). According to the prosecution theory, this is the "murder weapon" and Amanda is the person who stabbed Meredith. This item has clear circumstantial evidence weight. According to the defenses theory, the DNA found on the blade is LCN-DNA, thus too low in quantity to support a reliable conclusion, especially if it has to be linked to Amanda's guilt.

The Court of first degree accepts the experts' assessments made by the prosecution about the collection, preservation, and analyses of scientific evidence. Contrary to normal practice within the Italian courts, which usually appoint an independent expert to settle disputes among the experts, the Court rejectes the request made by the defense.

After eleven months of trial, the Court found Knox and Sollecito guilty on all counts in the stabbing death of Meredith Kercher. Sollecito received a 25-year sentence; Knox received 26 years. The Italian

criminal trial system, unlike the U.S., provides two levels of judgment, with the same possibilities.

November 24, 2010 Knox and Sollecito's murder appeal process began. Due to expert disputes arising in the first trial, two forensic experts from Rome's University are sworn in by the appeal court and retested the two crucial pices of forensic evidence used to convict Knox. They gave a second (neutral) opinion about the knife and the claps from Kercher's bra, which was cut from her body during her murder. The goal of the appeal court is to give the right value to those pieces of evidence, within the trial context, according to the most reliable science.

Forensic specialists told the court that DNA evidence linking Knox to the alleged murder weapon was unsound; that while they agree Knox's DNA was present on the knife handle, tests for Kercher's DNA were unreliable. The sample, however, was so small that forensic scientists were not able to double test it in accordance with international forensic science rules, which Knox's legal team says raises doubts about its validity. The Court appointed experts testified that police forensic scientists involved in the murder case made a series of glaring errors during their investigation.

In a point-by-point reconstruction, the experts say that because of the errors made by police during the original investigation, the evidence against Knox and Sollecito should be considered "inadmissible." On October 3, 2011, an Italian jury overturned the 2009 murder conviction of Amanda Knox and Raffaele Sollecito.

Amanda Knox Trial, Independent Expert, Evidence Submission

E50 Parental Alienation Syndrome as it Relates to Hague Abduction Convention Article 13b: To Be or Not to Be Admissible in the Courts

Serdar S. Kelahmet, MBA, Cumhuriyey Meydani, Besim Yucel Ishani, Kai 1 Daire 1, Iskenderum, TURKEY; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th St, Rm 223, Erie, PA 16501; Ayse Avci, MD, Çukurova Univ, School of Medicine, Child and Adolescent Psychiatry Dept, Balcali-Adana, TURKEY; Gokce Kelahmet, LLM, Ethemefendi Cad. Arsan Sok. Arsan Apt., No.1 K.6 D.13 34738, Iskenderum, TURKEY; and Mete K. Gulmen, PhD, MD, Cukurova Univ, School of Medicine, Dept of Forensic Medicine, Adana, TURKEY*

After attending this presentation, attendees will understand issues surrounding the controversial scientific evidence issues regarding parental alienation syndrome in light of the numerous children involved at international and local levels in these child custody disputed cases.

This presentation will impact the forensic science community by offering diverse and enlightening insights into this controversial scientific evidence issue of the court's admission or exclusion of Parental Alienation Syndrome (PAS) evidence, and by suggesting recommendations as to how courts and lawyers should handle cases involving PAS evidence in light of the numerous children involved at international and local levels in these child custody disputed cases.

Parental Alienation Syndrome (PAS) is a theory surrounded by much debate amongst scientists and lawyers as to its diagnostic legitimacy. Questions concern the scientific foundations, if any, of PAS and its practical applications in legal settings, particularly as PAS affects children and families across the globe. In most instances where a parent abducts a child from the other parent, the Hague Abduction Convention provides for the Court to exercise its discretion to return the child to his or her "habitual residence." However, in certain rare cases under Article 13b, the judge or administrative authority of the requested country (referred to as a State) is not bound to order the return of a child if the Court finds a grave risk exists and to return the child exposes that child to physical or psychological harm. Many States use Article 13b to request psychological profiles, detailed evaluations of parental fitness, evidence concerning the nature and quality of lifestyles and relationships. Clinical examinations and observations of interactions between the parents and the child are pivotal to understanding the family dynamics and unveiling the truth. How are and should these clinical findings, diagnoses and recommendations be implemented and accepted by the Courts across the globe? Is PAS acceptable science? Is a determination of PAS helpful to the Courts? Is their a comfort level achieved by the finder of fact - the judge or administrative body - in utilizing this information? Although parental alienation syndrome has not been recognized or included in Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-4) in the past, experts and others are discussing whether this concept of parental alienation should be included in DSM-5 which is due to be released early next year. What do these discussions encompass on this controversial topic known as PAS? Should parental alienation be considered as a syndrome?

Why is PAS so controversial? PAS, it is argued, lacks an empirical basis as a psychiatric diagnosis. However, Dr. Gardner, the first expert to acknowledge parental alienation as a syndrome in 1985, used the term "empirical" to mean direct patient observation only. Although he used no scientific experimentation, Dr. Gardner claimed he had ample "empirical" evidence to support PAS as a psychiatric syndrome to which he applied a statistical analysis methodology. Other scientists disagree with Dr. Gardner as to whether PAS should be classified as a syndrome and question whether PAS has been subject to peer review; whether PAS is generally acceptability in the field of psychiatry or psychology; and whether PAS has scientific empirical validity as to falsifiability, error rates, etc. Judges across the globe have struggled as gatekeepers of relevant and reliable scientific evidence to admit or exclude PAS evidence in their courtrooms.

Parental Alienation, Child Abduction, Syndrome Evidence

E51 Parental Alienation Syndrome: A Questionable Concept

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of PA, Erie County Court House, 140 W 6th St, Rm 223, Erie, PA 16501; James T. Richardson, JD, PhD, Univ of Nevada, Grant Sawyer Center for Justice Studies, MS 311, Reno, NV 89557; and Rebecca M. Thomas, MA, Univ of Nevada, Research Integrity Office, MS 0331, Reno, NV 89557-0331*

After attending this presentation, attendees will understand the issues surrounding the controversial concept regarding PAS, and how it affects the litigants and the judicial processes involved in determining child custody issues.

This presentation will impact the forensic science community by increasing understanding about the diverse perspectives on the admissibility or exclusion of Parental Alienation Syndrome (PAS) evidence. This should enable practitioners to be more competent, aware, and knowledgeable of the complexities of this concept in the performance of their duties in the courtroom. A more balanced and productive perspective on this issue, including the need for more research in this area will be presented. This presentation will address how this concept has become more of an adversarial weapon than a therapeutic tool to assist the families in resolving difficulties during divorce. The assumptions involved with this concept will be examined and the presenters will provide suggestions about the type of research needed in this area and how it can be accomplished.

Experts are testifying in courts across the globe about Parental Alienation Syndrome (PAS) which has become a popular concept used in custody battles; however, there has been significant debate inside and outside the courtroom over the admission of PAS evidence. Is their empirical data to support expert testimony concerning this so called syndrome? Does the concept meet the scientific admissibility standards of either *Frye* or *Daubert*? If these standards are not met, what is giving impetus to the growing use of PAS in the courtroom?

This presentation will address these questions after tracing the beginnings of the use of this concept, which was first presented in 1987, by Dr. Richard Gardner, a psychiatrist who dealt with divorce and custody issues. He defined the phrase as a concept based in part on the idea of "brainwashing," but also involving conscious elements and other factors such as subconscious and unconscious ones existing within a parent which contribute to that parent's negative intentions to

influence the child to reject the other parent. Dr. Gardner believed that a child can become so obsessed with animosity for the alienated parent that the child's animus becomes independent of the alienating parent's contributions. Minor altercations experienced by the child with the alienated parent become the child's justifications for his or her feelings toward the alienated parent.

Dr. Gardner categorized parental alienation cases as fitting on a continuum which included three categories from mild, moderate, to severe. However, his promotion of the concept has raised questions about the basis for his beliefs and opinions. Questions focus on the scientific basis of the concept. How should lawyers and judges view this evidence? Is this concept helpful to the trier of fact? What are the discussions amongst the experts as to the reliability and validity of the concept of parental alienation? Should lawyers and judges scrutinize expert testimony about parental alienation or should they accept this concept as a mental disorder even though there is currently no recognition as such in DSM-4 (Diagnostic and Statistical Manual of Mental Disorders)? What discussions have taken place about this concept's inclusion in DSM-5 which is due to be released in early to mid 2013?

PAS has universal appeal due to claims about the effects of parental alienation on the children experiencing it. Parental alienation has been cited by legal authorities in the United States and also in international jurisdictions and venues where parents abduct a child from one country to another country. In this world of ever-growing litigation, parental alienation as a concept needs to be explored more fully using proper scientific methods. More scientific research in this area can assist the experts and the courts providing appropriate remedies to address the possible harm allegedly caused to a child affected by parental alienation.

Parental Alienation, Child Custody, *Daubert*

E52 Straight Shooters or Hired Guns? Expert Forensic Evidence in English Courts

Stuart J. Hamilton, FRCPath, E Midlands Forensic Path Unit, Level 3, Robert Kilpatrick Bldg, Leicester Royal Infirmary, Leicester, LE2 7LX, UNITED KINGDOM*

After attending this presentation, attendees will gain insight into how forensic experts in the United Kingdom (UK) are trained, how they practice, and how they interact with the legal system.

This presentation will impact the forensic science community by stimulating discussion of the relative advantages and disadvantages of different approaches to both the concept of the expert and the way that expert evidence is weighed and judged by the court.

In the UK, there is no formal process for "judging" the admissibility of expert testimony equivalent to the "trilogy" in United States Law of *Daubert*, *Joiner,* and *Kumho*, and therefore the concept of the expert and the contents of expert testimony are very differently viewed and regulated in the two jurisdictions. The acceptance of expert testimony in English courts is a complex interaction between practical experience (both of the expert's own field of expertise and of giving testimony), observation of the work of other professionals (including observing more senior practitioners giving testimony and observing the testimony of an expert called by "the other side"), knowledge of current best evidence and research, informal teaching and formal training.

In English law, expert witnesses are defined as "witnesses to the court" that is to say the expert is expected to give unbiased testimony no matter whether they are called to give evidence for the prosecution or defense. Many forensic pathologists and indeed experts in other fields accept instruction from both prosecution and defense teams and are regularly called to give evidence by both prosecution and defense barristers. As a result of this, there is much less of a concept of the defense expert as a "gun for hire", as many forensic experts will be seen giving evidence for one side in a certain case, and for the other in their next case. This is generally considered to be a positive aspect of expert evidence, as it reduces the risk of the pathologist becoming excessively "prosecution-centric" or "defense-centric." The forensic expert witness in England is in a highly privileged position compared to other witnesses (eyewitnesses and professional witnesses) and often have extensive interaction with the legal teams who are relying on their evidence before his or her attendance at court which allows the prosecuting or defending barrister (counsel) to "tailor" their questioning to what the expert is confortable to say under oath. To mitigate against this, experts are permitted to listen to another expert's oral testimony, and even advise counsel during cross examination as to which areas of the evidence to explore more thoroughly and which to leave well alone (all the while attempting to remain an unbiased witness to the court of course)!

Finally, the potential problems that arise in any court of how a jury composed of people with no prior expertise in, or experience of, forensic pathology or science can be assisted to make a reasonable decision regarding conflicting opinions expressed by experts offering testimony and the concept of the "joint expert statement" will be discussed.

Expert Evidence, Prosecution, Defense

E53 Which Expert to Believe? Lessons Learned From a Leading English Tort Case

A.R.W. Forrest, LLM, Office of HM Coroner, Unit 1, Gilbert Dr, Wyberton Fen, Boston, PE21 7TQ, UNITED KINGDOM; and Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th St, Rm 223, Erie, PA 16501*

After attending this presentation, attendees will better comprehend the evidential issues related to experts and scientific evidence in two common law jurisdictions that may differ in detail but still retain much in common after evolving separately for more than 250 years.

This presentation will impact the forensic science community by conveying knowledge, competence and performance about diverse perspectives on these issues that will enable legal practitioners, whether lawyers or judges, to be more competent, aware and knowledgeable about the complexities inherent in judging the merits of the differing strands of opinion evidence that may be offered to the Court by the parties in adversarial proceedings and will thus assist in the performance of their duties inside and outside of the courtroom. The presentation will help forensic practitioners to best assist the Court as experts by exploring the factors that judges have to take into account in choosing one particular expert's opinion over another's.

It is well recognized that the 1997 case of *Bolitho v. City and Hackney Health Authority*, 4 All ER 771, is an important English tort law case on the standard of care required of medical specialists. The case involved the care given to a child with croup and the Court heard differing opinions about whether and when the patient should have been treated by endotracheal intubation. The House of Lords held in *Bolitho* that there must be a "logical basis" for a medical expert's opinion. The Court arrives at such a conclusion by weighing risks against benefits, and judges have the authority and responsibility of choosing between two bodies of experts and of rejecting the one the Judge considers "logically indefensible." Leading authorities in this area of English tort law have interpreted *Bolitho* as establishing the precedent that the Courts set the law, not the experts. This presentation will discuss both the impact and aftermath of *Bolitho* from both English and United States perspectives. This presentation will also give consideration to *Bolitho* in terms of factors derived from two very important leading cases on evaluating scientific evidence in federal and state courts in the United States, *Daubert and Frye*. Federal Rule of Evidence 702 on expert testimony will also be discussed as to the reliability of the "scientific knowledge" grounded in scientific methodology and connoting a body of known facts accepted as true on good grounds and as to the relevancy of this evidence as having a valid scientific connection to the pertinent inquiry in court. The Federal Rules of Evidence on Expert Evidence will be compared and contrasted with the English Civil Procedure Rules (Part 35 – Experts and Assessors) and the Law Commission Report No. 325 "Expert Evidence in Criminal Proceedings in England and Wales." The Law Commission is a statutory independent body created by the Law

Commissions Act 1965 to keep the law under review and to recommend reform where it is needed. The aim of the Commission is to ensure that the law is fair, modern, simple, and as as cost effective as possible.

Experts, English Tort Cases, *Daubert-Frye*

E54 Why and How — Reforming Medical Liability in Psychiatry

Gianluca Montanari Vergallo, JD, Serenella Serinelli, MD, and Paola Mancarella, MD, Vale Regina Elena 336, Rome, ITALY; Francesco P. Busardo, MD, Via del vespro, 129, Palermo, ITALY; Matteo Gulino, JD, 336, Viale Regina Margherita, 00161, 5, Viale Bruno Buozzi, Rome, ITALY; and Paola Frati, PhD, Univ of Rome, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, ITALY*

After attending this presentation, attendees will understand some of the principles of the medical liability in psychiatry, a field in which reaching the evidence of legal responsibility is particularly hard.

This presentation will impact the forensic science community by presenting a possible solution for reforming medical liability in psychiatry.

The necessary respect of the medical activity of the psychiatrists implies that their liability, as for other doctors, could be declared only in presence of convincing evidence both of negligence and of causality; however, reaching such evidence is extremely difficult, for many specific reasons. First, not every failure in judgment can be automatically translated into negligence, as there is negligence only when there is "a failure to meet the standard of care."

Furthermore, the predictability of the auto- or hetero- offensive acts must be evaluated *ex ante,* in concrete terms and cannot be deducted, in general and in theory, from the diagnosis. It would be improper to consider suicide as predictable in all patients affected by major depression or to assume homicide as predictable in all chronic schizophrenic patients. It is especially necessary to avoid being influenced by facts which occurred after the psychiatrist treatment.

Therefore, in order to avoid subjecting the psychiatrist to an excess of review, it is essential to interpret the predictability in a strict manner, by considering only those circumstances as foreseeable in which the clinical history and the specificity of the moment make to reasonably assume the harmful event as probable and not only possible in theory.

Moreover, the predictability requirement cannot be automatically inferred from the state of unsound mind of the murderer. Such condition could derive, for example, from an unforeseeable and sudden flaring up of the pathological state, linked to some peculiar events in the patient's life of which the psychiatrist was unaware (e.g., a death in the family, the loss of job by a person that was under therapy but able to normally work). Such an event could provoke an unforeseeable and uncontrollable reaction.

Furthermore, when there is not a total state of unsound mind, the homicidal or suicidal behavior can't be evaluated as exclusive expression of the psychopathologic state and therefore no certain judgment could be formulated concerning the foreseeability of the event from the doctor, just because the patient's conduct was not entirely "pathologic," but was also an expression of his/her self determination ability, even if partial.

Finally, the need to protect the freedom and the dignity of the patient prevents the ability to control him/her physically and pharmacologically, with the exception of rare cases. Therefore, it is often impossible to avoid the harm.

Because of the difficulty in demonstrating liability in psychiatry, in some cases the Supreme Italian Court tends to reduce the degree of proof necessary to convict the doctor. This solution is questionable because it compromises the professionalism of the psychiatrists and reduces their constitutional right of defense. On the other side, applying rigorously the rules of medical liability also in psychiatry would reduce the number of convictions and this could induce psychiatrists to have less careful conducts towards the patient's interest.

In order to prevent this risk, it appears necessary to create a statute that, on the one hand, binds the health facilities to provide doctors with more strict guidelines and, on the other hand, increases the power of the health facilities to sanction imprudent doctors independently from the occurrence of damage and the presence of causality.

In this way, the protection of the patient's health is reinforced through the prevention of negligence rather than through the compensation of damages. As a consequence, a general reduction of the legal proceedings is also obtained, improving the quality of clinical practice.

Psychiatry, Medical Liability, Reform

E55 Exposing a Document Examiner's Flawed Analysis in a $300 Million International Bank Fraud Case

Andrew Sulner, JD, Forensic Document Examinations, LLC, 220 E 57th St, Ste 200, New York, NY 10022*

After attending this presentation, attendees will: (1) have a greater appreciation of the need to use a competent board certified Forensic Document Examiner (FDE) at the outset of any case dealing with a questioned or disputed document and will know more about how to find and select such an expert; (2) learn about some of the basic examination procedures used by FDEs to detect altered documents and how such evidence is effectively presented in court; and, (3) learn the distinction between various certifications claimed by forensic experts, how to evaluate the stated credentials of a given expert, and what information contained on an expert's resume should be clarified before hiring an expert.

This presentation will impact the forensic science community by providing all stakeholders in the administration of criminal or civil justice – experts, lawyers, and judges – with a better understanding of the need for more meaningful training, certification, and proficiency testing of forensic experts.

The case presented highlights the need to have meaningful training, certification, and proficiency testing of forensic experts and why lawyers must exercise greater due diligence when selecting an expert.

In 2006, a lawsuit was filed in U.S. District Court, SDNY against the largest bank in the Philippines, to enforce a "Manager's Check" in the face amount of twelve billion pesos (equivalent to 225 million U.S. Dollars) that was allegedly issued by one of its municipal branches on March 21, 2000; the lawsuit also sought damages of $75 million dollars, representing interest accrued since the negotiable instrument was issued. In two well-written decisions, U.S. District Court Judge Sheira Schindlin initially granted the bank's motion to dismiss the complaint on the ground of *forum non conveniens*; several months later, upon a motion to reargue, reversed the earlier dismissal and determined that the trial of the action should be heard in the United States and not the Philippines.

The Plaintiff retained a document examiner with twenty years of experience in federal and state crime laboratories to examine and determine the authenticity of the Manager's Check in dispute. The Plaintiff's document examiner was not a Diplomate of either the Board of Forensic Document Examiners (D-BFDE) or the American Board of Forensic Document Examiners (D-ABFDE), both FSAB-accredited boards; nor was he a member of the American Academy of Forensic Sciences (AAFS). In addition to claiming expertise in document examination, the Plaintiff's expert claimed expertise and certification in fingerprint identification.

After examining the original Manager's Check and an original specimen of a contemporaneously issued "Cashier's Check," the Plaintiff's document examiner submitted a written report describing the results of his microscopic and optical examinations of the original documents submitted to him, opining that the "Manager's Check" was "consistent with being a genuine instrument" and "displayed no irregularities." Thereafter, a board certified forensic document examiner (D-BFDE) with more than thirty years of experience was hired by the defendant bank to examine the very same documents.

In this presentation, the fascinating background and intrigue surrounding this federal court case will be relayed and the actual

photographic and digital evidence presented to U.S. District Court will be displayed. It will be illustrated how the forensic examinations of the very same documents examined by the Plaintiff's expert revealed significant irregularities that led to irrefutable, demonstrative proof that the Manager's Check at issue was an outright forgery. The proof presented, which was subsequently confirmed by another board certified document examiner (D-ABFDE) retained by Plaintiff's counsel to examine the evidence and review Mr. Sulner's findings and conclusion(s), will illustrate how a standard bank check was altered and converted into a purported official bank check and negotiable instrument. Using this case as an example of how poor forensics can adversely affect the administration of justice, the need for more meaningful training, certification, and proficiency testing of forensic experts, why lawyers need to exercise greater due diligence when selecting an expert, and how lawyers should go about selecting an expert will be discussed.

Flawed Document Exam, Exposing FDE Error, Flawed FDE Findings

E56 Results of the FBI Laboratory's Evaluation of Compositional Bullet Lead Analysis Testimonies

Marc A. LeBeau, PhD, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will understand the process undertaken by the Federal Bureau of Investigation Laboratory in evaluating examiner testimony when results from Compositional Bullet Lead Analyses (CBLA) were used in court. The results of the review will also be presented.

This presentation will impact the forensic community by presenting a model to consider when the testimony of expert witnesses in other fields may require evaluation.

CBLA was a forensic discipline used by the FBI Laboratory for over four decades when either a firearm was not recovered or a fired bullet was too mutilated for microscopic comparison of physical markings. If crime scene bullets were "analytically indistinguishable" to other bullets, research suggested that they likely originated from the same source of molten lead. Thousands to millions of bullets may be produced of the same composition and are usually packaged within the same box and in other boxes of the same caliber and type over a relatively short time period.

In 2002, the FBI commissioned the National Academy of Sciences (NAS) to evaluate the scientific basis of CBLA. Specifically, the NAS was asked to assess and provide recommendations for future improvements in three areas: (1) the analytical method in use at the time; (2) the way that the FBI was conducting statistical comparisons of the analytical results; and, (3) the appropriate statements that can be made in interpreting the results of a CBLA comparison.

The NAS released their report, *"Forensic Analysis: Weighing Bullet Lead Evidence,"* in February of 2004. The report contained 22 findings and recommendations. Upon issuance of the report, the FBI Laboratory temporarily suspended all CBLA examinations in order to review and evaluate the report's recommendations. Over the next 15 months, all recommendations were implemented and a revised analytical protocol was developed and revalidated. But in mid-2005, the FBI Laboratory decided to permanently discontinue the CBLA examination due to conflicts in the recommended statistical techniques suggested in the report, lack of knowledge of geographical distribution data, and the media labeling the examination as "junk science." The FBI Laboratory affirmed that previously issued reports were not in error and the foundation of CBLA was valid. Nonetheless, notification was made to the FBI's case contributors, the National District Attorney Association, the National Association of Criminal Defense Lawyers, and the Innocence Project of the decision to discontinue the CBLA examination.

In late 2007, the FBI agreed to undertake an extensive review of CBLA testimony offered by its examiners in all criminal cases that could be identified. Over the next four years, over 2,200 case files were reviewed to allow for requests to be made for testimony transcripts.

Each CBLA testimony was evaluated following a process developed by the FBI and the U.S. Department of Justice with input from the Innocence Project. Testimonies were deemed "inappropriate" if they fell into one of three categories: (1) if at any point during the testimony, the examiner suggested that a crime scene bullet could be linked to single "box" of bullets to the exclusion of all others; (2) if at any point during the testimony the examiner made some other statement that overstated the significance of bullets being "analytically indistinguishable"; or, (3) if the examiner failed to provide information that there would be a large number of other bullets, unrelated to the case, that would also be "analytically indistinguishable" due to the bullet manufacturing process. Testimonies that were not deemed "inappropriate" using these criteria were, by default, classified as "appropriate."

CBLA testimony from 232 transcripts were evaluated. Using the above criteria, 150 of the testimonies were deemed inappropriate, while just 82 were appropriate. While these results were surprising, the stringent review process ensured that the evidence was not misconstrued by the courts or juries. The ramifications and lessons learned from the CBLA testimony reviews will be discussed.

Bullet Lead, Testimony, Review

E57 The Challenges Facing International Victims of Sexual Gender-Based Violence

Edwin F. Huffine, MS, Bode Technology, 10430 Furnace Rd, Ste 107, Lorton, VA 22079; Erin Helfert, MA, 280 Crown St, Apt E5, Brooklyn, NY 11225; and Amy M. Jeanguenat, MFS, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

The goal of this presentation is to educate the forensic DNA community on the judicial challenges faced internationally with the acceptance of DNA evidence in court.

This presentation will impact the forensic science community by detailing the powerful story of the adjudication of an international sexual assault case and advocating for judicial evolution across the world with the increase in the use of forensic evidence for such cases.

As a U.S. citizen who worked and lived in Morocco from 2008 to 2009, co-author Ms. Erin Helfert was raped by a Moroccan citizen in 2009, after which time she left Morocco. The clothing from the crime was sent to a laboratory in the U.S. for initial analysis, where semen was identified and samples of the clothing were then subsequently sent to the DNA laboratory in Morocco for testing. The equivalent of a Moroccan District Attorney asked the suspect to submit a buccal swab, which was provided. The Moroccan DNA Laboratory agreed to perform a comparative DNA test between the semen stain from the victim's clothing and the buccal sample from the suspect. Subsequently, a DNA match was found between the semen on the clothing and the suspect's DNA. The judge presiding over the case agreed to consider this as evidence, which represents the first time DNA results would be used in a sexual assault case in Morocco.

The plight faced in this case underscores a problem that may be faced by international travelers when visiting and/or working in foreign nations in which the application of forensic science is either in its infancy or not routinely applied. Due to great persistence and self advocacy, this case has established a series of legal precedents in Morocco and can be used as an example for other nations. Among these, this criminal rape case is the first in which forensic evidence has been considered by both the Moroccan equivalent of the district attorney and the judge. In light of forensic evidence, the case evolved from a hearsay situation to a legitimate criminal charge in the eyes of the Moroccan authorities.

Many times travelers and expatriates encounter judicial systems and standards of practice that are markedly different that those in their home nations. For victims of crime, these travelers often face cultural differences that impact the justice and resolution of each case as well as the ability of the judicial system to benefit from forensic analysis. This particular case represents not only an example of an individual's pursuit of justice, but also demonstrates how such cases can spur national judicial evolution and the increased application of forensic science in the

courtroom. It is also an example of how an individual can make a difference on a national scale and the lessons learned by pursuing justice in this case can serve as models for other nations.

The victim will be present in Morocco during the trial and will be involved in the courtroom proceedings. The introduction of DNA test results in Morocco and the ability of both the defense and prosecution to effectively argue their sides of the case in front of the judge will be precedent setting. A guilty conviction, supported by DNA evidence, will be a gain in a country where the conviction rate of rape cases is currently only six percent. The results of this case should have a significant impact in Morocco on the prosecution of future rape cases and thus may have a major cultural impact on a nation and serve as an impetus for greater reliance on DNA testing for rape cases.

Gender Violence, Sexual Assault, International Crime

E58 Court-Assessed Fees May Create Bias in Forensic Science

Roger G. Koppl, PhD, Syracuse Univ, Dept of Finance, 721 University Avenue, Syracuse, NY 13244; and Meghan Sacks, PhD, Dept of Social Science, Fairleigh Dickinson Univ, Madison, NJ 07940*

After attending this presentation, attendees will recognize that funding sources and methods constitute a potential source of bias in forensic science. Attendees will understand some of the mechanisms linking court-assessed fees to bias in forensic science analyses and interpretations. Attendees will learn that court-assessed fees are charged to defendants upon conviction and that persons found not guilty are not subject to them. Attendees will learn how several states have statutes mandating the partial funding of public crime laboratories through court-assessed fees. They will learn which 15 states have such statutes. Attendees will learn that in other jurisdictions court-assessed fees may help fund public crime laboratories as a matter of policy rather than state law. Finally, attendees will learn that a fee-based system in which fees are not contingent upon the outcome of the trial or of the forensic examination would reduce or eliminate the specific potential for bias created by court-assessed fees.

This presentation will impact the forensic science community, including forensic scientists, crime laboratory managers, prosecutors, and public defenders; because they all share a common interest in ensuring that forensic science analyses and interpretations are correct, objective, and unbiased.

This presentation's hypothesis or proposition may be expressed in one sentence. Court-assessed fees may create bias in forensic science analyses and interpretations, whereas non-contingent fees would present a much smaller risk of inducing such bias.

A brief synopsis of the content of the presentation emphasizes the incentive to convict rather than to distinguish between guilt and innocence. When crime laboratories are funded in part by court-assessed fees, lab funds are positively correlated to conviction rates. This correlation creates an incentive to convict rather than to correctly distinguish between the guilty and the innocent. This incentive to convict may induce unconscious bias in forensic-science analyses and interpretations. Non-contingent fees do not create a specific incentive to convict and are therefore less likely to induce unconscious bias.

The presentation suggests, as a general statement of conclusion, the importance of examining the methods of funding crime laboratories from the perspective of their potential to induce unconscious bias in forensic-science analyses and interpretations.

This presentation will impact the forensic science community by identifying a previously unrecognized source of potential bias in forensic science analyses and interpretation. The 2009 NAS Report, "*Strengthening Forensic Science in the United States: A Path Forward*" emphasized the importance of minimizing the risks of bias in forensic science. The report identified several potential sources of bias, including the organization of crime laboratories under law enforcement agencies. The report gave no direct attention to the potential of crime-laboratory funding methods to induce bias and it did not consider the role of court-assessed fees in the criminal justice system. If funding methods are a potential source of bias in forensic science analyses and interpretations, public officials, crime-laboratory directors, and other members of the forensic-science community should seek alternatives to the use of court-assessed fees to help fund publicly-funded crime laboratories. The possibility of moving to non-contingent fees to help support public crime laboratories should be reviewed by the forensic-science community.

Court-Assessed Fees, Bias, Funding

E59 How Italy Deals With the Increase of Medical Malpractice Claims: The Binding Mediation and the Gap in Understanding Between Patient and Physician

Matteo Gulino, JD, 336, Viale Regina Margherita, 00161, 5, Viale Bruno Buozzi, 00197, Rome, ITALY; Gianluca Montanari Vergallo, JD, Arianna Giovannetti, MD, Serenella Serinelli, MD, and Paola Mancarella, MD, viale Regina Elena 336, Roma, ITALY; and Paola Frati, PhD, Unive of Rome, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, 00161, ITALY*

After attending this presentation, attendees will understand some of the legal aspects of a mandatory mediation system recently introduced in Italy regarding medical malpractice litigation, how medical liability claims are handled by the mediator, statistic data collected by the Italian Ministry of Justice, potential benefits for physician-patient relationship, and differences between two examples of claims settled by mediator and court.

This presentation will impact the forensic science community by providing a model to drastically reduce the number of disputes in court and to promote the dialogue between physicians and patients. In fact, the traditional legal system emphasizes the physician-patient relationship and raises behaviors as reticence and retraction, delaying the achievement of the injury compensation and increasing the defensive medicine.

A new Italian law enacted March 21, 2010 enforces parties, in a medical malpractice action, to proceed with mediation before moving forward with the lawsuit. In the event the parties do not proceed with mediation, the court has the duty to suspend trial, ordering them to try to settle the claim through mediation. A fine is ordered to be paid by the party which does not take part in mediation. The law provides that the mediation must be completed within four months after the patient filed the claim, regardless of the achievement of agreement. If parties do not reach an agreement, the mediator can make a proposal on how he/she would settle the claim and, thus the parties can move to court to resolve their disputes. During the trial, the judge could discretionally evaluate the mediator's proposal. The high cost of mediation is split between plaintiffs and defendants and it is calculated regardless the requested amount for injury compensation claimed by patient. The mediation allows patient to hear explanations behind medical errors or complications and to hear a physician express apology. In the current practice, the mediator does not strictly ascertain the physician's fault by the evaluation of standard of care, but rather he/she promotes and facilitates the communication between patient (plaintiff) and physician (defendants) in order to achieve an agreement that meets their wishes. Parties must be assisted by a lawyer. The mediation is not overseen by court nor does the mediator have to be a judge. The mediator could evaluate the opportunity to be supported by a forensic scientist or specialist, charging fees to parties.

Two case studies will be highlighted, the first one settled by mediator and the other one by the court, comparing the dynamics, length, effects (on the patients' and physicians' quality of life), and the modalities of involvement of forensic scientist.

The impact of the new reform in the field of medical malpractice is also evaluated and discussed on the basis of statistic data collected by the Italian Ministry of Justice. The statistic survey was completed on March 31, 2012. The data confirm relevant decrease of medical liability

claims in front of courts. Moreover, a widespread skeptical attitude towards mediation was registered. Three main criticisms could be identified: (1) the compulsoriness of mediation; (2) the fact that mediation implies expensive costs for parties (remuneration of mediator, lawyer and forensic scientist) without guaranteeing a good compromise; and, (3) the concern in delaying the achievement of injury compensation in case of lack of agreement.

Overall, taking into account that the priority in medical malpractice litigation should be reduce the gap in understanding between physicians and patients, the Italian experience provides a practical example, which deserves international attention in order to discuss and argument whether communication approach could be incentivized by a binding system.

Medical Malpractice Litigation, Mandatory Mediation, Physician-Patient Relationship

E60 Issues in Age Estimation in Medicolegal Cases: Our Experiences in a Tertiary Care Hospital in India

Munish Sharma, MBBS, AIIMS, Dept of Forensic Medicine, Rm 301, 2nd Fl, New Delhi, INDIA; Sanjeev Lalwani, MD, and Tabin Millo, MD, AIIMS, Dept of Forensic Medicine, New Delhi, INDIA; Ashu S. Bhalla, MD, AIIMS, Dept of Radiodiagnosis, Ansarinagar, New Delhi, INDIA; Ajay Logani, MDS, AIIMS, CDER, Ansarinagar, New Delhi, INDIA; Chittaranjan S. Behera, MD, AIIMS, Dept of Forensic Medicine, Ansarinagar, New Delhi, INDIA; and Karthik Krishna, MBBS, AIIMS, Dept of Forensic Medicine, 2nd Floor, Ansarinagar, New Delhi, INDIA*

After attending this presentation, attendees will understand some of the principles on methods of age estimation, as well as daily dilemmas faced by forensic doctors in India, owing to a huge burden of medico-legal work supplemented with poor or lack of documented evidence for age of an individual. Authenticated birth certificates, school documents when available, are admissible in the courts as proof of age, and are considered to be superior to the age estimated through medical opinion. The courts rely on the medical opinion whenever there is disagreement on the documented evidence for age or in those cases, where they are completely missing. As the age progresses, the estimation of age-range also widens considerably.

The presentation will impact the forensic science community by sensitizing attendees toward the medicolegal issues that arise in determination of a person's age, hoping to convey that the technique is always a multi-disciplinary approach involving clinical, dental and radiological examination, but with individual limitations for each of these criteria.

Identification of the living person and the dead is of paramount importance for variety of reasons in forensic practice. While age estimation of unidentified corpses and skeletons for identification purposes has a long tradition in forensic sciences, age estimation of living persons have formed a relatively recent area of clinical forensic medicine which are becoming increasingly important. Not only it is important in the identification of victims and accused in criminal cases, but also in civil cases like marriage, inheritance of property, insurance claims and missing persons etc where determination of age is questionable.

Durnig day to day practice, it becomes challenging for a forensic doctor to pin-point and accurately comment upon the age of an individual, especially when the court of law needs specific age of either parties for fixing the level of punishment and dispensing the case. This presentation details cases referred from the courts, for age estimation of those in conflict with the law, who were pleading innocence on the grounds of age, stating to be juveniles at the time of committing the offense. Many of the crimes were committed by the accused years earlier and the trial took another set of years to complete, further complicating the issue of age. It was noteworthy, that most of the accused were related to cases of heinous crimes like homicide and wanted to benefit from the Juvenile Justice (Care and Protection of children) Act of India; 2000. The honorable court then asked for medical opinion, regarding the bone age of the individual through a board of doctors in the tertiary care hospital.

In practice age estimation. it is always a multidisciplinary approach involving clinical, dental, and radiological examination; however, there are individual limitations for each of these criterions. A careful scientific co-relation of various findings present during examination, when interpreted with the available background history will ultimately solve the problem. This preseneation shall share experiences of formulating medical opinion on estimation of age using various parameters, citing discrepancies in the available review of literature and the legal point of view of Indian courts, regarding age estimation popularly known as "ossification test" among jurists in India.

Age Estimation, Medicolegal, Courts India

F1 Ultimate Dental Chart for Medical Examiners

William E. Silver, DDS, 10 Edgewater Dr, 5G, Coral Gables, FL 33133; Richard R. Souviron, DDS, 336 Alhambra Cir, Coral Gables, FL 33134; and Bruce A. Hyma, MD, Miami-Dade County, Medical Examiner Dept, Number One on Bob Hope Rd, Miami, FL 33136*

After attending this presentation, attendees will learn of a new dental chart that will assist dentists, medical examiners, and law enforcement officers in the proper collection of dental evidence.

This presentation will impact the forensic science community by informing forensic dentists who participate in the charting of the dentition of unknown remains in finding a complete collection of data on one chart in an organized form. This chart should enhance the ability of the dentist or medical examiner to make more accurate conclusions regarding the identification of victims or suspects whose identity has not been established.

Not all medical examiner departments have the services of an ABFO forensic odontologist available on staff. Many are fortunate to have a dentist on call that may assist in the recording of dental evidence in the case of unknown remains. Some medical examiners have to take it upon themselves or enlist the aid of a forensic anthropologist to record the dental evidence. In any case, the medical examiner's department is in need of standardization of dental charting, in the collection of dental evidence, at the time of the dental autopsy. This chart should be clear, as well as comprehensive, and lead the investigator in the correct direction. Another important element is the ability of every satellite medical examiner's department and investigative agency to read and understand what has been recorded by their colleagues. Every medical examiner's department, as well as every dentist, has his/her own charting system, which only contributes to the confusion and the inaccuracy of dental charting. Standardization of dental charting should lead to easier computerization of dental charting in the distribution of evidence among missing and unidentified persons. Standardization also leads to better communication when we are all reading from the same page. This presentation of a dental chart contains the ultimate in knowledge required for a complete dental examination. The Universal Tooth Numbering system, as well as the Federation Dentaire International (FDI) system, are both employed in the permanent as well as the deciduous dentitions. Both systems are the most common means of reference nationally and internationally, and both systems are found in close proximity to the teeth being recorded in this chart. The Universal Tooth Numbering system is in use practically throughout the United States and is the standard system taught in dental schools in this country. The FDI Tooth Numbering System is most popular throughout the rest of the world and is an important element contained within this chart. Although Canada and INTERPOL rely on similar systems, it would be advisable to coordinate these systems into one compatible system that would not rely upon language specificity but would have a more universal appeal and character.

The coding for the identification and condition of individual teeth is charted by the WIN ID system. Although this may be the most popular system, it is not universally employed throughout the world. An odontographic representation of all teeth is available on the front of the chart to note the outline of restorations and/or special conditions. This is the same system used by National Disaster Medical System teams and is easily converted into NCIC codes, which is the system used by the U.S. Department of Justice and the Federal Bureau of Investigation. All WIN ID and NCIC codes are defined within the body of the dental chart. There is a guide to the standard series of dental radiographs and a recommended outline for dental photographs available on the back of the chart.

In addition, there are areas on the chart to note the Classification of Occlusion and a Classification of Remains. Separate areas allow for remarks, dentures, and pathology. The front of the chart contains space for the possible name, age, sex, race, medical examiner, number, and date, together with an area for the signature and license number of the examining odontololgist.

Ultimate, Dental, Chart

F2 3D Photography of Bitemarks and Digital Comparison With an Individual's Model

Holland Maness, DMD, 499 Fury's Ferry Rd, Martinez, GA 30907*

After attending this presentation, attendees will learn how an existing technology could be applied to forensic odontology and specifically, bitemark analysis.

This presentation will impact the forensic science community by demonstrating an established modality that can be applied to forensic odontology for more accurate photo documentation of human bitemark injuries. Accurate evidence collection is the first step to improved scientific analysis.

Photographs of bitemark injuries in 2D are the standard methodology utilized to document the injury for future analysis. Due to the curved anatomical surfaces on which many bitemarks occur, such as the human arm and breast, photographic distortion can be introduced as a factor complicating the analysis. This distortion, once introduced, is difficult to rectify without potentially creating further image distortions. Utilizing the advanced technology of 3D photogrammetry systems, this photographic distortion can be eliminated, leading to higher accuracy at the data collection stage.

3dMd is a high-precision 3D surface imaging system with current applications for both living and non-living subjects. The use of the 3dMd system and its precision and accuracy has been established in the scientific literature in sources such as: the American Journal of Orthodontics & Dentofacial Orthopedics, the International Journal of Oral and Maxillofacial Surgery, Facial Plastic Surgery Clinics of North America, and the Journal of Prosthodontics. The imaging system is currently in use in various fields ranging from anthropology and biometrics to craniofacial and cleft lip and palate treatments. Applying this technology to the capture of the bitemark injury could both improve the documentation of the injury as well as allow for 3D bitemark analyses to be performed.

Utilizing a digital imaging system, a digital model of an individual's dentition can be produced in Stereo Lithography (STL) format. STL is a file format native to the stereo lithography CAD software created by 3D systems. STL files describe the surface geometry of a 3D object such as an individual's dentition without any representation of color or texture. Current applications in the field of orthodontics allows STL files generated from cone beam computed tomography of a patient's craniofacial system to be "mapped" to the 3D photograph of the subject's face, allowing for comparison of hard and soft tissues without distortion or magnification.

Applying this same concept, the STL of an individual's dentition could be "mapped" to the 3D surface characteristics captured in the 3dMd photograph of the bitemark. In this manner, a 3D bitemark analysis protocol could be developed. This new protocol would improve upon the current industry standard 2D analysis by minimizing or eliminating photographic distortion.

The digital model technology and STL file capabilities exist today in an applied format; however. the 3D photogrammetry technology must advance to a more portable format in order to have a practical forensic application. This does not preclude the importance of studying the

technology's application to forensic odontology and beginning a scientific endeavor to apply this technology.

Forensic Odontology, Bitemark Analysis, 3D Photogrammetry

F3 Retained Bullet Fragments in the Maxillofacial Region

Stuart A. Caplan, DDS, Univ of Tennessee School of Dentistry, 875 Union Ave, Memphis, TN 38163; Brent Accurso, DDS, Oral Pathology Consultants, PLLC, St. John Hospital & Medical Center, 19251 Mack Ave, Ste 80LL, Grosse Pointe Woods, MI 48236; Howard Kaufman, MD, JD, 7813 Travelers Tree Dr, Boca Raton, FL 33433; and Yeshwant B. Rawal, MS, Univ of Tennessee School of Dentistry, 875 Union Ave, Memphis, TN 38163*

After attending this presentation, the attendees will recognize the radiographic appearance of bullet fragments in the maxillofacial region, obtain relevant history in a living subject, recognize the current and possible future morbidity associated with the condition, and be cognizant of the management challenges and options in the living subject.

Conflict and the use of ballistic projectiles including guns is an all-too-frequent occurrence in the society in which we live. Crime solving and management of injuries and the resultant complications is a complicated process. The proximity of vital, special sensory structures, the brain, and the gnathic apparatus makes this process a veritable challenge when the incident involves the head and neck. This presentation will impact the forensic science community by bringing about an awareness of potential injuries to the facial skeleton, soft tissues, and teeth. In addition, the presentation will also describe implications of ferromagnetic effect of retained bullet fragments on specialized imaging procedures.

It is proposed that forensic odontologists, oral and maxillofacial radiologists, head and neck surgeons, and dental surgeons recognize the implications of retained bullet fragments in the facial region and plan investigations, intervention, and reconstruction, while bearing in mind the potential complications.

Synopsis of Content: Three cases of gunshot injuries demonstrating the radiographic presence of retained bullet fragments as noted on panoramic X-rays are presented.

Case 1: A 30-year-old male presented to the dental department with a need to replace his maxillary obturator appliance because it was ill fitting and frequently dislodging from the palate. He had borne a gunshot to his face in 1996. He had undergone several surgical corrections of resulting facial deformities. The injury had laid him legally blind and with episodes of memory loss. The panoramic radiograph showed numerous, discrete, opaque, metal fragments of varying size and shape on the right side overlying the anterior ramus, condyle, disintegrated right maxilla, as well as in the left pterygoid space, and superimposing over the left orbit.

Case 2: A 46-year-old male presented to the dental department for consultation about his teeth. Intraoral examination revealed that he occluded only on two teeth. His history was significant for a gunshot wound that he had endured approximately 20 – 25 years ago. He had then declined reconstruction of his jaw and teeth. Apparently, at that time, he was too overwhelmed with his situation as well as the number of surgeries that he was subjected to, to care about his dentition. Regretting that decision, he was now interested in getting his teeth "repaired." A panoramic radiograph showed numerous bullet fragments within the soft tissue of the right face and pterygomandibular and infratemporal space. The right mandible was fragmented, partially resorbed and the replacing soft tissue was peppered with opaque bullet fragments. Some pieces were also seen within the right upper neck.

Case 3: A 50-year-old male presented for oral rehabilitation and replacement of missing teeth. His history was significant for three gunshot injuries to the face in 2008. The patient's right eye was lost. A panoramic radiograph revealed efforts at reconstructing the right and left maxilla, left palate, and floor of the orbits. His left coronoid process of the mandible was lost and several opaque bullet fragments were noted within the left maxillary antrum as well as in the left infratemporal space.

The implications following the incident, including trauma, disfigurement, fragmentation of the dento-maxillofacial apparatus, soft tissue injury, potential for infections, proximity to or involvement of major blood vessels with the potential for hemorrhage as well as the ferromagnetic interference while imaging, implications of nerve injury, elevated blood levels of lead, and the moving bullet syndrome, are discussed.

General Statement of Conclusion: Gunshot injuries and resultant retained bullet fragments present with life-threatening complications. Several special sensory organ structures, large vascular channels, neuronal tissue, teeth, the spine, as well as soft tissue lie in the potential path of the bullet fragments. Investigation and management of head and neck gunshot wounds are very complicated and challenging procedures. An interdisciplinary approach in a specialized trauma center is warranted.

Gunshot, Fragment, Maxillo-Facial

F4 The Identification in 2011 of 77 Victims After the Bomb Attack on the Government Buildings in Oslo, Norway, and the Shooting at a Youth Camp at Utøya, Norway

Sigrid I. Kvaal, PhD, Institute of Clinical Odontology, Oslo, NORWAY; and Tore T. Solheim, PhD, Box 1052 Blindern, Oslo, NORWAY*

After attending this presentation, attendees will understand the importance of good Antemortem (AM) and Postmortem (PM) information for correct identification of all victims in two tragedies.

This presentation will impact the forensic science community by discussing how a broad and thorough examination of all bodies should be completed. A small detail may be the essential element to establish identity. Identification cannot be made without comparative AM material and dental information may be just as essential as DNA and fingerprints and, together with medical and police evidence, help to secure a correct identification.

On July 22, 2011, after several years of preparation, 32-year-old Anders Behring Breivik, placed a van with 950kg of explosives outside the government buildings in Oslo. The buildings included the offices of the Norwegian Prime Minister and Minister of Justice. Several buildings were almost com destroyed, but only eight people were killed. Approximately two hours later, Breivik, in homemade police uniform with guns and ammunition, ordered a boat to take him to Utøya, an island on the lake Tyrifjord approximately 40km to the west of Oslo. On the island, he shot 69 young people from the Labour Party's youth camp. He later argued that the reasons for his actions were to save Norway and Europe from the Muslims. The relatives and public expected an almost immediate identification of the victims. This required good AM and PM information for comparison. The Norwegian Identification Commission connected to National Criminal Investigations Service (Kripos) in Oslo, is responsible for identifications in such disasters. Because this was a criminal offense, a full autopsy was carried out on all victims. The victims from the government buildings and the streets nearby were severely mutilated by the explosion. Many of the victims from Utøya were shot in the head and face. During the autopsies, two dental teams consisting of either two or three dentists served five autopsy teams. All victims were subjected to a systematic examination including full registration of dental status. Digital photographs and radiographs were taken by the same dentists who did the examination using a Nomad handheld X-ray machine. Documentation of injuries from the shooting was important for the reconstruction of the event. Manual registrations of PM records were made on Interpol forms during the autopsy at the Institute of Forensic Medicine and later transferred to the PM forms in the computer program DVI System International (Plass Data) at the ID-center at Kripos. Photographs and radiographs from each victim were also included in the program.

AM information was transferred directly to the AM forms in the computer program for comparison. Computers aided the search for

identity and facilitate printing professional comparison reports to be included as documentation of the identification.

In this incident, collection of comparative DNA samples wase made at the Relative Centers and this enabled a rapid identification by DNA. Dental records from 57 victims (74%) were collected. Once identity was established further search for dental records was stopped. For 31 persons (41% of the victims) identity was established by dental means. This constituted 54% of those with available dental records. This was higher than expected as the average age of the victims at the time of the shooting was 18 years and many of them had no or few fillings. The identification of all 77 victims was concluded in six days using all methods and combinations of methods for identification.

Terror Attack, Identification, ID-Commission

F5 Missing People and Nameless Cadavers: Implications for Human Rights and Forensic Odontology

Emilio Nuzzolese, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, ITALY; Rossella Colonna, PsyD, Psychologists for the People, Bari, ITALY; Annalisa Loconsole, Association "Penelope Puglia," Viale Conc. Vaticano II 82, Bari, ITALY; and Pietrantonio Ricci, MD, Viale Europa—Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will have an understanding of the issues arising from common psychological conditions of family members of missing people.

This presentation will impact the forensic science community by suggesting the importance of maximizing the efficacy of postmortem collection and recording by following Interpol directions and putting greater emphasis on the role of the forensic odontologist.

The non-profit association, "Penelope," created in 2002 with the sole purpose of pursuing social solidarity, people, and dignity, focuses particular attention on the issue of missing people. With expert help, it supports families by organizing conferences and publishing information, aiming to raise public awareness, so that missing people are not forgotten.

Among the goals of the organization is that of the promotion of suitable instrumentation for the collection and elaboration of data regarding missing people in both Italy and abroad, acting as a connection between other organizations and both national and local governmental authorities.

In 2011, the "Penelope" Association created a *pro bono* legal assistance service, made up of lawyers and forensic experts, supporting families looking for their missing family members. In order to offer psychological assistance to families living the painful experience of the disappearance of a loved one, cooperation with the association "Psicologi per i Popoli" (*Psychologists for the People*) was also set up.

The Italian data is disconcerting: approximately 25,000 people have disappeared since 1974, with an annual increase of 800 – 1,000 people. Out of these, 1,651 are Italian children and as many as 8,153 are foreign children. To date, 832 bodies have been found and still await identification.

In 2006, the regional branch of "Penelope" was founded in Apulia. Since 1974, a total of 1,702 people have been reported missing and a total of 53 cadavers currently await identification.

In order to describe common psychological conditions, some cases of missing people in Apulia have been included: for family members of missing people, time becomes suspended and indefinite, and there is a gradual confusion regarding the perception of time as well as disruption of the sleep-wake rhythm. Everyday activities, routines, and work engagements are all suspended, as the return of the missing person becomes top priority. The absence of a person due to uncertain causes leads to an endless wait, which destabilizes the cognitive system and affects the ability to remember, to reason, to calculate times and distances, and to understand time and space. This creates an uncertain social representation of the self and can even lead to one losing the perception of reality.

In order to maximize the efficacy of the autopsy as well as the identification process of human remains, it is necessary to perform a postmortem examination following Interpol recommendations. The incomplete collection of such data could represent a violation of human rights, because once the fate of a missing person has been determined to be death, all available means must be undertaken to ensure recovery of the body and any personal effects.

Greater emphasis needs to be placed on the role of the forensic odontologist and on their collaboration during the autopsy of unidentified cadavers, regardless of the circumstances. Of the 832 bodies, it appears that only 61 bodies received an odontological assessment with a proper odontogram charting. The failure to routinely employ odontologists in missing persons investigations may result in a reduction of additional findings which, together with other circumstantial evidence, could lead to a delay in positive identification and actually prolong the condition of suspended grief, a situation which needs a body, even if such a body is lifeless, in order to bring a ritualistic "end" to the relationship.

Missing Persons, Human Rights, Forensic Odontology

F6 Fatality Management of a Multi-Vehicle Accident

Kenneth F. Cohrn, DDS, 422 Teague Tr, Lady Lake, FL 32159*

After attending this presentation, attendees will gain insight in the management of an accident with multiple fatalities by a state disaster team, Florida Emergency Mortuary Operational Response System (FEMORS). The overall result was the expeditious identification of the victims utilizing the appropriate resource allocation and minimum miscalculations. The nimble response was the result of 10 years of training augmented by several incident activations, including two minor hurricanes.

This presentation will impact the forensic science community by illustrating the efficiency of a successful disaster mitigation team, despite its limited size.

FEMORS was established in 2002 as part of the Health Department's ESF-8 Division of Emergency Management. Since then, FEMORS has been alerted for four hurricanes and activated for two more during the busy 2004 – 2005 hurricane seasons. Over the last 10 years, the team has engaged in annual disaster training including bi-yearly mock disasters. One of the important lessons learned from previous incidents is the importance of utilizing an assessment team deployed in advance to evaluate the true needs of the medical examiner. For example, initial estimates of deaths for both hurricanes Charley and Ivan were 20 – 60. These predictions were grossly inaccurate and, in the case of Hurricane Charley, led to a misallocation of valuable resources. Attendees will see in this case that the decisions of the assessment team and incident commander led to an efficient activation of only those resources actually needed for the incident. The entire operation was completed in four days utilizing limited personnel and resources with a total cost of approximately $20,000.

The Incident: Interstate I-75 Accident, Paynes Prairie, Florida, January 29, 2012. At about 4:00 a.m. on I-75 in Alachua County, just south of Gainesville, Florida, dense smoke from a brush fire along with fog rendered a stretch of the highway completely impenetrable.

Two major crashes occurred within minutes of each other due to vehicles stopping on the roadway. The northbound crash involved eight vehicles resulting in seven deaths and the southbound accident resulted in another four deaths and fire. Initially, there were thought to be 20 deaths and counting. In addition, there were dozens of victims taken to several hospitals with various injuries.

By 6:00 a.m., the Florida Highway Patrol (FHP) notified the Medical Examiner's (ME's) office of the accident and by 6:15 a.m., the Commander of FEMORS was also notified. FEMORS was activated for deployment a little more than an hour later. By 10:00, the entire designated team of 16 FEMORS members, including the assessment team, investigators, VIC personnel, forensic odontologists, and

command staff, were either already on the scene or on their way from various locations in Florida to the command center at the ME's office.

Two of the charred vehicles with occupants were moved to the Sheriff's office for collection of remains by 3:00 p.m. and the VIC center was conducting interviews with relatives by 4:00 p.m. By mid-afternoon the next day, Monday, five of the victims had been positively identified with two more presumptively identified. On Tuesday, 15 of the 16 individuals on all the missing person reports were accounted for, with one being one of the victims. Tuesday was devoted to careful extraction of burned, fragmented, and comingled victims from two vehicles by the forensic anthropologists and odontologists. One family had not been declared missing initially. Infrared (IR) examination of a charred document led to the names of the remaining individuals.

Finally, on Wednesday morning, the forensic odontologist identified the final victim, a 17-year-old female passenger. FEMORS was deactivated that day with a total of four days activation. Over the next several days, the medical examiner completed the final reports for identification.

Deficiencies were few and minor with the exception of the possibility of an incorrect identification by the hospital between two sisters of one family. Teamwork between the medical examiner and staff, FHP, and the FEMORS team led to an efficient recovery and identification of the victims.

Vehicular Accident, Disaster Response, Incident Response

F7 Mesio-Distal Width of Canines: A Tool for Sex Determination

Pradeep K. Gouda, MD, and Shankar M. Bakkannavar, MD, Kasturba Medical Coll, Manipal Univ, Manipal, INDIA*

After attending this presentation, attendees will be able to determine the sex of an individual from a canine tooth in cases of bodies found as fragments or skeletal remains.

This presentation will impact the forensic science community by imparting a new tool in the determination of sex from a tooth.

Teeth, in the living as well as the dead, are the most useful objects in the field of forensic investigation. Their ability to survive in situations like mass disasters makes them an important tool in victim identification.[1] Though the morphology and structure of a tooth is similar in both men and women, there are subtle variations that could be valuable in the determination of sex. "Sexual Dimorphism" refers to those differences in size, stature, and appearance between male and female and can be applied to dental identification since no two oral cavities are alike.[2] Variations in the dental size can give a clue about differences between the sexes. Many authors have measured the crowns of teeth in both men and women and found definite variations. Canines, that are reported to survive air crash and hurricane disasters, are perhaps the most stable teeth in the oral cavity because of the labio-lingual thickness of the crown and the root anchorage in the alveolar process of the jaws.[2-7] Measurement of mesio-distal width of the mandibular and maxillary canines provides good evidence of sex identification due to dimorphism.[5]

Materials for the present study consisted of 500 students belonging to various parts of Karnataka, India, in the age group of 15 – 25 years comprised of 250 males and 250 females. The mesio-distal crown width of mandibular and maxillary canine teeth, i.e., the greatest mesio-distal width of the crown between the contact points of the teeth on either side of the jaw, was measured. The results obtained were subjected for analysis to derive conclusions. Sexual dimorphism in the right and left mandibular and maxillary canines was calculated using *Garn & Lens (1967)* formula.[6] The data obtained were quantified and analyzed statistically using a stastistics software package to determine the significance of differences between the sexes.

It was observed that the mean value of the mesio-distal crown width of right and left mandibular canines were higher in males than in females with statistical significance ($p < 0.001$). Similarly, the mean value of mesio-distal crown width of right and left maxillary canines was also more in males than in females with statistically significant value ($p < 0.001$)

The conclusions drawn were:

- Mesio-distal width of canines in all the quadrants for a given gender did not show any significant variation.
- The mean mesio-distal width of mandibular canines was greater in males than females.
- The mean mesio-distal width of maxillary canines was greater among males than females.

The results of the mesio-distal width of canines obtained could be of importance to anthropologists and of help to the clinical orthodontist for space assessment. It even helps forensic experts in cases of mass disasters in assessing the sex of an unknown remain.

Mesio-Distal Width, Canine Tooth, Sex Determination

F8 Critical Effects of Improper Exposure of Digital Dental Radiographs Derived From PSP Plates

Richard A. Weems, DMD, Univ of Alabama, School of Dentistry, SDB Box 39, 1530 3rd Ave S, Birmingham, AL 35294-0007*

After attending this presentation, attendees will understand the potential for erroneous dental X-ray image orientation (right vs. left) resulting in reversed (mirrored) radiographic data when images are improperly obtained using digital X-ray systems based on some Photostimulated Luminescence (PSL) systems.

This presentation will impact the forensic science community by demonstrating the results observed when properly and improperly placed image receptors are exposed on an X-ray phantom using both the traditional film-based systems compared to the emerging technology used in digital dental radiography. An understanding of the results presented will provide information critical to the accurate victim identification through dental findings by helping to prevent errors.

Dental radiographs, whether film-based or digital, may be viewed from either the "front" or "back." Thus, if an observer evaluates the radiographic image from a viewpoint opposite from the image surface which was exposed, the determination of whether the structures seen are from the subject's right or left will be incorrect. This means, for example, that what may be perceived as the maxillary right first molar (tooth #3) in actuality is the first molar on the left side (tooth #14).

Any putative dental identification must be ruled out if any unexplainable disparities are noted between the antemortem and postmortem dental findings. Incorrectly orienting or viewing image media can erroneously create such disparities and prevent an accurate dental identification. Dental film manufacturers have traditionally placed a palpable "dimple" or "bump" on every film. This can be used to assure that the image is properly oriented when viewed. Additionally, a metal foil backing with a distinct pattern is included in the film packet behind the film to warn the viewer if the film was exposed from the improper side (from the non-exposure or "back" side).[1]

Typically, duplicated antemortem radiographic series do not provide the aforementioned physical bump for the examiner as a reference. This has been shown to be particularly troublesome when there are a very large number of decedents and when many of the antemortem images submitted are duplicated rather than original radiographs. There are several ways to determine the film's original orientation but most forensic odontologists accomplish this using the spatial location of the bump within the image itself. When the bump appears at either the lower right or upper left corner of the image, this assures that the dental structures are being viewed as if the viewer is facing the dental arches (bump-up). Bumps in the upper right or lower left corners of the images mean that the structures are being observed from the vantage point of the tongue (bump-down).[2,3] Also, panoramic images are typically labeled with "left" and "right" indicators in the image using letters either placed within the film cassette or on the device's head-holders.

However, there is a great potential for inadvertent spatial errors when interpreting improperly placed dental X-ray images captured by the Air Techniques ScanX™ Phosphor Storage Plate (PSP) system. PSP technology is considered an indirect digital radiographic system in which plates coated with photostimulable phosphor capture and store X-ray energy when images are taken. The exposed plates are then passed (scanned) through a laser which releases the stored energy in the phosphor as light. The light released varies according to the amount of stored energy, thus producing a radiographic image. The failure in the system arises from the fact that a plate which has been improperly exposed from the non-exposure side produces a "flipped" image with no indication after image processing that a spatial error has occurred. This is because the plates have no reference to indicate errors in that they lack the lead foils found in film packets. Also, the design of placing a reference letter "a" on the exposure surface of the plate is flawed and is not indicative of orientation as are the "bumps" in specified film corners previously mentioned. Additionally, this possible confusion concerning "left-and-right" orientation may occur with both intraoral and panoramic PSP images.

In conclusion, it is impossible to determine from a single digital radiograph if the portrayal of the decedent or victim's left or right is correct when created using the Air Techniques ScanX™ PSP system.

PSP Dental X-Ray, X-Ray Errors, Dental Identification

F9 Dental Identification Without Antemortem Dental Records: Case Example From Central America

Kenneth F. Cohrn, DDS, 422 Teague Tr, Lady Lake, FL 32159*

After attending this presentation, attendees will understand an application of "smile line" dental identification in a murder case in Central America. Dental identification without antemortem records is certainly problematic. Yet there are a number of circumstances where this scenario might occur: cold cases, mass graves, gang-related murders, drug violence, civil war, fraud, misidentification, etc. DNA recovery may not be an option leaving few other options for identification.

Central America is plagued by a prolonged history of civil war, drug violence, and femicide. According to the United Nations, the homicide rate in Central America has reached a crisis point with the Honduras homicide rate at 82/100,000, El Salvador with 66/100,000, Mexico at 18/100,000, as compared to the U.S. with 5/100,000. This presentation will impact the forensic science community by showing how dental identity can be accomplished without antemortem records in limited situations.

Not surprisingly those countries with the highest overall rates of violent crime have the highest rates of femicide as well. The pervasive culture in Central America is that women are easily disposed of with impunity. El Salvador leads this metric with 12/100,000 female population with Guatemala third at 9.7/100,000. The violent nature of these crimes has resulted in countless unidentified victims and grieving families.

Dental identities by traditional comparative methods often are not possible. Typically, there is a lack of dental history as a consequence of poverty or intentional concealment because of illegal activities. Yet with the ubiquitous use of cell phones with cameras, a creative approach to dental identification may be applicable. This "smile line" concept of identification is not new in the odontology armamentarium. However, participation in a human rights symposium for women in Central America revealed a total lack of awareness of the application of this methodology for identification. The participants overwhelmingly expressed an interest in this simple, inexpensive, fairly effective modality when identifications are an issue.

Case in point, a forensic team consisting of two forensic anthropologists, a medical examiner, a forensic odontologist, and support staff were tasked with determining the cause and manner of death and a dental ID for a young woman believed to have been murdered in a Central American country.

The court granted permission for an exhumation and autopsy to be done with the resident pathologist. The forensic team was sent from the U.S. to work with the local officials. The victim was exhumed and transported to the morgue where a thorough autopsy was performed on the decomposed remains including a complete dental examination with digital images. Based on the quality of the dental restorations and the fact that the family resided in the U.S. for several years, there was a presumption of available dental records. None were discoverable. A visual ID was not possible due to severe decomposition but a presumptive ID was originally done based on artifacts accompanying the body. The family provided several photographs of the decedent showing the anterior teeth. The photos were imported into Adobe® Photoshop® for appropriate enhancements. The photos were of fair quality but somewhat grainy which led to pixilation when enlarged. Visual examination of the victim revealed a number of individual dental characteristics including rotated and tilted teeth, several amalgam restorations, and incisal irregularities. The photos provided a dental profile sufficient to compare to the dentition of the victim. The cause of death was determined to be homicide, the manner to be strangulation, and a positive identification was made.

Beyond the relevance of just this individual case, the utility of using images from a digital camera or a cell phone camera as a source of antemortem images for potential dental identifications in situations where there are limited or no dental records is beneficial.

Dental Identification, Smile Line ID, Murder Case

F10 The History of Tattoos and Their Use as a Means of Identification

James C. Schneider, DDS, Cuyahoga County Coroner's Office, 8660 Columbia Rd, Olmsted Falls, OH 44138*

After attending this presentation, attendees will have a better knowledge of the development of tattoos and how they can be used as a means of identification.

This presentation will impact the forensic science community by demonstrating how tattoos can be used as an identifier.

As one can imagine, the art of tattooing was been around for quite some time. In fact, there is evidence to demonstrate that tattooing was done thousands of years ago.

One of the oldest known specimens is that of Otzi the Iceman, dated around 3300 B.C. He had 57 separate tattoos. Among these were a cross on the inside of the left knee, six straight lines, fifteen centimeters long above the kidneys, and numerous small parallel lines thought to be possible therapeutic tattoos for the treatment of arthritis. There have also been several mummies from West China as well as mummies from permafrost dated around 300 B.C. It is obvious, therefore, that tattooing has been around for quite some time. In fact, evidence shows that tattooing was quite prevalent in China as well as Egypt, India, and the Philippines, just to name a few. Further, in the Philippines, tattooing to some was a form of rank and accomplishment. Some believed that tattoos had magical qualities. Many tribes have a tattoo culture, such as those found in Indonesia.

In Europe, pre-Christian Germanic, Celtic, and other central and northern European tribes were often heavily tattooed. During the gradual process of Christianization in Europe, tattoos were often considered remaining elements of paganism and were, for the most part, legally prohibited.

As previously mentioned, tattooing was exhibited in China as early as 3300 B.C.; however, recently, tattooing for spiritual and decorative purposes in Japan is thought to extend back to at least the Paleolithic period. This would be about 10,000 B.C.

In Samoa, the traditional male tattoo is called the pe'a and the traditional female tattoo is called the malu. The word tattoo is believed to have originated from the Samoan word "tattoo."

Tattooing has obviously been a practice for thousands of years as evidenced in many cultures although the reasons vary greatly because of culture, religious beliefs, and society. Some consider tattooing an art form, while others consider it a ritual or requirement to have performed. During the latter decades of the 20th-century, tattooing became a popular social practice worldwide. Many younger (and some older) people today either have aspirations to have a tattoo somewhere on their body, or already have one or more. As we all know, the reasons vary as well as the shape and size of the tattoos.

Some cultures and religions ban tattoos. The orthodox Jews, for example, abide strictly to the third chapter of Leviticus, which states that one should not make gashes in one's skin for the dead: "Do not make marks on one's skin." Modern tattooing is included in this belief and is, therefore, not permitted. The Christian churches do not prohibit tattooing so long as the tattoo is not an image directly opposed to Christian teaching or religious sentiment. As with the Jews, the Muslims also forbid tattooing.

It is therefore observed that tattoos are obtained for a variety of reasons. Further, tattoos can obviously be used as an identifier of an individual. Actually, tattoos can identify an individual in one of two ways. First, at times, an individual may have a tattoo as a requirement or a symbol of a group he or she belongs to, such as a gang. Perhaps someone is tattooed against one's will, as in the case of a prison camp. Secondly, a tattoo can simply be used to identify a person because of the fact that someone else is aware of the tattoo and the location on the body of the tattoo.

In conclusion, whatever the reason, tattoos have been around for thousands of years. And, tattoos most likely will be around for many thousands of years in the future. Of the many ways to identify an individual, tattoos are simply another way to acquire a positive identification.

Tattoos, Skin Markings, Identifying Tattoos

F11 The Case of the Missing Molar

Janice W. Klim-Lemann, DDS, 1802 Canyon Rd, Redlands, CA 92373; and Roger D. Metcalf, DDS, JD, Tarrant County, Medical Examiner's District, 200 Feliks Gwozdz Pl, Fort Worth, TX 76104*

After attending this presentation, attendees will understand how identification of an unidentified decedent by using dental records is not always straightforward, and that it is imperative to carefully review the antemortem and postmortem dental records. Dental identifications are generally thought of as being a somewhat routine forensic odontology procedure, but presented here is a case with a very interesting "twist." This case has interesting ramifications for both dental identification and dental age estimation procedures.

This presentation will impact the forensic science community by demonstrating that the accepted axioms in a field may not always hold true in every case. For example, this study contends one of the well-accepted foundation beliefs in the theory of dental identification is that, in the permanent dentition, if a particular tooth is *missing* in the antemortem records, but is *present* in the postmortem records, there is an unexplainable inconsistency that indicates an exclusion. But this case will demonstrate that this idea may not always be true.

In 1995, the skeletal remains of a young woman were found near Houston, Texas. Virtually the entire skeleton was recovered, including the cranium and the mandible, both with intact dental arches. The skeleton was sent to an anthropology laboratory for examination and analysis. The anthropologist charted the condition of the teeth and the dental restorations present. The anthropologist compared these postmortem dental records to the antemortem dental records of a young female (JC) who was missing in the Houston area. The anthropologist concluded that, while there were many "similarities between the dental records of JC and the dentition of the unidentified skeletal remains," there were two dental inconsistencies that indicated the remains were probably not those of JC. He concluded "although this exclusionary trait casts doubt on the remains being JC, I suggest that it be evaluated by a forensic odontologist for confirmation." Regrettably, this suggestion was not followed until 2012 when the written dental records were submitted for review in July of 2012. It was noted the exclusionary factors which had been documented by the anthropologist, but urged the investigating agency to obtain the skeletal remains and original dental records for examination. The records were sent for review and a second opinion, and it was agreed that the original dental records and the remains should be obtained for examination before a definite conclusion could be reached.

In 2008, the skeletonized remains had been submitted to a DNA lab for examination and analysis. In early August of 2012, a DNA profile was extracted and the analysis indicated it was 4.4 trillion times more likely that the remains were those of 20-year-old JC rather than a random female from the Caucasian population. The decedent's remains and the dental records of JC were hand-delivered by the investigating agency in late August of 2012.

One of the potential exclusionary factors, a tooth noted in the antemortem dental radiographs to have a restoration while the corresponding tooth in the remains had been charted as unrestored, was immediately resolved upon examination of the actual remains. Now the "twist:" tooth #32 (Universal) was clearly missing in several antemortem dental panoramic films (the other third molars were present and unerupted), and, on visual inspection, tooth #32 also appeared to be missing from the remain's mandible. However, postmortem radiographs of the mandible showed #32 was clearly present but unerupted. The DNA analysis said "match," the dental records said "exclusion." The attendees viewing this presentation will learn how the case was resolved.

Dental ID, Age Estimation, Exclusion

F12 Forensic Dental Analysis of Degraded, Fragmented, and Commingled Human Remains

Diana Aparicio, DDS, and Soledad Martinez, MD, Servicio Médico Legal, Avenida La Paz 1012, Independencia, Santiago, CHILE*

After attending this presentation, attendees will recognize the morphological, anatomical, and pathological criteria used in forensic dentistry and its application as an important tool in identifying commingled remains of skeletonized bodies in a mass grave intentionally disturbed.

This presentation will impact the forensic science community by demonstrating how an accurate forensic dental analysis of degraded, fragmented, and commingled human remains can be essential for

individual identification even when antemortem records are not available.

During the military regime in Chile, thousands of people were killed. In many cases, they were caught and killed in groups and illegally buried in mass grave sites. After a period of five to ten years, when some of the graves were discovered, the military carried out an operation to remove the bodies from the mass graves to make evidence disappear. At that time, bodies were skeletonized so they could not remove all the remains, leaving in place bone fragments, teeth, and other small evidence. With democracy, judicial investigation of these cases started and the state forensic institution "Servicio Medico Legal" (SML) was called to perform exhumations of remains in different disturbed burial sites.

This particular case involves a group of farmers killed in a creek and buried in a mass grave that was disturbed from remotion five years later. Despite this, the SML was able to recover human bone fragments, dental remains, ballistic evidence, personal objects, and non-human skeletal remains, all commingled, incomplete, and degraded.

Forensic dentistry is a useful tool in human identification, which achieves its goal through the comparison of antemortem and postmortem information. The postmortem examination is affected in this case by the admixture of remains as well as postmortem tooth loss caused by the intentional relocation process. Additional difficulties derived from the long interim from burial to judicial exhumation (30 years). Performing a thorough dental macroscopic study using morphological, anatomical, and pathological criteria, evidence was organized in skeletal and dental clusters, partially or completely reconstructing the dental arches and providing the minimum number of individuals present in the mass grave.

One hundred and twenty-seven human remains good for dental analysis were recovered: 111 (87%) consisted of isolated teeth (including crown fragments), ten (8%) were mandibular fragments (four with *in situ* teeth), five (4%) were maxillary fragments (three with *in situ* teeth), and one consisted of a removable upper dental prosthesis. All specimens presented taphonomic erosion with the teeth being the least affected due to dental enamel resistance.

Odontological analysis classified 87 of 127 specimens into 21 groups obtaining two complete upper arches, one complete lower arch, two partial upper arches and one partial lower arch, and other smaller parts. This led to a minimum of nine individuals for the burial site, considering only the odontological point of view.

The lack of adequate antemortem dental records ruled out postmortem comparison for identification purposes, thus genetic testing appeared as the only possibility to get individual identities. Teeth from some of these twenty-one groups and eight ungrouped teeth were subjected to nuclear DNA sampling; one to three samples from each group were sent separately. A consistency up to 100% was obtained between odontological analysis and DNA testing: identical genetic profiles in all loci typed for teeth coming from the same group. The genetic testing results confirmed the odontological clusters and also provided other associations between upper and lower arcades and ungrouped teeth.

The dental analysis methodology and evidence organization allowed grouping and adequate selection of samples for genetic analysis that led to successfull identification of individuals, preserving dental remains suitable to be returned individually to relatives, and terminate the grieving process. Multidisciplinary approach integrating judicial information, forensic archaeology, forensic anthropology, forensic odontology, forensic pathology, and forensic genetics was essential for this goal.

Commingled Remains, Odontology, Identification

F13 The Characteristics of Dental Restorations in Korea Before 1970: To Differentiate Between American and Korean Remains From the Korean War

Kyung-Seok Hu, DDS, PhD, Yonsei Univ, College of Dentistry, 50 Yonsei-ro, Seodaemun-gu, Room 601, Seoul, KOREA; Braddley Jones, DDS, Central Identification Laboratory, Hickam AFB, 310 Worchester Ave, HI 96853; Yu Ryang Jang, PhD, 65 Hyeonchung-ro Donggak-dong, Donggak-gu, Seoul, 156-080, KOREA; and Jinsuk Lee, DDS, and Calvin Y. Shiroma, DMD, JPAC, Central Identification Laboratory, Hickam AFB, 310 Worchester Ave, HI 96853*

After attending this presentation, attendees will be able to better identify remains of Koreans from those of American soldiers lost in the Korean War through understanding the characteristics of Korean prosthetic restorations performed before 1970.

This presentation will impact the forensic science community by providing information on the distinctiveness that can identify Koreans from commingled remains – even those found in other countries due to the different conflicts, mass disaster, or aircraft crashes which occurred in the 20th-century.

Dental prosthetic restorations artificially substitute for lost teeth. The first evidence of the dental prosthetics was the gold wire ties used for fixing neighboring teeth in Egypt around 2500 BC. Afterward, the dental prosthetics have developed tremendously. In the 18th-century, French surgeon Pierre Fauchard, credited as the "Father of Modern Dentistry," published the fundamental dental book which was the advent of modern dentistry. In Korea, modern Western dentistry was first introduced in early 1900s. The first dental school, Department of Dentistry in Severance Union Medical College, opened in 1915 while the first dental college, Baltimore College of Dental Surgery, was established in 1863 in the United States of America. The emergence of Korean dentistry was delayed due to the late introduction of modern dentistry during the Japanese occupation (1910 – 1945) and the Korean War (1950 – 1953). The imperialist Japan even licensed the dental technicians and let them practice dentistry freely. It is speculated that such historic background might be one reason for the unique prosthetic restorations in Korea at that time. The purpose of this presentation is to investigate the characteristics of Korean prosthetic restorations performed before 1970.

This study used 74 prosthetic restorations from 57 remains of Korean servicemen excavated from Korea in 2009. These dental remains are believed to be Koreans because they shared similar and unique restorative patterns. Forty-two remains were estimated to be male with 15 having no sex determination. Thirty-six remains were estimated to be young adults (17 – 25 years), four middle-age adults (26 – 40 years), and 17 undetermined.

Single crown and crown and bridge comprised 48 and 26 respectively out of 74 prosthetic restorations. Among crown and bridges, 18 restorations had one or more missing teeth in that structure, but eight restorations didn't involve any missing tooth. An interesting feature is that most of these crowns were oversized compared to normal teeth. Totally, 124 crowns including single crowns (48), abutments (55), and pontics (21) were observed. Fifty-seven were full crowns, 55 were ¾ crowns with open face on the facial surface, and 12 were wrapped crowns with open face at occlusal surface. It is assumed that most of these restorations were probably fabricated not by a casting method but by a sealing-and-forging method because the teeth were barely prepared. Therefore, it was found that many crowns were open at the occlusal, lingual, and facial surface. It is also speculated that even full crowns had very thin occlusal and incisal surface because of the lack of tooth preparation.

Out of 74 prosthetics, 56 restorations (75.7%) were found at the maxillary anterior teeth area while nine (12.2%) were found at the mandibular anterior teeth, six (8.1%) were at the mandibular posterior teeth, and three restorations (4.0%) were at the maxillary posterior teeth area. It is interesting that most restorations on the maxillary anterior teeth area included maxillary lateral incisors (43/56, 76.8%) which were

not missing. According to the traditional Korean beliefs, good luck "leaks" through the space between the teeth. In order to prevent this, soldering rest or big-sized crowns were fabricated. Also, there were no esthetic considerations choosing materials for most of the restorations. For example, cheap metal materials (56/74, 75.7%) were used most often, even for the anterior teeth (87.8%). Some restorations were made of gold (8/74, 10.8%) and stainless steel (10/74, 13.5%).

The characteristics of Korean dental restorations fabricated before 1970 can be summarized as follows. First, crowns have an enlarged shape, probably in order to close the space between teeth. Secondly, restorations are opened or very thin at the occlusal and facial surface due to the difficulties of tooth preparation. Lastly, there is little esthetic consideration for the anterior teeth. These characteristics might help identify Koreans from commingled remains of past wars or disasters.

Prosthetic Dental Restoration, Korean Identification, Forensic Odontology

F14 A Brief History of Forensic Odontology in Turkey

Huseyin Afsin, PhD, Hacikadin Caddesi 18-1 Kocamustafapasa-Fatih, Istanbul, TURKEY; Sadi A. Cagdir, MD, ATK Kimiz Sok No 15, Istanbul, TURKEY; Yalcin Buyuk, MD, Adli TipKurumu Yenibosna, Istanbul, TURKEY; and Beytullah Karadayi, PhD, Hacikadin Caddesi. No 18 Kocamustafapasa-Fatih, Istanbul, TURKEY*

After attending this presentation, attendees will learn about the development of forensic odontology in Turkey.

This presentation will impact the forensic science community by describing different odontological cases in Turkey.

Though being a very important discipline of forensic sciences, the scientific use of forensic odontology as a forensic field in Turkey is new, starting in 1994. The first case was a homicide case with a bitemark and the bitemark was successfully identified; this finding was accepted as evidence by the court. After this, papers on the application of dentistry in forensic cases emerged and increased in Turkish forensic journals. This presentation attempts to summarize the history of forensic dentistry which gained its important role in forensic cases very late in Turkey with sample applications carried out in the Council of Forensic Medicine of Turkey.

Samples of forensic odontology cases in Turkey in a chronological manner:

1993 – A Skeletonized Human Corpse Found in Antalya: A skeletonized corpse was found in the hilly region of Antalya together with his bags. There was information of a missing German tourist who was interested in mountain climbing. Skeletal remains of the case and personal belongings were sent to the Council of Forensic Medicine for identification. The skeletal remains were examined by a forensic pathologist and forensic odontologist and comparison of dental restorations with antemortem dental records resulting in positive identification of the case.

1994 – Bitemark Analysis in Elmali, Antalya: In a homicide case, the photograph of a bitemark on the left humeral region of the victim and a dental cast of the suspect were sent to the Council of Forensic Medicine for comparison. After examination, it was reported that dental characteristics of the bitemark and the dental cast of the suspect were the same.

2003 – A Serial Killer in Istanbul: A serial killer created terror in Istanbul and drew the attention of both the public and press. The victims of the killer were older woman living alone. With the first victim, there were many bitemarks on the arms, face, and buttocks. The next victim was killed by stab wounds. There were bitemarks on this woman as well. One and a half months later, he assaulted an elderly American woman living alone in the same region. After careful examination of bitemarks and comparisons with the dental casts of the suspects, the serial attacker was successfully identified.

2003 – Success in International Works: As a part of the ABFO workshop in Chicago of 2003, photographs of the bitemarks and dental casts of three suspects were sent to eighteen experts for comparison. Using five methods, comparisons were performed, results presented, and the cases were successfully identified.

2003 – Mass Disasters in Diyarbakır: A Turkish RJ 100-type aircraft crashed at the military airport that is also used for civilian flights. Only five persons out of 85 survived. The remaining 72 adults, three babies, and five flight personnel were dead. Despite the presence of the burns (almost to the degree of charring), identification of 55 victims was possible. The identification of five of the remaining 20 victims was carried out by the DVI team from the Council of Forensic Medicine in Istanbul by comparing antemortem and postmortem dental records and photographs.

Historical Cases: Historical skeletal remains were found in Maiden's Castle during an archaeologic dig. Kiz Kalesi (Maiden's Castle) is located on a small island approximately 60km from the Mediterranean city of Mersin. It was reportedly built in the 12th-century AD. During its restoration, archaeologists unexpectedly discovered human remains. After excavation, these remains were sent to the State Institute of Forensic Medicine in Istanbul for dental and cranial examination. V-shaped dental mutilation and craniofacial mutilation were identified in two of the skeletons. These cultural custom V-shaped dental mutilations matched Romero Dental classification A1.

Odontology, History, Identification

F15 Assessment of Age by Teeth

Charles E. Georget, DDS, PhD, and Aime H. Conigliaro, MA*, Institut de Recherche Criminelle de la Gendarmerie Nationale, 1 Blvd Theophile Sueur, Rosny Sous Bois, FRANCE*

After attending this presentation, attendees will be able to understand the methodology for estimating the dental age-aided design software and layout of data and results for how adults and elderly victims died.

This presentation will impact the forensic science community by showing how computerized methodology of age assessment provides reliable ergonomics and how its use in laboratories or mobile laboratories is important. This methodology is currently being tested in the Forensic Science Institute of French Gendarmerie (I.R.C.G.N). The practical applications presented can be used as a guideline available to forensic odontologists.

Each method of age assessment has advantages and disadvantages. The search for precision includes many factors (conditions of nutrition, life, growth, normal or premature aging, and disease). Currently, forensic practices are moving toward a dual assessment of age in two different systems, the evaluation of bone age and dental age (Pasquier 1999).

Age assessment is an important element of dental forensic examination. It is often required by magistrates and investigators as part of the dental analysis. Different methods exist to determine the dental age with the most appropriate depending on the case to be examined. The choice of method is multifactorial and depends not only on the categorical age of the victim (child, adolescent, adult, elderly), but also on the status of the victim (living or dead), and finally the technical constraints.

The goal of this work is to develop a suitable methodology for assessing age in deceased adults and elderly victims. This methodology involves the use of two methods, taking into account the histological and physiological factors. The Lamendin Method (1990) uses the entire tooth without preparation and studies the root transparency (root dentin sclerosis) and periodontosis factors. The Johanson Method (1971), derived from the Gustafson Method (1947), takes into account attrition, secondary dentin, periodontosis, cement apposition, root resorption, and root transparency. A value is assigned to each factor correlated with age. Each factor has seven levels of interpretation. Using two methods tends to confirm the probabilities when the results are consistent. Otherwise, it is necessary to seek the cause of inconsistent results.

A second step consists of automating data collection and calculation of age for both methods. Regarding the Lamendin method, the teeth selected for the evaluation are photographed on a light box. A camera connected to a computer allows shooting with remote target monitor. This photograph is included in the processing software. Measurements of the height of the root, the heights of periodontosis, and root transparency are made, then the estimated age is automatically calculated. On the Johanson method, a fine cut is performed with a microtome equipped with a diamond saw. This cut is photographed and six factors are measured. The results are automatically plotted on a summary explanation.

The use of different dental methods of estimation is interesting. Estimation applied to several teeth of the same victim is recommended. Consistency of results is essential; if there are significant differences, the cause must be investigated. The use of photography and processing software allows reliable measurements, observations, and facilitated automated results. In the end, the system provides significant time savings.

Dental Age Assessment, Lamendin Method, Johanson Method

F16 Correlation Between Biological and Chronological Age of Bodies in Colombia — Exhumed and Identified

Sandra Beatriz Garcia Pinto, DDS, Calle 23 D No 82 - 71 Int. 4, Apt 314, Bogota, COLOMBIA; and Angela Maria Saenz, Calle 55 Bis No. 78-34, Bogota, COLOMBIA*

After attending this presentation, attendees will understand the reasons why there is a need for studies of skeletal remains in samples of Colombian population.

This presentation will impact the forensic science community by showing how some of the methods that are currently applied in Colombia for the estimation of biological age in skeletal remains are not adequatefor such a purpose considering that most of the methods were supported from samples of foreign populations.

In Colombia, there had not been a study to establish the correlation between biological age estimated by skeletal remains using both dental and anthropological analysis methods with the chronological age of the same provided by the National Registry of Civil Status in bodies exhumed and identified from 2005. Age is a key variable for the process of identifying bodies and searching for missing persons; it is important to note that most of the methods used for estimation of biological age in bony debris were performed on samples of foreign populations and only some of these methods have been validated for Colombian populations. In Colombia, there exists a high number of human rights violations. Through the years, dozens of people have disappeared or died due to armed conflict and has resulted in buried and unidentified corpses in unmarked graves, morgues, and cemeteries, which has led to state agencies actively promoting the process of identification. In the course of daily practice, forensic experts often analyze different cases of skeletal remains exhumed somewhere in the country. This is why it is important that estimated biological age in skeletal remains is as close to chronological age of the victim so that the identification process is properly oriented and thus reducing the number of unidentified bodies.

Objective: To determine the correlation between biological age, estimated in skeletal remains, by two analysis methods (dental and anthropological) with chronological age.

Materials and Methods: The study was based on the traditional positive scientific method of investigation and was framed in descriptive research with a non-experimental design. The sample consisted of 123 cases of bodies exhumed, identified, and returned to their families, who were selected at random from a total of 1,070 cases. The determination of the sample and the analysis of the study were conducted with the implementation of Estata 10. Descriptive analysis was made of the information unifying age variables, obtaining averages, and standard deviations. To evaluate, the correlation coefficient used Lin's concordance and correlation with their respective ranges of 95% confidence. The study was approved by the research and ethics committee of the Faculty of Dentistry, Pontificia Universidad Javeriana Bogota-Colombia. Throughout the implementation and application of the results, there was no effect, positive or negative, in the short, medium, and long term, on the environment and natural human health.

Results: A coefficient value was obtained for anthropological analysis Lin (0.782) and dental analysis (0.765).

Conclusions: This research demonstrated, according to Lin, a degree of good concordance; however, there are cases that conclude that some methods are not reliable for the Colombian population. In such cases, to use the biological age as a parameter, identification would exclude a group of bodies in the process of tracing missing persons. Forensic experts apply established methods for estimating biological age. When cases come forward with a wide age difference with the concordance perfect line, this indicates that the proficiency of the forensic experts is good; however, some methods that are currently applied in Colombia for estimating biological age are not suitable for this purpose, considering that most methods were supported in samples of foreign populations.

Studies are recommended in bony debris of Colombian population samples in order to endorse all the methods currently applied for the estimation of biological age.

Biological Age, Chronological Age, Skeletal Remains

F17 Human Third Molars Development: Comparison of 13 Country Specific Populations

Patrick W. Thevissen, DDS, Dendermondsesteenweg 483, Sint-Amandsberg, Oost Vlaanderen, BELGIUM; and Steffen Fieuws, PhD, and Guy Willems, PhD, Katholieke Univ Leuven, School of Dentistry, Kapucijnenvoer 7, Leuven, BELGIUM*

After attending this presentation, attendees will be informed on the detected differences in third molar development comparing 13 country specific population samples.

This presentation will impact the forensic science community by increasing awareness on how the comparisons of third molar development between individuals from different countries revealed distinctions in speed and onset of development, but although reaching statistical significance, these differences were small and not constant over the considered age range.

Dental age estimations in the sub-adult age group are mainly based on the development of the third molar(s). In forensic practice, these age estimations are primarily requested to advise legal authorities in their judgments related to the age of unaccompanied young asylum seekers. Although the majority of age estimation models based on third molar development are constructed on reference samples with ethnically and/or geographically well-described and outlined origin, these studies can rarely be compared for the evaluation of possible ethnical or geographical influences on third molar development.

In an ongoing data collection, previously nine country specific samples (Belgium, China, Japan, Korea, Poland, Thailand, Turkey, Saudi Arabia, and South India) were investigated on third molar development. In the present study, four new country specific datasets (Brazil, Italy, Malaysia, and United Arab Emirates) were added, analyzed, and compared. The goal of this study is to collect country specific databases of third molar development and to evaluate and compare third molar development between the collected countries.

A total of 10,117 panoramic radiographs from subjects out of the previously listed 13 countries were collected. For each country, the individuals were homogeneously distributed in the age range between 16 and 22 years and in sex. Third molar development of all present third molars was registered, according to the ten stages technique of Gleiser and Hunt, modified by Köhler.[1,2] Missing third molars received a zero score. Consequently, each subject received a third molar score sequence for the upper right, upper left, lower left, and lower right third molar, respectively. To obtain a factor score for each subject,

representing the degree of third molar development in the total dataset, a generalized linear mixed model for multivariate ordinal data was fitted on the third molar score sequences of all subjects from the 13 countries. Differences in degree of third molar development between countries were analyzed using gender-specific regression models for these factor scores with age and country as predictors.

Comparisons between countries revealed differences in speed and onset of third molar development. Among the different ages, the degree of third molar development changed between countries in an unordered way. No clear patterns of differences in degree of third molar development could be distinguished between the countries. Compared to all other countries, Belgium subjects were generally developing fastest. As such, using for age estimations purposes, third molar development information from Belgium instead of country specific information will result in underestimated age predictions. This is the best judicial reference if country specific reference information is lacking. Indeed, legally speaking, an advantage is then provided of the doubt for the individual under examination.

In conclusion, no evidence was detected for important differences in degree of third molar development between the 13 examined countries. This implicates that geographical differences between examined individuals are of minor influence on the age predictions based on third molars development.

Age Determination, Third Molar Development, Country Specific Population

F18 Optimal Dental Age Estimation Practice in United Arab Emirates (UAE) Children

Salem Altalie, MSc, OCME, Abu Dhabi Police GHQ, Ministry of Interior, Abu Dhabi, UNITED ARAB EMIRATES; Patrick W. Thevissen, DDS, Dendermondsesteenweg 483, Sint-Amandsberg, Oost Vlaanderen, BELGIUM; and Steffen Fieuws, PhD, and Guy Willems, PhD, Katholieke Universiteit Leuven, School of Dentistry, Kapucijnenvoer 7, Leuven, BELGIUM*

After attending this presentation, attendees will understand how there is a need to develop a United Arab Emirates (UAE) reference model, or that the Willems model can be used to perform dental age estimations in UAE children.

This presentation will impact the forensic science community by imparting knowledge that verifies the Willems model on a UAE sample and comparing the outcomes with the verification of a UAE specific model revealing no or negligible differences.

Willems et al. dental age estimation method for children was developed on a Belgian reference dataset of 2,523 subjects.[1] The goal for this study was to detect if this method could be used for age estimations on UAE children or if it should be modified using a large UAE reference dataset. Furthermore, verification was needed to determine if adding third molars development information to permanent teeth development information in children provides more accurate age predictions.

Retrospectively, panoramic radiographs of 1,900 children with UAE origin and nationality were collected (950 female, 950 male). The selected individuals were homogeneously distributed in the age range between four and twenty-three years. All included individuals who had no medical history and no obvious dental pathology affecting the development of permanent teeth or third molars. The development of left mandibular permanent teeth was registered according to the eight-stage technique described by Demirjian et al.[2] The third molars development was registered using the ten-stage technique developed by Gleiser et al. and modified by Köhler et al.[3,4] The registrations of the tooth development was tested with Kappa statistics on inter and intra observer reliability after rescoring 100 randomly selected panoramic radiographs. The obtained permanent teeth data were used to validate the Willems et al. method. Next, these data were randomly, but stratified on age and sex, divided in a reference and a test dataset. The reference dataset was used to develop a UAE specific model according to the Willems et al. method. The established UAE specific model was verified using the test dataset. Multiple regression models with the scores of permanent tooth development, third molar development, and permanent tooth and third molar development as an independent and age as a dependent factor were developed. These models allowed detecting if adding in child third molar development to permanent tooth development, providing more accurate age predictions.

Almost perfect agreement was detected for intra and inter observer agreement (Kappa >0.86). Verifying the Willems et al. method on the UAE children dataset provided a difference in mean chronological age minus mean predicted age for males and females combined of -0.01 year (overestimation). The verification of the Willems et al. method compared to the verification of the UAE specific model revealed differences in: mean error of -0.12 (F) and 0.12 (M) year, mean absolute error of -0.07 (F) and 0.02 (M) year, and root mean squared errors of 0.08 (F) and 0.01 (M) year. The accuracy of age prediction adding third molar development to permanent teeth development was expressed in an increase of root mean squared errors of 0.02 years for males and a decrease in root mean squared errors of 0.02 years for females.

The results indicate that the Willems et al. model developed on a Belgian reference dataset can be used with negligible error for dental age estimations in UAE children. Adding third molars development information to the permanent teeth information in UAE children does not provide an overall gain in accuracy of the age predictions.

Age Determination, Willems Method, United Arab Emirates

F19 Cementochronology: Improvement of the "Tooth Cementum Annulations" Method for Age Estimation

Thomas Colard, DDS, PhD, Institut de Médecine Légale, Place de Verdun, Lille, 59045, FRANCE; Benoit Bertrand, MSc, Direction de l'archéologie, 227 rue Jean Perrin, Douai, 59500, FRANCE; Stephan Naji, PhD, PACEA, Avenue des Facultés, Université de Bordeaux 1, Talence, 33405, FRANCE; and Didier Gosset, MD, PhD, and Anne Becart, PhD, Institut de Médecine Légale, Faculte de Médecine, Place de Verdun, Lille, FRANCE*

After attending this presentation, attendees will understand and appreciate how the Tooth Cementum Annulation (TCA) method can provide accurate results for individual age estimation, which is one of the most crucial biological variables obtained during an osteological examination of human remains.

This presentation will impact the forensic science community by demonstrating how the TCA method improves the field of age assessment through a distinct physiological phenomenon.

Growth markers can be found both in bones and teeth, the latter being the most reliable due to their hard and compact composition. Within tooth tissues, acellular cementum begins its regular growth with tooth

eruption and then continues to be produced throughout as incremental layers of alternating dark and light bands of controversial origin. Cementochronology, or TCA, involves the counting of these incremental lines in tooth root acellular cementum using light and polarized microscopy.

Stott et al. (1982) were the first to precisely correlate the number of cementum annulations directly to calendar age in humans. Since then, many researchers published correlation rates above *r=0.9* effectively making cementochronology the most precise technique for individual skeletal age estimation.

In this study, 250 recent teeth from known age individuals, collected at the Lille Dental Surgery Department, were used. Within this sample, 50 teeth were specially extracted because of periodontal disease and 50 were selected from individuals above 65 years of age. The study focused on two main issues in order to improve the TCA method:

1. Correlation between estimated age and calendar age, with a specific attention to the influence of periodontal health and advanced age.
2. Better understanding of the histologic structure of the observed light and dark layers, using Raman Spectrometry.

In the first part of the study, all teeth were embedded in a two-component epoxy resin and dried in a vacuum chamber. Six sequential 100mm – 130mm undecalcified cross sections were prepared for each tooth, from the middle third of the root, with a precision saw, in order to be properly observed under light and polarized microscopy. QSegments that showed readable lines were captured as JPEG images and read with appropriate software. Three observers were involved in each counting process.

In the second part of the study, five finely polished, thick cross sections (700mm), essential to optimal exploitation of Raman spectrometry, were prepared.

The results showed a statistically significant (Spearman Test) strong correlation ($r > 0.88$ for all observers) between estimated age and calendar age. Inter observer errors were minimal between the three observers (Pearson's $r > 0.9$) with the highest correlations obtained from the most experienced author. Also demonstrated was the influence of periodontal disease and old age, which both decrease the accuracy of the technique.

The Raman spectrometry observations yielded promising preliminary results that seem to indicate a difference of orientation of hydroxyapatite crystals and collagen fibers rather than a difference in organic or mineral composition between incremental layers.

Odontology, Age Estimation, Tooth Cementum Annulations

F20 Updating a Dental School Forensic Odontology Curriculum in the Post 9/11 Era

Harry K. Zohn, DMD, 150 River Rd, Bldg B, Ste 2B, Montville, NJ 07045; Roger A. Mitchell Jr., MD, HCME, 1885 Old Spanish Trail, Houston, TX 77054; Lawrence A. Dobrin, DMD, OCME, 471 E Westfield Ave, Roselle Park, NJ 07204; Sheila Dashkow, DDS, 7675 Maple Ave, Pennsauken, NJ 08109; and Gerald Guzy, DDS, 492 Hensler Ln, Oradell, NJ 07649*

After attending this presentation, participants will be able to describe a predoctoral forensic odontology curriculum responsive to community needs post 9/11, develop a well-rounded curriculum in forensic odontology, and develop partnerships between a dental school and a regional medical examiner's office to offer student rotations to a medical examiner's office.

This presentation will impact the forensic science community by stimulating the interest of future dentists to the field of forensic odontology, providing graduating dental students with an understanding of the importance of record keeping and the role of their patient records in a victim identification effort, and developing a cadre of dentists who will have the necessary foundation knowledge to volunteer in a time of crisis.

This paper presents a course developed to reflect the current needs of the dental curriculum in a post 9/11 world and to help prepare dentists to serve their community.

The overall objective is to familiarize senior dental student with the various aspects of forensic dentistry including an overview of the role of the medical examiner, medical legal investigator, the forensic dental team, and the community dentist; as well as an introduction to victim identification based on dental records, bitemark analysis, photography for the forensic dentist, forensic anthropology, and forensic dental software. In addition, the course has been designed to provide students the foundational knowledge necessary to be a productive member of a mass fatality forensic identification team.

Curriculae include:

- **Introduction to Forensic Dentistry and Medicine**: This is a general overview of the field.
- **The Forensic Dental Team**: An explanation of the various components of the forensic dental team, roles of the various components of the team, and how to create a forensic dental team.
- **Dental Identification**: The importance of assisting in victim identification and what role the forensic dentist plays in the identification.
- **Bitemarks and the Role They Play in Criminal Investigations**: A discussion of past and present research into bitemark analysis and the uniqueness of the human dentition.
- **Mass Disasters**: The role of the dentist in assisting and making a dental identification during a mass fatality incident, i.e., antemortem, postmortem, comparison, and recovery teams.
- **Forensic Anthropology**: This lecture reviews the role of the forensic anthropologist in assisting in the identification of victims of a mass fatality incident as well as the unknown.
- **The Role of the Medical Legal Death Investigator (MLDI)**: This lecture covers what an MLDI is and their function relative to an investigation.
- **The Role of All Dentists in Forensic Dental Investigations**: This lecture covers the dentist's legal and ethical obligation during a forensic investigation, their role regarding record keeping, and their obligations to cooperate with the authorities when records are requested.
- **The Medical Examiner's Office**: This lecture explains the role of the Medical Examiner's Office within the community from monitoring illness to death investigations.
- **Imaging**: This lecture explains the role photography and radiology plays in victim identification and bitemark investigations and the pros and cons associated with forensic photography as it relates to dentistry.
- **Forensic dentistry software**: This session will expose dental students to the various types of software programs available to aid in victim identification of persons unknown and for managing mass disasters.

An optional rotation will provide an opportunity for students to visit the Northern Regional Medical Examiner's Office in Newark, New Jersey, to enable senior dental students to become familiar with the day-to-day workings of a medical examiner's office. Dental students must have attended the didactic forensic dentistry elective offered by the New Jersey Dental School. This is a unique opportunity for dental students to witness firsthand, as well as having a hands-on experience, in the field of forensic odontology. The rotation takes place over three consecutive days from 8:30 a.m. to 1:00 p.m and two students at a time participate in the rotation so as not to interfere with the day-to-day operations of the office.

The students shadow the medical staff of the office while they are performing their daily duties. On the third day of the rotation, each student is required to give a 15-minute presentation on dentistry/forensic odontology. The presentation is given to the Medical Examiner's office staff, medical students, and medical residents rotating through the Medical Examiner's Office. After the presentation, the students accompany dental school faculty associated with the Medical

Examiner's Office to the autopsy area. Students will participate in a hands-on experience of doing dental examinations and obtaining radiographs on a decedent.

Forensic Odontology, Curriculum, Education

F21 Aligned Education, Cooperative Learning, and International Collaboration in Forensic Dentistry

Armin A. Farid, DDS, Podmaniczky Utca 33, III Fl, 8, Budapest, HUNGARY*

After attending this presentation, attendees will gain a clearer understanding of the effects of international collaboration in the establishment and development of forensic dentistry in countries where this science has not received attention in the past.

This presentation will impact the forensic science community by raising awareness that, through aligned education, learning, international collaboration, and exchange, forensic dentistry can become an integral and vital part of police investigation work and disaster victim identification everywhere.

In the dental forensic community, it is a known fact that some countries are more advanced than others in utilizing forensic dentistry in crime investigation and/or disaster victim identification while others struggle to achieve a united vision and understanding among the different government agencies involved. Therefore, it becomes the moral and ethical responsibility and privilege of the more advanced forensic communities to engage in a collaborative effort to integrate this science into police investigation work in the less developed territories.

An example of this kind of international collaboration took place in Hungary where interest in the field of forensic dentistry first emerged at a time when little attention was given to this topic due to low criminal activity. Upon attending seminars and courses on the topic in the United States, including the symposium offered at the Center for Education and Research in Forensics in San Antonio, and through continued education, learning, and support from colleagues and mentors in the United States, this learning and experience was brought back to Hungary. The importance of bitemark analysis and victim identification was brought to light not only for the Hungarian Crime Scene Investigation Team but also for the general public through the mass media. Furthermore, a Disaster Victim Identification Forensic Expert Team was established which is now under the umbrella of the Hungarian Police Department. Additionally, the Hungarian Immigration Body is exploring possibilities to implement an age estimation program based on wisdom teeth development, a program originally developed and taught by the University of Texas Health Science Center at San Antonio.

This knowledge and awareness has not been limited to Hungary. The International Law Enforcement Academy (ILEA) in Budapest, which is run by the FBI, has asked for these topics to be incorporated into the training of their international police recruits and agents. Thus, the knowledge has been transmitted to Bulgaria, Kosovo, Romania, Macedonia, Montenegro, and other countries in Europe. The Semmelweis Medical University Department of Forensic Medicine in Budapest, which has integrated bitemark analysis, age estimation, and disaster victim identification into its curriculum, has contacted its partner agencies in Israel and, as a result, the National Israeli Police has so far arranged two workshops on bitemark analysis with follow-up programs for in the near future. Moreover, upon completion of their dental education at the Semmelweis University, newly trained dentists bring their knowledge and learning back to their home countries including Germany, Norway, Austria, Sweden, the United Kingdom, Greece, Cyprus, Iran, Israel, and other countries in the Middle East.

These incredible unforeseen accomplishments have been made possible because of the continued collaboration, exchange of knowledge and ideas, accompaniment and capacity building, and the support and encouragement received from mentors and colleagues working in the field in the United States. In facing common challenges and service to humanity, the concept of accompaniment and assistance in developing capacities are vital in chartering an individual path for progress. Great accomplishments in public service are achieved through unity of vision and action and mutual and ongoing collaboration and support.

Education, Learning, Collaboration

F22 Mass Disasters: Training Dentists in Switzerland

Michel M. Perrier, MS, Av de Rumine 7, Lausanne, SWITZERLAND*

The goal of this presentation is to present and discuss a model for continued training in odontology applied to the context of a mass disaster.

This presentation will impact the forensic science community by showing a model of continuing education in mass disaster management aimed at dentists.

In recent years, the variety and the quantity of mass disasters such as transportation accidents, terrorist attacks, bombings, earthquakes, and nuclear accidents have increased.

Accurate identifications of victims remain one of the critical issues in the management of any mass disaster. Most of the time, visual recognition is an insufficient and unscientific approach to obtain reliable results. Dactyloscopy, genetic analysis, and odontology are the best techniques that may lead to a positive identification. These methods need to be performed by specific experts along with the general autopsy.

The teeth are among the most resistant structures of the human body and thus represent a high potential of individualization in situations of highly decomposed, cremated, or skeletonized bodies.

In order to optimize the chances of obtaining reliable results, any postmortem, antemortem, and reconciliation procedure has to be carried out by an odontologist who has sufficient training in this discipline.

Any mass disaster involving a high number of victims may involve a sudden larger number of professionals to cope with the need of rapid and accurate identification.

Since 2006, the Medicolegal Institute of the University of Lausanne and the Disaster Victim Identification Unit of Switzerland has organized organizing courses designed as an introduction to the essentials of odontological identification. The participants learn the basics of identification: postmortem examination, analyses of antemortem records, and reconciliation. They are also exposed to the key features of odontological identifications based on fragmentation and commingling in the context of a mass disaster. They learn how to use the DVI digital identification system (PlassData).

Currently, the courses span two days. In 2006, 2007, 2009, and 2012, the program was advertised to approximately 400 dentists in the French-speaking part of Switzerland. It was also advertised in the monthly Swiss Journal of Odontostomatology. In each case, over 200 dentists responded but only 30 could enroll because of the limitations inherent to the organization of practical, hands-on exercises.

The speakers and other staff (odontologists, forensic scientists, and investigators) are appointed on the basis of their academic training, experience in the field of identification, and teaching experience. All of the specialists have actively participated in the management of several mass disasters.

The first day of the course comprises an introduction to legal medicine, to forensic odontology, and to the principles of odontological identification. This theoretical part is followed by a practical exercise of identification of human dentitions carried out by teams of two participants.

During the second day of the course, the participants are introduced to mass disaster management. After a theoretical introduction, practical exercises are carried out to simulate a mass disaster scenario in which mixed fragments of human dentitions have to be identified.

The activities and behavior of the participants as a whole group and within the teams are observed by the teaching staff that is present throughout the course.

Each participant receives a written evaluation form designed to assess some general features of the course, such as overall organization and the usefulness and quality of the provided information. In addition, each participant is asked to define his or her motivation in attending this type of training. Last but not least, each participant has to assess his or her readiness to become involved in the management of a real mass disaster event on short notice and for an indefinite period of time. Every questionnaire distributed to the participants is returned to the organizers for thorough analysis.

Any motivated participant is then invited to be involved in a continuing education system organized by the DVI of Switzerland to keep up.

The presentation consists of a critical assessment of the course's organization, follow-up, and the feedback that was received.

Odontology, Mass Disaster, Education

F23 "Ri.Sc." Database: The Italian Governmental Solution Regarding Missing Persons and Unidentified Cadavers

Emilio Nuzzolese, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari, ITALY*

After attending this presentation, attendees will have an understanding of the issues arising from Italian legislation on missing persons and unidentified bodies and how the collaboration of forensic odontologists can rapidly facilitate the identification process.

This presentation will impact the forensic science community by stressing the importance of a high degree of collaboration between police, the family of the missing person, and forensic odontologists.

Dental identification is one of the principle ways in which a cadaver can be positively identified. The results of a dental autopsy partially constitute the information which leads to the creation of a general biological profile through which initial compatibility testing with antemortem cadaver information may be executed.

In Italy, since April 1, 2010, in the Sistema Ricerca Scomparsi (Ri.Sc) missing persons search system database for missing persons and unidentified cadavers, the forensic odontologist has been able to play an active role with the medical examiner regarding the compilation of the Ri.Sc. form in order to collate pertinent dental data and oral radiographs of the cadaver with the goal of making a positive identification.

In order to test the functionality of the record system itself, the system was used on a sample of four unidentified cadavers (one well-preserved cadaver, one decomposed, one skeletonized, and one carbonized). The study revealed that the recording system allows for an immediate and simple method of data collection for the creation of a general biological profile while at the same time allowing for amplification of the odontological profile.

The forensic odontologist is of fundamental importance, not only in the analysis of the restorations *in situ* in the oral cavity but also for maxillary and dental radiography from which geographical origin, personal habits, and an estimated dental age can be derived.

Digital radiographs are easily archived and may be forwarded and used as an internal instrument of comparison for the Ri.Sc. system. The PM record "dental section" should be compiled by both a medical examiner and an odontologist.

This study underlines the importance of the dentist also being an expert in forensics so that all pertinent information may be retrieved and rendered useful for identification purposes and thus archived as a complete profile of the unidentified cadaver. This importance should also be underlined during the collection and coding of antemortem dental data during investigative procedures carried out by investigative police who do not have odontologists as part of their team of specialists who are routinely commissioned to deal with this type of data collection. With this in mind, a checklist to facilitate both the investigative police and the relatives of the missing person has been compiled regarding the collection of all dental data. The odontologist could also record information revealed during the postmortem exam on an appropriate international form, such as those suggested by Interpol, should the nationality of the cadaver be uncertain. Interpol forms are aimed at the identification of mass disaster victims, but in light of the lack of an international standard for antemortem and postmortem odontological data and the need to overcome language barriers and diversities in foreign legal systems, they are also an excellent way of fostering the mutual exchange of information which may lead towards the positive identification of unidentified human remains.

Missing Persons, Human Identification, Forensic Odontology

F24 What Are We Accomplishing With Dental Information? Obstacles Facing Forensic Odontologists and Working Solutions

Donna A. Fontana, MS, NJ State Police, Office of Forensic Sciences, 1200 Negron Dr, Hamilton, NJ 08691; Stuart E. Alexander, DMD, 19 N Main St, Cranbury, NJ 08512; and Sheila Dashkow, DDS, 7675 Maple Ave, Pennsauken, NJ 08109*

After attending this presentation, attendees will be able to understand the importance of a multidisciplinary approach to entering dental information into national databases, such as the National Crime Information Center (NCIC) and the National Missing and Unidentified Persons System (NamUs). Additionally, attendees will be able to understand the obstacles encountered and the solutions needed in the process of ensuring accurate dental coding.

This presentation will impact the forensic science community by emphasizing the importance of working with law enforcement, medical examiners/coroners, and forensic odontologists. In this way, forensic odontologists will be able to acquire, evaluate, interpret, and code missing and unidentified person's cases. Furthermore, through NamUs, families of missing persons are now aware that vital information of their loved ones is available in national databases, providing hope for future identification. It is not uncommon for potential matches to be made through the information provided by family members who routinely search the Internet. For this reason, it is vital that a protocol be provided that will ensure that the dental information is accurately entered into the appropriate databases in hopes of securing a positive identification.

The initial phase of this initiative concentrated on the NCIC dental coding entries and their inaccuracies. In identifying this problem, protocols were phased in to correct coding and thus ensure dental accuracy in NCIC. The initiative obtained original dental records and radiographs, provided coding review by experienced forensic odontologists, and digitized dental radiographs.

The second phase of this initiative now encompasses over 200 cases entered in both NCIC and NamUs. Observations and experiences since the initial phase have called for modifications and streamlining of protocols due to the prevalence of miscoded dental data. The accuracy of New Jersey's dental information has greatly improved in NCIC and NamUs since the inception of this initiative which can better assist in additional positive identifications; however, challenges remain. There have been many obstacles that have been encountered in continuing this initiative. These include the lack of reviews by more than one experienced forensic odontologist when coding missing and unidentified persons, the recognition that family dentists are unfamiliar with the different database codes, thus providing inaccurate dental information, and the awareness that law enforcement working missing person cases rely on the information provided by the family dentist. These and other obstacles will be discussed. Ensuring accuracy is still of paramount importance to this initiative in order to provide an avenue for positive identification.

By identifying these obstacles during this second phase, there is currently a concentration on creating training models in dental coding to forensic odontologists, education models for the law enforcement community, and on networking with families and family dentists. Solutions to these challenges such as access to additional training and more experience and familiarity with the coding systems for missing and

unidentified persons will also be discussed. This presentation will discuss the information learned throughout this second phase. It is anticipated that the obstacles and possible solutions presented in this presentation would help to assist other jurisdictions in the productive management of dental information into our national databases. This can only improve the identification of unidentified persons in this country and around the world. An overall update on the current status of this initiative will be presented.

Dental Information, NCIC, NamUs

F25 Contrast Enhancement of Bitemark Images Using the Greyscale Mixer in ACR in Photoshop®

Sam T. Evans, MPhil, Cardiff Univ, School of Dentistry, Dental Illustration Unit, Cardiff, UNITED KINGDOM*

After attending this presentation, attendees will have an understanding of the method employed in this experimental image enhancement technique and be aware of the limitations in use as evidence.

This presentation will impact the forensic science community by helping investigators research the benefits and limitations of image enhancement techniques in analysis of bitemarks and patterned bruises.

Forensic odontology can best be defined as the overlap that represents the dental and legal professions. Bitemark analysis is one aspect in which a forensic dentist can assist the courts. Teeth are often used as weapons, and the resultant bitemark can aid forensic odontologists to exclude or otherwise appraise a suspect's dentition. Claims that the size, shape, and pattern of the biting edges of the upper and lower anterior teeth are specific to an individual have recently been challenged, leaving the question of uniqueness of the dentition unresolved.

Analysis of bitemarks for the purpose of identifying a perpetrator is further compounded by distortion introduced into the bitemark and its record from the moment of infliction. Researchers have recently revisited the concept that skin is a poor impression material and the resultant difficulties that this imposes on bitemark analysis. Movement during infliction and the lapse of time also introduce distortion, which complicates further the interpretation of a diffused patterned bruise.

In recent years, the advent of digital photography has, among other things, made possible the application of digital enhancement to an image, thereby increasing the possibility of achieving better edge definition for analysis. A number of studies have demonstrated such use of computer software to enhance the edge definition of patterns within images in various forensic applications. Some examples include color separation, which uses algorithms within Adobe® Photoshop® for removal of distracting background patterns from fingerprint and handwriting evidence, and Red, Green, Blue (RGB) channel extraction, which removes one or more of the three RGB channels to decrease background interference in a variety of crime scene images. A similar method is used in footmark analysis where details are extracted and the background information is reduced by viewing the image separated into RGB and Cyan, Magenta, Yellow, Black key (CMYK) color channels. The layers containing information or distractions can be identified and, following a mixture of blending and removing color layers, the subject can be made clearer.

In an attempt to apply more subtle and precise enhancement methods to the analysis of bitemark images, a novel contrast enhancement technique based on the adjustment of the brightness pixel values, similar to that attained by the level or curves function in Photoshop® was developed. This studies goal was to acquire initial data on the end user's preference for either RGB color, greyscale, or the grayscale-enhanced images in order to validate the benefit of this contrast-enhancement technique. With the understanding that there are other inherent problems affecting bitemark analysis, which will not be overcome by applying edge-definition enhancement. The suggested technique goal is to widen the range of tools available to the expert when looking to undertake bitemark analysis.

Enhanced images may improve bitemark edge definition, assisting forensic analysis. Current contrast enhancement involves color extraction, viewing layered images by channel. A novel technique, producing a single enhanced image using the greyscale mix panel within Adobe® Camera Raw®, has been developed and assessed here, allowing adjustments of multiple color channels simultaneously. Stage 1 measured RGB values in 72 versions of a color chart image; eight sliders in Photoshop® were adjusted at 25% intervals, all corresponding colors affected. Stage 2 used a bitemark image, and found only red, orange, and yellow sliders had discernible effects. Stage 3 assessed modality preference between color, greyscale, and enhanced images; on average, the 22 survey participants chose the enhanced image as better defined for nine out of ten bitemarks. The study has shown potential benefits for this new technique; however, further research is needed before use in the analysis of bitemarks.

Bitemark Analysis, Contrast Enhancement, Adobe® Photoshop®

F26 Lip Prints: The Argument for Research in Cheiloscopy

Winnie Furnari, MS, 82 Onondaga St, Yonkers, NY 10704*

The goal of this presentation is to report and describe the existing research on cheiloscopy. Attendees will discern that there is sufficient evidence from the literature to determine the need for further efforts to include lip prints as a means to identification.

This presentation will impact the forensic science community by demonstrating the potential cheiloscopy has on identification as a sole or supportive paradigm. The forensic science community will be asked to accept the uniqueness and forensic value of lip prints as a legitimate identification method. The argument will be made for the need of further study in order to use cheiloscopy as a means of identification and possible adjunct in bitemark analysis.

A very different, less known, and unconventional form of identification is presented. Cheiloscopy is the study and examination of lip prints. The human lips have a pattern as do fingers, palms, and feet. They have been referred to as grooves, wrinkles, lines, and creases with extremely fine details. It is a form of impression evidence similar to ear prints and elbow prints. Of late, these have been the topic of varied research and are also occasionally mentioned in literature by a detective, crime scene investigator, or an examiner in another field of evidence comparison. Subject comparisons have been recorded in the thousands. They have been done at universities using students and in specific communities throughout the world. Research studies on lip prints have been contributed mainly by forensic dentists and anthropologists in countries throughout the world. This includes, but is not limited to, Brazil, Spain, Germany, Russia, Japan, Canada, India, Saudi Arabia, France, Italy, Great Britain, Iran, Czechoslovakia, and Poland.

One method of comparison appears often. It was designed by Tsuchihashi in 1970. The lips are divided in segments and the grooves are typed and compared. Examiners determine if the pattern is Type I—vertical, Type II—Branched, Type III—Reticular, or Type IV—Undetermined. There has been much success in identification via the recorded prints on cellophane tape and white paper. This method has been reported exclusively in the recent research. Researchers have also been studying the patterns more associated with gender and raise the possibility of determining gender from lip prints.

The search for existing studies was made through Pub Med, and Scopus using the search words "lip prints" and "cheiloscopy." There were 35 retrieved. Thirty-three were in English, one in German, and one in Russian. These articles range from the years 1970 to 2011. In order to evaluate the latest published reports, the bulk of the articles retrieved (24) were published from 2005 to 2011. Some of the publications included: *Journal of Forensic Odonto-Stomatology, Forensic Science International*, *Indian Journal of Public Health Research & Development*,

Journal of Forensic Dental Sciences, and *Journal of Forensic Identification*.

The key to the argument is in latent lip prints, those not made by any cosmetic material and unseen by the naked eye. These are not usually "dusted" at crime scenes. Nor have they been considered when a bitemark is present. Research would be able to aid in finding out whether or not the latent lip print can be lifted around a bitemark on human skin. A forensic pathologist, Esperanza Navarro, and others in Spain researched this on cadavers using invisible lipstick (commercially obtained cosmetic) but the need is present to test on human subjects. Studies should include lip prints using lipstick, and the latent prints made by invisible lipstick and no cosmetics at all. If this can be done, it would be an enormous adjunct to bitemark analysis. The potential to match lip prints to a suspected biter would further validate bitemark analysis. A proposal will be made to a university IRB committee in the interim.

Cheiloscopy, Lip Prints, Bitemarks

F27 Study of the Palatal Rugae Patterns Among the Indians and Chinese at Manipal, India

Shankar M. Bakkannavar, MD, Pradeep K. Gouda, MD, and Manjunath Sathyanarayanachar, MD, Manipal Univ, Kasturba Medical Coll, Dept of Forensic Medicine, Manipal, INDIA*

After attending this presentation, attendees will: (1) gain knowledge about the existing problem of identification in mass disasters and the role of a forensic odontology in relation to this; (2) be briefed on the various comparative data and techniques that are useful in establishing the identity of an individual with specific stress on the upcoming field of palatoscopy or rugoscopy; and, (3) gain information on the various palatal rugae patterns in an individual and application of this knowledge in a given population to aid in establishing identity.

This presentation will impact the forensic science community by shedding new light on the less explored field of rugoscopy. It provides sufficient information of the biological diversity present in this part of the Indian subcontinent. It may prove useful in comparison to other studies of a similar nature and can be applied to various other populations. This research will arouse an interest in others to conduct a similar study in their respective countries which may go a long way in aiding the establishment of the identity of an individual. In other words, we, the medical community, will be better prepared in facing mass disasters to help mankind.

In this world of natural and man-made disasters, identification of an individual becomes an important task for any Disaster Victim Identification team. In almost every disaster, there is an urgent and pressing need to identify the victims on behalf of the next of kin. Comparative data/techniques play a vital role to aid in identification.

Palatoscopy or palatal rugoscopy is the name given to the study of palatal rugae in order to establish a person's identity.[1] Despite the ongoing problem of describing palatal rugae pattern, qualitatively and quantitatively, their uniqueness to individuals has been recognized as providing a potentially reliable source of identification.[2-4] Rugae patterns have been studied for various purposes mainly in the fields of anthropology, comparative anatomy, genetics, forensic odontology, prosthodontics, and orthodontics.[5] The present study is an attempt to compare the palatal rugae patterns among the Indians and Chinese students at Manipal from a small part of peninsular India.

Maxillary dental casts of 63 Indian (32 males, 31 females) and 61 Chinese (31 males, 30 females) students of the age group 17 – 23 years were assessed for the length, shape, and unification of rugae based on the classification by Thomas and Kotze (1983).[6] Association between rugae forms, ethnicity, and gender were tested using 2-way ANOVA (Univariate Analysis of Variance) and contingency tables.

Statistical analysis showed the total number of rugae on the right side of the palate was greater among the Indians than the Chinese. Females had a larger number of curved and straight rugae whereas males had more wavy rugae in both races. The incidence of rearward-directed rugae was greater among the Chinese females and Indian males than their respective counterparts. There was no significant difference in the converging and diverging type of rugae among the Indian and Chinese populations of both sexes.

The statistical analysis of the data revealed significant differences among the Indians and Chinese. Rugae patterns are complex and are so open to individual interpretation that a very careful observation is essential. These patterns are highly individualistic and could form a useful tool to aid in identification, especially in cases of mass disasters.

Mass Disaster, Identification, Palatal Rugae

F28 Anterior Bite Force and Association of Bitemarks with Dental Models

Robin A. Scheper, DDS, 24240 Club View Dr, Gaithersburg, MD 20882*

After attending this presentation, attendees will be able to: (1) measure maximum voluntary anterior bite forces, generated at baseline and aroused emotional states; (2) assess force consistency from day to day; and, (3) review the effect of an emotional state on bite force to assess whether dentists with forensic experience can match photographs of wax bite impressions to corresponding dental models.

This presentation will impact the forensic science community by providing foundational data to direct future research that evaluates the validity of human bitemark analysis in criminal investigations.

Teeth are used as weapons for offensive (perpetrator) and defensive (victim) purposes, and bitemark injuries are often evident on victims of sexual assault, child abuse, and homicide.[1] Assailants often use their front teeth to inflict injuries. Although bitemarks are analyzed in criminal investigations, the science supporting bitemarks as evidence is weak.[2] In addition, bitemark analysis is confronted by numerous controversies and challenges.[3-5] How emotion influences anterior bite force is unknown, and whether experts can correctly associate bitemarks and dental models has not been substantiated.[6] An improved understanding of the factors that affect how and why human bitemark injuries are made will enhance analysis of bitemarks as evidence during investigation and prosecution of such crimes.

Phase 1 of this pilot study measures maximum voluntary anterior bite forces, generated at baseline and aroused emotional states, to assess: (1) force consistency from day to day; and, (2) the effect of an emotional state on bite force. Phase 2 assesses whether dentists with forensic experience can match photographs of wax bite impressions to corresponding dental models.

Phase 1: Thirty participants will have stone dental models fabricated from full arch dental impressions. Participants will make four maximum anterior force bites on a wax-covered gnathodynamometer on two separate days (two bites each day). They will be asked to rate their baseline stress level on a 100mm visual analogue scale (VAS) with 0 = no stress and 100 = the worst stress imaginable. Stress will be

assessed before each bite. Before the fourth bite, each participant will be asked to recall an event that aroused anger (and re-estimate their stress level). Photographs will be taken of the wax impressions made by the second and fourth bites. Phase 2: Five dentists with forensic experience will attempt to match photographs of the wax bite impressions to corresponding dental models.

Phase 1: Mean bite force will be calculated for the four bites and compared using Repeated Measures ANOVA and Tukey HSD post hoc tests (α=0.05) to determine (1) if baseline bite forces (bites #1, #2, and #3) differ from one another, and (2) from the anger induced bite force (bite #4).

Phase 2: The number of correct matches will be recorded and percent agreement calculated for each examiner. Kappa statistics will assess the level of agreement.

F29 Transfer of Dental Patterns to Human Skin

Hannah Holtkoetter, MS, Nienborgweg 20, Munster, GERMANY; Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, S Campus, Buffalo, NY 14214; H. David Sheets, PhD, Dept of Physics, 2001 Main St, Buffalo, NY 14208; and Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main St, Buffalo, NY 14214*

After attending this presentation, attendees will: (1) understand how tooth characteristics may not be reliably transferred and recorded in the bitten subject; (2) understand that alterations in height and displacement of particular teeth may affect the position of adjacent teeth in the bitten subject; and, (3) be introduced to additional distortion in a bitemark.

This presentation will impact the forensic science community by providing a better understanding of how individual tooth characteristics are recorded in bitten tissue.

Previous studies on human cadaver models have reported significant levels of distortion of bitemarks in skin, and matches among the anterior dentition in open population studies have been found. The goal of this study is to establish a threshold as to what degree of difference in shape of one dentition will be distinguishable from another as reflected in a bitemark in human cadaver skin.

HSIRB exemption was granted for this project. Eight sets of dental casts were produced and divided into two groups. One group varied the affects of height changes in teeth while the other varied tooth displacement affects. In the first group, the lateral incisors were systematically shortened in 1mm increments up to 3mm. In the other group, the lateral incisor and canine were facially/lingually displaced in 1mm increments up to 5mm. Each of the models was scanned on a flatbed scanner for comparison with the bitemarks they produced.

A series of ten repeated bites, distributed over arms and legs of unembalmed cadavers, were inflicted with each model, and digitally photographed with an ABFO #2 scale in place.

Comparison analysis using landmark-based geometric morphometrics indicated that alterations of a limited number of teeth not only introduced additional distortion in the bitemark, but also affected the apparent position of adjacent teeth in the bitemarks. Displacing the lateral incisor and canine resulted in a relative shift in position of the central incisors and unaltered canines, while the shortening of the lateral incisors resulted in a shift in relative position of the central incisors. Moreover, the features of displacement were more pronounced in the inflicted bitemarks than in the dentition used to make the bites, thus the bitemarks tended to exaggerate the differences. Also, the observed distortion was more significant in the mandibular than maxillary arch, suggesting that the mandible expresses higher variation than the maxilla.

Thus, due to shift in relative tooth position and resulting distortion, nearly every bitemark consequently looked unique, and no matches within measurement resolution were found between the bitemarks and the dentition used to inflict them. It was found, however, that a displacement of 5mm between teeth enabled distinction between the dentitions. No such threshold of distinction could be established for the height variation of teeth under the given experimental conditions. In other words, it was not possible to establish a reliable threshold of how different dentitions have to be in order to be distinguishable from one another.

The study was conducted under a controlled situation on cadaver skin with limited variables. In a real biting situation, more variables are involved, such as dynamics of the bite or movement of the victim, which would possibly lead to more distortion of a bitemark than under the controlled conditions of this study. The results of this study indicate that bitemark evidence should be used with caution.

Bitemarks, Bitemark Research, Distortion

F30 Violating the "Biologic Width" — Is It Worth It?

Gregory S. Golden, DDS, 8577 Haven Ave, Ste 105, Rancho Cucamonga, CA 91730*

After attending this presentation, attendees will comprehend the importance of the natural biologic width of gingival attachment that exists in human dentition, and why it is necessary to determine its actual dimensions prior to crown lengthening procedures. Violation of the biologic width leads to post-operative gingival hyperplasia, bleeding, and severe pain.

This presentation will impact the forensic science community by educating odontologists engaged in civil dental malpractice case review and establishing the criteria for understanding the importance of maintaining the biological width, accurate documentation, and record keeping during their own general and prosthetic work, and assist in the civil litigation cases they may review in the course of forensic investigation of dental malpractice. A case presentation will photographically depict and verbally describe the events and procedures leading to a failed prosthetic reconstructive result, investigation of the post-operative consequences with a conclusion of gross negligence and perjury by the defendant, and resolution of the treatment performed by the defendant.

Traditional crown lengthening is a frequent procedure used to reduce excessive gingival display (gummy smile).[1,2] Treatment involves close coordination between the treating restorative dentist and the periodontist in order to protect the biologic width of the connective tissue attachment. This is pre-determined by sulcus depth probing wherein the biologic width is sounded and a periodontal flap is used to expose the root surfaces and alveolar bone.[2,3] Bone is then removed and the gingiva repositioned according to the appropriate width of the attachment.[4,5]

A 39-year-old female patient consulted a well-known and highly profiled cosmetic dentist from Orange County, California, for treatment of her gummy smile and repair of a discolored front tooth which had an unsightly fracture sustained as a teenager. The dentist then proceeded to complete 3mm gingival recontouring by laser surgery and preparation of 22 teeth in two hours and forty minutes, resulting in severe pain in several of the patient's teeth. Following a series of unsuccessful subsequent appointments, the patient and her husband determined that they should seek second opinions from several specialists in the area.

It was concluded that not only were several teeth over-prepped, which required eight root canals to alleviate pain, all crowns needed to be removed and replaced after correct crown lengthening, along with correction of a malocclusion created by the original restorations.

The litigation by binding arbitration occurred over seven days, wherein experts from both plaintiff and defendant testified to their opinions. During testimony by the defendant, it was found that records were falsified and that pre-treatment and post-treatment photos and models had been purposely destroyed by the defendant.[6] Subsequent damages award, current and future economic loss, and court costs were given to the plaintiff in excess of $700,000.

This case study is an example of what may occur after neglecting the importance of the biologic width in prosthetic and reconstructive cosmetic dentistry, and the need for maintaining accurate records.

F31 Dental Death — Unfortunate Fatal Results From Errors of Omission and/or Commission

Richard R. Souviron, DDS, 336 Alhambra Cir, Coral Gables, FL 33134*

After attending this presentation, attendees will learn the serious and fatal results from both medical and dental errors in judgment. They should learn the importance of making a proper diagnosis, as well as taking a complete history and treatment plan for what may seem a minor dental condition.

This presentation will impact the forensic science community by discussing the seriousness of dental infection, and how the lack of proper and timely treatment can lead to the death of a patient. Likewise, the omission of following the American Heart Association (AHA) and American Dental Association (ADA) standards for pre-medication may and can result in the death of a patient. By recognizing the serious consequences of not following proper preventive procedures, the practitioner should be cautious and mindful to avoid the errors of omission and/or commission that can result in fatal consequences.

This study covers over 35 years experience in reviewing over a dozen cases of death from dental treatment or lack thereof, all the cases having been ruled natural as to manner of death. The causes range from SBE (sub acute bacterial endocarditis) secondary to dental treatment, subdural empyema from dental infection or CVA (cerebral vascular accident) from discontinuation of anti-coagulant medications. Dental infection, whether from an abscessed tooth, periodontal disease, or defective root canal treatment can result in systemic infection and death of a patient. The improper protocol for IV sedation has had the unfortunate result of death of the patient. Does this breach of the standard of care rise to the level of manslaughter? The dental professional has a duty to his patient to know his/her medical history and always consult with the primary physician when there is a question or need to alter medications. The injection of local anesthesia containing epinephrine should be used with extreme caution when treating medically compromised patients such as ones with pulmonary edema.

Pre-medication requirements have changed over the years from one gram twice a day for one day before, day of, and day after an invasive procedure, to today's single dose of two grams one hour before procedure. For patients at risk, not following the proper protocol may have fatal results. Something as simple as a restoration at the crest of the gingival—a Class V—can cause bleeding and thus require the necessary pre-medication protocol. In cases of patients with prior rheumatic fever, damaged heart valves, or those with any type of valve replacements, any invasive dental procedure such as extractions, implants, cleanings, certain fillings in sub gingival cases, and crown preparations may seed the *Streptococcus Viridans* bacteria that is present in the oral cavity and produce SBE (subacute Bacterial Endocarditis). The dentist is responsible for taking precautions with this infection and must follow the AHA's and ADA's guidelines.

It seems only logical that a medical history be taken before treatment is instituted and reviewed for any potential problems of the proposed treatment. Why would a dentist perform an extraction in the presence of cellulitis, a history of dizzy spells, weight loss, constant severe unilateral headaches, and not take a temperature, review prior medical history, and make a timely referral? A simple extraction of a wisdom tooth on a 23-year-old male did not cause his death. But the undiagnosed systemic infection with subdural empyema present did. All dental practitioners need to be more aware of the seriousness of dental infections, reaction to anesthetics, importance of medical history, and strict adherence to pre-medications in order to avoid these tragic consequences.

Empyema, Manslaughter, Cellulitis

F32 Passing *Voir Dire* and Avoiding Cross-Examination: A Follow-Up Case Report

Henry J. Dondero, DDS, 2 Emerald Dr, Glen Cove, NY 11542*

The goal of this presentation is to show how the forensic odontologist must be able to defend in court whatever forensic evidence was promulgated by established methodology.

This presentation will impact the forensic science community by encouraging forensic odontologists to be aware of the techniques involved with being an expert witness.

This case was used as an example of proper coding techniques presented at the American Academy of Forensic Sciences' Annual Scientific Meeting in February 2009, by Dashkow, Fontana, and Dondero. This is a follow-up presentation to highlight the litigation techniques used especially in preventing a possibly devastating cross-examination experience.

In July of 2008, skeletonized remains were discovered in a wooded area adjacent to the Southern State Parkway, in Nassau County, New York. A preliminary estimate based on the extent of decomposition and local climate conditions fixed the time of death at six to eight months. Initial examination by a forensic anthropologist was that the remains were of a Caucasian female approximately twenty-eight to thirty-two years of age. A forensic pathology examination determined a cause of death to be by "blunt force trauma" to the skull resulting in numerous fractures of the cranial structures. Most significant was a fracture extending from the left frontal-parietal suture across the frontal bone through the right orbital ridge. The New York State Police could not find any missing person from this period to match this individual.

Initial forensic dental examination revealed an intact maxilla with all sixteen teeth present. Several amalgam restorations were noted. Seven digital periapical radiographs were taken and a clinical dental chart was produced. Teeth numbers seven and nine were subsequently removed for DNA analysis.

The intact yet disarticulated mandible was then examined. All teeth were present except for numbers twenty-three, twenty-four, and twenty-six, which appeared to have been lost through postmortem evulsion. Several amalgam restorations were also noted to be present. What was noted immediately was the presence and full eruption of both third molars as well as an impacted supernumerary "fourth" molar located distal to both third molars. Seven digital periapical radiographs were taken and a clinical dental chart was produced.

The State Police investigator was notified of the uniqueness of the decedent's dentition. The investigator contacted the New York State

Dental Society which agreed to send an email to its members asking if anyone had possibly examined a patient with such a dental anomaly. Dr. Frank Pappas received the email and forwarded it to a New Jersey colleague, Dr. Sheila Dashkow. Dr. Dashkow recalled entering a missing person's dental information with similar characteristics into the database and contacted the New York State Police investigator who forwarded this information to Dr. Henry Dondero. Dr. Dashkow emailed a copy of the missing person's panoramic radiograph and a tentative identification was made. Several days later, the original radiograph was brought to the Nassau County Medical Examiner's Office by the State Police where the identification was confirmed and an affidavit of Dental Identification was completed.

In April 2010, Dr. Dondero was notified by the Bergen County Prosecutor's Office was notifed that testimony would need to be required in this case. This case was mainly circumstantial in nature and the forensic evidence overwhelmingly corroborated the prosecution's assertions. The prosecutor was concerned that the defense would be highly critical of all the forensics. In preparation for trial, the procedures for dental identification were reviewed as well as Dr. Dondero's *curriculum vitae* which was anticipated to be scrutinized in *voir dire*. During opening statements, the defense postulated that the forensics were faulty because of the time difference between the approximate date of the crime, October 2007, and discovery of the remains, July 2008. Even the circumstances surrounding the identification would be questioned.

At trial, the prosecution spent considerable time reviewing many details contained in the *curriculum vitae* before making a motion to have the testimony accepted as an expert witness, which he was without objection. In describing the identification process every procedure was explained in detail and the prosecution asked very pointed and probing questions. Antemortem and postmortem radiographs of every restoration were compared and shown to the jury. The pedigree of the original radiographs was documented as well as the unique search for the missing person record. No cross-examination was forthcoming and all dental evidence was accepted.

***Voir Dire*, Cross-Examination, Litigation**

F33 Developing Age Estimation Standards for a Western Australian Population Using the Coronal Pulp Cavity Index

Shalmira Karkhanis, MFS, and Daniel Franklin, PhD, Univ of Western Australia, Center for Forensic Science, MBDP M420, 35 Stirling Hwy, Crawley, AUSTRALIA*

After attending this presentation, attendees will understand the principles and application of the coronal pulp cavity index method for age estimation. This is a non-invasive and simple age estimation method based on secondary dentin deposition. It has significant forensic applications because this method can be applied in living individuals who do not have the appropriate proof of age documentation.

This presentation will impact the forensic science community by describing the process of formulating age estimation standards specifically developed for a Western Australian population. As a result of increasing global mobility, contemporary age estimation standards are required and this study contributes to the body of information in this regard. This method facilitates in chronological age estimation in living individuals based on an uncomplicated and non-destructive method.

Age estimation is an integral aspect of forensic odontology and a crucial element toward establishing the positive identification of living individuals and skeletal remains. In modern multicultural societies where legal and illegal immigration is rising, an increasing demand exists for age estimation in living persons who have no documentation for proof of identity. Age estimation methods, such as aspartic acid racemisation and cementum apposition, require sophisticated laboratory techniques and are time consuming. Furthermore, these methods analyze extracted teeth and, hence, are unsuitable for application in living individuals and/or situations where extractions are not possible for religious and cultural reasons. Simple, non-invasive, and accurate methods are therefore required for age estimation in adults to develop population-specific standards.

Previous research has verified the association between age and secondary dentin deposition. The subsequent reduction of the coronal pulp cavity and its correlation with chronological age is assessed in a Western Australian population following the method of Drusini et al.[1] A total of 450 digital orthopantomograms (220 female and 230 male) from a Western Australian population were analyzed. The age range was 9 to 60 years with a mean age of 28.33 years for females and 27.71 years for males. The crown height (CH) and coronal pulp cavity height (CPCH) was measured in mandibular premolars and molars (excluding third molars) using the in-built visualization software. The tooth coronal index (TCI) was calculated using the formula TCI=CPCH x 100/CH. Linear regressions were performed by regressing the TCI against chronological age. The standard error of estimate (SEE) for the pooled sample was lowest at ±9.64 years for the mandibular left first and second molars. This was followed by the mandibular left second molar and first molars at ±10.74 and ±10.78 years respectively. In females and males, the SEE was lowest for mandibular left molars at ±9.54 years and ±9.74 years respectively. The SEE values obtained by Drusini et al. for their pooled sample ranged between ±5.88 years for the right side molars, to ±6.66 years for the left side premolars.[1] Although the SEE values in this study are considerably higher than those obtained by Drusini et al., these standards will be useful in classifying a Western Australian individual within adult age groups (i.e., young, middle, and older adult).[1]

The level of accuracy achieved using the coronal pulp cavity index is higher as compared to methods using skeletal markers, such as the sternal extremity of the fourth rib (SD=14.93 years in an American population) and the pubic symphysis (SD= 12.4 and 12.2 years for females and males respectively in Phase VI).[2,3] This study represents the first ever investigation of this method in a Western Australian population and the results indicate the method is suitable for forensic application.

Age Estimation, Secondary Dentin, Western Australia

F34 A Comparison Between Restorative and Flowable Resins at Varying Temperatures Using X-Ray Fluorescence

Robin A. Scheper, DDS, 24240 Club View Dr, Gaithersburg, MD 20882*

The goals of this presentation are to describe: (1) the uniqueness of inorganic properties of various resin materials; (2) the change in properties of resins when exposed to high temperatures; and, (3) the significance of these findings as they relate to victim identification.

This presentation will impact the forensic science community by increasing understanding of how documentation in the dental chart of the brand names of the restorative materials used is critical and may further strengthen the ability to provide positive identifications of remains.

With cosmetic dentistry becoming more in demand, the use of amalgam has steadily declined over the past decade. Although more esthetically pleasing, resin composite restorations pose a unique challenge to the forensic dentist when it comes to identifying remains, as they can be difficult to see clinically and on radiographs. If the remains have been incinerated, visual identification of restorations becomes

even more challenging. Resin composites are comprised of two primary components: organic monomers and inorganic fillers. It has been shown that the inorganic composition is, for the most part, unique to the brand.[1] The use of an SEM with Energy Dispersive X-ray Spectroscopy (SEM/EDS) has proven useful in identifying the elemental composition of specific resin restorative materials.[2] However, the SEM/EDS is a large machine, and it is not practical for a field or morgue setting. A portable X-ray Fluorescence spectrometer (XRF) can be used to overcome this challenge, and still correctly identify resin composition.[3] This table clinic will use XRF to determine compositional differences among three brands of conventional and flowable resin composite materials at various temperatures.

Three brands of conventional and flowable resin composites were chosen: Filtek Supreme (3M ESPE), Esthet-X (Dentsply), and TPH3 (Dentsply). Twelve disks of resin material (two from each type/brand), 1cm in diameter, were prepared and cured according to manufacturer's instructions. Six individual disks (one from each type/brand) were then placed in a ceramic crucible and placed in a burnout oven and heated from room temperature to 300°C, 600°C, and 900°C, with a 30 minute hold at each temperature. The portable XRF was scanned over the disks both at room temperature and after being heated at each of the three target temperatures. The X-ray spectra were compared to the control disks and to the manufacturer's stated elemental compositions.

Dental identification can be challenging in the best of circumstances. When remains are incinerated, the ability to obtain fingerprints and DNA is either gone or greatly diminished. This places the burden of scientific proof on the forensic dentist. The antemortem dental record, including both written text and radiographs, is an absolutely critical piece of the identification puzzle. Because the inorganic components of resin composites are unique to the type and brand of material, accurate documentation in the dental chart of the brand names of the restorative materials used is critical, and may further strengthen the ability to provide positive identifications of remains.

F35 The Use of the Incise Dental Scanner to Compare Bitemarks in Cheese With Models of the Suspects' Dentition

Mark Hector, PhD, Administration Office, Dental School, Park Pl, Dundee, UNITED KINGDOM; Peter Tomlins, PhD, and Lifong Zou, PhD, Barts and the London School of Medicine & Dentistry, Queen Mary, Univ of London, Garrod Bldg, Turner St, Whitechapel, London, UNITED KINGDOM; and Amal Al-Ali, DDS, 199 Weedon House, Du Cane Rd, London, UNITED KINGDOM*

After attending this presentation, attendees will become better aware of how digital imaging techniques can be used in the quantification and analysis of bitemarks.

This presentation will impact the forensic science community by providing insight into how the application of digital imaging technology may help in the more objective assessment of deformations caused by weapons or tools in the investigation of crimes.

This study presents a technique developed for 3D imaging and quantitative comparison of the human dentition and bitemarks created in a perishable substrate, cheese. Six adult volunteers from the biometric lab, Queen Mary, University of London, had study casts made of their dentition and also bit into 40mmx20mmx20mm blocks of cheese. Impressions of the bites were made in putty fixture (Extrude, type 0, Germany). The dental models and the corresponding bite impressions were digitized by a contact coordinate measuring machine, (Incise Dental Scanner). The digitization strategy was set as follows: 1mm-diameter probe tip of 30mm length, scanning at Y direction, 0.1mm scanning interval, and scanning speed of 500 points per minute. The dental and bite models from which the incise Dental Scanner can capture coordinate data, from these data points, produces a model of the surface, thus providing a means of obtaining objective and accurate measurements and comparison of morphology.[1] Sets of dental models and corresponding bite impressions were numbered. This technique allows pattern association comparison to be made between the 3D images of the dental models and a bitemark.

Data analysis was based on the use of a 3D image analysis software package Cloud (UCL).[2] It is a versatile tool used to reconstruct 3D coordinates (X, Y, Z) into a color digital image for visualization and to analyze a free form surface. Cloud software has several tools for digital model analysis and measurement. It provides functions of superposition, calculates the geometric shapes, and analyzes the geometric relationship of surfaces. Superposition as a method of comparison is the procedure of bringing geometric objects into appropriate alignment but is dependent on the quality of the 3D digitized images of these objects.

The biting edges are usually the only clear feature in a bitemark and, therefore, were selected as the reference frame for the comparison. Based on the mathematical least square within the common area in the registration procedure using the Iterative Closest Point (ICP) algorithm within the software, the two surfaces were superposed; at this superposed position the difference along the surface at each single digitized point then was calculated and displaced on the computer screen corresponding to the cursor position on the image.[3] Different colors present depth differences between the surfaces: zero differences represented by sea blue color; +10µm to +20µm differences presented by orange, red, and purple; black colors represent -10µm to -20µm differences. Furthermore, the Cloud software provides the absolute numerical differences between the two superposed images; these differences demonstrate the distribution of the differences in relation to every single registered point.

A pattern-associated comparison using the superposition method between the 3D digitized images of the dental models and their corresponding cheese impressions was performed demonstrating a high degree of similarity of the incisal edges outline confirmed to be produced by the corresponding model. The descriptive statistics revealed that the average differences between the dental models and their corresponding bite impressions range between 0 and 3µm and mode between ±12µm. The standard deviation and the square root of the mean were exactly the same which recorded a range between 9µm and 11µm. These findings agree with the distribution of the absolute differences between the images which was extracted from the subtracted image and plotted using bar graph; the data was in bimodal shape with the peaks falls around ±10µm.

F36 What Should Counsel Do in a Bitemark Case? Competency of Counsel Issues in the Post-Conviction Context

Alissa L. Bjerkhoel, JD, 225 Cedar St, San Diego, CA 92101*

After attending this presentation, attendees will understand the prevalence of wrongful convictions in cases that contained bitemark evidence and guidelines for defense counsel who engage in seeking out and investigating these cases post-conviction.

The presentation will impact the forensic science community by serving to identify the very serious and continued implications of prior flawed bitemark evidence and providing those seeking to rectify wrongful convictions guidelines to do so in order to end the continued suffering of those convicted on the basis of such evidence.

The scientific validity of bitemark comparisons has been challenged for many years. In 1985, two researchers wrote: "crime-related bitemarks are grossly distorted, inaccurate, and therefore unreliable as a method of identification." Similar conclusions were reached in a study of wrongful convictions. Finally, those criticisms were echoed in the recently published study of the National Research Council entitled "Strengthening Forensic Science in the United States: A Path Forward" (NAS Report). Of the nation's 941 known exonerations, 225 involved false or misleading forensic evidence, including bitemark evidence. There are numerous examples of people who were convicted on the basis of bitemark analysis and later exonerated by subsequent DNA evidence. The DNA exonerations of Ray Krone, Bennie Starks, Kennedy Brewer, Roy Brown, Willie Jackson, James O'Donnell, and Calvin Washington provide clear evidence that bitemark evidence continues to be a cause of wrongful conviction across the nation.[1-4]

It is important to note that, despite the documented problems with bitemark "matches," bitemark exclusions are still considered reliable and can be extraordinarily helpful in the post-conviction context. For example, the NAS Report states: "Despite the inherent weaknesses involved in bitemark comparison, it is reasonable to assume that the process can sometimes reliably exclude suspects." Similarly, Wilkinson's and Geroughty's article points out: "It is easier to conclude that a person's dentition and a bitemark do not match than it is to find a match. This is due to the fact that any unexplained inconsistency between the bitemark and the dentition means that the suspect could not have made the bitemark." One case currently pending in front of the California Supreme Court is that of William Richards. In 1997, Richards was convicted of killing his wife, Pamela. In his third jury trial (the other two resulted in hung juries), the prosecution, for the first time, introduced evidence which suggested that Richards was responsible for a bitemark found on Pamela's hand and that only 2% of the population had a dentition (like Richards') which could have made that bitemark. In a later post-conviction hearing, Richards proved that the bitemark evidence was false and that the statistics presented at trial had no factual basis. In addition, using new computer technology to correct for distortion, Richards proved that he could not have been responsible for the bitemark.[5]

The colossal injustices and failures in the U.S. justice criminal system which lead to the conviction of the innocent are becoming ever more apparent. The flippant use of bitemark evidence in the past has been troubling and the continued use of such evidence despite the known problems is worrisome. Defense counsel should critically evaluate any case in which bitemark evidence was involved and there is a potential for innocence. To adequately represent such defendants post-conviction, defense counsel should be cautious to collect all of the original documentation, photos, and notes relied upon by the prosecution's bitemark experts, evaluate the bitemark for possible exclusions, seek DNA testing on any swabs of bitemarks, and talk to the original prosecution experts to see if their position has changed. Further suggestions will be discussed.

Defense Counsel, Post-Conviction, Wrongful Conviction

G1 A Peculiar Case of a Perineal Injury Miming Sexual Abuse in a Child Run Over by a SUV

Sara Gioia, MD, and Fabio Suadoni, MD, Via Tristano di Joannuccio SNC, Terni, ITALY; and Massimo Lancia, MD*, and Mauro Bacci, MD, Univ. of Perugia, Via Del Giochetto SNC, Perugia, ITALY*

After attending this presentation, attendees will become aware of the occurrence of non-intentional traumatic anogenital injuries in children run over by motor vehicles. These accidents can sometimes conceal the findings of sexual abuses.

This presentation will impact the forensic science community by underlying the necessity of making investigations and carefully putting forward opinions, in a multidisciplinary perspective, led by the strict application of the forensic medical methodology.

A case is described of a suspected pediatric sexual abuse case, involving a nine-year-old female. The girl, while running out of her stepfather's shop, was run over by a slow-moving SUV. The stepfather had a crimal record for prior sexual abuse.

When the ambulance arrived, the little girl was found locked in the shop restroom. The girls mother did not want the doctor to enter. After repeated requests, the doctor entered the restroom where he saw the girl standing with bloodstained panties and trousers. Additional bloodstains were observed in the toilet bowl. Deeply upset and in a state of amnesia, the girl first refused to be seen by the doctor. She relented due to repeated requests and was taken to the first aid hospital in Terni. Multiple excoriations on upper and lower limbs were found by the medical staff who also confirmed the presence of the bloodstains in the panties.

A gynecologist was contacted who, because of the girl's reluctance, decided to continue the exploration under general anesthesia. He described a second-degree perineal laceration between the labial back commissure and the anal sphincter of 2.5cm long which was soon sutured. According to the gynecologist, this injury could be due either to a sexual abuse or post-traumatic injury from the road accident.

The doctors at the hospital reported the fact to the judiciary which, because of the girl's stepfather's criminal records, started a file of documents in the event of a sexual abuse (Art. 609 bis; art. 609 ter, Italian PC). The judiciary entrusted inquiries to the Carabinieri and to the department of forensic medicine in Terni.

The inquiries, at first, strongly indicated sexual abuse and showed that the road accident occurred unexpectedly, while the child was trying to elude her stepfather; however, when questioned by the medical examiner, new witness evidence had been admitted together with an examination of the SUV. Only after these further inquiries did he exclude any hypothesis of violence and declared that the perineal injury was due to the car accident.

In literature, perineal and anogenital injuries are described as the consequence of a car.[1-6] As a matter of fact, these injuries can resemble the ones caused by sexual abuses.

The finding of an anogenital injury in a child can become a diagnostic dilemma in distinguishing a sexual abuse from a non-intentional injury, and medical examiners should always ponder both possibilities, especially if the history is vague or appears unlikely.

A multidisciplinary approach, led by an experienced medical examiner, is fundamental in such cases in order to avoid misdiagnoses. The latter could have devastating results for the children and their families.

Perineal Injury, Sexual Abuse, Road Accident

G2 A Molecular Approach: Species Composition of the Maggot Mass in Human Cadavers in the Pineywoods Ecoregion of Southeastern Texas

Sarah E. Bahlmann, BS, 15511 Oakmont Cub Ct, Houston, TX 77059; Ashleigh M. Faris, BS, 131 Freddie Dr, Georgetown, TX 78626; Sibyl Bucheli, PhD, Sam Houston State Univ, Dept of Biological Sciences, Box 2116, Huntsville, TX 77341; and David A. Gangitano, PhD, 14723 TC Jester Blvd, Apt 1118, Houston, TX 77068*

After attending this presentation, attendees will understand that through collection, extraction, quantification, amplification, and sequencing analysis of the DNA from maggots that colonize a human corpse, the species composition of the maggot mass can be determined. Until now, the maggot mass has been assumed to be of a multiple species composition due to the observation that several species of females will visit the body within a 24-hour period. It was unknown if adult female flies of different species would lay their eggs in the same location on a corpse as other adult female flies. This study tested the hypothesis that a maggot mass is composed of several different species of larval flies.

This presentation will impact the forensic science community by demonstrating how a maggot mass composed of multiple species will bear significant impact on fly developmental studies and growth rate models since the presence of one species can slow or accelerate the development of another species. These developmental rates will thus have a direct effect upon the Postmortem Interval (PMI) estimation. DNA-based methods for identification of maggot species are preferred since the first and second instars of many forensically related maggot species are difficult to identify due to the lack of defining anatomical characteristics and identifying each maggot according to distinguishing morphological characteristics can be time consuming. In addition, the process can suffer from human error if performed by an untrained forensic entomologist.

Depending on time of day and ambient temperatures, adult flies arrive at a human cadaver within minutes to hours after the body has been placed outdoors to decompose. During initial human decomposition, it has been observed that several adult female fly species arrive at the body. Adult female flies arrive gravid and oviposit

immediately. The resulting eggs hatch after a period of time dependent upon the temperature, rate of body decomposition, species of the maggots, and other factors, resulting in the maggot mass. Even closely related carrion species can differ in growth rates, diapauses response, and/or ecological habits. Therefore, accurate identification of an insect specimen is crucial for PMI estimation.

First and second instar maggots were collected from three bodies from September to November 2011. Maggot DNA was extracted using a silica-based method and quantified by real-time PCR. Co-Oxydase enzyme I (COI) and Co-Oxydase enzyme II (COII) gene sequences were amplified by PCR and sequenced. COI and COII are unique markers that are highly conserved because they code for respiratory processes making them species-specific genes. Sequencing products were analyzed by capillary electrophoresis with fluorescent detection. Preliminary data on the second cadaver, through phylogenetic analysis, showed that four first instar samples were related to *Cochliomyia macellaria* and that twelve first instar samples were related to *Phormia regina*. This preliminary data supports the hypothesis that the maggot mass is composed of multiple species.

Forensic Science, DNA Typing, Forensic Entomology

G3 Unusual Work-Related Fatality: Importance of Scene Investigation Combined With Autopsy Findings

Giancarlo Di Vella, MD, PhD, Lucia Tattoli, PhD, Giorgia Pinto, MD, and Biagio Solarino, PhD, Univ of Bari, Piazza Giulio Cesare, Bari, 70125, ITALY*

After attending this presentation, attendees will understand the importance of the reconstruction of an unusual, fatal occupational accident by a detailed workplace investigation, combined with the evaluation of circumstantial, radiological, surgical, and, most of all, autopsy findings. The definition of a fatal accident at work adopted by the European Statistics of Accidents at Work project is "accidents at work leading to the death of the victim within a year (after the day) of the accident." In Italy, the main source of information about occupational injuries is the Institute of Insurance for Occupational Illness and Injury (Istituto Nazionale per l'Assicurazione degli Infortuni sul Lavoro; INAIL). According to INAIL, in 2011, 920 Italian workers died from work-related injuries. The majority of the accidental deaths occur either immediately at the time of the accident, or within a few days or a few weeks after the accident.

This presentation will impact the forensic science community by emphasizing how autopsy can play a key role about the reconstruction of the dynamics involved in the occupational event, allowing the identification of any legal responsibilities of the worker or the employers.

A case is presented of a 44-year-old man who was working in a building site, driving a tractor with a rear-mounted flail mower. While he was mowing grass close to a crane, he was struck in his left eye by something propelled by the mower's blades. The victim was rescued by his coworkers and brought to a local emergency department in a comatose state. At the hospital, a CAT scan of his brain revealed a metallic foreign object in the left occipital area, which had penetrated the left eyelid and orbital bone, making a channel into the left fronto-temporo-parietal region. Despite early craniotomy and intensive care, the victim died four days later and organ donation was authorized. Trying to understand the dynamics of the event, a medicolegal autopsy was performed. The external examination of the body showed a 0.6cm wound on the left superior eyelid. A 0.6cm keyhole wound on the superior wall of the orbital bone was also found. During gross examination of the brain, left hemisphere findings included a subdural hematoma, subarachnoid hemorrhage, and intra-axial hematoma. In the occipital lobe, a fragment of a frayed copper cable segment was found which was 4cm in length and 0.3cm in diameter. No alcohol or drugs of abuse were found in the blood, and urine collected at autopsy. The cause of death was identified as diffuse brain damage due to a penetrating head injury.

The workplace investigation showed the presence of a severed electrical cable, partially buried, protruding from the ground, just beneath the mower. The cable revealed the same characteristics as the fragment found in the brain. Therefore, it was thought that, as the man was driving the tractor, the moving mower blade hooked the electrical cable, pulling it out from the ground and severing it. A piece of that cable was projected forward striking the victim's head as he turned to investigate the obstacle interfering with his mowing.

In the case presented, the pre-autopsy reconstruction of the work-related fatality was incomplete because of the lack of detailed information concerning the accident scenario. In fact, it is known that there are many potential contributing factors to work-related accidents including: the nature and duration of the work; type of equipment, tools, or machinery used; the environmental conditions; and, the behavior of the worker. In the majority of cases, the information provided to inspectors and the police by coworkers facilitate a reasonable reconstruction of the occupational accident, but sometimes only the autopsy may detect the real cause of the death and what actually happened to the victim at the scene.

Brain Injury, Occupational Fatality, Workplace Investigation

G4 Iron in the Human Brain: Age-Related Changes and Anatomic Region Specific Differences

Patricia Ramos, BSc, and Agostinho Almeida, PhD, Porto Univ, Rua de Jorge Viterbo Ferreira n. 228, Porto, PORTUGAL; Nair R. Pinto, MS, National Institute of Legal Medicine and Forensic Sciences, Avenida da Portela, 193, Paços de Brandão, PORTUGAL; Ricardo Mendes, MD, Rua S. Sebastiao n. 10, Frossos, Braga, PORTUGAL; and Teresa Magalhães, MD, PhD, and Agostinho Santos, MD, PhD, Porto Univ, Jardim Carrilho Videira, Porto, PORTUGAL*

The goal of this presentation is to show the first results of a research work aiming to clarify the role of iron in brain functions, and particularly its implication in neurodegeneration. Since neurodegenerative diseases are strongly age-related and there is a specific region of the central nervous system that seems to be particularly affected in each disease, the main objectives of this research are to study: (1) the changes on iron levels in human brain in relation to age; (2) the regional anatomic differences of iron levels within the brain; and, (3) the differences between individuals with and without evidence of neurodegenerative diseases.

This presentation will impact the forensic science community by giving epidemiology background data concerning iron levels in the healthy human brain. Since no updated and comprehensive data about trace elements in the human brain are available, this study is a relevant scientific contribution for establishing "normal" human brain levels, allowing a comparison with a brain affected by neurodegenerative diseases in an attempt to clarify trace elements' role in the disease process.

The etiology of neurodegenerative diseases is multifactorial, assuming that it involves a complex interaction between natural aging, environmental factors, and genetic predisposition. The involvement of trace elements, particularly iron, in neuronal damage in distinct areas of the brain has been demonstrated in Alzheimer's and Parkinson's disease. However, despite the research work that has been done on the relationship between trace elements and neurodegenerative diseases, the evidence is still fragmentary, and their role remains poorly understood. Most of the current information about the relationship between trace elements and human brain functioning is based on animal studies or relies on determinations in cerebrospinal fluid, blood, and serum. To fulfill this lack, iron levels were quantified directly in human brain tissue in this research. Direct determination of trace elements in samples from patients with neurodegenerative diseases and normal individuals is essential to extend the

understanding of the underlying disease mechanisms, to validate animal models, and to develop therapies that can delay or reverse neurodegeneration processes.

Two groups of individuals submitted to autopsy, performed at the North Branch of the National Institute of Legal Medicine and Forensic Sciences of Portugal, in the first quarter of 2012, were studied. Group A consisted of ten individuals in each age sub-group: 50 – 60; 60 – 70; 70 – 80; 80 – 90 and over 90-years-old. Ten healthy accident victims 20 to 30-years-old were included as controls ("baseline"). Group B consisted of individuals submitted to autopsy with previous diagnosis of Alzheimer's and Parkinson's disease. After verifying all current legal regulations in Portugal for human tissue collection for scientific research purposes, the following areas were sampled from each individual: (1) frontal cortex; (2) superior (2 – A) and medium (2 – B) temporal; (3) basal ganglia including, caudate nucleus (3 – A), putamen (3 – B) and globus pallidus (3 – C); (4) cingulated gyrus; (5) hippocampus; (6) inferior parietal lobule; (7) visual cortex of the occipital lobe; (8) midbrain including the substantia nigra; (9) pons—locus coeruleus; (10) medulla; and, (11) cerebellum—dentate nucleus. Iron levels were determined by Graphite Furnace Atomic Absorption Spectrometry after the microwave-assisted acid digestion of samples.

Results showed that iron distribution in an adult human brain is not homogeneous: the highest levels are found in basal ganglia and the lowest in pons and medulla. In specific areas, iron deposition seems to be age-related since there is a direct correlation between iron levels and age, namely in putamen, cingulated gyrus, visual cortex of the occipital lobe, midbrain, and cerebellum. However, in caudate nucleus and globus pallidus, iron levels seems to decrease with age. In Alzheimer's disease, significantly increased iron levels in basal ganglia were found when compared with healthy people of the same age sub-group.

Aging, Iron Accumulation, Neurodegeneration

G5 Atherosclerosis in Youth — A Study in the North of Portugal

Agostinho Santos, MD, PhD, and Dina Almeida, MD, Porto Univ, Jardim Carrilho Videira, Porto, PORTUGAL*

The goal of this presentation is to study the prevalence and severity of atherosclerosis via autopsies performed on victims aged between 18 and 45 years of age in the North of Portugal, regardless of the cause of death, in order to better understand its impact on the Portuguese population.

This presentation will impact the forensic science community by providing information regarding the prevalence of atherosclerotic vascular disease and how it has been on the rise in developed countries, and the increasingly early onset of acute diseases caused by this phenomenon which may be fatal, particularly acute myocardial infarction or stroke. It is, therefore, essential to discover the prevalence and severity of this disease, especially in the younger population, as in the majority of the cases it is "silent" and the first manifestations of malaise may be sudden death.

International statistics indicate that by 2020, cardiovascular disease, particularly atherosclerosis, will become the leading cause of reduced quality of life due to the resultant disability, morbidity, or sudden death.

Few studies have been performed for this age group in Portugal, and investigations were based on the study of cadavers, being able to determine the prevalence and severity of atherosclerotic disease in young individuals. This will, therefore, give some knowledge as regards the prevalence of atherosclerosis in this age group in Portugal. Another objective is to determine whether results collated with the existing data in international literature of the same subject

In order to assess the extent of disease in the population, vascular tissue samples were collected from all individuals aged 18 to 45 years, regardless of cause of death, who had been autopsied at the Forensic Pathology Service of the North Branch of the National Institute of Legal Medicine.

In each selected case, some of the factors associated with this pathology were also noted: gender, age, smoking, hypertension, obesity, as well as the presence or absence of cardiovascular disease in the family history.

All legal proceedings in Portugal for sampling were observed, and in each case, collection and processing of vascular structures were performed. Particular focus was given to some arteries of larger calibers (ex: aorta, iliac artery, pulmonary artery) with analysis of the type of vascular injury (lipidic striae/atherosclerotic plaque/atheromatous calcification and/or ulceration) to compute a severity score in terms of atherosclerosis.

Arteries of lower calibers responsible for the irrigation of some important organs (ex: middle cerebral artery, coronary artery, renal artery) were also studied. All samples were stained with hematoxylin-eosin and categorized into qualitative classes of increasing severity related to the degree of arterial obstruction utilizing specific software for measuring the vascular percentage of each arterial obstruction (Image J software). The histological examination of the atherosclerotic plaque tissues included the study of its components: presence of calcification, degree of macrophagic infiltration, density of intraplaque vessels, plaque hemorrhage and some of its possible complications, such as thrombosis.

In the majority of the cases studied, manifestations of atherosclerotic disease, including cases in which no risk factors were identified prior to the arterial study were found. In some of the cases, the cause of death was directly associated with the atherosclerotic phenomenon. The results obtained through the study of the arterial specimens in order to better understand the prevalence and severity of atherosclerotic disease will be presented.

This study will also draw attention to an increasingly early onset of cardiovascular disease in the Portuguese population, which will necessitate the implementation of measures involving the control or reduction of some avoidable risk factors, namely those related to lifestyle (eating habits, physical activity, smoking, etc.), particularly in some public facilities like schools or companies.

Atherosclerosis, Sudden Death, Portugal

G6 Utility of Multi-Phase Postmortem Computed Tomography Angiography in Two Lethal Cases of Great Height Falls: A French Experience

Camille Rerolle, MD, Hospital Trousseau, Service de Medecine Legale, CHRU Tours, Tours, FRANCE; Fatima Zohra Mokrane, MD, Frederic Savall, MD, and Anthony Blanc, MD, Centre Hospital Univ Rangueil, 1 Ave Professor Jean Pouilhès, Toulouse, FRANCE; Pauline Saint-Martin, MD, Hospital Trousseau, Service de Medecine Legale, CHRU Tours, Tours, FRANCE; Hervé Rousseau, PhD, Daniel Rouge, MD, Norbert Telmon, MD, PhD, and Fabrice F. Dedouit, MD, Centre Hospitalier Univ Rangueil, 1 Ave Professeur Jean Poulhès, Toulouse, FRANCE*

After attending this presentation, attendees will understand the utility of investigating great height fall deaths by postmortem CT angiography.

This presentation will impact the forensic science community by showing how the pre-autopsy postmortem CT angiography can complete the conventional autopsy results and help to understand more precisely the death chronology.

Background: Multi-Slice Computed Tomography (MSCT) has been introduced in forensic sciences in the last decade and the efficacy of this technique has been proven, especially for bone injuries. The use of enhanced MSCT has been recently developed in order to improve detection of vascular injuries and traumatic solid organ injuries.

In the beginning of 2012, the forensic hospital department associated with the University Radiological Center of Toulouse

(France) introduced the use of Multi-Phase Postmortem Computed Tomography Angiography (MPMCTA). Since then, two cases involving falls from significant heights have been studied at the department. The relevant literature was reviewed in order to compare the observed cases with the actual knowledge and to establish the contribution of MPMCTA to the forensic purpose.

Summary of Cases: The first case studied (F1) was that of an 81-year-old woman with known suicidal tendencies. The second case (M2) was that of a 45-year-old man with documented suicidal attempts and previous psychiatric hospitalizations. The estimated heights of fall were about 13 and 12m (42 and 39 ft), respectively.

Methods: For the purposes of MPMCTA, both corpses were prepared with a surgical cannulation of femoral vessels (MAQUET Gmbh & co.KG). The non-enhanced MSCT phase, performed on a 16-units MSCT (Sensation 16, Siemens), facilitated sampling of biological liquids for further toxicological and biochemical analyses. The controlled perfusion device used (Virtango, Fumedica AG) and the injection of paraffin oil mixed to Angiofil® (the contrast agent) allowed acquisitions at three different times: arterial, venous, and dynamic (arterial phase with venous aspiration).

The first radiological view was performed by a Forensic Radiologist, who also performed the autopsies. The second radiologist proceeded to the MDMCTA data analysis without knowing the autopsies' results. Neither of the radiologists knew the radiological reports of the other.

Results: The comparison of MPMCTA-derived data with autopsy reports led to different findings. Most of the pathologic findings, like important cephalic, thoracic, and abdominal injuries, were diagnosed by both techniques. Some diagnoses, observed only by autopsy, included T7-T8 discal disjunction (F1), testicular fractures and contusions (M2). The diagnoses established exclusively with MPMCTA were hemopneumatoceles (F1) and deep bone fractures of fibula's head and a metacarpal bone (M2).

In addition to these classical findings, rare injuries such as double thoracic aortic rupture (F1), right coronary avulsion, and inferior vena cava laceration with right atrium extension (M2) were diagnosed by both techniques.

Discussion: Classical lesions seen in great hight falls have been described in the literature data set for decades. These lesions are mostly due to a deceleration mechanism. All typical lesions were found by both MPMCTA and autopsy; however, there are some subtleties.

The posterior rib fractures, a typical finding in high deceleration lesions, were underestimated during the autopsies. This is due to the difficult access to this anatomical region. It is almost the same for the haemopneumatocele. Indeed, the pulmonary macroscopic dissection collapses the haemopneumatocele, making the diagnosis difficult. On the other hand, some lesions were only found during autopsy. The soft tissues, like the testes, are poorly seen with MSCT, which explains the lack of diagnosis in this case. The discal disjunction has been seen with MPMCTA but was misdiagnosed as a degenerative lesion.

Rare lesions (double aortic rupture and right coronary desinsertion) were clearly individualized by both approaches. Epidemiology and mechanism of aortic traumatic ruptures have been studied by many authors. Depending on the series, aortic lesions due to great height falls represent up to 15% of traumatic aortic injuries. The distinctiveness of our case is the association between an isthmus and descending aortic ruptures. Multifocal aortic lesions, including those involving the descending aorta, are least frequent. Post-traumatic lesions of the right coronary ostium are also rare, with a sparse literature data. The existence of this lesion in our case highlighted torsion and shearing force mechanisms due to the great deceleration velocity. Until now, the few reported cases concerned only object projection or motor vehicle accidents.

Conclusion: The study of these two cases of great height fall deaths using the MPMCTA shows the different injuries related to the high velocity death mechanisms. Compared to the non-enhanced MSCT, MPMCTA has a better sensibility, especially for vascular lesions. Furthermore, this new technique helps in understanding the chronology of injuries before death. For example, the death chronology for M2 was inferior vena cava rupture associated to the right coronary desinsertion, haemopericardium, communication between pericardium and right pleura via a penetrating rib fracture, hemopneumothorax.

CT Angiography, Great Height Falls, Postmortem Imaging

G7 Monolithic Substrate Assisted Micro Liquid-Liquid Extraction of Alprazolam From Urine Samples

Kaitlyn Schorr, BS, 1235 Josey St, No 169, Huntsville, TX 77340; and Jorn C. Yu, PhD, Sam Houston State Univ, Coll of Criminal Justice, Box 2525, Huntsville, TX 77341*

The goal of this presentation is to provide information regarding a new monolithic substrate which was developed for Micro Liquid-Liquid Extraction (MLLE) of alprazolam from urine samples. Under the optimized extraction condition, the new MLLE achieved an extraction recovery of 37% for a 100ng/mL alprazolam-spiked urine sample.

This presentation will impact the forensic science community by discussing microextraction techniques that benefit the chemical analysis by consolidating analytical steps and streamlining analysis. This project presents a newly developed technique that combines the advantages of liquid-phase and solid phase microextraction, while minimizing their common disadvantages.

Even with rapid advances in analytical instrumentation, sample preparation represents the majority of the analysis time and has a significant impact on the analysis outcome. One of the oldest and most prevalent forms of sample preparation is Liquid-Liquid Extraction (LLE). LLE utilizes the properties of solubility and solvent polarity to sequester analytes into an extraction solvent. In traditional LLE, extraction solvent is added to a pH-adjusted sample and mechanically stirred to encourage the analyte to partition into the extraction phase and separate from the matrix components. The extraction phase containing the analyte is isolated, dried, and reconstituted. This technique is time consuming, labor intensive, and relies heavily on the skill of the analyst. In an effort to reduce these factors, MLLE techniques were developed. MLLE techniques use a small amount of extraction solvent (2 to 20µL) to concentrate the analyte from the sample. In MLLE, the analyte is concentrated in microliters of extraction phase, and then the extraction phase is removed and injected directly onto the analytical instrument. The aim of this work was to make a Monolithic Substrate to assist Micro Liquid-Liquid Extraction (MSA-MLLE). The main approach is to synthesize an inert and porous material that is capable of holding microliters of organic extraction solvent in an aqueous environment.

In this work, the monolithic substrate was prepared by sol-gel chemistry. Methyltriethoxysilane (MTES) was found to increase the pore size of resulting siloxane. The addition of bulky alkoxysilanes, such as Phenyltrimethoxysilane (Ph-TMS), to the reaction mixture was shown to contribute to hydrophobicity. The addition of a bulky alkoxysilane increased hydrophobicity by reacting with open hydroxyl groups present on the alkoxysilane. MTES and varying levels of Ph-TMS were chosen as the siloxane precursors. The sol-gel reaction was optimized to a molar ratio of 1:13:4.8:0.1 Methyltriethoxysilane:Methanol:Water:Phenyltrimethoxysilane with the reaction adjusted to pH 10 with ammonium hydroxide. The selected sol-gel produced a large-pored, hydrophobic, and viscous siloxane that could be adhered to a metal surface (a pyrolyzer hook) for MLLE.

The Monolithic Substrate-Coated Hook (MSCH) was used for MLLE. The MSCH appeared porous under magnification and were able to hold organic extraction solvent from 0.3 to 1.4µL of toluene prior to exposure to water. After 20 minutes of exposure to stirred water, the retained solvent dropped to 0.1 to 0.2µL depending on the molar ratio of Ph-TMS. Alprazolam is used as a test drug in this

experiment because it is commonly encountered in toxicological analysis. It is also readily available and has been studied by using other microextraction techniques. One of the MSCHs was able to concentrate alprazolam from a spiked urine sample using both toluene and octanol as extraction solvents. The best condition for MSA-MLLE was extraction with octanol for 20 minutes with 600rpm stirring. This condition achieved an extraction recovery of 37% for the low spike (100 ng/mL) and 7% for the high spike (500ng/mL). Unfortunately, the MSCH could be thermally degraded after 5 – 10 runs using thermal desorption. Increase the thermo-stability of the MSCH should be addressed for future work.

Forensic Science, Alprazolam, Extraction

G8 Deaths Due to Blast Effects of Electrocution: A Case Series

Karthik Krishna, MBBS, Sunay Mahesh, MD, Chittaranjan S. Behera, MD, and Shashank Pooniya, MD, All India Institute of Medical Sciences, Dept of Forensic Medicine and Toxicology, Ansarinagar, New Delhi, INDIA*

The goals of this presentation are to discuss the dangers of electrocution, the blast effects of electrocution, circumstances of hazardous exposure and the possible prevention of the hazard through the cases done in India. The attendees will be briefed on the mechanism of electrocution deaths with the case history and all the relevant details with detailed description of injuries supported with photographs. Discussion will be also extended to the pathology of electric shock accompanied with histology of cases.

This presentation will impact the forensic science community by sensitizing them to the issue of deaths due to electrocution, especially the blast effects of electrocution. The demarcation line between the injuries caused by electrocution and lightning runs very thin when it comes to differentiating them, which needs to be probed. As the severity of the electrical injury depends on the pathway of the electric current, it becomes vital to determine how the injury occurred. The autopsy findings of the cases will be highlighted along with supporting photographs and histology slides, concluding that there is no specific therapy for electrical injuries and that's the reason to believe that prevention remains the best way to reduce morbidity and mortality due to electrocution.

Death caused by electric shock is simply referred to as electrocution. Despite widespread and extensive usage of electricity for household as well as industrial purposes, the proportion of deaths due to electric shock is meager. Gross/visible damage due to electrocution may range from nil to extreme. Many factors, related both to victim and environment, play a role in determining the effects of electrocution. Death can be instantaneous due to cardiac fibrillation, respiratory arrest, or electro-thermal injuries caused by heat generated by the current. The heat, thus generated within the body in the latter situation, may cause explosive injuries, including amputation or rupture of organs themselves. Blast effects on the victim are more commonly noted in cases of lightning injuries where the lesion is attributed to direct current flow or due to a secondary fall after being struck.

Three different cases with blast effects of electrocution which were not witnessed and, hence, created undue anxiety for the investigating agencies, the victims' families, as well as the general public regarding the manner of death in those victims will be presented. Doubts were raised due to atypical and bizarre distribution as well as patterns of injuries on the victims. Electrocution deaths are mostly accidental, rarely suicidal, and more rarely homicidal. It becomes important to thoroughly investigate and document the circumstances of electrocution for insurance claims and to take precautions in relation to safety measures. History, in these cases, was insufficient. The deaths occurred instantaneously, and, hence it, was challenging for the forensic doctors to co-relate various findings. The findings at autopsy mimicked those of blast injuries due to lightning or explosives, but careful documentation and interpretation, along with the crime scene investigation, clinched the diagnosis.

Electric Shock, Blast Injuries, Autopsy

G9 Sudden Death by Occult Metastatic Carcinoma

Stephanie A. Dean, MD, 350 E Willow Grove Ave, Apt. 711, Philadelphia, PA 19118; Benjamin Mathis, MD*, 555 NE 34th St, Apt 2002, Miami, FL 33137; Leslie A. Litzky, MD, 3400 Spruce St, Founders 6, Philadelphia, PA 19107; and Ian C. Hood, MBChB, JD, MEO, 4 Academy Dr, Westampton, NJ 08060*

After attending this presentation, attendees will learn about an unusual cause of natural sudden death from pulmonary hypertension as a result of an unusual pattern of pulmonary metastasis from an occult gastric adenocarcinoma.

This presentation will impact the forensic science community by illustrating a rare but important presentation of occult metastatic carcinoma which led to sudden death in a young patient. The objective is to inform forensic pathologists and medicolegal investigators of this bizarre mechanism and cause of death that can only be discovered through careful autopsy.

A 33-year-old Filipina female, with no significant past medical history, was admitted to the emergency room with a several-month history of a cough. She reported taking antibiotics without relief. Imaging revealed slight coarsening of the interstitial markings and no evidence of a pulmonary embolism. Laboratory values were remarkable for an elevated D-dimer (>5000). She was discharged from the emergency room with prescriptions for albuterol inhaler and oral prednisone. One month later, she returned to the hospital with a two-week history of abdominal pain, nausea, vomiting, dyspnea, lightheadedness, and chest pain. The CT was again negative for pulmonary embolus, showing bilateral infiltrates in her upper lung lobes. Her white blood count at that time was elevated to 15K/uL. She was admitted for presumed pneumonia; however, a rapid response was called within hours of admission due to an acute hypoxic episode and subsequent syncope when she tried to get to the bed from the bathroom. After approximately two hours of advanced cardiac life support, the patient expired.

Autopsy revealed an adult female with gross edema and scattered purpura from terminal resuscitation efforts but no significant trauma. Internal examination revealed a thickened stomach wall which, on microscopic examination, was infiltrated by poorly differentiated adenocarcinoma in a linitus-plastica type pattern. Grossly, multiple abdominal lymph nodes were involved by metastatic tumor. Immunohistochemical staining was strongly positive for CK7 and CK20, supporting the diagnosis of a primary gastric carcinoma.

The lungs were notable for fine reticular nodular densities bilaterally. Microscopic examination showed a tumor infiltrate involving the microvasculature, significant arteriolar fibrointimal hyperplasia, and interlobular septal lymphangitic spread. These findings are consistent with Pulmonary Tumor Thrombotic Microangiopathy (PTTM) with the additional finding of extensive extravascular compression by tumor cells.

PTTM is a well-described complication in patients with adenocarcinoma. The typical presentation involves acute pulmonary hypertension (as evidenced by progressive dyspnea, hypoxemia, cough, and hemoptysis), progression to right-sided heart failure and sudden death, often before the adenocarcinoma is discovered. It has been reported in 3% of patients who die with adenocarcinoma (breast, prostate, lung, pancreas) and 25% in patients who die with gastric adenocarcinoma; however, only 8% of patients with tumor emboli experience morbidity or mortality. The diagnosis of tumor emboli is typically not made until postmortem examination. Patients with PTTM develop rapidly progressive pulmonary hypertension secondary to tumor cells occupying a large proportion of small pulmonary arterioles. This in turn leads to fibrointimal hyperplasia and a significant

reduction in the pulmonary vasculature available for gas exchange. The pathophysiology of PTTM remains elusive. It has been suggested that carcinoma cells may produce certain substances that influence the surrounding pulmonary vasculature.

Histologically, medium-sized peripheral pulmonary arteries and smaller arterioles are involved with acute and organizing platelet-fibrin thrombi, small artery intimal fibrosis, and adjacent intralymphatic tumor. These elements do not cause simple mechanical obstruction of the affected vessels. By adhering to the vascular endothelium, they are thought to activate the coagulation cascade and release inflammatory mediators, thus resulting in the formation of microthrombi, stimulation of subintimal proliferation, and smooth muscle colonization of these lesions. The result is a diffuse narrowing of the pulmonary arteriolar system, increased vascular resistance, and marked secondary pulmonary hypertension. The patient had both the classic clinical and histologic features of PTTM with the additional prominent feature of extravascular compression by intralymphatic tumor cells. These features undoubtedly caused her precipitous decline and the mechanism of death in this case is lethal pulmonary hypertension induced by underlying adenocarcinoma.

In the practice of forensic pathology, PTTM should be considered and recognized as a potential cause of pulmonary hypertension. Medical examiners must, therefore, search for occult malignancy via autopsy in order to identify or exclude metastatic cancer as the underlying cause of death.

Thrombotic, Microangiopathy, Adenocarcinoma

G10 A Clinicopathological Correlation of Non-Compaction Cardiomyopathy

Benjamin Mathis, MD, 555 NE 34th St, Apt 2002, Miami, FL 33137; Stephanie A. Dean, MD*, 350 East Willow Grove Ave, Apt 711, Philadelphia, PA 19118; Rachel Anolik, MD, 609 Albany St, Boston, MA 02118; and Carolyn L. Cambor, MD, 3400 Spruce St, 7 Founders, Philadelphia, PA 19146*

After attending this presentation, attendees will learn about the entity of Non-compaction Cardiomyopathy (NCCM) and how to determine or confirm the diagnosis through postmortem examination.

This presentation will impact the forensic science community by discussing that even though non-compaction cardiomyopathy is uncommon, forensic pathologists should be familiar with this abnormality, not only because it can lead to heart failure, arrhythmias, and embolic events, but also because it demonstrates an increased frequency of familial occurrence.[1]

The deceased was a 46-year-old woman with a history significant for cardiomyopathy, cardiac arrhythmias, congestive heart failure, and alcoholism. An echocardiogram performed two years prior revealed heavy trabeculation consistent with a myocardial NCCM. She suffered from recurrent atrial tachyarrhythmias, including atrial fibrillation with rapid ventricular response, that was refractory to multiple ablation procedures.

While attending a regularly scheduled appointment with her cardiologist, the patient developed tachypnea at rest and atrial fibrillation. She was immediately transferred to the cardiac care unit where she developed increasing dyspnea at rest, productive cough, and lower extremity edema. Chest auscultation revealed atrial fibrillation and bibasilar crackles. Electrocardiogram findings were negative for myocardial infarction. Two days later, the patient spontaneously converted to a normal cardiac rhythm, and she was put on sotalol for rhythm control. A few hours later, the patient experienced a torsades de pointes arrhythmia, a potential complication of sotalol therapy. A successful code was performed; however, the patient aspirated at the time of intubation. Following the code, she remained persistently hypotensive with hypoxemia refractory to medical treatment. Her chest roentgenogram showed extensive consolidation of both lungs. Clinically, the patient remained unresponsive with fixed and dilated pupils. Given the poor prognosis, care was withdrawn and the patient expired.

Autopsy revealed a globally enlarged and dilated heart weighing 424g, which was significantly greater than the sex and body mass adjusted mean of 251g (expected range 171g – 368g), a finding consistent with her history of congestive heart failure. Cross sections of the heart revealed an extensive amount of non-compacted myocardium in the left ventricle, which was most prominent in the distal half and on the lateral wall of the left ventricle. The ratio of non-compacted-to-compacted myocardium was 4.3:1. These findings supported the antemortem diagnosis of NCCM. Microscopically, increased amounts of non-compacted myocardium were seen with variable fibrosis within the non-compacted myocardium. No acute changes were seen. Additionally, the foramen ovale was patent (1.2cm), and multiple old intraparenchymal brain infarcts were identified. The etiology of these infarcts could not be determined with certainty; it is possible that they may have been embolic in origin and associated with the NCCM and arrhythmias and/or associated with the patient's patent foramen ovale.

NCCM is a rare myocardial abnormality with an unclear prevalence. Several studies have determined a prevalence of 0.05% – 0.25%.[1] The age at presentation is highly variable. The cardiac manifestations include heart failure, arrhythmias (atrial and ventricular), and embolic events, all of which were seen in the deceased.[1] In most cases, it is a congenital abnormality due to the arrest of normal embryogenesis of the endocardium and myocardium and is often associated with other congenital cardiac malformations.[2] Familial and sporadic forms of NCCM have been described with both X-linked and autosomal patterns of inheritance.[3]

The mechanism of death in the case presented was aspiration pneumonia secondary to complications of intubation at the time of cardiac arrest. The cardiac arrest was initiated by a torsades de pointes arrhythmia which was most likely induced by the sotalol therapy. NCCM should, therefore, be deemed the underlying cause of death since the intended purpose of the sotalol therapy was to manage the atrial arrhythmia, which is a known complication of NCCM.

In the practice of forensic pathology, NCCM should be considered and recognized as a potential cause of heart failure, fatal arrhythmia, and embolic events including cerebrovascular accidents. Medical examiners must be especially aware of this anomaly since it has been recommended that surviving first-degree relatives be screened by echocardiography given the increased familial association.[2,4]

Noncompaction, Cardiomyopathy, Left Ventricle

G11 Delayed Death Following Penetrating Stab Wound to the Heart

Nicole M. Masian, MD, Wendy M. Gunther, MD, and Jeffery J. Gofton, MD, OCME, Tidewater Dist, 830 Southampton Ave, Ste 100, Norfolk, VA 23510*

After attending this presentation, the attendees will: (1) better understand characteristics of delayed cardiac tamponade, as described in a case presenting for medicolegal autopsy in which the

medical examiner determined that death resulted from a homicidal stab wound three weeks following the event; (2) evaluate the role of medical records, police report, and time course in determining the cause and manner of death in such cases; and, (3) evaluate impact of such characterization of cause and manner of death on courtroom testimony.

This presentation will impact the forensic science community by utilizing a case presentation with literature review to evaluate the common factors which should be present in order to assign a remote injury a role in certification of medicolegal death.

A 24-year-old man was stabbed in the left lateral chest during an altercation three weeks prior to his death. He was admitted to the hospital for treatment. A computed tomography scan on the day of injury showed a mild pericardial effusion with pneumopericardium and a moderate left hemothorax. An area of linear hyperenhancement was noted near the left ventricular apex. A chest tube was placed and drained a large (800mL) left hemothorax. Follow-up X-rays showed normal mediastinal contours and cardiac silhouette with resolution of the hemothorax. The patient remained stable and was released from the hospital after three days and did not seek any follow-up care.

After a symptom-free interval of three weeks, he was brought back to the hospital by EMS complaining of sudden-onset, left-sided chest pain and syncope. He stated that he “had to take a knee” and said, “I feel like there is air in my lungs.” While being evaluated, he deteriorated suddenly and an emergency intubation was performed. Ultrasound revealed a large pericardial effusion. 30mL blood was removed via pericardiocentesis. Due to persistent pericardial effusion, thoracotomy was performed with the evacuation of an additional 150mL of mixed clot and fresh blood. Despite these interventions, the patient could not be resuscitated.

At autopsy, the decedent was noted to be well-developed and muscular. Multiple fresh puncture wounds of the subxiphoid region, a nine-inch stapled thoracotomy incision, and a one-inch healing linear scar with evidence of suturing (believed to the site of chest tube placement during initial hospitalization) were noted. A one and one quarter-inch obliquely oriented healing linear scar was present on the skin of the left chest just below the sixth rib and slightly anterior to the mid-axillary line.

On internal examination, there was 500mL bloody left pleural fluid, an additional 500mL bloody peritoneal fluid, and abundant clot within the pericardial sac, left pleural cavity, and peritoneal cavity. Indistinct fibrous scarring marked the site of injury on the parietal pleura. Areas of scarring (likely healed injuries) were noted in the lingular portion of the left lung. A one-quarter-inch defect with surrounding hemorrhage was present in the pericardium overlying the apical portion of the anterior left ventricle.

There was a large area of epicardial hemorrhage over the apex of the heart. A half-inch-in-diameter defect of the anterior apical left ventricular myocardium was identified underlying the pericardial defect. Surrounding the defect was a zone of softened and hemorrhagic myocardium measuring up to one inch in diameter. Upon sectioning, it was revealed that the defect perforated the left ventricular wall. Microscopic sections of the injured myocardium showed extensive hemorrhage and necrosis with evidence of chronicity (hemosiderin deposition and fibroblast proliferation).

A large percentage of patients with stab wounds to the heart, between 80% and 90%, develop acute cardiac tamponade. Delayed cardiac tamponade, however, is a rare complication of stab wounds to the chest, with delays of up to 100 days between injury and development of tamponade reported. The causes of delayed cardiac tamponade vary and may include displacement of thrombus from a cardiac mural wound, tearing of adhesions formed during wound healing, or pericarditis due to postcardiac injury syndrome.

It is believed that the initial injury to this decedent’s heart penetrated, but did not perforate, the left ventricular wall and that the injury resulted in infarction and necrosis leading to a weakening of the heart wall with subsequent perforation and tamponade.

Tamponade, Stab, Heart

G12 Usability of RNA Purified From Forensic Pathology Tissue Samples for Molecular Investigations: The Effect of Tissue Decay on RNA Quality

Jakob Hansen, PhD, Brendstrupgaardsvej 100, Aarhus N, DENMARK; Iana Lesnikova, MD, PhD, Havkaertoften 14, Tilst, DENMARK; and Jytte Banner, PhD, Brendstrupgaardsvej 100, Aarhus N, DENMARK*

After attending this presentation, attendees will learn more about the quality and integrity of RNA extracted from human tissue samples with variable degree of tissue decomposition, and its usability for molecular research. Knowledge about the postmortem stability of RNA and usability of RNA, purified from forensic samples with variable degree of tissue decomposition, can contribute to resolve numerous causes of unexpected deaths. The molecular RNA investigations, such as gene expression analyses, can be a usable supplement to routinely perform histopathological and toxicological investigations.

This presentation will impact the forensic science community by improving the knowledge about the influence of postmortem degradation of RNA due to decomposition of tissue on the results of molecular analyses based on Polymerase Chain Reaction (PCR) in order to support the growing interest in applying molecular analysis in forensic pathology.

RNA is generally considered to be more unstable than DNA, and its usability in PCR-based analysis is more challenged. The goal of this study is to perform a systematic investigation of how body decomposition affects the quality and usability of RNA extracted from muscle tissue samples taken at forensic autopsies and from the corresponding samples of muscle undergoing the standard procedure of fixation in formaldehyde and embedding in paraffin (FFPE).

The degree of decomposition was based on postmortem interval in bodies stored under similar conditions. In order to study the influence of storing condition at low temperature, a group of bodies which were found in water, which is normally cold in Denmark, were identified.

Using the internal autopsy database; random samples of 40 bodies of adults who were found inside at room temperature and had different degrees of body decomposition ranging from no sign of body decomposition to severe body decomposition with mummification and sceletation prior to autopsy, were identified. Moreover, nine bodies were identified that had been missing at least two weeks and were found in the water. The cases were routinely autopsied at the Department of Forensic Medicine University of Aarhus between 2009 – 2011. The study samples were stratified into five groups according to postmortem interval and storing condition.

RNA from unfixed muscle samples was isolated by organic extraction and isopropanol precipitation. RNA from FFPE muscle was isolated using the commercially available kit (Roch). Complementary DNA (cDNA) was synthesized by using the RT-for-PCR kit cDNA synthesis kit with the use of random hexamer primers. The real time PCR assay targeted an 86 basepair amplicon of the human ACADM gene. The thermal cycling consisted of 15 min at 95°C followed by 50 cycles of 30 s at 95°C and 1 min at 60°C with collection of fluorescent data at 60°C.

It was found that the RNA from unfixed samples yield, quality, and ability to support RT-PCR amplification though decreasing with increasing decay of the source tissue. Interestingly, it was found that the ACADM transcript was detectable in almost all samples with the least decay (until one week after death). In contrast, RT-PCR amplification of the ACADM transcript was only possible for one sample with the high degree of decay with a quantification cycle of 38 (indicating low abundance). Furthermore, the ACADM transcript was amplifiable in all RNA samples from tissue derived from bodies found in water, thus, supporting that RNA molecules are well-preserved within water-immersed bodies. The only RNA, purified from FFPE muscle samples taken from bodies with no decay (one to three days

after death), were able to support RT-PCR amplification of the ACADM transcript.

The data supports that the standard FFPE procedure increases degradation of RNA. RNA transcripts from unfixed muscle samples often were detectable in muscle tissue up to one week postmortem that may stimulate further RNA-based molecular analysis in forensic science.

Forensic Pathology, RNA Recovery, Autopsy

G13 On the Effects of Preservation, Blade Angle, and Intra- and Inter-Individual Differences on the Identification of Tool Class Characteristics Retained on Human Costal Cartilage in Cut Marks Analysis

Katerina Puentes, MD, and Hugo F. Cardoso, PhD, Porto Univ, Jardim Carrilho Videira ao Carregal, Porto, PORTUGAL*

After attending this presentation, attendees will understand how the preservation method, knife blade angle, and intra- and inter-individual differences in human cartilage samples affect the ability of costal cartilage to retain the original class characteristics of the knife, as measured by the distance between consecutive striations in cut mark analysis.

This presentation will impact the forensic science community by contributing to the identification of tool-class characteristics with new data concerning the analysis of cut marks on human costal cartilage which is a valuable source of data to forensic scientists. Human tissue has seldom been utilized in experimental studies, although its structure and biomechanical characteristics differ from that of non-humans, thus challenging the interpretation of the results acquired from animal models in order to extrapolate them to a human model.

Materials and Methods: The 160 cartilaginous samples used in this study originated from the ribcage of seven male cadavers that underwent autopsy at the North Branch of the National Institute of Legal Medicine in Portugal. Three different serrated knives were purchased from a large department store to be used in the study. Initially, 40 samples of dissected costal cartilage were manually cut using the same knife following a motion parallel to the long axis of the teeth in the serrated edge. Casts of the "fresh" cut surface were made using casting material for forensic use. The 40 samples of the dissected costal cartilage were then placed in a formalin 10% solution for seven days after which were all re-casted. Both "fresh" and "preserved" casts from each of the 40 samples were observed and photographed. The "fresh" casts images were then compared with the "preserved" casts images by direct image superimposition. In the second phase of the study, a total 120 samples of costal cartilage were used. Samples from two individuals were assigned to each knife. Each individual provided 20 cartilage samples. Cartilage samples were manually cut using each of the three knives following two motions, one parallel and one perpendicular to the blade's teeth long axis. Casts of the samples were made with a casting material for forensic use. Image capture and processing were performed with a stereomicroscope and its software. Direct image superimposition was used to test how the preservation method used for the cartilage samples (formalin 10%) affects preservation of cut marks on the cartilage surface. The distance between striations in the acquired image was measured and data was statistically analyzed.

Results and Conclusions: Assessing the influence of formalin preservation on the striation pattern, direct and complete image superimposition, when comparing the two groups of casts ("fresh casts" vs. "preserved casts") showed that no significant distortion or shrinkage of the striation pattern occurred by preservation of the cartilage samples in a 10% formalin solution for seven days. The blade's penetration angle and the inter-individual differences were shown to affect the identification of the tool class characteristics from the striation pattern observed in a kerf wall, although this fact seems to be related only to the degree of calcification of the costal cartilage. Intra-individual differences do not seem to be relevant enough as to affect in a significant way the identification of the tool class characteristics from the striation pattern observed in a kerf wall for the same knife following the same motion. The degree of calcification of the cartilage is a source of great variation regarding the interpretation of striations pattern in cartilage.

Cut Marks, Tool Marks, Knives

G14 A Method for the Separation and Isolation of Intact Single Cells From Paraffin-Embedded, Formalin-Fixed Tissue Using Laser-Dissection Microscopy

Jason C. Kolowski, PhD, Metropolitan Police Dept, Crime Laboratory, 10430 Furnace Rd, Lorton, VA 22079; Zoran M. Budimlija, MD, PhD, NY City OCME, Dept of Forensic Biology, 421 E 26th St, New York, NY 10016; Margaret M. Wallace, PhD, John Jay Coll, Criminal Justice, Dept of Sciences, Rm 4510, 445 W 59th St, New York, NY 10019; Mechthild K. Prinz, PhD, OCME, Dept of Forensic Biology, 421 E 26th St, New York, NY 10016; Lawrence Kobilinsky, PhD, John Jay College/CUNY, 445 W 59th St, New York, NY 10019; Thomas Schmidt-Glenewinkle, PhD, Hunter Coll, 695 Park Ave, New York, NY 10065; Noelle J. Umback, PhD, OCME, Dept of Forensic Biology, 421 E 26 St, New York, NY 10016; and Tatiana S. Batson, BA, 305 S Strong Ave, Copiague, NY 11726*

After attending this presentation, attendees will gain an understanding of the methods used to separate, identify, and isolate single cells from paraffin-embedded tissue blocks for the purposes of single-cell studies or assays, as well as the specific methodologies employing laser-dissection microscopy, and the success rate using this method in capturing single cells.

This presentation will impact the forensic science community by providing results from replicate experiments in an area with applications to histology, pathology, DNA analysis, and molecular genetics. This presentation will add to research being carried out in forensics by demonstrating a reliable process by which single cells from archival paraffin-embedded tissues can be isolated for the purposes of single-cell assays.

The separation and isolation of single cells from formalin-fixed, paraffinized tissue was necessary in a recent study into the effects of mitochondrial heteroplasmy at a cellular level. While the results from the study were inconclusive due to an issue in the SNP primer design, the methodology for the removal of paraffin, the mashing of the tissue to free cells, and the use of laser-dissection microscopy was seen to be highly effective at the isolation of intact single cells from a previously formalin-fixed and paraffinized tissue source. The use of laser-dissection microscopy is a commonly accepted approach for cell isolation along with flow cytometry and the use of optical tweezers.[1-3]

The cells were freed from the tissue using a combination of heated water washes to melt the paraffin, followed by the mashing of the tissue block between the frosted ends of microscope slides. The frosted glass acted as a grinding surface to release cells from the intact tissue, while the remaining space between the slides allowed the lateral migration of the intact cells without further mechanical breakdown of the cell structure. The mashed tissue and cells were then sieved to separate the cells from the gross tissue, after which the cells were counter-stained with a combination of a mitochondrial-specific fluorescent dye (MitoTracker® Green FM) and Nuclear Fast Red and then affixed to the laser dissection microscope slides.

The use of laser-microscopy on such cells following separation and fluorescent and optical staining was critical for the proper identification of intact single cells. The methodology used in the process of laser dissection was highly controlled to ensure the proper isolation of a single cell, which was shown to be highly reproducible.

To ensure collection, the cells were ablated from the microscope slide and into a collection buffer ensconced within the one ml collection tube cap. The capture buffer was not only a support medium to trap the isolated cell, but also contained the appropriate volume of amplification buffer to send the single cell directly to a one-step amplification which simultaneously lysed the cell and amplified the cellular mtDNA. The resulting detection of the SNP base in question demonstrated an overall collection efficiency of 94.6%, with 681 out of 720 collected cells yielding a signal upon fluorescent detection.

The results of the study demonstrated that the methodology for separating and isolating the cells from the paraffinized tissue was reliable and reproducible. The use of the laser dissection microscopy was effective under the controlled conditions for collecting single cells and was highly specific for single cells selected on a slide when other cells and cellular debris were present within the same viewing field. The confirmation of the single cells was based on the downstream testing and resolution of the SNP base from the mtDNA, which confirmed not only the presence of a captured cell but the presence of only one cell compared to clusters of cells.

G15 The Importance of Microscopic Examination of the Lungs in Decedents With Sustained Central Intravascular Catheters

Heidi H. Hamilton, MD, Michael J. Caplan, MD, Nicholas I. Batalis, MD, S. Erin Presnell, MD, Cynthia A. Schandl, MD, PhD, and Lee M. Tormos, MD, Medical Univ of South Carolina, Medical and Forensic Autopsy Section, Dept of Pathology and Laboratory Mecidine, 165 Ashley Ave, Ste 309, MSC 908, Charleston, SC 29425*

After attending this presentation, attendees will understand the pulmonary vascular complications of intravenous injection of oral medications and appreciate the frequency of fatal misuse of prescribed long-term vascular access devices, such as central venous lines and peripherally inserted central catheters. Attendees will gain insight into the need for microscopic examination of lung tissue with polarized light and be able to accurately identify, characterize, and diagnose various states of disease microscopically. In addition, the attendees will gain an understanding of some common indications and complications for prescribed placement of long-term vascular access devices.

This presentation will impact the forensic science community by demonstrating the frequency of fatal intravenous injection of oral medications in people with indwelling central intravascular catheters. By highlighting the importance of microscopic examination with polarization of lung tissue in all patients with central intravascular catheters, these findings may directly affect the cause and manner of death in individuals with numerous medical comorbidities.

Recreational intravenous drug users may choose to inject suspensions of oral medications into peripheral veins, muscle, or subcutis using a hypodermic needle. However, central lines, peripherally inserted central catheters (PICCs), implanted vascular ports, and hemodialysis catheters may provide convenient vascular access without the stigmata of other methods. Pulmonary vascular lesions including microemboli, vascular wall and interstitial granulomas, and eventual pulmonary vascular bed destruction frequently result. Herein, the a seven-case series is presented of forensic autopsies performed during the last five years at the Medical University of South Carolina where the decedents all had pulmonary vascular complications stemming from intravenous administration of oral medications through a residing central venous line, peripherally inserted central catheter, vascular access port, or hemodialysis catheter. All of the decedents were in their fourth decade of life; two were male and five were female. Comorbidities that resulted in central venous line, hemodialysis catheter, or vascular access port placement will be delineated and discussed, and concurrent toxicology results will be reviewed. The frequency of these cases and the misuse of medically prescribed long-term vascular access catheters require particular attention. An autopsy of an individual with a vascular access device should include microscopic examination of the lungs under polarized light to identify the fillers and binders used in the production of the oral medications. These insoluble, birefringent substances include compounds such as magnesium trisilicate (talc), microcrystalline cellulose, corn starch, and potato starch. The location of such material should be documented, and long-term effects, such as foreign body granulomas and vascular changes, should be described. Massive embolization of foreign material evident in the pulmonary vasculature explains sudden death in cases where acute drug toxicity may not. Chronic findings including granulomatous obliteration of the pulmonary vasculature with the resulting pulmonary hypertension and right heart failure may explain a cardiogenic death due to intravenous drug use. Therefore, without such investigation, the cause and manner of death may be inaccurately ascribed to the decedent's comorbidities, or the contribution of pulmonary vascular complications stemming from intravenous administration of oral medications may not be appreciated.

Central Lines, Drug Use, Lung Microscopy

G16 Sudden Death From Aggressive Pansinusitis and Pituitary Abscess With Clinical Features Suspicious for Intracranial Trauma

Stephen Lenfest, MD, and Jerri McLemore, MD, Wake Forest Univ, Medical Center Blvd, Winston-Salem, NC 27157*

After attending this presentation, attendees will be aware that severe pansinusitis can lead to pituitary abscesses that can be rapidly fatal and have clinical features suggestive of intracranial trauma.

This presentation will impact the forensic science community by describing a rare, fulminant natural disease process that was initially suspicious for trauma.

Pituitary abscesses are rare lesions that are usually confined to the pituitary gland and can be found arising from other pituitary lesions. They can infrequently occur from direct extension of severe or chronic bacterial and fungal sinusitis. They are usually associated with chronic or indolent headaches and facial pain that leads the patient to seek treatment, but they can be rapidly progressive with systemic manifestations resulting in sudden death.

Case Description: The decedent was a 38-year-old male with a past medical history of sciatica and morbid obesity who was found unconscious at home by a co-worker after not appearing for work. He had not complained of any headache, facial pain, or ear pain the night prior; however, he had consumed a large amount of alcohol and taken prescription pain medication that night.

After transportation to the hospital, traumatic head injury was suspected because of diffuse soft tissue swelling involving the left side of his face and head and rust-colored drainage from his left ear and nose. A Computer Tomography (CT) scan of the head found no overt trauma but did show opacification of the left external auditory canal associated with marked soft tissue edema. The paranasal sinuses also had mucosal thickening, mild opacification, and air fluid levels. A Magnetic Resonance Imaging (MRI) scan performed a few hours later showed extensive soft tissue edema and newly developed

opacification of the bilateral mastoids and middle ear spaces. There was also a marked increase of the paranasal sinus opacification, mucosal thickening, and fluid levels in comparison to the earlier CT images. The opacification in the posterior sphenoid sinus abutted the anterior sella turcica with focal destruction of the bone. Diffuse cerebral edema with cerebellar tonsillar herniation and global hypoxic-ischemic injury was identified. Although his condition stabilized, he had suffered a global cerebral insult eventually culminating in brain death.

The case was referred to the medical examiner due to continued concerns about possible trauma because of the rust-colored drainage being suspicious for possible blood issuing from the left ear and nasal passages and because of the acute decompensation.

The major findings at autopsy included thick yellow-pink purulent discharge from the left ear and nares. The left side of the face and head had diffuse soft tissue edema, and an eight by six centimeter (cm) erythematous and purulent ulceration involved the left preauricular area with extension into the external ear canal. The sphenoid bone was dissected to reveal purulent, mucoid material filling the paranasal sinuses consistent with pansinusitis. The purulence and necrotic debris extended into the sella turcica raising the concern of a pituitary abscess. This was confirmed histologically by acute inflammation and marked necrosis involving the majority of the pituitary gland. Thin tan-yellow purulent fluid drained from the middle ear when the petrous portion of the left temporal bone was removed. Multiple bacterial and fungal cultures were performed but did not isolate a causative organism. No intracranial trauma was present.

The autopsy was able to confirm that the decedent suffered from a rare, fatal, natural disease consistent with rapidly progressing pansinusitis leading to a pituitary abscess and severe sepsis. This case illustrates the importance of pituitary examination at autopsy, particularly in the setting of sudden death and severe sinusitis.

Pituitary Abscess, Sinusitis, Sudden Death

G17 Child Homicides in Adana, Turkey

Ahmet Hilal, MD, Kenan Kaya, Burak E. Celik, Necmi Cekin, MD, and Mete K. Gulmen, PhD, MD, Cukurova Univ, Dept of Forensic Medicine, Adana, TURKEY*

After attending this presentation, attendees will learn the incidence of child homicides in Adana, Turkey, from January of 2009 to December of 2011, and its comparison to larger studies

This presentation will impact the forensic science community by increasing awareness, which weapons are mostly used in childhood homicides, the most common age groups of homicides, and if there is any relationship between the weapons used and age groups.

Violence is a common and important public health problem in Turkey, as it is all over the world.[1,2] Homicide is the last point of no return and solution. In nearly all communities, homicide is being accepted as a most serious crime, and it is being punished with severe sanctions while prevention strategies are being developed. It was said that violence-caused deaths (homicide and suicide) induce more than 50,000 people's deaths between the ages of 15-24 every year in the U.S. with homicide being the second most common reson of death.[3]

According to the United Nations Convention on the Rights of the Child, all human beings below the age of 18 are considered children, except for those who have previously attained majority.[4] According to the same convention, contracting countries are obligated to make a maximum effort for the survival and development of children. They are obligated to take precautions and make legal arrangements, correcting incommodities of their laws due to the necessity of convention. Governors must know that childhood deaths, which are caused by violence, are preventable only by taking precautions.

For this study, 5,159 cases were investigated retrospectively and were medicolegally autopsied at the Institute of Forensic Medicine Adana Group Authority Morgue Specialty office between the years of 2009 and 2011. One hundred twenty cases below the age of 18, which were determined to be homicides according to prosecution records, crime scene investigation reports, and autopsy signs, were used in the study. Cases were investigated according to cases' ages, genders, objects (weapons) causing death, and localization of wounds. Toxicological analyses of all cases were reviewed.

It was seen that 79 (66%) of 120 child victims were male and 41 (34%) were female. The youngest was 7-month-old and the eldest 18-years-old. The average age was 13.5 years. It was detected that, when the children were grouped according to their ages, most cases 85 (70.8%) were between the ages of 13 and 18. Looking at methods of homicide, it was seen that firearms were in first place with 73 (60.8%) cases, sharp objects followed with 28 cases, and obtuse traumatic lesions were in third with 14 cases. Looking at injured parts of the victims, it was detected that the head was in first place with 50 (41.7%) of the cases, followed by the rib cage area with 21 cases. It was seen that the most wounds by firearms in a single case was six and the most penetrating stab wounds in a single case was 33. It was detected that, when looking at shooting ranges in the cases killed by firearms, the shooting was done from an adjacent range in 40 cases. Tetrahydro Cannabinoid (THC) was found in three cases and amphetamine was found in one case per toxicological reports.

This study was done with the goal of revealing the incidence of childhood homicides at Adana with the goal of calling the attention of governors whose charge was protecting the children exposed to that violence. It also provides data needed for fulfilling the responsibilities of governors according to the international conventions which they were signed.

Even if removing the violence isn't possible, revealing its reasons and methods provides the possibility of forming strategies. In our study, it was seen that, like most developed and developing countries, homicides by firearms is in first place. But it was seen that in some countries, where the firearms' usage is seriously limited, penetrating stab wounds take first place. Limiting the access to firearms will lead to a decline in childhood homicides in all age groups.

Child, Homicide, Teenage

G18 Homicide or Suicide? An Unusual Case of "Spiritual" Death

Eloisa Maselli, MD, Biagio Solarino, PhD, Roberto Vaglio, MD, Maricla Marrone, MD, and Alessandro Dell'Erba, PhD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will be able to understand that crimes with spiritual aspects are unlikely to be interpreted. The crime scene investigation and autopsy data with histological, biological results and circumstantial elements are basic to reconstruct a crime hypothesis.

This presentation will impact the forensic science community by demonstrating that making a possible link between religion, spiritualism, and manner of death is not easy. Durkheim in 1897 published one of the most important studies about the role of religion in suicide. After this report, many authors presented cases and statistical reports about crimes with spiritual backgrounds.

A case of a 36-year-old man who, after being missing for one day, was found in a cave close to an olive grove will be presented. According to the parents' story, shortly after reading a book titled

Celestino's Prophecy, the victim showed a state of spiritual delirium characterized by the intention to "purify the world" and to "free the world from evil and technology." He left the house, saying to his wife and sons that he "would return only with the spirit."

The crime scene examination revealed the body was found supine, wearing only underpants. A hammer and a hacksaw were found less than one meter to the right and above his right hand.

The external examination of the body showed diffuse, numerous yellowish-red abrasive lesions due to the action of the local microfauna (ant activity). The frontal region of the head displayed a 23-centimeter (cm) lacerated wound extending to the occipital area. Below this injury, two parallel, longitudinal lesions of 17cm and 10cm with large hemorrhagic infiltration of the periosteum were found. The brain tissue showed one cut injury (5cm long and 2cm deep) with surrounding hemorrhagic infiltration. Near major cuts were numerous longitudinal and oblique scratches (hesitation marks). Histological examination confirmed macroscopic evidence.

No alcohol or drugs of abuse were found in the blood or urine collected at autopsy. The cause of death was identified as diffuse hemorrhage and brain damage caused by multiple blunt and sharp force head injuries.

Crime scene investigations showed the presence of numerous blood spots on the cave walls and floor with a large pool of blood about a meter from the head of the victim. In the surrounding area 16 olive trees were found whose trunks had bloodstains that genetic analysis showed belonged to the victim. Regarding the manner of death, the victim banged his head on each of 16 olive trees; thereafter, the head was cut twice. It is difficult to say if someone was present at the moment of his death.

The case was closed as homicide (spiritual/satanic homicide?) by unknown, despite doubts about the possibility of the case being a very unusual suicide. Crime scene investigation and successive genetic analysis did not reveal the presence of another person on the scene; on the other hand, only a great alteration of the victim's behavior (mystic delirium?) could explain a suicide with such head injuries.

Spiritual Crime, Traumatic Brain Injury, Crime Scene Investigation

G19 Sudden Unexpected Death in a Pregnant Young Woman at 23w+6 Hospitalized for Kidney Infection

Luisa Andrello, MD, Carnelli St 9/A, Cairate, Varese, ITALY; Luca Tajana, MD, Viale Borri, 57, Varese, 21100, ITALY; Francesca Castelli, MD, and Marta Sozzi, MD, Via Guicciardini, 9 bis, Varese, ITALY; and Antonio M. Osculati, MD, Via Meraviglia 22, Lainate, Milan, ITALY*

After attending this presentation, attendees will learn about an autopsy regarding a case of sudden, unexpected death in a hospitalized pregnant young woman, using a complete forensic approach: autopsy, histological and microbiological examinations, and study of medical documentation. In particular, histological findings are the most important elements to find causes of death.

This presentation will impact the forensic science community by showing that myocarditis could be a cause of sudden death, even in cases of a negative test during a hospital admission for therapy of a renal infection in a pregnant woman at 23 weeks, 6 days.

Myocarditis is a histological diagnosis characterized by mixed inflammatory cells within the myocardium. Clinical presentation includes a wide spectrum of non-specific signs and symptoms from the absence of any pathological findings to aspecific signs or symptoms like fever, shortness of breath, chills, cough that can only indicate a pathological status to more specific elements like chest pain and arhythmia. Diagnosis is possible only with an echocardiogram study (low ejection fraction and decreased left ventricular systolic function) and a endomyocardial biopsy. When successfully diagnosed (a very low percentage of cases), myocarditits can be treated with anti-inflammatory drugs (like Non-Steroidal Anti-Inflammatory Drugs); beta-blockers, ACE inhibitors (angiotensin converting enzyme inhibitors), and diuretics to support heart failure; corticosteroid to reduce the inflammatory process that is involving the myocardium. In some cases, a temporary pacemaker is indicated to prevent fatal arhytmia. Prognosis is strictly linked to ventricular function recovery.

A case is reported of a 35-year-old pregnant woman at 23 weeks, 6 days who was admitted for a renal infection two days before death. The woman's clinical history was negative for any chronic diseases but positive for renal diseases cystitis and pyelonephritis (urine analysis of four months and a month before were positive for *Escherichia Coli*), which were treated with antibiotic therapy. Gynecological anamnesis: five years prior she had a pregnancy with cesarean birth and one year later she had a second pregnancy with voluntary termination.

Suffering from pain at the left renal loggia with fever (39.6°C), she went to the hospital. At admission, the objective exam showed a fever (body temperature 38.4°C) with normal cardiovascular parameters (arterial pressure 110/70mmHg, heart frequency 82bpm, rhythmic); at echography, the pelvis and ureter of left kidney were expanded; the urine analysis showed the presence of leucocytes and erythrocytes. There were no abnormalities of pregnancy parameters. Antibiotic therapy (Zinocef (cefuroxime) 1.5g 2/die e.v.) was administered to the woman. The following day the fever was reduced (maximum body temperature 37.4°C) and cardiovascular parameters were regular. The second day after admission, signs and symptoms showed a progressive improvement: apyrexia, reduced level of PCR (from 415mg/l to 212mg/l), normal lymphocyte count. In the afternoon of the same day, the young woman was found unconscious on the floor of the bathroom. The resuscitation was useless and death was confirmed.

External examination of the body was completely negative. Autopsy revealed bilateral subpleural effusions (lung congestion). The heart was normal in size and shape, and the myocardium didn't show abnormal findings except for a thickening of mitral valve. The placenta exam and fetus autopsy didn't reveal pathological findings.

Histological examination showed lymphocytes infiltration of the myocardium, especially in the right ventricle and some outbreaks of necrosis. Other lymphocytes infiltrations were found in the lungs and placenta. The cause of death was attributed to malignant arhytmia by viral myocarditis.

Sudden Death, Myocarditis, Pregnancy

G20 Violence Against Women Victims: Forensic Autopsies Findings in Istanbul

Esra Unal, MD, Sermet Koc, MD, and Volkan Unal, MD, Adli Tip Kurumu, Istanbul, TURKEY; and Gulnaz T. Javan, PhD, Alabama State Univ, 915 S Jackson St, Montgomery, AL 36104*

After attending this presentation, attendees will be familiar with the prevalence of crime against women in Turkey.

This presentation will impact the forensic science community by providing actual data obtained from autopsies performed on victims of violence against women.

Because of a widespread public health problem and a human rights violation, violence against women, and its causes and consequences, carries a particular importance. Violence against women causes women's health deterioration, mutilation, and even death.

Istanbul contains approximately 18% of Turkey's population and is the most important cosmopolitan city in the country. According to statistics from 2006 to 2010 census reports, there are nearly 36 million females living in Turkey. There are 6.5 million females living in Istanbul, and since this cosmopolitan city houses a big portion of Turkeys female population, the result of the study of violent female death can be an indicator for the whole country. This study retrospectively evaluates the results of autopsies performed at

Ministry of Justices Department of Forensic Medicine Mortuary on victims of violence against women for the five year period between 2006 and 2010.

There were 4,165 cases of female deaths out of a total of 20,486 autopsies conducted during this period. The female death cases were categorized as follows: 459 cases of death due to violence against women, 72 cases due to suspicion of murder, and six cases of death not directly related to an act of violence but due to diseases, for total of 537 autopsy cases.

Based on total autopsies (n= 20,486), 2.6% (n=537) of the female deaths were due to violence. Extrapolating these data result in 12.9% of total female deaths being a result of violence against women.

While subjects' age ranged from newborn babies to 90-year-old females, 49.7% of the subjects were women aged 21 – 40. The most frequent violent environment was home, where 51.2% (n = 275) of incidences occurred. Women who suffered violence on the streets were 14.5% (n = 78) of the reported cases. 6.7% of the cases happened at vacant land, while 4.3% of them occurred in buildings. Violence against women in the workplace was 23.3% of the autopsies. The location of one-third of the cases could not be identified.

Although perpetrators of 172 cases were not identified, 20.1% of the violence against women was committed by their spouses. This number increased to 52.3% when we added boyfriends' violence against women. The number of subjects who were killed by family members other than the spouse is 73 (20%). 4.4% of violent individuals were females (n = 16). 10.6% (n = 57) of perpetrators committed suicide after the incident, and only 9.7% (n = 52) turned themselves in to the police station.

76.4% of subjects were found to be dead at the scene, while 15.5% of them died on the way to hospital, and 8.2% died after a period of hospitalization.

According to the autopsy results, death as a result of gunshot wounds (50.1%, n = 269) was identified as the top reason for death, while stab wounds (28.3% (n = 152) took second, and strangulation deaths (8.4%, n = 45) took the third place. Handguns were used in 84% (n = 230) and hunting guns in 13%, n = 35 of deaths. The most common fatal shots were to the head region. Death occurring as a result of stab injuries was determined to be the reason in 172 of the cases, with 42.7% (n = 73) of these deaths due to cuts suffered by victims while defending themselves. Ten cases (2%) were victims of sexual assault, ranging in age between 10 and 83 years old.

Violence against women is gaining more importance in todays world. Although there are several studies showing the extent of violence against women in Turkey, this study is the most comprehensive research on forensic autopsy. Violence against women encompasses a multidisciplinary approach; however, exposing these horrible crimes against women will enable our scientific communities to find a better approach in elimination or reduction of these violent acts.

Women, Violence, Autopsy

G21 Antemortem and Postmortem Colonization Interval by Insects: A Case Report

Paola A. Magni, MS, Univ of Torino, Via Accademia Albertina 13, Torino, 10123, ITALY; Francesco Ausania, MD, Magna Graecia Univ, Largo Francesco Vito 1, Rome, ITALY; Isabella Aquila, MD*, Policlinico Univ, Viale Europa, Località Germaneto, S. Venuta-Medicina Legale, Catanzaro, ITALY; Moreno Bertoni, MD, Medicina Legale ASL, Via San Secondo 29, Torino, ITALY; Ian Dadour, PhD, Univ of Western Australia, Centre for Forensic Science, 35 Stirling Hwy (M420), Nedlands, AUSTRALIA; and Pietrantonio Ricci, MD, Magna Graecia Univ, Viale Europa, Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand the importance of the discrimination between antemortem and postmortem insect colonization on a corpse, in order to correctly estimate the time since death.

This presentation will impact the forensic science community by demonstrating that with a complete investigation in a case, it is possible to obtain a complete set of data concerning both the antemortem and postmortem period; moreover, it underlines the efficacy of the diverse knowledge required of a forensic entomologist in understanding the insect colonization of a corpse.

The use of insects and other arthropods in forensic investigations (medicolegal entomology) is considered a gold standard for the estimation of the time since death. However, another important branch of medicolegal entomology is the analyses of dipterous feeding on a host's necrotic or living tissues (myiasis) to determine if the insect colonization can be considered in a forensic context (e.g., neglect of elderly). In some particular cases, a myiasis event can happen within a certain period prior to death, such as the colonization of a bloody lesion, bedsores, or the necrotic tissue of a living person who generally is unable to look after themselves. In such cases, the discrimination between a myiasis colonization and a postmortem colonization based on the insects present on a corpse (species, instar, colonization interval) may provide the time since death (Postmortem Colonization Interval, PMCI) and the time of colonization before death (Antemortem Colonization Interval, AMCI).

In June 2007, the corpse of an 82-year-old woman was found on the floor of her apartment in Turin, located in northwest Italy. The neighbors were alarmed by an odor emanating from her apartment, and when the medicolegal and entomologist arrived, the corpse appeared to be in a fresh stage of decomposition. Rigor mortis was still evident and only blow fly egg clusters were observed on the woman's eyes. In contrast to this, her left foot was largely decomposed and a large number of third instar maggots were present.

No domestic animals that may have fed on the body were found in the apartment, but many diabetic drugs and medication were present. In particular, a medical prescription concerning the treatment of a diabetic sore on the left foot and a medical certification of the woman's senile dementia were found.

Insects present on the corpse were sampled at the scene and during the autopsy with particular attention not to mix the samples from eyes and foot. Part of each sample was immediately fixed and the remainder was reared in a growth chamber until the adults eclosed. A temperature data-logger was placed in the apartment for seven days after the corpse was taken to the mortuary, and the apartment temperature was compared with the temperature data over the same period recorded by the meteorological station closest to the apartment. This procedure allowed extrapolation of the temperature of the scene in the period prior to the corpse being discovered.

The entomological analyses determined the presence of *Lucilia sericata* (Meigen) (Diptera: Calliphoridae) eggs on the eyes, and *L. sericata* and *Sarcophaga* sp. (Diptera: Sarcophagidae) third instar on the diabetic wound. These species are typical myiasis insects and they are common in the urban environment of northwest Italy during this period of the year.

The correlation between the entomological data and the temperature information, together with the anatomo-pathological examination, determined that the woman died the day before the corpse was discovered. The PMCI was obtained using the age of the egg cluster on the eyes, the decomposition stage, and the rigor mortis. The diabetic wound on the foot was colonized four to five days before the death. AMCI was obtained using the age of the insects feeding on the lesion. In all likelihood, due to the senile dementia of the woman, she failed to administer her diabetic drugs some days which placed her in a diabetic coma. It would seem that, during the four to five days of coma, insects colonized the wound on her foot, and only after death were her eyes colonized. This case underlines the importance of the diverse knowledge required of a forensic entomologist and understanding insect colonization of a corpse.

Blow Fly, Myiasis, PMI

G22 Child Abuse and Interview of Pediatricians: Incidence in Southern Italy

Francesco Ausania, MD, Magna Graecia Univ, Largo Francesco Vito 1, Rome, ITALY; and Isabella Aquila, MD, Debora De Bartolo*, Francesca Pepe, MD, Maria Chiarelli, MD, and Pietrantonio Ricci, PhD, Policlinico Univ, Viale Europa, Località Germaneto, S. Venuta-Medicina Legale, Catanzaro*

After attending this presentation, attendees will have a better understanding of the mechanisms underlying child abuse, risk factors, and the social value of child maltreatment.

This presentation will impact the forensic science community by providing useful data to prevent the maltreatment and psycho-physical consequence of the abuse.

Introduction: Child abuse and neglect are widespread problems found all over the world and have received considerable publicity over the past three decades. Child abuse represents an important cause of infant mortality and it is a sentinel event in a community, reflecting the effectiveness of prevention strategies, social security policy, and primary care for children.[1] UNICEF data (2003) found that in industrialized countries about 3,500 children <15 years die from abuse or neglect annually. Spain, Greece, Italy, and Ireland have the lowest rates of deaths with 0.1-0.2/100,000 children, while the United States and Mexico have the highest rates with 2.2/100,000 children. The child abuse is committed particularly on children younger than four years.[2] Seventy five percent of abuse is not diagnosed because the physicians fail to recognize signs of abuse. Due to this lack of diagnosis the opportunity to intervene early is lost, and many children suffer repetitions of abuse.[3] Currently in the territory of Southern Italy there are not estimates of the size of this problem.

Objective: The goal of this study is to estimate the incidence of the phenomenon of child abuse in Southern Italy, analyzing the population of pediatric medical centers in the geographical areas of Catanzaro and Cosenza (ITA).

Materials and Methods: A questionnaire was given to physicians of seven pediatric centers. The Chair of Legal Medicine collaborated with the Department of Pediatrics Faculty of University "Magna Greacia" of Catanzaro. The sample involved children aged zero to six years, admitted between January 2004 and December 2011. The questionnaire (closed answers) allowed, at each pediatric center, the investigation of case studies, characteristics of victims, social stratification of families, perpetrators of abuse, different types of child maltreatment in relation to age, type of injuries, and psycho-physical consequences on the victims.

Results: The preliminary results are available. Even in relation to data in the scientific literature, the underestimation of the phenomenon of child abuse determined by technical difficulties in diagnosis of psychological abuse and neglect, abuse committed by parents (81, 1%), denial by attackers, unpreparedness of many operators, delays and omission of reports, lack of collaboration between health centers and law enforcement was expected.[4-5]

Conclusions: Because of the increment of child maltreatment and its social consequences, identification and early intervention may help to minimize the probability of future violence and the consequences of child abuse. So, it is essential to extend the competences of the physicians in the identification and documentation of maltreatment in children for prevent child neglect.

G23 Postmortem Diagnosis of Marfan's Syndrome In Pregnancy: Cause of Death or Incidental Finding?

Isabella Aquila, MD, Ester De Luca, MD, Francesca Pepe, MD, and Silvia Boca, MD, Policlinico Univ, Viale Europa, Località Germaneto, S. Venuta-Medicina Legale, Catanzaro, ITALY; and Ciro Di Nunzio, PhD, Santo Gratteri, MD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Legal Medicine, Catanzaro, ITALY*

After attending this presentation, attendees will have a better understanding of the importance of an adequate Marfans Syndrome (MS) diagnosis to realize an appropriate monitoring of pregnant patients to prevent and control pregnancy-related risk.

This presentation will impact the forensic science community by highlighting prevention pregnancy-related risk in Marfans syndrome.

Introduction: In the vast area of connective tissue diseases are also counted MS, Loeys Dietz Syndrome (LDS), and the Ehlers-Danlos syndrome. These diseases are all characterized by mutations of genes that encode proteins that are the constitutive elements of elastic fibers and that determine elasticity alterations of the involved tissues. Marfan's syndrome (OMIM #154700) is an inherited, autosomal dominant disorder that affects the skeletal, ocular, and cardiovascular systems. The disease displays high penetrance and wide clinical variability both within and between families, therefore a patient may have mild to severe symptoms that may or may not correlate with other affected family members. Although Marfan's syndrome has a range of characteristic morphological features involving the ocular, cardiovascular, and musculoskeletal systems, the phenotype is variable. In addition, mutations have been identified in the gene encoding for fibrillin-1 and also in the transforming growth factor-b receptor 2 (TGF-bR2) gene. In the postmortem diagnosis of these pathologies, it is necessary to detect external anatomical characteristics and peculiar internal signs. Common phenotypic findings are muscle-skeletal and cutaneous alterations. Among the internal signs are found ocular, cardiovascular abnormalities, and pulmonary manifestations. The most common internal signs of vascular origin are structural abnormalities of the aorta. The pregnancy is, for these patients, a high risk event, especially in consideration of the anatomical and structural anomalies that the high weight involves, as well as the intrinsic risks to the pregnancy state.

Case Report: The case of a young woman, pregnant, at the 37 weeks of pregnancy, with a weight of 129kg, operated with a caesarean section, who died two days later for unknown causes was

analyzed. The external inspection of the corpse showed the presence of *facies lunaris*, wide attack of the palate, cutaneous striations, and muscle-skeletal anomalies in correspondence of the right hand. The autopsy stated pituitary hyperplasia, thymic hyperplasia, massive pulmonary embolism, and complete aortic dissection, type A in Stanford classification. Histological examination showed a complete degeneration of the tunica media of vessels affected by the dissection.

Results: In the studied case, the postmortem diagnosis of connective tissue disease, in the absence of aorta rupture, has not been only an accidental finding but a pathological, pre-existing, and concurrent (dissection) cause of the pulmonary thrombo-embolic event, regarded as the cause of death of the young woman.

Conclusions: It is possible to say that pregnancy in obese patients with connective tissue diseases, particularly in patients with aortic ectasia, presents a high risk of mortality and morbidity in relation to the genesis of aortic dissection. For this reason, a correct and adequate MS diagnosis is fundamental, to prevent pregnancy-related risk and realize an adequate monitoring during pregnancy through implementation of a proper diet and timely eco-cardiotographic controls.

Marfan's Syndrome, Pregnancy, Aortic Dissection

G24 Usefulness of CT Scan Before Autopsy in Case of Firearm Homicide

Alain Miras, PhD, 49 Cours Vitton, Lyon, FRANCE; Isabelle Sec, MD, IML de Paris-Place Mazas, Paris, FRANCE; Arlette Bel Balayer, MD, Hopital d'Ajaccio, FRANCE 20090, Catherine Douws, MD, Hopital d'Arcachon, Arcachon, FRANCE; and Federic Dupuch, INPS-Rue Pierre Baronnier, Ecully, FRANCE*

The goal of this presentation is to explain the advantage of a CT scan for autospy in known cases of gunshot wounds.

This presentation will impact the forensic science community by discussing how CT is currently the preferred radiological investigation before an autopsy in case of homicides by firearm.

The objective of this presentation is to highlight the interest of the use of a scanner in gunshot wounds, but also to show its limits. The use of a scanner before autopsy identifies projectiles or projectile fragments in the body, highlights the bone's and other organ's damages (liver, heart, lungs, brain), defines intracorporeal trajectories, and sometimes establishs a chronology of the different shots. The scanner is useful in order to conduct an autopsy in good conditions and to make adapted samples for microscopic examination. Indeed, the autopsy allows taking some sample tissues (entrance and exit wounds), but also aids in the recovery of projectiles (wads and pieces of bullet jacket).

The scanner also offers the advantage of being interpreted by other experts if necessary, which can sometimes prevent exhumations in cases of disagreement. The interest is also to use scanner pictures at trial that are as representative as photographs of injuries but psychologically less aggressive to the victim's families.

In France, it is necessary for the judges and investigators to know the different shooting distances and define the positions of the victim and the perpetrators during gunfire. To illustrate this, several cases are presented of wound ballistics for which a scan was performed prior to autopsy. The interpretation is immediately made by a radiologist and a pathologist after the acquisition of computer data and a 3D reconstruction is completed, printed, and given to the pathologist before autopsy.

This presentation will be illustrated with many pictures and photographs of entrance wounds, bone lesions (vertebrae, ribs, skull), and exit wounds. The cases presented in this session show an obvious superiority of CT compared to conventional radiology, including digitized radiographs.

Thus, after the scanner, the external examination, and the autopsy, forensic medical examiners or pathologists must be able to define or estimate:

- The initial trajectories (between the muzzle and the victim)
- The firing angles and the direction of the passing projectile
- The skin distances
- The intracorporeal trajectories
- The sequence of shots
- The possible displacements of the victim during the gunfire

The limits of this approach are mainly related to its lower efficiency compared to conventional radiography combined with the autopsy, when a number of projectiles are grouped in a limited area (e.g., skull), or when multiple trajectories intersect with one another.

In conclusion, CT is currently the preferred radiological investigation before an autopsy in case of homicides by firearm. In France, it is gradually replacing conventional radiography, even if the cost is higher (300 € for a body scanner - 200 € for an autopsy). But the limitations of its use are related to the fact that all forensic services do not have console access to a CT scan and radiologist. Also, psychologically, it is difficult to convince doctors, nurses, and patients that the same CT scan can be used all day long for either living or deceased persons

CT Scan, Gunshot Wounds, Autopsy

G25 Cold Case Investigation: The Los Angeles Coroner Experience

Lakshmanan Sathyavagiswaran, MD, and Christopher B. Rogers, MD, OCME, 1104 N Mission Rd, Los Angeles, CA 90033*

After attending this presentation, attendees will understand the importance of archiving evidence and case records, maintaining chain of custody, and following procedures and protocols.

This presentation will impact the forensic science community by bringing closure to families and the community in the forensic investigation of cold cases.

The investigation of various long-unsolved murders in Los Angeles County through the use of modern forensic science techniques, especially recent advances in DNA, will be discussed. Three case examples will be used to discuss the challenges involved, including verification of identification, retrieval of records and photos, authentication of physical and sexual assault evidence, chain of custody documentation, need for following procedures, and maintaining an archive of old procedure manuals including testing techniques/standards. The need to withhold information from family members in the interest of not jeopardizing an investigation is paramount.

Case 1: Involved a decomposed young female found in a drainage culvert in 1985. She was identified by a forensic odontologist after charting of her teeth and comparison with her missing person ante mortem dental X-rays. There was evidence of sharp force trauma in the neck and torso. There was extensive organ tissue loss from decomposition/maggot activity. The use of a tool mark criminalist consultation in case evaluation will be discussed. A suspect was apprehended using DNA techniques and circumstantial evidence. Challenges faced by the medical examiner during trial preparation nearly three decades later included verification of identification. The problem was that the original forensic odontologist was not available due to illness and another dental consultant had to review films, photos, and reports of the original consultant to validate the identification. The medical examiner on case had also charted the teeth independently and this became important in trial preparation, as the removed jaws were not available for review.

Case 2: Involved a 33-year-old female who was strangled and sexually assaulted in 1979 in her Westside apartment. DNA evidence in the CODIS database identified a suspect and linked him with the sexual assault evidence recovered from the victim. Details of the interview process of the suspect, importance of maintenance of chain of custody logs during evidence collections, and detailed knowledge about testing procedures used all became important during trial preparation more than 30 years later.

Case 3: Involved a 15-year-old girl found in a suburb in 1974 with ligature marks on her neck, ankle, and wrists. The case was certified as suicidal hanging. Later, at an inquest, the manner was changed to death at the hands of another. The lack of follow-up by law enforcement and the Coroner-Medical Examiner's Office will be discussed, bringing up the importance of quality assurance in any medicolegal death investigation system.

In 1998, the current Chief Medical Examiner-Coroner reviewed the case because of a zealous detective and prosecutor and reopened the case. Problems in retrieving inquest transcripts after 24 years will be discussed, as they had not been transcribed and there was only one company that had the proper equipment to retrieve the information. Use of DNA techniques in linking the sexual assault evidence taken from the victim to the suspect and ramifications for the community safety in these delays will also be discussed.

Cold Case, Evidence Collection, Archiving

G26 The Use of Several Different Weapons and Ammunition in Order to Make Police and Forensic Investigations Very Difficult: A Specific French Island Behavior That Continues to Grow

Alain Miras, PhD, National Institute of Forensic Sciences, 49 Cours Vitton, Lyon, FRANCE; Isabelle Sec, MD, Institute of Forensic Medicine, Place Mazas, Paris, FRANCE; Lakdar Attar, INPS, Rue Pierre Baronnier - BP 30169, Bordeaux, 69134, FRANCE; and Thierry Valette, INPS, Laurent Pene, INPS, and Federic Dupuch, INPS, rue Pierre Baronnier - BP30169, Ecully, FRANCE*

The goal of this presentation is to show forensic and ballistics difficulties and how to specify characteristics when multiple gunshots occur.

This presentation will impact the forensic science community by highlighting an innovative methodology that associates forensic medical examiners and ballisticians in crime cases with multiple different weapons, ammunitions, and shooters.

Currently in France, when mobsters decide to kill someone in a context of conflicts between gangs, the current most popular method is to use multiple people with several types of weapons and ammunitions.

The goal of this presentation is to demonstrate the value and the current need of multidisciplinary work involving forensic and ballisticians during crime scene examination, autopsy, and sample tissues' microscopic analysis.

As an example, this study reviewed cases that happened in the French territory of Corsica, which is known for its passion for weapons and its code of honor. Corsicahas has a unique weapon ownership rate in France. One in 54 inhabitants own handguns which represents a rate ten times higher than ownership in Paris and numbering more than 30,000 weapons legally by only 280,000 inhabitants. Indeed, Corsica has been one of the deadliest regions in Europe since 1995. There were:

- An average of 32 homicides or attempted homicides per year, three times more than the French average (11.7 versus 4.1)
- In 2007, the homicide rate was 7/100,000 against 2.9/100,000 in the rest of France and even 9/100,000 in 2009.

The perpetrators of these attacks have adapted to advances in forensics and ballistics. Now, usually, homicides are carried out by several people using various weapons, several types of ammunition and shooting distances, and different firing angles. Shortly afterward all weapons are found in a burned vehicle.

These methods are intended to delete all traces of DNA (criminals and accomplices) and to prevent weapons from being traced back to other crimes. But these actions are also intended to prevent ballisticians from doing their work (identification of weapons, comparison shots, etc.).

In addition, for forensic pathologists, the multiplicity of lesions and shooting greatly complicates the determination of trajectories, firing angles, skin distances of shots, and, therefore, the position of shooters in relation to the victim.

Different cases were reviewed and studied in a collegial collaboration including forensic pathologists, ballistics experts, investigators, etc. The cases detailed the different types of weapons, various calibers, and gauges that were used that combine handguns (9mm, essentially), Kalashnikov, and shotguns firing buckshot. A summary is provided of the various skin and organic lesions found during the external examination and the autopsy. The projectiles were recovered and examined immediately by the Laboratory of Forensic Science ballisticians.

In a second step, in the laboratory (police department), the clothes were analyzed and firing tests were conducted to determine the skin distances and the firing angles. Then, assumptions are developed about positions of the perpetrators and victim during the crime scene. These assumptions were then validated later by a reconstruction of the crime scene.

This presentation is a practical application of an innovative methodology proposed in France in recent years, which is more and more appreciated by the judges, and which associates medical examiners and ballisticians working in forensic service (police department).

Homicide, Weapons, Multidisciplinary

G27 The Contrecoup Phenomenon: Do Classical Concepts Trump Witness Accounts?

Natasha L. Grandhi, MD, 22 S Greene St, NBW43, Baltimore, MD 21217; Michael A. Markey, MD, and Joyce L. DeJong, DO, Sparrow Forensic Pathology, Sparrow Hospital, 1215 E Michigan Ave, Lansing, MI 48912; and Rudy J. Castellani, MD, Dept of Pathology, 22 S Greene St, Baltimore, MD 21201*

After attending this presentation, attendees will be able to: (1) describe major biomechanical theories attempting to explain the contrecoup phenomenon; (2) predict likely sites of cerebral contusion in blunt head trauma as a function of the biomechanics of the injury and physical properties of the brain and skull; (3) summarize relevant literature of the reliability of witness accounts; and, (4) stratify likely head trauma scenarios in a case as a function of witness accounts versus knowledge of the contrecoup phenomenon.

This presentation will impact the forensic science community by discussing how the forensic pathologist is often called upon to interpret head trauma as a function of biomechanics, and speculate on relative likelihood of different scenarios, based on the anatomical findings. To the extent that witness accounts may contradict more likely scenarios based on those anatomical findings, it is important for the forensic pathologist to be able to weigh the reliability of both the anatomic findings and that of witness accounts. The two cases presented highlight this controversy, as the biomechanics of the contrecoup phenomenon are discussed in parallel with literature addressing witness account reliability.

It has long been recognized that cerebral contusions tend to occur opposite the point of impact after a fall. Orbitofrontal and inferior temporal contusions, in particular, often result from a fall on the back of the head. This empirical fact has led to complex theories involving the physical properties of the brain and cerebrospinal fluid, angular acceleration, and the elaboration of shearing forces to account for this so-called contrecoup phenomenon, a subject which continues to be debated. Nevertheless, the forensic pathologist is left with the practical implications of such a lesion and is occasionally called upon to offer an opinion about the nature of an injury that may

assist law enforcement officials to piece together crimes and even assign culpability to one individual or another.

Here, two cases of individuals who died as a result of bar fights are presented. In the first case, several witnesses noted that, during the course of an altercation, a 42-year-old man suffered a severe blow to the face, and fell, hitting the back of his head. He immediately lost consciousness, went into cardiorespiratory arrest and was pronounced dead on arrival to an emergency department. At autopsy, he had a severe anterior frontal contusion, bilateral subdural hemorrhage, generalized brain swelling, central herniation, and cerebellar tonsillar herniation.

In the second case, a 30-year-old man was followed from a bar by several individuals who collectively attacked the man with a series of punches and kicks, according to witnesses. At least one of the assailants was also wielding a baton. Importantly, none of the witnesses to the attack noted a fall on the back of the head. The victim arrested at the scene and resuscitation attempts were unsuccessful, and he was pronounced dead on arrival at a nearby emergency department. Despite the reported events, at autopsy, he had a linear skull fracture centered on the right occipital region extending to the skull base, indicating some type of impact to the back of the head. Examination of the brain revealed a large anterior frontal contusion with cerebral swelling, central herniation, and cerebellar tonsillar herniation. The combination of impact injury to the back of the head with a large frontal contusion indicates a contrecoup-type injury. Furthermore, no significant soft tissue injury to the face or forehead was present, making a coup-type injury a less likely cause.

These two contrasting cases raise the issue of the contrecoup phenomena, particularly the reliability of general understanding of the contrecoup phenomenon versus witness accounts. Studies evaluating the accuracy of witness accounts have shown a large variability in the reproducibility and accuracy of recounted events. Details pertaining to physical characteristics and action sequences are commonly evaluated and are more frequently erroneous, despite other aspects of the account remaining reproducible over time. Ultimately, it is concluded that angular acceleration of the brain accompanied by blunt, and essentially, instantaneous impact occurred in both cases. Moreover, a blow to the occipital region of a stationary head is unlikely to account for a large frontal contusion, thereby emphasizing the mechanism of contrecoup injury over witness reports.

Contrecoup, Contusion, Witness

G28 Erroneous Notification of Sexual Abuse in an 8-Year-Old Female, Who Died From Acute Chest Syndrome in Sickle Cell Disease Combined With Deficit of Glucose-6-Phosphate Dehydrogenase

Silvia Tambuscio, MD, Univ of Verona, Piazzale L.A. Scuro 10, Verona, ITALY; Patrizia Polonia, MD, Via Pellizzo 39, Padova, ITALY; and Rossella Snenghi, MD, Univ of Padova, Via Falloppio 61, Padova, ITALY*

After attending this presentation, attendees will understand the crucial importance of careful detection and skilled interpretation of anogenital findings in deceased pediatric subjects. Very often, normal postmortem artifacts and physiological variants of genital anatomy, especially in prepuberal children, can be misinterpreted by unskilled examiners and wrongly attributed to sexual abuse, with a poor forensic outcome.

This presentation will impact the forensic science community by improving knowledge of what is normal in anogenital anatomy during the postmortem interval and what is not. Attendees will also focus on the peculiar, different significance that one morphological sign may have on the living's, as opposed to the deceased's, anatomy. The health care practitioner whose sole experience ranges in the antemortem scenario, when operating untrained in a postmortem context, may dramatically confuse common cadaveric anogenital artifacts with traumatic injuries. In the reported case, such an occurrence is described.

An Italian 8-year-old black female of Western-African ancestry, suffering both low levels of glucose-6-phosphate dehydrogenase (G6PDH) and sickle cell disease requiring multiple hospitalizations for micro-occlusive crises, was admitted to the emergency room complaining of bilateral leg pain, fever, and general malaise. Laboratory tests revealed severe anemization (hemoglobin 3.6g/dL) and elevation in hemolysis markers. Clinical course showed acute chest syndrome unresponsive to repeated blood transfusions and intensive care therapeutic efforts, leading to death 48 hours after hospital admission. A few hours after death, during the recomposition of the body, nurses and pediatricians noted abnormal anogenital findings consisting in the absence of hymen and wide dilatation of the anal sphincter. Such findings were suspected as traumatic origin and confirmed by the gynecologist consultant.

Forensic autopsy took place six days after death and showed the following main findings: (1) at the anogenital exam, hypoplasia of the hymen with intact edges, but remarkable dilatation of the anal sphincter with two round-shaped abrasions above the pectinate line; no other anogenital or perineal injury; (2) at histology, rectal abrasions consisted in disepitelization with glandular damage, and microvascular disruption with blood cells and fibrin extravasation; no cellular infiltrate was detected, neither fibrosis or sclerosis in the mucosal and perineal specimens; and, (3) at autopsy, meningeal congestion and cerebral edema; hydrothorax (1200ml), pleural and pericardial adhesions; haemorrhagic edema and diffuse microthrombosis of the lung vessels; erythro- and granulo-blastosis of the lung, heart, and kidney; myocardial hypertrophy and focal myocardiosclerosis; acute tubular necrosis; hepato-splenomegaly with hepatic iron storages.

Autopsy was completed by microbiological analyses of anorectal and cervicovaginal specimens, excluding the occurrence of sexually transmitted infections.

The death of this young patient was related to an acute chest syndrome consequent to a severe sickle cell crisis. Suspected sexual abuse was definitely ruled out by expert examination of the body. In fact, the reported "absent hymen," considering its intact edges and the peculiar morphology, was interpreted as an anatomical variant (semilunar hypoplastic). Anal dilatation was itself explained by childhood anatomy, with underdeveloped glutei showing anal sphincter as "abnormally" evident, and by postmortal dynamic anal alterations. In fact, as reported, sphincter relaxation occurs immediately after death, followed by narrowing during rigidity onset, and by definitive anal relaxation.[1] Furthermore, skilled external examination and histopathology related the two anal "abrasions" to postmortem disepitelization in the site of insertion of a therapeutical suppository, occurred very short time before death.

In conclusion, the interpretation of genital postmortem findings remains an issue of main concern also for the forensic pathologist. In fact, until recently, scarce information existed on the nature and appearance of the anogenital tissues during the postmortem interval. Findings like mucosal disepitelization at different sites of the anogenital tissues have been widely classified as normal postmortem artifacts, but they can be eventually confused with traumatic findings by examiners whose sole prior experience lies in the antemortem forensic context.[2] Moreover, pediatric age makes the interpretation of suspected lesions even more challenging, since relevant interindividual variability in hymen conformation is characteristic of prepuberal young female population.

Anogenital Exam, Sexual Abuse, Hymen Variability

G29 The Assessment of Refugees for Signs of Torture: An Italian Glimpse

Daniele M. Gibelli, MD, Laboratorio di Antropologia e Odontologia Forense, Sezione di Medicina Legale, Dipartimento di Scienze Biomediche per la Salute, V. Mangiagalli, 37, Milan, ITALY; and Marco Grandi, MD, Danilo De Angelis, DDS, and Cristina Cattaneo, PhD, Univ of Milan, Via Mangiagalli 37, Milan, ITALY*

After attending this presentation, attendees will become acquainted with the medicolegal service for the assessments of refugees in Milan, and in detail, the limits that are usually encountered in the evaluation of signs of torture.

The presentation will impact the forensic science community by providing information in this sensitive and recent field of application of forensic clinical pathology.

Assessment of torture allegations is one of the most recent fields of application of clinical forensic pathology, which is often affected by specific diagnostic limits, especially for what concerns the assessment of scars and the reconstruction of their origin.

In Italy, specific committees actually exist for the recognition of the status of refugee, which only in the last year have begun to include forensic pathologists.

The goal of this presentation is to familiarize attendees with the signs of torture in an initial sample of refugees examined at the Institute of Legal Medicine of Milan in order to show the difficulties which are encountered in establishing a correct coordination between the different types of professionals involved in the specific committees and the pitfalls in the interpretation of lesions and scars.

Twenty-six cases have been assessed thus far between 2008 and 2012. Each alleged victim was interviewed and examined. Every scar and lesion was analyzed, especially those concerning morphology and size, and photographed. In several cases X-rays were taken, for a better understanding of bone calluses.

The final report concerning the consistency between lesions and the given history was performed according to the indications of the Istanbul protocol.

In most cases, the subjects came from African countries and a high number of them went through Libya during the civil riots. Almost all the subjects are male, and, in 56% of cases, they are aged between 20 and 30 years. Only in 32% of cases, the history revealed torture for political reasons, whereas in 28% of cases a history of random military aggression was given. Blunt and thermal lesions were most frequently reported (respectively 49% and 23%). Blunt lesions were most frequently performed by truncheons and wooden sticks (respectively 26% and 24%) and were observed on the limbs and the torso; thermal injuries were performed by torches (45%) and cigarettes (30%) and highly affected the limbs. Sharp force injuries were produced by knives in 70% of cases and were observed most frequently on the trunk. Gunshot lesions, dog bites, and chemical and blast lesions were present.

One of the most relevant results concerns the correlation between scars and the origin of the lesions reported by the refugee. In almost all cases, the analysis led to a general concordance with the presumed history, although other origins could not be excluded. In a few cases, the scars were highly suggestive for the reported history according to the existing literature and concerned specific modalities, such as thermal and sharp force lesions.

This presentation highlights the lack of information in literature concerning the correct assessment of scars and the need for further studies in this relatively recent and sensitive field. Another important point of discussion concerns the need for a correct coordination between the different professional figures involved in such committees in order to produce a useful and clear report of the alleged tortures.

Human Rights, Torture, Refugees

G30 A Bus Crash With School Children in Sierre, Switzerland: Identification of the Victims

Marc D. Bollmann, MD, Centre University Romand, de Medecine Legale, Rue du Bugnon 21, Lausanne, SWITZERLAND; Christian Zingg, MD, Waisenhausplatz 32, Bern, SWITZERLAND; Tatiana Ivaneanu, Ruiterijlaan 2, Brussels, BELGIUM; and Sophie Pitteloud, Police Cantonale du Valais, Avenue de France 69, Sion, FRANCE*

After attending this presentation, attendees will get an overview of the identification process of the 28 Belgian victims who died in a bus crash and learn about difficulties and possible solutions. They will also get an overview of the Disaster Victim Identification (DVI) response in Switzerland.

This presentation will impact the forensic science community by showing how international standards and collaboration aid in the management of a mass disaster.

On March 15, 2012, at 9:15 p.m., a Belgian bus crashed head on against a highway tunnel wall near Sierre, Switzerland. Of the 54 occupants, 46 were children from two Belgium schools on their way home after a ski camp. During the vast rescue operation, the first responders faced many problems because of the confined space in the tunnel. It took time to access and extract the injured and the dead from the bus wreck, as the seats were torn away and stuffed together in the impacted front area of the bus, trapping most of the accident victims. Twenty-eight bodies were retrieved from the bus, including 22 children, four tutors, and two drivers. All bodies were numbered on the site of the accident and transported to a local mortuary with funeral cars. Some local stakeholders contemplated a visual recognition process in order to identify the victims, but the decision for a scientific identification was reached quite rapidly and a request for a Swiss DVI Team operation was issued. A visual confrontation of families and bodies was still expected to be conducted. On the morning of the 26th, the DVI Identification procedure started in the regional mortuary using local means and personnel. These first responders were then reinforced and later relieved by one Belgian and two Swiss DVI teams. All bodies and personal objects were documented (inventoried and photographed), and DNA samples were taken according to a simplified Interpol protocol. Few identifying features were present on most children, and many bodies were heavily traumatized. All bodies underwent a full body CT scan for which they had to be transported to the University Centre of Forensic Medicine of Lausanne (CURML), Switzerland. The autopsies of the drivers and a few dental exams also took place there. The Belgian DVI-Team arrived together with the families of the injured and the dead. The Belgian Team joined the Swiss investigators in order to obtain the antemortem (AM) data. The ability to approach the families in their native language was of paramount importance to obtain high-quality AM data. The presence of the families as well as the political and mass media interventions put enormous pressure on the DVI crews in order to hasten the release of the bodies. The antemortem-postmortem comparisons were performed during the second night of the event and the identifications were all based on several identifiers. A specially designed visual acknowledgement process also gave supportive information. The multidisciplinary validation of the identifications was associating a Belgian DVI-Team member, which provided a mutual endorsement of the results. All 28 victims, as well as one surviving comatose child, were identified according to international DVI procedures within two days after the accident. All bodies were then repatriated in the morning of the third day. This rapidity was only possible because of optimal circumstances (weekday, trained personnel, and rapid access to AM data) and the coordinated action of local police force, forensic pathology, Swiss and Belgian DVI

Teams, and the DNA-Lab, which rendered the comparison results within eight hours after receiving the material. The CT scans of the bodies were not much used in the identification process in this case, because the combination of the other methods sufficed. The CT data did aid in the reconstructive workup, as no autopsies were performed on most victims. The rapidity of the response and identifications, however, also posed problems regarding logistics and psychological aid for the AM and PM teams.

Disaster, International, Identification

G31 The Efficacy of Combining Various Fingerprint Acquisition Techniques to Obtain Examination-Quality Postmortem Fingerprints From Unidentified Human Remains

Marzena H. Mulawka, MFS, 520 First Ave, Rm 124, New York, NY 10016; Michael A. Mosco, MS*, 472 Bay Ridge Ave, Brooklyn, NY 11220; Aaron Uhle, MS, 2501 Investigation Pkwy, Quantico, VA 22135; and Lisa M. Mokleby, MS, 421 E 26th St, New York, NY 10016*

After attending this presentation, attendees will understand the problems involved with acquiring fingerprints from Unidentified Human Remains (UHR). The unpredictable condition of UHR is widely known throughout the identification community. This unpredictability leads to the issues involved with acquiring examination-quality fingerprints for identification purposes.

This presentation will impact the forensic science community by exposing the procedures and techniques utilized for daily UHR cases at the NYC OCME and emphasizing the success of their combination and subsequent identification of the deceased. As a result, widespread use of these techniques may help identify the tens of thousands of UHR that are being held within Medical Examiner's/Coroner's (ME/C) offices throughout the United States. Additionally, these decedents will now have a name and can be returned to their families, who will finally have closure as to the whereabouts of their loved one.

Fingerprint acquisition is quite uniform in the realms of the living and crime scene processing where techniques and technology are developed specifically for each purpose. However, the methodology for fingerprinting the deceased is not uniform, and use of techniques must be determined on a case-by-case basis. A major difference in printing the deceased versus the living is the manipulation of the fingerprinting medium (i.e., fingerprint card, ink pad, etc.). When printing the deceased, the fingerprint medium is being manipulated against the decedent as opposed to the living, where the person is being manipulated against the medium. Therefore, in the case of UHR, a combination of traditional and newly developed techniques are required to obtain examination-quality fingerprints. The challenge lies within the unpredictable condition of the UHR that are being printed. Often the UHR are in various stages of decomposition, which can negatively affect the condition of the hands and fingers. Conditions such as rigor mortis, skin slippage, and mummification can all discourage the attempt of obtaining fingerprints from the decedent. Contrary to the notion that the decedent is not printable, ridge detail on the epidermis and the dermis could still allow for acceptable fingerprints despite the aforementioned conditions. As a result, reconditioning techniques should be used followed by attempting fingerprint acquisition techniques.

The techniques described in this presentation are proven to yield examination-quality prints from UHR that range from fresh to significantly decomposed. The wide range of techniques include the use of reconditioning of skin using tissue injection and soaking/rehydration, boiling, manipulation of degloved skin, as well as recording techniques such as ink/card, fingerprint powder/adhesive lifter/acetate sheet, fingerprint powder/casting putty, photography under microscope, and photography using macro settings. While some of these techniques are by no means foreign to forensics, their usage was adapted to serve the cause for fingerprint identification of UHR. Case studies will be presented detailing particularly interesting and/or challenging cases in which a unique combination of these techniques was used that resulted in a positive identification. Statistics will also be provided to further substantiate the efficiency and success of these techniques and the importance of utilizing them throughout the identification community.

Specific resources and supporting data for utilization of various advanced fingerprint acquisition techniques currently available to the forensic community will be provided. It is recommended that ME/C offices and agencies tasked with the identification of UHR become familiar with the various fingerprint techniques which can assist in cleaning and reconditioning remains, leading to the successful recording of examination-quality postmortem fingerprint impressions.

Fingerprint, Unidentified Deceased, Fingerprint Technique

G32 The New York City Office of Chief Medical Examiner Fingerprint Project Strategy — A Model Approach for Standardized and Systematic Postmortem Fingerprint Identification

Marzena H. Mulawka, MS, Frank DePaolo, 520 First Ave, Rm 124, New York, NY 10016*

After attending this presentation, attendees will understand that, contrary to popular belief, all available fingerprint databases are not linked to one another and, thus many forensic professionals tasked with the identification of Unidentified Human Remains (UHR) are unable to perform complete searches of Postmortem (PM) fingerprint records against all Available Antemortem (AM) fingerprint records. After attending this presentation, attendees will understand the major issues regarding PM fingerprint identification for Medical Examiner/Coroner (ME/C) offices that are not affiliated with Law Enforcement Agencies (LEAs). The submission of PM fingerprint records to various agencies for adequate searching against AM fingerprint records will be discussed, as well as the potential solution developed at the New York City Office of Chief Medical Examiner (OCME).

This presentation will impact the forensic science community by augmenting UHR identification efforts through the proposal of a step-by-step process to utilize current resources available for postmortem fingerprint acquisition, submission, and reporting. As a direct result, utilization of the OCME Fingerprint Project Strategy may aid in the identification of numerous UHR that are currently being held within ME/C offices throughout the United States. In addition, law enforcement agencies will be able to resolve open missing person cases and investigations, as well as close out active warrants. More importantly, the next of kin of these deceased individuals will no longer question the whereabouts of their missing family members and will be able to pursue proper disposition and burial.

Current fingerprint databases utilized by ME/C offices and LEAs exist at federal, state, and local levels, and thus, do not always overlap with the information they contain. In addition, not all ME/C offices and LEA's possess the ability to search every one of these databases—a fact often unfamiliar to many forensic professionals who lack expertise in fingerprint searching and analysis techniques. The OCME Fingerprint Project Strategy was developed to streamline PM fingerprint acquisition, digital conversion, submission, reporting, and case management. Additionally, an electronic fingerprint workflow was developed to integrate with OCME's Unified Victim Identification System (UVIS)/Case Management System (CMS), creating a paperless procedure to minimize manual data entry, redundancy, and reduce chances of human error.

Statistical data from unknown and unverified deceased cases at the OCME will be presented to demonstrate the effectiveness of

utilizing the OCME Fingerprint Project Strategy. As of February 14, 2012, PM fingerprint records were acquired from all available UHR and submitted to multiple fingerprint databases in an attempt to exhaust all efforts for forensic fingerprint identification. Prior to this study, fingerprints from UHR at the OCME were generally only submitted to be searched through a local fingerprint database, yielding minimal or no hits and exhibiting a stagnant and unpredictable turnaround time. As a result, these UHR cases were forwarded to the OCME Forensic Biology laboratory for DNA analysis, a costly and lengthy process that is successful only when AM DNA reference samples are available from a missing person or family members.

A very high success rate was achieved resulting in a multitude of positive identification—many that would have been submitted for DNA analysis. Therefore, the results of this study indicate that to ensure all UHR fingerprint files are being searched thoroughly through multiple databases, PM fingerprint records must be submitted to various local, state, and federal agencies. This would allow maximum exhaustion of all resources to attempt identification of the PM fingerprints. An obvious decline in the number of unidentified and unverified deceased was yielded after the OCME Fingerprint Project Strategy was implemented, confirming a direct correlation and acknowledging the significance of leveraging all available fingerprint databases.

Specific resources currently available will be provided to the forensic community and supporting data regarding the OCME Fingerprint Project Strategy. It is recommended that ME/C offices and agencies tasked with the identification of UHR become familiar with the various fingerprint databases.

Fingerprint, Fingerprint Database, Unidentified Decease

G33 The Contribution of a Digital Fingerprint Protocol to the Medicolegal and Mass Fatality Contexts

Jason M. Wiersema, PhD, HCIFS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Tr, Houston, TX 77054; Deborrah C. Pinto, PhD, 208 Hollyberry Tr, Toronto, ON M2H 2P4, CANADA; and Sharon M. Derrick, PhD, HCIFS, and Luis A. Sanchez, MD, HCIFS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Tr, Houston, TX 77054*

The goal of this presentation is to provide attendees with an example of the benefit of incorporating a digital fingerprinting system into the medicolegal and mass fatality procedures.

The presentation will impact the forensic community by providing data in support of the perceived advantages of the application of digital fingerprint technology in the medicolegal setting. The data presented are extracted from a large medicolegal jurisdiction that acquires the vast majority of its scientific identifications from fingerprint comparison as opposed to other methodologies.

The process of identifying or confirming the identity of the dead is both a core component and a frequent bottleneck in the medicolegal process. This is particularly the case in the mass fatality context, during which the frequent disparity between the time required for scientific identification and the time an average case requires to progress through the disaster morgue can compromise the efficiency of the disaster morgue process. The Harris County Institute of Forensic Sciences (HCIFS) processes approximately 4,000 cases per year, about 800 of which require confirmation of identification. Greater than 90% of these decedents are currently identified using fingerprint comparison, primarily because it is the most efficient and cost-effective option. However, traditional paper and ink fingerprint collection at the IFS required coordination between multiple departments, and considerable hours spent managing the transfer and translation of data. The process regularly takes longer than the remainder of the morgue process from check-in to completion of the autopsy. The HCIFS transitioned to a digital fingerprint process in 2010. The end result has been a significant impact on the time required to identify decedents.

An important distinction is the difference between the turnaround time of the fingerprint identification itself, hereafter referred to as Print Turnaround, and the overall identification (ID) process, hereafter referred to as ID Turnaround (which also includes entry of the fingerprint results into the HCIFS database). Since 2010 was the year that digital fingerprints were made part of the morgue standard operating procedure, the comparative sample was composed of a pre-conversion group represented by cases from 2009 (200 cases) and a post-conversion group represented by cases from 2011 (229 cases). In an analysis of the daily HCIFS caseloads before and after the conversion, it was noted that the conversion to digital fingerprint technology drastically reduced both Print Turnaround and ID Turnaround. This presentation will illustrate the benefits of digital fingerprint technology on the HCIFS daily caseload and on mass fatality incident response.

The median Print Turnaround prior to conversion to digital fingerprints was approximately one-and-a-half hours, with 35% of cases requiring more than two hours, and 18% of cases requiring more than four hours. The median Print Turnaround time following conversion is approximately ten minutes with 94% requiring less than two hours and 89% requiring less than one hour. An additional advantage of the conversion is significant reduction in labor and materials associated with ID. The post-conversion Median ID turnaround for the daily HCIFS caseload is 13 hours as compared to 23 hours pre-conversion. This process involves entry and reconciliation of the fingerprint results for each case into the HCIFS case management system.

The implication of the transition to a digital fingerprint system is that in a mass fatality event with the same demographics as the Harris County population, approximately 90% of the decedents resulting from a Mass Fatality Incident (MFI) can be positively identified via fingerprints before the end of the disaster morgue process, if: (1) prints are taken early during the disaster morgue flow; and, (2) the ID Turnaround is reduced via the disaster morgue operating procedures. This finding has prompted rearrangement of the disaster morgue scheme in the HCIFS Mass Fatality Plan to: (1) place the fingerprint station much earlier in the disaster morgue process; and, (2) to task the Disaster Morgue Data Entry Team with management and rapid entry of fingerprint results. The result is a significant reduction in the separation between Print Turnaround and ID Turnaround, which translates into a substantial boost to the efficiency of the overall disaster morgue process.

Digital Fingerprint, Mass Fatality, Disaster Morgue

G34 Blast Injuries in a Non-Military Setting: Findings and Future Implications

Pramod Gumpeni, MD, Jason M. Wiersema, PhD, and Glenn Sandberg, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will observe a multi-disciplinary presentation of a non-military blast injury case that will illustrate the pathologic, anthropologic, and neuropathologic sequelae of such injuries. They will also learn of new research directions in the area of blast injuries.

This presentation will impact the forensic science community by describing the findings in a non-military blast injury case, a generally rare occurrence in the non-military setting. This information will directly impact fellows and residents in training, who are not exposed to these types of cases in a routine medical examiner setting. This education will prove useful in mass disaster scenarios.

Blast injuries are a form of trauma most common in military settings with military-grade weapons and ammunition. Because of this, non-military forensic pathologists, medical examiners, forensic anthropologists, and death investigators rarely see blast injuries, and

the associated findings, in a decedent. Investigation of a potential blast injury case may require specific information and/or autopsy procedures that are not gathered in a routine death investigation or autopsy.

The most common non-military setting is industrial accidents. Industries involved with flammable/explosive/incendiary materials can yield situations in which workers can be subjected to the types of forces associated with blast injuries. All workplace fatalities must include an OSHA investigation, as they can be very helpful with providing specific information for that type of industry that would not necessarily be readily available.

In this case, the decedent was working on a chemical tank when the tank ignited. The decedent was not hit by shrapnel from the tank but instead was thrown against a chain link fence. He was transported to the hospital but died shortly after admission. His injuries were consistent with previously described typical blast-type injuries, including internal organ lacerations (without overlying cutaneous injuries), barotrauma, pulmonary trauma and bleeding, atypical skull fractures, and deep white matter hemorrhages in the brain.

The findings in this case bring to light the need to be familiar with blast injuries and the classification schema, which includes primary, secondary, tertiary, and quaternary injuries. This study had the benefit of having an in-house forensic anthropologist and an in-house forensic neuropathologist who were both available for consultation on this case, and were able to provide reports detailing the specifics of this unique type of trauma.

In addition, the case was referred to the working group on a Department of Defense grant for traumatic brain trauma from blast injuries. The working group is hoping to use this case in furthering their research for protecting soldiers from traumatic brain injuries and treatment as well.

In order to properly document and work-up a blast-related injury, it is quintessential to have a firm understanding of the pathologic consequences of blast injuries. By reviewing the case reports and classification schema, forensic pathologists and death investigators can be better equipped to deal with non-military blast related injuries, and possibly help further research to protect military personnel who are exposed to this type of injury on a regular basis.

Blast Injuries, Military, Neuropathology

G35 Death Due to Acute Respiratory Failure After Irritating Gases Exposure: Forensic Diagnosis

Isabelle Plu, MD, PhD, and Isabelle Sec, MD, Institut Médico-Légal, 2 Place Mazas, Paris, FRANCE; Marc Deveaux, MD, Laboratoire Tox Lab, 7 Rue Jacques Cartier, Paris, FRANCE; Marc Taccoen, MD, and Christian De Brier, MD, Institut Médico-Légal, 2 Place Mazas, Paris, FRANCE; Gilbert Pepin, PhD, Laboratoire Tox Lab, 7 Rrue Jacques Cartier, Paris, FRANCE; and Patrick Barbet, MD, PhD, and Dominique Lecomte, MD, PhD, Institut Médico-Légal 2 Place Mazas, Paris, FRANCE*

After attending this presentation, attendees will become familiar with the injuries which should suggest the involvement of irritating gases in the death of a victim, in particular, the respiratory tract injuries (pulmonary edema and irritation of the respiratory tract mucosa). Finally, attendees will learn to perform the appropriate samples in such cases.

This presentation will impact the forensic science community by highlighting the risks of death after exposure to irritating gases by law enforcement agents or by an assailant with criminal purpose. With these case reports, the attendees will have help determining if death is consistent with irritating gas exposure, in taking into account the results of histological and toxicological findings, and predisposing factors to fatal outcome.

Irritating or incapacitating gases, in which “tear gases” or “lacrimatory gases” such as CS (ortho-chlorobenzylidenemalonitrile) or CN (chloroacetophenone) aerosols or other aerosol-dispersed chemicals, can be used by policemen to arrest offenders, to control riots, or by offenders to commit assault or robbery. Their physical toxicity is well documented, such as eye, skin, nose, mouth, and respiratory tract irritations. They are considered as non-lethal chemical agents but can be, nevertheless, responsible for acute pulmonary distress syndrome, lethal asphyxia, and death.

Here three cases of death by pulmonary failure after irritating gas exposure are reported: two obese men, 35-years-old and 50-years-old, respectively, were restrained by policemen at home, handcuffed behind their back, faced down on the ground, and died during the interpellation (cases 1 and 2); a third man, 32 years old, was discovered dead in a cave (case 3). Electronic Control Device (ECD) were used in cases 2 and 3.

Autopsy findings were asphyxia signs and conjunctival hyperemia in the three cases, conjunctival petechiae (cases 2 and 3), massive congestion of the mucosa of the trachea and the bronchial tubes in the three cases, overinflated lungs (in cases 1 and 3), massive congestive lungs (case 2), liver of cardiogenic shock (cases 2 and 3), and deep congestion of the organs in the three cases. A hypertrophic heart was discovered in the case 1.

Histological analyses showed hemorrhagic pulmonary edema (cases 1 and 2), partially necrotic (case 1), macrophage in the pulmonary alveoli or bronchi in the three cases, polymorph lung tissue with focal alveolar dilation, alveolar ruptures (case 3), focal necrosis and ulceration of the mucosa of the trachea with hemorrhagic suffusions (case 2).

Toxicological analyses found ortho-chlorobenzylidenemalonitrile in lung tissue and on the clothes of the deceased (case 2), but neither in the blood nor in the tracheal and laryngeal swabs (cases 1 and 2). Phosphoric and sulfuric acids were found on the tracheal and laryngeal swabs (case 3), derived from the ammonium phosphate and sulfate found in a fire extinguisher discovered on the crime scene. Cocaine (0.307µg/ml), cannabis (THC-COOH: 7.7ng/ml), alcohol (0.81g/l), and therapeutic level of doxylamine and valenfaxine were found in blood (case 3).

In cases 1 and 2, it was concluded that death was caused by acute respiratory failure due to irritating tear gas exposure (ortho-chlorobenzylidenemalonitrile) in a closed space (apartment) with possible participation of postural asphyxia (cases 1 and 2) and shocks by ECOs (case 2).

In the third case, it was concluded that death was caused by acute respiratory failure due to the association of a chemical lung irritation by the fire extinguisher gas and an obstructise asphyxia by the fire foam. The involvement of drug intoxication and of the shocks by ECOs cannot be excluded.

Conclusion: In these three cases, acute pulmonary failure can be considered as a multifactorial cause of death. Nevertheless, irritating gas exposure is the main lethal factor in the three cases because of tracheal and pulmonary injuries and the presence of some residue of gas in samples performed. Furthermore, these three cases are illustrative of the predisposing factors to death in case of exposure to irritating gas: dispersed gas in a closed space, obesity, a person under the influence of drugs, prone restraint, and taser gun shocks.

Tear Gases, Irritants, Pulmonary Edema

G36 A Rare Case of Biphasic Malignant Mesothelioma Due to Occupational Asbestosic Exposure

Tommaso Savì, MD, Paolo Procaccianti, Antonina Argo, Antonino Nicosia, MD, Emiliano Maresi, and Cettina Sortino, MD*, Univ of Palermo, Via del Vespro 127, Palermo, ITALY*

After attending this presentation, attendees will understand some aspects about the incidence of malignant mesothelioma and the histological classification of this disease, with particular reference to the biphasic mesothelioma histotype with prevalent polymorphic sarcomatoid and desmoplastic aspects.

This presentation will impact the forensic science community by considering the likely gradual increase in judicial autopsies in the next decade for deaths from malignant mesothelioma in subjects with occupational exposure, in order of the expected peak incidence in the coming years. Assuming that the diagnosis of mesothelioma is histological, the purpose of this presentation is to share the experience and opportunity to evaluate rare histological aspects of the case. The malignant pleural mesothelioma is an aggressive tumor with a growing incidence. Clinical studies predicting cases of mesothelioma have estimated that this growth will continue for 10 – 15 years and that in the next 20 years, the number of cases will double in Western Europe, rising from 5,000 deaths in 1998 to 9,000 in 2018.[1]

However, the malignant disease, unlike other asbestos, related diseases, remains a rare tumor, an event considered "sentinel" of exposure to asbestos because of the low incidence in the general population (in Italy 3.42 cases per 100,000 in males and 1.09 cases per 100,000 in females) and of the high causal specificity.[2]

The relationship between asbestos and mesothelioma, first identified by Wagner *et al*. in South Africa, has now been documented all over the world.[3]

The average prevalence of mesothelioma in people with prolonged heavy exposure to asbestos is 2% to 3%, but has reached up to 10% in some series. The latency period is usually 20 years or longer.[4]

Malignant mesothelioma is usually seen in older adults, although well-documented cases in young individuals are on record.[5]

In some instances, a familial clustering has been demonstrated and it was hypothesized a genetic background. In most instances, the initial involvement is in the lower half of a hemithorax but spread to the rest of the pleural cavity is the rule.[6]

The diagnosis of mesothelioma is complicated by a peculiar characteristic that differentiates it from many other cancers, namely the extreme histologic polymorphism.

The differential diagnosis is also very difficult for the fact that the pleural and peritoneal cavities, in addition to mesothelioma, often localize metastases of primary tumors located in distant organs that may also be clinically silent.

It is now widely accepted, and repeated by the most recent treaties, the fact that a diagnosis of mesothelioma can be made only after the histological examination of abundant material (at least 10 grams of tissue according to Cotes and Steel), supplemented by a very accurate survey on the major organs and systems (autopsy or clinical and instrumental evaluation), which allows exclusion with certainty all other possible primary tumor's.

Epithelial mesothelioma is the more frequent (50 – 75%), histological variant, followed by the biphasic form (25 – 30%) and the sarcomatoid one (15 – 20%).[7]

In view of its unusual occurrence, a case of biphasic mesothelioma with prevalent polymorphic sarcomatoid and desmoplastic aspects is reported.

Biphasic, Mesothelioma, Occupational

G37 First Oviposition Timing of Blow Flies on Human Cadavers

Yangseung Jeong, MA, 560 Prestwick Ridge Way, No 100, Knoxville, TN 37919*

After attending this presentation, attendees will understand the degree to which the first oviposition timing of blow flies varies depending on temperatures and/or covering and the importance of consideration of this information during estimation of the Postmortem Interval (PMI).

This presentation will impact the forensic science community by providing information that will enhance the prediction accuracy of PMI mathematical models using entomological evidence. As a result, the potential error produced by simply assuming that blow flies deposit eggs shortly after a victim's death is reduced, resulting in a more accurate estimation of PMI.

The goal of this research was to understand the relationship between temperature and the first oviposition timing of blow flies and to test whether covering on a body can delay the first oviposition timing. The hypotheses of the study were first, that fly eggs will be observed on a cadaver earlier in warm weather than in cold weather, and secondly, that covering on a body will delay the first oviposition timing.

It is generally understood that blow flies are the first insects that approach and deposit eggs on a cadaver. Due to the extensive literature on the life cycle of blow flies in various temperature conditions, it is believed that PMI can be calculated by mathematical models developed with great accuracy. However, the first oviposition can be delayed due to a number of factors, and as such, the delayed oviposition still remains a potential source of error in estimating PMI.

This research was conducted at the Anthropology Research Facility at the University of Tennessee, Knoxville. A total of 60 donated individuals were observed each day for the timing of fly egg deposits between April 2011 and March 2012. Approximately half (n = 36) of the individuals were covered in black plastic sheeting, while the rest were uncovered and unclothed.

For this study it was found that the first oviposition timing was largely dependent on temperature. In the month of July, when the monthly temperature was 28°C, which was the highest of the year, fly eggs were observed within 24 hours after placement of bodies at the facility. Also, from May to September, when monthly temperatures were above 20°C, it took three days or less for the first oviposition to occur. Conversely, in January, when the monthly temperature was 6°C, which was the lowest of the year, fly eggs appeared about 19 days after placement on average.

More specifically, the first oviposition timing was found to have varied more in cold weather than in warm weather. From May to September, it took between one and three days for the first oviposition to occur. However, in January, fly eggs were observed between 10-28 days after placement. Even though average monthly temperatures of October and March were equal (16°C), the first oviposition timing of October was faster than that of March. This difference can be attributed to the population density of currently existing flies. That is,

in October, at the end of the summer season, it is likely that there still remain a large number of active flies as well as pregnant flies; however, in March, at the end of the winter season, it is likely that there are few active flies over the landscape and even less numbers of pregnant flies. Because there are not many existing flies at this time that are prepared to oviposit, it is likely to take some time for flies to emerge and mate.

Finally, the timing of the first oviposition was only marginally affected by covering. While black plastic sheeting delayed the first oviposition timing during summer, the delay was one day at most. Unfortunately, this study cannot present the effect of black plastic sheeting during winter because all the cadavers placed between December 2011 and March 2012 were covered in black plastic sheeting.

In conclusion, forensic anthropologists and entomologists must be aware of the varied effect of temperature and covering on the first oviposition timing of blow flies. This detailed information should be taken into account when PMI is calculated using blow fly evidence.

Oviposition Timing, Blow Fly, Postmortem Interval

G38 Evaluation of Head Trauma With Antemortem Radiology and Postmortem Pathological Data

Nursen Turan, MD, Tevfik Saglam C. No:45/10 B Blok, Altintepe Kucukyali 34840, Istanbul, TURKEY; Esin Akgul, MD, Onsekiz Mart Universitesi Tip Fakültesi, Canakkale, Canakkale, TURKEY; and Mete K. Gulmen, PhD, MD, Cukurova Univ, School of Medicine, Dept of Forensic Medicine, Adana, 01330, TURKEY*

The goal of this presentation is to show how antemortem imaging data including conventional radiography and Computed Tomography (CT) were compared to the postmortem pathological data that served as the gold standard with regard to common forensic neurotrauma findings such as skull fractures, soft tissue lesions of the scalp, various forms of intracranial hemorrhage, contusion, axonal injury, signs of increased brain pressure or herniation, edema and ischemia. In this study, the purpose is to establish if any difference between radiological and autopsy data occurred in the short period of time after trauma and if conventional radiography and CT is beneficial for forensic head and brain examination.

This presentation will impact the forensic science community by showing how cases underline the importance of a detailed investigation and a thorough evaluation of all circumstantial, clinical, radiological, and autopsy data in the reconstruction of forensic fatalities to identify any possible legal responsibilities of anyone.

Introduction: Head trauma is one of the leading causes of traumatic deaths. The radiological reconstruction of trauma before the autopsy will guide exploring the circumstances of many forensic deaths including occupational, accidental, and medical malpractice cases, especially in the case of hospitalization for a long period of time. The increasing applications of forensic radiology and the wide use of conventional radiography and CT in clinical practice also demonstrate the potential of these technologies as tools for verifying the correspondence between an unidentified body and an identity suspect. CT is the imaging modality of choice for 2D and 3D documentation and analysis of postmortem findings including fracture systems, pathologic gas collections (e.g., air embolism, subcutaneous emphysema after trauma, hyperbaric trauma, decomposition effects), and gross tissue injury. Various post-processing techniques can provide strong forensic evidence for use in legal proceedings. Besides, Magnetic Resonance (MR) imaging has also had a greater impact in demonstrating soft-tissue injury, organ trauma, and nontraumatic conditions.

Methods: The antemortem imaging data, including conventional radiography and CT, were compared to the postmortem pathological data that served as the gold standard with regard to common forensic neurotrauma findings such as skull fractures, soft tissue lesions of the scalp, various forms of intracranial hemorrhage, contusion, axonal injury, signs of increased brain pressure or herniation, edema, and ischemia

Findings: Reports of both postmortem pathological and the antemortem radiological examination of brain and skull in 31 head trauma cases were evaluated. Age range was between 1 to 90. Gender included 25 male and 6 female cases. Any distinct difference between the antemortem imaging and the autopsy data was not found in the case of skull fracture and various forms of intracranial hemorrhage. Axonal injury and contusions were detected more sensitively with the autopsy than with the imaging techniques. During the time the autopsy and radiology reports were performed other brain lesion findings were discussed.

Conclusion: The cases underline the importance of a detailed investigation and of a thorough evaluation of all circumstantial, clinical, radiological, and autopsy data in the reconstruction of forensic fatalities to identify any possible legal responsibilities of anyone. The documentation and analysis of antemortem findings with CT and MR imaging is investigator independent, objective, and noninvasive and will lead to qualitative improvements in forensic pathologic investigation. In addition, as with other morphological methods for identification, comparisons between antemortem and postmortem data require standardization and statistical analysis, especially concerning the admission in court of evidence obtained by anthropological and radiological methods. In consideration of these facts, radiological techniques have the power to play an important role in the forensic pathological examination.

Head trauma, Radiology, Autopsy

G39 An ELISA Examination of Pro-Inflammatory Proteins in Human Blood Samples: A Potential Means for Investigating Diabetes in Postmortem Human Remains

Shannon E. May, MA, Univ of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37966*

After attending this presentation, attendees will become familiar with cytokines and their relationship to the metabolic disorder diabetes mellitus.

This presentation will impact the forensic science community by demonstrating how blood cytokines may be successfully analyzed in human remains, and how results may be used to suggest diabetic condition. This is the first time that cytokine data has been applied to postmortem material to provide additional information that may advance human identification in forensic contexts.

The number of individuals suffering from diabetes has reached epidemic proportions globally and within the United States. In 2007, diabetes was cited as the seventh leading cause of death in the United States and was a contributing factor in another 160,000 deaths.[1] Forensic anthropologists must be prepared to recognize diabetes in skeletal remains as they would any other well-documented pathology. The purpose of this research is to investigate diabetes in postmortem material employing blood serum protein analyses.

Diabetes mellitus is a group of metabolic disorders characterized by chronic hyperglycemia and disturbances in carbohydrate, fat, and protein metabolism, resulting from defects in insulin production and/or function.[2] Insulin regulation is crucial because this hormone is primarily responsible for transporting blood glucose into cells, providing a vital energy source. The present study will selectively focus on Type 2 diabetes, as it is most prevalent and the only form of diabetes documented in the William M. Bass Skeletal Collection.

The predominant theory explaining pathophysiology of diabetes involves activation of the immune system in response to metabolic stress, caused by over-nutrition. Normal physiological response to exogenous stress triggers inflammation of the affected tissue. When stress is acute, inflammation has positive effect, resulting in cell repair and tissue regeneration; however, when the condition is chronic, like obesity and insulin resistance, inflammation may become deleterious and maladaptive.[3] Researchers have identified that patients suffering from Type 2 diabetes demonstrate inflammation in tissues related to adiposity and glucose handling.[4] Studies have uncovered autoimmune inflammation in the insulin-producing pancreatic β-cells of diabetics. Cytokines are cell-signaling proteins that serve as primary mediators of immune responses. Many cytokines are secreted by adipocytes, demonstrating a link between obesity and insulin resistance. Pancreatic inflammation has been termed "insulitis" and may be is characterized by elevated levels of leukocytes and cytokines in the blood stream.[5] Biomarkers of inflammation, like cytokines, can be quantified and may be used as proxy variables to track the progression of insulin resistance.

The William M. Bass Skeletal Collection provides a unique opportunity to investigate diabetes in an extensively documented modern population. Blood sample collection was initiated in 2008 by the UT Forensic Anthropology Center for donated human remains. For this research, four preliminary samples were selected: two known diabetics and two non-diabetics who were pair-matched based on demographic characters (age, sex, ancestry, and body mass index). Diabetic status must be assumed from self-reported medical history.

Blood samples were extracted from the bloodcard paper matrix using a repo-buffer solution. A Bradford Quantification Assay was used to test and verify sufficient amounts of proteins present in each sample. Samples were then subjected to an ELISA multiplex. ELISA analyses determine the presence and concentration of an unknown biomarker. The multiplex investigated 26 pro-inflammatory cytokines. Elevated values were determined in eleven cytokines, six of which warranted statistical testing. Significant difference between the diabetic versus non-diabetic samples was assessed with univariate ANOVAs with a single fixed factor. Assumptions of normality and variance were tested and proven with a Shapiro-Wilks and Levene's test (respectively). To avoid Type 1 error, a Bonferroni Correction was applied (modified α=0.008). After adjusting the alpha, one cytokine (IL-8) significantly differentiated between sample groups (α=0.001); however, another cytokine (MCP-1), demonstrated a tendency toward significance prior to Bonferroni adjustment (α=0.019) which may be recognized given a larger sample size. Both of these cytokines show high correlation with insulin resistance, and are reported to interact with bone cells

Results from this preliminary study indicate that cytokines may be successfully tested in postmortem samples. Data may be used to suggest diabetic status in unknown remains.

Postmortem Pathology, Diabetes, ELISA Analysis

G40 The Role of *Lepas Sp. Crustacea Cirripedia Pedunculata* in the Evaluation of Postmortem Interval in Aquatic Environments

Francesca Pepe, MD, Isabella Aquila, MD*, and Silvia Boca, MD, Magna Graecia Univ, Viale Europa, Località Germaneto, Catanzaro, ITALY; Paola A. Magni, MS, Univ di Torino, Via Accademia Albertina 13, Torino, ITALY; Ester De Luca, MD, Debora De Bartolo, Carol Pileggi, MD, Ciro Di Nunzio, PhD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand what investigative role water fauna plays in the evaluation of PMI and PMSI in cases where the discovery of corpses is in aquatic environments.

This presentation will impact the forensic science community by demonstrating how product and entomological surveys could give clues on the origin and permanence of an unidentified corpse.

Introduction: The interval between death and the discovery of a body is known as postmortem interval. Backdating the time of death is useful for resolving legal issues when a corpse is recovered. It is particularly useful to: (1) know when the crime was committed; (2) identify the victim; (3) exclude some suspects in the murder case; (4) direct the investigations of law enforcement; and, (5) verify the statements of a suspect. Among the methods used to calculate the PMI include: analysis of consecutive abiotic phenomena (algor mortis, rigor mortis, livor mortis), analysis of ocular changes, analysis of cadaveric fauna (insect larvae, insects, fish, shellfish), and analysis degree of decomposition.[1-4] In particular, the permanence of a water body causes alterations of both phenomena cadaveric (putrefaction) finds in the exterior and interior of the body. The permanence of the body in water can result in the appearance of cadaverous transformative special phenomena, such as the saponification, with consequent formation of adipocere, and maceration. Of particular interest is the relief of foreign materials and lesions produced in the aquatic environment. These lesions can be produced by the impact of body against rocks and cliffs or into water fauna (vertebrates and invertebrates) and it can cause different types of lesions or sometimes some problems in the distinction of antemortem and postmortem lesions. The wildlife that tends to colonize the corpse in the water allows the evaluation of Postmortem Submergence Interval (PMSI), due to the different timing of colonization of the body by the aquatic fauna and different species of algae found.[5]

The goal of this study was to estimate the time of growth of some types of shellfish to determine the postmortem interval and PMSI. This investigation, in case of naval or air mass disasters, also allows one to determine the possible origin of the body relative to the place where the corpse was found.

Case report: A male subject found on a beach in Central Tyrrhenian of the Southern Italy was analyzed. The external examination showed a corpse in a state of saponification with some areas of maceration from a long stay in the water. For this reason, the external somatic features couldn't be recognized. A survey of clothes was carried out and showed the presence of specific clothing imported from the United States and Italy. Also on the trousers of the victim were crustaceans that were analyzed. In particular, the species found were categorized as belonging to the family of *Lepas sp. (Crustacea: Cirripedia pedunculata)*. The autopsy was completed at the Unidentified Corpse Board (RiSc) for the Ministry of Justice in Italy, then sent to a competent authority. Following the compilation of the board we were contacted by the Police Station of Giglio Island for a possible correspondence with a missing passenger on the Costa Concordia, whose shipwreck occurred on the Ligurian coast January 13, 2012.

The results of autopsy showed the saponification resulted from long permanence in water (three months). An entomological survey was carried out on the time of growth of these crustaceans and the natural habitat of the same was studied. The data obtained was

compared and showed an elapsed time from death to the discovery of approximately three months. This time interval was compatible with the Costa Concordia's sinking. For many reasons, the genetic investigation was performed to confirm or reject the hypothesis.

From a scientific point of view, this study is important because it emphasizes the role of marine life in the evaluation of PMI and PMSI, especially in cases of discovery of unidentified bodies in the aquatic environment. This resolves, at times, problems related to the origin of the corpse from the place where it was found or any information on the country of origin where the accident occurred.

G41 The Hidden Side of Sudden Cardiac Death: Forensic Experimental Protocol and Its Applications

Giovanni Cuda, MD, PhD, Arianna Serra, MD, Isabella Aquila, MD*, Francesco Ausania, MD, Ciro Di Nunzio, PhD, Francesca Pepe, MD, Silvia Boca, MD, Maria Chiarelli, MD, and Pietrantonio Ricci, PhD, MD, Magna Graecia Univ, Viale Europa, Germaneto, Catanzaro, 88100, ITALY*

After attending this presentation, attendees will understand the role of gene mutational analysis in sudden cardiac death.

This presentation will impact the forensic science community by discussing the importance of a rigorous genetic testing protocol in sudden cardiac death diagnosis when autopsy examination is not performed.

Introduction: Sudden Cardiac Death (SCD) is death from cardiac causes within one hour of the onset of symptoms. The sudden death of young people is a devastating event for both the family and community. Over the last decade, significant advances have been made in understanding both the clinical and genetic basis of sudden cardiac death. Most commonly, sudden cardiac death can be the first presentation of an underlying heart problem, leaving the family at a loss as to why an otherwise healthy young person has died.

At external examination on a victim of SCD, the features of hypostasis are the most important gross findings. On examination, hypostasis in these cases show, especially, a typical dark red/blue color on the face, neck, and anterior thoracic wall. There is a deep cyanosis on lips and nail beds. The diagnosis is suggested by the absence of external gross injuries. Genetic factors are important factors to the risk of SCD. Coronary artery disease is the major determinant of SCD, and its predisposing genetic role is complex. The other main causes of sudden cardiac death are some hereditary non-structural diseases such as Catecholaminergic Polymorphic Ventricular Tachycardia (CPVT), long QT, and the Brugada Syndrome, as well as structural diseases such as Hypertrophic Cardiomyopathy(HCM) and Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) which cause a significant number of cases of sudden cardiac deaths in the young. Many times for economic reasons, in the cases of SCD judicial authorities do not require an autopsy examination performed by a forensic pathologist. As an unfortunate result, forensic investigation of SCD often involves only the external examination of the victim's body. Especially in these cases, genetic testing may be useful because many mutations in several genes are implicated in arrhythmic syndromes including SCN5A, KCNQ1, KCNH2, RyR2, and genes causing HCM, specifically MYH7 and MYBPC3. In these cases of SCD when autopsy examination is not performed, an important progress in diagnosis depends on the use of a rigorous protocol in order to analyze biological samples of saliva of the victim according to the informed consent of the victim's relatives.

Case Reports: Twenty cases of sudden cardiac death were analyzed. In these cases, autopsy examination was not required. For 18 cases, forensic pathologists made external examination and for two cases autopsy was carried out. In these last cases, the cause of death was thromboembolic death ARVC. In the others, the cause of death remained unknown.

The goal of this study is understanding the importance of investigation protocol in order to investigate gene mutational analysis in both structural and non-structural genetic heart disease including SCN5A, KCNQ1, KCNH2, RyR2, MYH7, and MYBPC3. If the victim's test is positive, this information is important for relatives who might themselves be at risk of carrying the disease-causing mutation.

Conclusions: This protocol has to be applied in all cases where forensic pathologists must identify the cause of death without autopsy examination. The main goals of this protocol is to evaluate exact incidences of cardiac causes of sudden death, counseling for victims' relatives, and potential therapy for genetic mutations carried.

Sudden Death, Autopsy, Genetic Mutation

G42 The Role of Forensic Investigations in Child Abuse: Two Case Reports and a Review of Literature

Ciro Di Nunzio, PhD, Isabella Aquila, MD, Carol Pileggi, MD*, Francesca Pepe, MD, Maria Chiarelli, MD, Arianna Serra, MD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the impact of the forensic science in cases of rape in children.

This presentation will impact the forensic science community by providing information to allow a method that recognizes signs of sexual abuse of minors.

Introduction: This research explores sexual violence, which is a major problem for healthcare. One in six people are victims of rape or attempted rape. A total of 20% of women and 10% of men say they had experienced sexual abuse during childhood. There are 40 million children under age 15 who suffer abuse and neglect. Disabled children are at a level of risk for physical and sexual abuse more than double that of healthy children. The 1.5% of total violence is the incestuous relationship within the family. The proportion of other relatives who commit sexual violence is 4%. All forensic investigations of the victims of rape left particular signs: hyperthermia, bruising, laceration of the mucous membranes of the genitals or perigenital regions, body injuries, marks of constriction, junction lesions by excitement or torture, and the presence of biological traces. A careful review of the literature revealed that the major problem for forensic investigations is detecting signs of violence on the victims. The research demonstrates that many conditions have been mistaken for signs of abuse. The etiological diagnosis based on physical examination is often difficult because the physical signs are

not always present and, if they are present, can be ambiguous; however, for a forensic pathologist it is essential to differentiate accidental injuries and inflicted injuries.

Case Reports: Two cases of incest are reported. One act of violence was perpetrated on a young girl (12-years-old) by the father and an uncle. In this case, the victim filed a complaint six months after the incident, but through careful examination by the coroner, the presence of a hymen was found without evident marks of violence. In this case, the hymen of the young girl revealed elastic characteristics. For this reason, the forensic pathologist could confirm violence occurred and was also confirmed through the testimony of the child. In the second case, a young boy (12-years-old) affected by mental retardation was analyzed. The violence was perpetrated on the child by his uncle. The forensic examination established the presence of possible signs of violence. Also, in this second case, there was confirmation of violence from the child's testimony. These unusual cases were solved by forensic ivestigation. Through forensic investigations the accused were sentenced. The results of forensic examinations were compared with psychological examinations on the victims. In both cases it confirmed the forensic physician results.

Conclusions: For victims of rape, the forensic medical examination is the first step toward solving the crime. In cases of sexual violence, the role of forensic pathologist, through expertise and training, is crucial for the analysis and production of visual evidence. This presentation shows that the uncertain cases were solved with the help of forensic documentation and sciences evidence. Therefore, in order to be more efficient, this study proposes the creation of a multidisciplinary center for anti-violence, implementing a specialized system. In this center, the intervention of a specialist team will allow for correct identification and interpretation of exterior signs and marks on the victims. This team will consist of the forensic pathologist, gynecologists, psychiatrist, pediatrician, forensic geneticist, and other operators. This study indicates that this system is adjusted to various types of forensic cases, and many will benefit.

Child Abuse, Forensic Pathologist, Rape

G43 Technical Data of Intimate Partner Homicide-Suicide in Turkish Mass Media Between 2008-2011 Through Autopsy Reports

Bunyamin Baspinar, MD, The Council of Forensic Medicine, Yenibosna, Istanbul, TURKEY; Ipek Esen Melez, MD, Adli Tip Kurumu Cobancesme, Istanbul, TURKEY; Deniz O. Melez, MD, Basaksehir Mahallesi, Anafartalar Caddesi, Oyakkent 2 Etap B04, Daire 45, Basaksehir, Istanbul, TURKEY; and C. Haluk Ince, PhD, Ministry of Justice, Council of Forensic Science Med, Sanayi cd. Kimiz sok. No. 1, Istanbul, TURKEY*

After attending this presentation, attendees will have an idea of technical details of intimate partner homicide-suicide autopsies.

This presentation will impact the forensic science community by discussing the procedures of autopsy reporting and autopsy findings in intimate partner homicide-suicide cases through optimal standards.

The term "Homicide-Suicide" (HS) can be defined as "the committing of suicide by the same individual after his/her commitment of a homicide." HS is most frequently seen among intimate partners and, within this scope, is an important part of the sexual violence in society. Besides, violent features of these incidences mostly find a place in mass media. This study is intended to elicit scientifically the technical data, or autopsy findings, of these mass media cases which have been constituting a good "image" of the general "picture" all around the country about Intimate Partner Homicide-Suicide (IPHS).

A media monitoring agency has been used with specific keywords to detect all the detectable incidences of IPHS which had found place in mass media between 2008 and 2011 in Turkey. Then, the cases were searched in the Turkish judicial system through the autopsy report archives of forensic medicine units all around Turkey, which are organized in the structure of the Council of Forensic Medicine, a unique official forensic medical expertize institution, as a whole. No matter how long the optimal interval between homicide and suicide is defined, in this study all cases for which "homicide-suicide" term between intimate partners has been used in autopsy reports between January 1, 2008, and December 31, 2011, have been accepted as IPHS. Judicial records were evaluated in order to have the autopsy data of the victims. The data collected were analyzed through descriptive statistics and chi-square test with predictive analytics software.

Among 122 IPHS cases, only the autopsy reports of 96 cases could be found. For the remaining 26 cases, the reason for the lack of an autopsy report was either the victim's burial without autopsy through only a death examination report or the autopsy's being performed by another physician (most probably not a forensic medicine specialist) working out of the Council of Forensic Medicine.

According to obtained data, among 96 victims with autopsy reports, only three victims were found to be males. The most frequent method in homicides was determined to be firearm injury (69.7% (n:85) pistol, 18.9% (n:23) shotgun), as the total 89.6% (n:86) of the victims had been killed with a firearm. Lethal lesions were most frequent, as 32.6% (n:28), on the head as a single lesion. There were, in all, 217 injuries resulting from gunshots on 86 victims killed with a firearm, while there were at most 11 injuries per victim with a mean injury number of 2.26 for each victim. When checked according to the features of these injuries, 19.8% (n:17) of the injuries were from contact shots, 10.5% (n:9) were from near contact shots, 20.1% (n:18) were from intermediate range shots, 19.8% (n:17) were from distant shots. Toxicological tests were performed for 75% (n:72) of the 96 victims. Among 72 victims, ethanol was found in 12.5% (n:9).

Among perpetrators' suicides, again the most frequent method of suicides was firearm injury (69.8 % (n:84) pistol, 20.5% (n:25) shotgun) as total 89.6% (n:86) of the perpetrators had committed suicide with a firearm. Lethal wounds were most frequent, as 76% (n:73), on the head as a single wound (with a pistol in 80.8% [n:59], with shotgun in 17.8% (n:13), with falling from a height in 1.4% (n:1). The suicide of the perpetrator was more frequently and statistically significant in the first hour after the homicide, and the method was more frequently and statistically significant with the same homicide method. Toxicological tests were performed for 71.9% (n:69) of the 96 perpetrators; among 69 perpetrators, ethanol was found in 12.5% (n:9) and insecticide was found only in one perpetrator explaining the origin.

Besides the discussion of these technical details above about the nature of injury, the ratio of autopsy in IPHS cases as 96/122 indicates some legislation problems in Turkey in letting other physicians perform autopsies or allowing burial without a forensic medicine specialist's consent, but instead with the assignment coming just from the prosecutor. Quality standards like 99/3 Autopsy Harmonization Standards across Europe or any ISO 17020 execution can help to convert the legislation according to scientific standards of authorization in autopsy performance.

Homicide-Suicide, Intimate Partner, Autopsy

G44 Oblique Lighting Applications in Forensic Sciences

Ashley M. Wright, 837 Walker Rd, Rockwood, PA*

The goal of this presentation is to demonstrate the effective use of oblique light to enhance surface texture and illuminate subtle features in a forensic setting.

After this presentation, attendees will have a better understanding of when and how to use the oblique lighting technique during a forensic examination.

Photographic documentation of autopsy findings is of particular importance, especially in cases which could result in judicial

proceedings. When in court, expert witnesses use these visuals to present what was initially observed during the examination; therefore, documenting accurate images are vital for this process. Typical photography technique used during autopsy examinations for documentation involves perpendicular direct light on the region of interest. Oblique lighting is commonly used to reduce glare that may obscure the subject matter. This presentation discusses the use of oblique lighting to highlight subtle features and traumatic injuries so that detailed visual documentation is available. This technique was used in three different types of examinations in a medical examiner setting: pathology, neuropathology, and anthropology.

The study was conducted during a three-month Forensic Photography Internship Program at the Harris County Institute of Forensic Science (HCIFS), Houston, TX. Photographs of 15 cases were taken as part of the autopsy using the standard operating procedures defined by the Forensic Imaging Division. Photographs were taken using a digital SLR camera fitted with a 35-70mm lens as well as a 105mm macro lens. The camera also included a digital SLR off-camera Through the Lens (TTL) flash and a digital SLR TTL off-camera flash cord. The cases photographed required one or multiple types of examinations including pathology, neuropathology, and anthropology; therefore, the subject matter included both soft and hard tissue. Photographs were taken at the request of the forensic pathologist as needed during the autopsy for each case. Neuropathology photographs were taken after the brain and eye samples were formalin-fixed and dissected for examination. Anthropology photographs included cases recently exhumed as part of the HCIFS Unidentified Decedent Review. Photographs were taken prior to processing the exhumed remains as well as after the remains were processed for anthropology analyses. All the cases photographed for this study used direct perpendicular light and oblique lighting to demonstrate the efficacy of oblique light when surface texture details are required.

Results show that when oblique lighting is applied the amount of detail being documented is increased. In pathology examinations, soft tissue impressions were highlighted when oblique light was used. The lighting was best used in cases of motor-vehicle accidents to emphasize the presence or absence of seatbelt injuries; in cases of gunshot wounds where the presence of Gunshot Residue (GSR) needed to be recorded; and in cases of hanging/strangulation where the details of the ligature furrow needed enhancing. To document neuropathology examinations, oblique lighting was used to illuminate the eye to visualize retinal hemorrhages as well as to reduce the glare caused by vitreous fluid. These types of hemorrhages are particularly important in suspected child abuse cases. With photographs of the brain, oblique light reduced the glare typically encountered with direct perpendicular light. In anthropology examinations, oblique light successfully captured billowing on the surfaces of the pubic symphyses as well as epiphyses from the long bones of young individuals. These features are particularly important in estimating age. Furthermore, oblique lighting was best suited to document cases of subtle perimortem injury, in particular sharp force trauma, when present on bone.

This study demonstrates the usefulness of oblique lighting for photographic documentation of subtle surfaces details acquired during examinations in a medicolegal setting. These details play a vital role in assessing cause and manner of death and are especially important in cases where this information will be presented in court.

Forensic Photography, Oblique Lighting, Technique

G45 Death Due to Renal Toxicity Following Bath Salts Abuse

Joseph A. DelTondo, DO, 709 Sloop Rd, Pittsburgh, PA 15237; Todd M. Luckasevic, DO, and Baiyang Xu, MD, OCME, 1520 Penn Ave, Pittsburgh, PA 15222; Abdulrezak M. Shakir, MD, OME of Alleghany County, 542 Fourth Avenue, Pittsburgh, PA 15219; and Karl E. Williams, MD, OCME, 1520 Penn Ave, Pittsburgh, PA 15222*

The goal of this presentation is to illustrate a case of death associated with the use of Psychoactive Bath Salts (PABS) and the associated renal findings.

This presentation will impact the forensic science community by illustrating the unusual renal findings in a death associated with PABS and a novel theory.

The abuse of PABS has become increasingly common in the United States since being introduced in the early 2000s. Cases of overdose are increasing in presentation and significant morbidity and mortality have been reported.

PABS belong to a family of drugs known as synthetic cathinones. Cathinone is a naturally occurring amphetamine analogue found in the *Catha edulis* plant. The most commonly isolated synthetic cathinone found in PABS appears to be Methylenedioxypyrovalerone (MDPV). In one study analyzing patient blood, urine, and PABS samples, no other synthetic cathinones other than MDPV were detected. Testing for MDPV poses an issue in forensic medicine as MDPV is not commonly screened for in routine toxicological testing and may cause a false-positive result for Phencyclidine (PCP).

The effects of PABS are similar to those attributed to other amphetamines and central nervous system stimulants by inhibiting dopamine and/or norepinephrine reuptake. Rhabdomyolysis, hepatic and renal failure, and cardiac and neurologic toxicity have been reported.

Although illegal in the United States, PABS are reportedly accessible via the Internet and are commonly produced overseas, often in China. Currently, the short- and long-term physiologic effects of PABS and their etiology are not fully understood.

Materials and Methods: The case involved a 42-year-old Caucasian male with a history of alcohol abuse, Hepatitis C, and liver disease. He was found unresponsive by family members at his residence where he had reportedly been ingesting PABS.

Initial toxicology screening performed at the treating hospital was positive for PCP and opiates and negative for alcohol. He ultimately developed multisystem organ failure and sepsis after a prolonged stay in the intensive care unit. Death ensued thirteen days after initial presentation. Treating physicians could not rule out a possible overdose.

Results: External examination revealed mild anasarca, moderate pulmonary congestion and edema, jaundice, and one liter of ascites fluid. Microscopic examination of the liver revealed portal lymphocytosis and stage III bridging fibrosis compatible with the clinical history of Hepatitis C virus. Sections of the kidneys demonstrate mildly dilated tubules containing round to ovoid, lightly eosinophilic, green crystals with concentric peripheral lamellations and central radiations, both singly and in small aggregates. Literature review revealed that these crystals are compatible with melamine/cyanuric acid crystals.

Conclusions: Considering these findings in the context of reported PABS abuse and what little is known about PABS manufacturing, it is possible that melamine toxicity contributed to the renal failure in this case. Melamine is an organic compound used in the production of plastics, dyes, fertilizers and various textiles. In the late 2000s, melamine was found to be present in several products produced overseas including pet food, livestock feed, and infant milk, where it was used as filler to falsely increase the protein content.

Both the acute and chronic toxicity of melamine has been well documented. In one study, sheep fed a single 100g dose of melamine all died of renal failure within 11 days.

In this case, melamine may have served as an unintentional contaminant of PABS manufacturing or as filler to falsely increase the

amount of the crystalline drug. Future plans for research are to analyze various PABS with both Fourier Transform Infrared Spectroscopy (FTIR) and Gas Chromatography-Mass Spectroscopy (GC/MS) for the presence of melamine.

Additional pre- and postmortem investigation is required to further establish an etiology of multisystem organ toxicity in PABS abuse.

Bath Salts, Melamine, Renal Failure

G46 The Ability to Shoot Back: Review of Multiple Suicidal Gunshot Wounds to the Chest

Jacqueline Nunez, MD, 85 N Sprague Ave, Pittsburgh, PA 15202; Todd M. Luckasevic, DO, and Baiyang Xu, MD, OCME, 1520 Penn Ave, Pittsburgh, PA 15222; Abdulrezak M. Shakir, MD, Alleghey County MEO, 542 Fourth Ave, Pittsburgh, PA 15219; and Karl E. Williams, MD, OCME, 1520 Penn Ave, Pittsburgh, PA 15222*

The goal of this presentation is to illustrate three cases of multiple gunshot wound suicides involving seemingly incapacitating injuries on the initial attempt with a firearm with the ability to follow-up with a second gunshot.

This presentation will impact the forensic science community by illustrating the ability to survive extensive and devastating damage caused from an initial gunshot wound, and the potential for physical activity to inflict additional gunshots with a firearm.

Multiple gunshot wound suicides are encountered infrequently but are well documented in forensic pathology. The literature covers a range of unusual circumstances and settings that have involved common target sites and the use of multiple firearms. The cases are often challenging to law enforcement personnel and to the pathologist.

Suicides involving firearms are generally lethal and certain vital regions of the body are targeted for rapid incapacitation. These areas are physiologically necessary to maintain central nervous system function. The most common sites are gunshots to the head causing direct disruption of cerebral tissue, and gunshots to the chest causing cerebral hypoperfusion and hypoxia from massive blood loss from the heart and major blood vessels. The possibility of physical activity after sustaining massive damage is crucial in the reconstruction of shootings involving more than one gunshot wound.

Materials and Methods: Three cases of multiple suicidal gunshot wounds to the chest are presented. All three cases involve Caucasian males ranging in age from 40 to 87 years with two self inflected gunshot wounds to the chest region. The investigative report and scene photographs are reviewed for type and caliber of firearm and the autopsy report and photographs are reviewed for bullet injury profiles.

Results: The first case (87-year-old) revealed two contact penetrating gunshot wounds to the left chest with one bullet causing injury of the left lower lobe of lung and the second bullet perforating the thoracic aorta and heart. Associated injuries included a left-sided 400ml hemothorax, 200ml of hemopericardium and periaortic hematoma. The firearm was a .38 special revolver.

The second case (40-year-old) revealed one contact penetrating gunshot wound to the right chest with bullet injury to the middle and lower lobes of the right lung and the liver and one contact perforating gunshot wound to the left chest with bullet injury to the left lung including the pulmonary artery and vein. Associated injuries included 1,200ml bilateral hemothorax. The firearm was a 45-caliber semiautomatic handgun.

The third case (75-year-old) revealed two contact penetrating gunshot wounds to the midline chest with one bullet causing injury to the right lung, heart, vena cava, and aorta and the other bullet causing injury to the liver, thoracic spine, and descending aorta. Associated injuries included a 2,000ml right hemothorax, thoracic spinal cord subdural and subarachnoid hemorrhages, and a 200ml hemoperitoneum. The firearm was a 9mm semi-automatic handgun.

Conclusions: Multiple gunshot wound suicides can help elucidate the potential for meaningful physical activity after sustaining catastrophic injuries to vital organs. These cases can help law enforcement and forensic personnel understand the amount of time that can elapse from wound to loss of cerebral function and the ability of an individual to perform meaningful physical activity. The cases presented here highlight the extraordinary human capacity and a desertion of the primal nature for survival.

Suicide, Firearm, Multiple Wounds

G47 Use of Therapeutic Intravenous Catheters in Drug Addiction: A Series of Three Cases

Shari Brown, MD, PO Box 645, Ramseur, NC 27316; Patrick E. Lantz, MD, Donald R. Jason, MD, JD, and Jerri McLemore, MD, Wake Forest Univ, School of Medicine, Medical Center Blvd, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will become aware of a potentially overlooked deadly method of intravenous drug use. This poster will provide the attendees with a review of the stigmata of clinical and histopathologic findings associated with illicit drug use using therapeutic intravenous catheters.

This presentation will impact the forensic science community by bringing attention to an easily overlooked method of intravenous drug abuse, especially in the hospital setting.

Numerous creative methods and behaviors for abusing prescription and illicit drugs have been detailed in the literature over the years, including the recent tendency to inject or snort crushed prescription medications that are designed for oral ingestion. Numerous articles and news stories have discussed deaths of debilitated people injected by lethal doses of medication or poisons by caretakers, often in hospital settings; however, there has been little discussion of the use of therapeutic intravenous catheter ports in the addicted population. This presentation will discuss two Medical Examiner (ME) cases and one hospital-based autopsy case in which this behavior was reported in the patient's history and/or was shown to contribute to the patient's demise.

Case Description: Case one was an ME case involving a 26-year-old female undergoing chemotherapy for recurrent Hodgkin's Lymphoma who died of acute morphine toxicity. A prescription for morphine sulfate was filled two days prior to her death with only 93 of 120 tablets remaining in the bottle. Investigators at the death scene were suspicious that she had accessed the port of her chemotherapy line for the purpose of injecting her oral medications. At autopsy, microscopic sections showed numerous intravascular and perivascular granulomata with polarizable foreign material, with additional foci of polarizable material found within the splenic and hepatic macrophages. Case two was an ME case involving a 47-year-old female with end stage renal disease secondary to Goodpasture's syndrome who died of acute cocaine toxicity. The investigation revealed she had a history of accessing her port for administering illicit substances. Postmortem toxicology revealed the presence of cocaine and its metabolite in her blood. Case one and two demonstrate the difficulty in managing drug addiction in the chronically ill and palliative care populations.

Case three was a hospital-based autopsy of a 38-year-old male with a history of polysubstance abuse who was admitted for multilevel epidural spinal abscess with cultures positive for *Staphylococcus aureus*. His condition was attributed to intravenous drug abuse. Treatment for his abscess required intravenous antibiotics, so an intravenous portacath was placed. During treatment in the hospital, he was encouraged to ambulate and often left the hospital floor on his own. Some of these excursions were followed by episodes of respiratory desaturation and decompensation leading to extensive workups to rule out a pulmonary thromboembolus. For this reason, clinicians obtained consent for a hospital-based autopsy. At autopsy,

microscopic sections of the lungs revealed much polarizable crystalline material both in the lumens and within the walls of vessels accompanied by granulomatous inflammation with multinucleated giant cells. Some of the vessel walls were thickened due to myofibroblastic proliferation around the foreign material; changes consistent with his two-week stay in the hospital.

Summary: These three cases represent a method of intravenous drug abuse in an addicted population leading to death that is most likely underreported due to lack of recognition, especially when the death occurs in a hospital setting. Chronically ill and palliative care patients, particularly those with terminal illnesses, may not trigger an extensive investigation including autopsy since death may be easily ascribed to the natural disease process. Clinicians working with patients who have addiction problems should consider the increased potential of drug-related fatalities if these patients have in-dwelling intravenous catheters. A closer review of these types of cases is needed to properly assess the true incidence of this behavior.

Pulmonary Granuloma, Intravenous Catheter, Intravenous Drug Use

G48 Homicide, Suicide, or Accident? An Unusual Case of Hanging Attempt

Eloisa Maselli, MD, Domenica Laviola, MD, PhD, Annamaria Lobifaro, and Biagio Solarino, PhD, Univ of Bari, Pizza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, attendees will be able to understand that sometimes the evidence does not necessarily correspond to what we think. Crime scene investigation needs a skeptical approach to evaluate the better way all the evidence is useful to establish the manner of death.

This presentation will impact the forensic science community by demonstrating the importance of a multidisciplinary competence in crime scene investigations that need a well-established methodology by forensic pathologists rather than emergency physicians or policemen that arrived before them and could misrepresent the evidence and autopsy findings in differential diagnosis between self-inflicted hanging and blunt lesions.

Hanging has many features in common with ligature strangulation. Death is, however, more often caused by reflex cardiac arrest from pressure on the carotid structures. It is difficult to evaluate the survival time after hanging; hence, if death is not sure, the physicians have to cut the rope to start resuscitation. Hanging's victims are generally found with pale faces, rather than the congested, hemorrhagic appearance of the slower asphyxia type of death. Most hangings are self-suspension. This may be carried out by a wide variety of methods, but a typical method of self-suspension is to attach a thin rope to a high point, such as a ceiling beam or staircase. The lower end is formed into either a fixed loop or a slipknot, which is placed around the neck while the intending suicide stands on a chair or other support.

The case presented is of a 32-year-old man who was found suspended from a balcony in a courtyard. Police and Emergency Medical Service (EMS) was called immediately but, physicians believed the man was dead when the crime scene investigation started. The right hand of the victim was grasping a node on the right side of the neck and the left hand was grabbing the unstable loop knot. After few minutes, the body fell to the floor and the ear started bleeding.

At external examination, a late-onset right orbital hematoma was found, suggesting a fracture at the skull base. The occipital region of the head showed a star-shaped lacerated wound. A typical hanging mark was evident around the neck, not completely encircling it because of the two gaps at the sides of the neck, for the interposition of fingers between noose and skin. The autopsy showed brain epi and subdural hemorrhage with skull base fracture. The histological analysis of the lung tissue showed alternating areas of alveolar collapse and overinsufflation by compensatory emphysema, typical of a slow asphyxia. No alcohol or drugs of abuse were found in the blood and urine collected at autopsy. All these findings demonstrated that the cause of death was due to traumatic cranio-cerebral injury which occurred when the subject was still alive, even if in agonal state following the hanging. Circumstantial data revealed that the victim was homosexual, and he was falling out of love with his boyfriend. In the past, he simulated other self-inflicted hangings, the last one occurring two days before his death.

The case was closed as an accident consequent of a suicide attempt. The manner of death and focus on possible liability of EMS personnel in determining death was speculated.

Hanging, Suicide, Crime Scene Investigation

G49 Cell Death Proteins as Markers of Early Postmortem Interval

Sara C. Zapico, PhD, HURLE, Dept of Anthropology, NMNH, MRC 112, Smithsonian Institution, PO Box 37012, Washington, DC 20560; Sofia T. Menéndez, PhD, Hospital Univ Central de Asturias, IUOPA, HUCA and Univ of Oviedo, C/Celestino Villamil s/n, Oviedo, Asturias SPAIN; and Paula Núñez, PhD, Dept de Biologia Funcional Fisiologia, Facultad de Medicina Univ de Oviedo, Julian Claveria s/n, Oviedo, SPAIN*

After attending this presentation, attendees will consider the possibility of studying early postmortem interval based on the biochemical events related with cell death.

This presentation will impact the forensic science community by introducing a potential quantitative indicator of postmortem interval in the first hours of death, as well as the reliability of using mRNA toward this purpose.

Mainly, the estimation of postmortem interval is analyzed from one day to years after death, using multidisciplinary approaches. A panel of physical methods, such as body temperature, and thanatochemistry methods, like potassium or amino acids measurements, were the subject of further studies and seem to be useful in combination with other factors. However, there have been few reports on RNA expression in a dead body. These studies have evaluated mRNA stability using human housekeeping genes, finding a correlation between these parameters.

Decomposition begins approximately four minutes after death with a process called autolysis. It is a cell necrosis, similar to the process induced when an organ suffers isquemic or anoxic alterations. During the decomposition, the cells will be progressively destroyed. As a consequence of that, there is a release and damage of cellular components and metabolites, which induces inflammation and cell death. However, the nucleus remains without alterations until four days after death, which will permit applying molecular biology methods in order to determine time-since-death.

This research was to study early postmortem interval, between two and eight hours, using the analysis of the expression of two dead/inflammatory proteins, FasL and PTEN, by Quantitative-PCR and assess reliability of this method for mRNA in specimens from dead bodies.

Four adult male Wistar rats (250-300g, aged three months) were euthanized at the same time with intraperitoneal injection of 0.15ml/Kg Rompun® (Bayer). Immediately after death, as a time zero or control, 20mg of gastrocnemius muscle were biopsied from each rat. The rat bodies were placed in the laboratory at room temperature. From two until eight hours after death, 20mg of this muscle were collected bi-hourly. The samples were homogenized and total RNA was extracted using GenElute Mammalian Total RNA Miniprep Kit (Sigma), according to the manufacturer's protocol. The RNA was quantified using NanoDrop 2000c (Thermo Scientific, NanoDrop Products, Wilmington). RNA was subjected to reverse transcription using High-Capacity cDNA reverse transcription Kit (Applied Biosystems), according to the manufacturer's protocol. Quantitative analysis of FasL (implicated in death cell signaling and inflammation) and PTEN

(inhibitor of PI3K/Akt pathway, which promotes cell proliferation) mRNA levels was performed by the SYBR Green Real Time PCR. Each sample was tested in triplicate. The analysis of relative gene expression data was calculated using the $2^{\Delta CT}$ method.

A total of 20 muscle samples were obtained over an eight-hour period. RNA quantification showed variability between subjects and times, ranging concentrations between 1-25ng/µl; however, this amount of RNA was enough to perform reverse transcription.

Quantitative-PCR results were similar in the two genes. There was a time-dependent increase in the mRNA levels of FasL and PTEN until six hours after death. Though, at eight hours, the levels of these two genes decreased, probably due to the degradation of RNA as a consequence of the progress in the autolysis process. Using regression analysis in the first six hours after death, a positive linear correlation was found between the mRNA expression of these genes and the time-since-death. These results are in agreement with the initial hypothesis, since FasL and PTEN are implicated in cell death and inflammatory signaling pathways.

The findings from this research provided a new quantitative tool for estimating early postmortem interval based on the biochemical events of the autolysis process, even though it could not be estimated past six hours after death due to degradation of RNA. Future research may be able to expand on these results, looking for other cell death markers and extending time-since-death estimates.

Postmortem Interval, Cell Death Markers, mRNA

G50 The Application of Flow Cytometry as a Rapid Screening Method of Samples of Vitreous Humour to Avoid Miscalculation of the Postmortem Interval

Cristina Cordeiro, MD, Instituto Nacional de Medicina Legal, IP, Largo da Sé Nova, Coimbra, PORTUGAL; Rafael Seoane, PhD, Elena Lendoiro, BS, and María Sol Rodríguez-Calvo, PhD, Univ of Santiago de Compostela, Calle San Francisco, Santiago de Compostela, 15782, SPAIN; Duarte N. Vieira, PhD, MD, Univ of Coimbra, Rua Antonio Jose de Almeida, No 117, Coimbra, PORTUGAL; and José Ignácio Muñoz-Barús, PhD, Inst of Forensic Science, Univ of Santiago de Compostela, Calle San Francisco, Santiago de Compostela, SPAIN*

After attending this presentation, attendees will understand the confirmation and quantification of possible accidental contamination with blood of samples of vitreous humour by means of applying the flow cytometry method to the estimation of the Postmortem Interval (PMI).

This presentation will impact the forensic science community by demonstrating the susceptibility of vitreous humour to blood contamination and how this can affect PMI estimates. The determination of PMI is a critical issue in forensic science and methodologies based on the biochemistry of the vitreous humour can provide good results.

In the field of Legal Medicine, the correct determination of the time of death is of crucial importance due to its criminal and civil repercussions. In recent years, research into maximizing the precision and reliability of this estimation has been a recurring subject of investigation, and it is of utmost importance to have recourse to a method that can provide this information quickly and accurately. The best results for estimating time of death derive from the biochemistry of the Vitreous Humour (VH) and are based on examining the relationship between PMI and increases in K+ and hypoxanthine (Hx) levels. Latest reports in the literature suggest that the manner of death can also modify this relationship and computerized programs which take into account these variables have been published. However, contamination by causes not readily apparent, such as blood from the accidental puncture of blood vessels, can occur, and thus lead to an erroneous estimation of PMI.

Objective: The goal of this presentation is to confirm and quantify blood contamination in samples of vitreous humour by using the Flow Cytometry method which reveals how this contamination substantially alters the estimate of the PMI.

Method: Vitreous humour samples were obtained from fresh bodies, and artificially contaminated with known concentration of human blood (5µl of 10% blood in 300µl of HV) and serially diluted in FACSflow™ (Coulter) in order to determine the minimum amount of erythrocytes detectable and its relation to hypoxanthine quantification.

Samples were run in a Facscalibur cytometer (Coulter) at medium flow (12µl/min) and erythrocytes detected in an FCS vs. SSC density plot.

The detection was considered valid when the detected number of erythrocytes stood at the theoretical logarithm ± 0.3. Greater dilutions showed values closer to background noise.

Determination of Hx by LC-MS/MS: A Quattro Micro tandem mass spectrometer (Waters) was employed for the detection of Hx. Chromatographic separation was performed using an Atlantis T3 (2.1x100mm, 3µM) analytical column, working in gradient mode, with acetonitrile and ammonium acetate 10mM (pH=4.5) as mobile phase. Two precursor-product transitions per compound were monitored except for Internal Standard (IS).

Results and Discussion: This contamination noticeably affects the result, and thus emphasizes the importance of careful sample extraction. The cytometric method was able to detect erythrocytes in 1:1250 dilution of contaminated HV. This represents a presence of 6,000 erythrocytes per ml, much lower than that detectable by microscopic counting. This concentration is 0.0017µ| of blood in 1 millilitre of HV.

The sensitivity of the technique, its widespread distribution in the laboratories, and the speed of the results recommend it for the rapid screening of samples.

Postmortem Interval, Vitreous Humour, Flow Cytometry

G51 DNA Sequencing for Identification of Funambulus Species With Possible Forensic Implication for Conservation of *Ratufa Indica Elphinstoni*

Sangeeta V. Ghumatkar, MSc, C-43 Yogeshwar Apt, Vadgaon Budruk Sinhgad Rd, Near Canal, Pune, Maharashtra, INDIA*

After attending this presentation, attendees will be aware how poaching cases of endangered species are handled in India.

This presentation will impact the forensic science community by increasing knowledge on wildlife DNA for forensic work.

Wildlife forensics is a relatively new field of forensic science. Wildlife forensic scientists must be prepared to identify evidence from any species in the world that is illegally killed, smuggled, poached, or sold illicitly. Despite the frequency of poaching, the perpetrators are seldom charged with breaking the law; even more rarely are such individuals caught in the act of transgression. The modern advent of molecular DNA forensics now adds a new dimension to wildlife law enforcement and may, eventually, also serve as an added deterrent. Molecular data is sometimes the only type of information available to conservation officials in their field investigations. The latest DNA-based technologies today make it feasible to identify single individuals by DNA typing from only trace amounts of their genetic material. The application of DNA technologies in wildlife forensics demands not only that gender and individual profiling be determined, but that the target animal species be also identified correctly.

The Indian giant squirrel, *Ratufa indica*, is a large-bodied diurnal, arboreal, and herbivorous squirrel found in South Asia commonly known as “Shekru” (*Ratufa indica elphinstoni*). It is the state animal of Maharashtra. It inhabits in the deciduous or mixed forests and is abundant in the forests of the Western Ghats of Maharashtra. The animal is protected in Bhimashankar Wildlife Sanctuary. *Ratufa indica*

elphinstoni is a conservation priority for the State of Maharashtra in India. It is imperative to secure *Ratufa indica elphinstoni* populations in all the areas they currently occupy, whilst encouraging expansion into some of their former range. The identification of the species becomes an essential part in forensic work in cases involving Wildlife Protection Act (1972) cases.

DNA sequencing allows unequivocal identification of species in forensic cases. Molecular techniques such as DNA barcoding are gaining importance in recent years to resolve these questions. Here in this study, we have checked the utility of DNA barcoding for species identification of *Funambulus* and *Ratufa indica elphinstoni* using mitochondrial genes Cytochrome Oxidase I (COI) and two ribosomal genes (12S and 16S). This analysis successfully discriminated both the species.

When identification of species is essential in forensic wildlife cases, the above technique can be used unequivocally for identification of these species.

The use of animal DNA evidence in forensic investigations is a new and emerging field. In particular, the modern DNA-based molecular methods will aid in the fight against the poaching of endangered and protected species, and in the prevention of cruelty to animals. The illegal culling, collecting, and trading of animals (and animal products) can now be revealed more effectively, and a link between the victim and the suspect established with a far greater degree of confidence. The continued development of a standardized set of protocols for wildlife forensics will further enhance the capacity of law enforcement officials to protect and conserve animals in the wild.

Species, DNA, Forensic

G52 Cotton Swabs vs. 4N6 FLOQSwabs™: A Comparative Study for Optimal Recovery of Touch DNA

Rebecca Santiago, BS, 1738 D St NE Apt 2, Washington, DC 20002; and Glorianna Caves, BS*, and Daniele S. Podini, PhD, Dept of Forensic Science, 2100 Foxhall Rd NW, Washington, DC 20007*

After attending this presentation, atattendees will have a better understanding of how touch DNA recovery could vary between different collection swabs, swabbing techniques, and extraction processes, and how different surfaces affect touch DNA recovery with two different types of swabs: 4N6 FLOQSwabs™ and cotton swabs.

This presentation will impact the forensic science community by discussing the comparison of the 4N6 FLOQSwabs™ and standard cotton swabs used in crime labs in their ability to recover touch DNA from various surfaces as well as the comparison of their ability to preserve touch DNA in the presence of common environmental contaminants.

Over the last few years, the boost in sensitivity and robustness of forensic STR kits has increasingly made touch evidence a potential source of DNA profiles that can become useful to an investigation. Thus, the ability to properly collect and handle touch DNA plays an important role in this process, given the small amount of genetic material left behind from handling an object, mostly from epithelial cells. Standard practice in many laboratories is the use of moistened cotton swabs to swipe the surface allegedly touched by the suspect. These swabs are made of cotton fibers wrapped around the tip of a ~ 6" stick. Although highly absorbent, this type of swab has an inside core that can trap cellular materials within its fibers. The 4N6 FLOQSwabs™ are instead made by applying glue to the tip of an applicator and perpendicularly spraying onto this surface tens of thousands of short nylon strands. Liquid absorption is obtained by capillary action induced by the surface tension between the nylon strands. Furthermore, 4N6 FLOQSwabs™ lack an inside core to trap cellular materials.

For the purpose of this study, a common sterile, DNAase/RNAase-free cotton swab was compared to the 4N6 FLOQSwabs™ manufactured by Copan Italia specifically for forensic applications. The FLOQSwabs™ are produced in a controlled human-free environment and are certified human DNA, DNAase and RNAase-free, are treated with an antimicrobial reagent, and undergo ethylene oxide sterilization; they have a breaking point right above the swab tip to facilitate the transfer of the swab inside the Nucleic Acid Optimizer (NAO™).

Touch DNA evidence was simulated by having volunteers handle specific objects for one minute (glass, wood, and leather). The handled objects were divided into quadrants and swabbed with the two different types of swabs in duplicate. Multiple experiments were performed and different combinations were tested: multiple individuals, different swabbing techniques (wet vs. dry), and the use of a NAO™—a basket with a semi-permeable membrane) that is used during extraction. The experiments were designed in order to standardize conditions as much as possible and ensure that the amount of cells on the various quadrants were similar; nevertheless, the amount of cells that are shed by an individual is somewhat unpredictable. Thus, to determine the actual percentage of DNA recovery, known amounts of DNA were spotted onto glass slides and allowed to dry. Slides were then swabbed with the two different types of swabs and subjected to extraction (DNA is basically being re-extracted). Due to the expected loss of DNA during the re-extraction process, results were normalized against the same amount of DNA re-extracted directly from the tube.

Results show that, on average, 4N6 FLOQSwabs™ yielded greater amounts of DNA than the cotton swabs, particularly when sample collection was performed with the moistened swab and extraction was conducted with the aid of the NAO™. This presentation will also discuss how the antimicrobial treatment protects the DNA from bacterial degradation after sample collection.

Touch DNA, Cotton Swab, Flocked Swab

G53 Some Like It Extra-Dry: Specific Skeletonization Patterns Due to Larder Beetles (*Dermestes spp.*)

Damien Charabidze, PhD, Institut Médico-Légal, Lille, France 59045, FRANCE; Thomas Colard, DDS, PhD, Institut de Médecine Légale, Place de Verdun, Lille, Nord 59045, FRANCE; Didier Gosset, MD, PhD, Institut de Medecine Legale, Faculte de Medecine, Lille, 59045, FRANCE; and Valéry Hedouin, PhD, Iml de lille, Lille, France 59045, FRANCE*

After attending this presentation, attendees will understand how the presence of larder beetles (*Dermestes spp.*) may affect the decomposition and skeletonization processes. Through the years, several authors reported bodies discovered in flats or houses with thousands of larvae and adults actively feeding on them. However, these reports are scattered and, no study addresses this question from both anthropological and entomological point of view.

This presentation will impact the forensic science community by summarizing the cases reported in the literature, by establishing the skeletonization patterns caused by larder beetles and by offering a PMI estimation process based on adults, larvae, and molts abundance.

In a dry and warm environment, skeletonization usually occurs in a few weeks. When fly larvae (maggots) are present, they feed on soft tissues, especially the eyes or mouth. The presence of hundreds of larvae actively feeding on a corpse may thus result in a quick skeletonization of the face; however, necrophagous fly' larvae avoid hard or dry tissues, and thus do not contribute to the skeletonization of feet or hands. On the contrary, larder beetles feed on dry tissues.

Dermestes spp. (larder beetles) are coleoptera species frequently observed on dry human remains. These species are well adapted to exploit all kinds of dried animal tissues: skin, fur, leather, bones, etc. They are widespread among fish and meat smokehouses or saltering, in poultry houses (due to the presence of manure), or even natural history museums. Some decades ago, they were

common pests of stored food products or tanneries. Hundreds of species have been reported, but only five to ten of them are commonly observed on human remains. As these species often travel with food or furs, they have a worldwide spread.

The adult female laid several egg-batches of two to twenty eggs (depending on species) in cracks or cavities of the substrate. Both adults and larvae avoid bright light. Larvae feed on surface, but burry themselves for each molt. They have seven or eight molts before pupation. Just before pupation, larvae stop feeding and move away to find a suitable place to pupate. After several days of pupation, adults emerge and start again to feed. Under favorable conditions, *Dermestes* are rapid breeders. Depending on temperature and species, an entire generation may be developed in five to six weeks. During her life, a female can lay more than 200 eggs. So, in warm conditions and with sufficient food available, *Dermestes* species may have more than five generations annually. In such cases, it is common to observe on the same place a high number of adults, larvae, molts, and frass (i.e. fecal material wrapped in peritrophic membrane).

In a forensic context, *Dermestes* (adults or larvae) are usually found from active decay phase until skeletonization. However, they are especially abundant on dry remains. They first remove flesh from limbs and face. This feeding pattern produces a quick and quite specific skeletonization of the extremities. Furthermore, larvae excrete frass in abundance. Together with molts, these residuals can create a substantial amount of material around or even inside the corpses. This is especially true for long Postmortem Interval (PMI) indoor cases, when victims are discovered several months after death. Lastly, due to the possible feeding of *Dermestes* larvae on empty puparia or dead flies, the former presence of Calliphoridae species is often difficult to assess. However, the time needed to complete several *Dermestes*' development cycles can be calculated depending on ambient temperature and species.

To be answered, the PMI estimation of such cases needs the highlight of both a forensic anthropologist and entomologist. Working together, they should be able to interpret the skeletonization and the abundance of insects to estimate the time of death.

Long PMI, Indoor Cases, Entomology

G54 Estimation of Postmortem Interval by Direct Analysis of the Skin Surface Through FT-NIR

Agostinho Santos, MD, PhD, and Teresa Magalhães, MD, PhD, Univ of Porto, Jardim Carrilho Videira, 4050-167, Porto, PORTUGAL*

After attending this presentation, attendees will be familiarized with the basics of Fourier Transform-Near Infrared (FT-NIR) spectroscopy and multivariate analysis using common chemometric techniques such as Partial Least Squares (PLS) and Principal Component Analysis (PCA). In particular, the audience will learn about the potential for creating models for the estimation of the Postmortem Interval (PMI) when joining chemometrics and NIR spectroscopy. General ideas for the application of such techniques to other forensic problems may be also addressed.

This presentation will impact the forensic science community by introducing modeling techniques over NIR spectroscopy to the problem of estimating the postmortem interval in a fast, reliable, and rather accurate method. Besides, the procedure proposed requires minimal to none sample treatment or preparation and can be performed *in situ*.

The estimation of the PMI, the time since death, is of paramount importance and a significant challenge for the pathologists. Methods currently employed have considerable inaccuracy.

Following the developments of the last few years regarding the application of mid-infrared spectroscopy for studying skin, and the possibility of easy direct *in situ* analysis that has risen with fiber optics apparatus for Attenuated Total Reflectance-Fourier Transform Infrared (ATR-FTIR), the FT-NIR was applied spectroscopy to directly test the human skin for possible chemical changes occurring after death that could correlate with PMI.

The sample population consisted of 25 corpses (male and female) with different causes of death and ages ranging from 20 to 96 years old. The bodies were submitted to autopsy at the North Branch of Portuguese National Institute of Legal Medicine and Forensic Sciences and the spectra recorded at the premises by the local staff. FT-NIR spectra have been acquired using an Antaris 1 (Thermonicolet) spectrophotometer equipped with a diffuse reflectance fiber optical probe (SabIR, Thermonicolet). Spectra (in duplicate) were taken from the upper right lateral toraco-abdominal area and internal side of upper third of right arm at each postmortem acquisition point and the changes in skin chemistry were followed during time periods of 9 hours (minimum) to 69 hours (maximum), depending on the subject, until a maximum of 72 hours.

Several chemometrics techniques were applied for the multivariate analysis of the spectra, namely PCA, PLS, and Partial Least Squares Discriminant Analysis (PLS-DA). All modeling and data analysis was done using Matlab (version 7.9, Mathworks) and PLS toolbox 5.5.1 (Eigenvector Res1earch Inc.) for Matlab. On creating the model, specific functions were written for variable selection, using genetic algorithm, and for sample selection for cross-validation.

The models obtained, although having a restricted number of corpses available for calibration, present promising results.

Postmortem Interval, Infrared Spetroscopy, Skin Chemestry

G55 Autopsy Approach in Forensic Investigation of Child Abuse

Agostinho Santos, MD, PhD, Katerina Puentes, MSc, Patrícia Jardim, MD, and Teresa Magalhães, MD, PhD, Univ of Porto, Jardim Carrilho Videira, Porto, PORTUGAL*

After attending this presentation, attendees will hear standardized recommendations followed by investigative procedures and data collection instruments in child abuse fatality autopsies at the North Branch of the National Institute of Legal Medicine and Forensic Sciences in Portugal, as well as contributing to a new approach in these types of autopsy by standardizing methods and procedures.

This presentation will impact the forensic science community by showing the importance of standardization of investigative procedures in forensic investigation of fatal child abuse situations. This type of investigation must be as complete and thorough as possible, and ideally, observe standardized procedures. It must also be executed by experienced professionals in the area of child abuse who are able to adjust and adapt to standard techniques for every specific situation.

Although a high-detail skeletal survey reported by a radiologist is mandatory in order to identify and record skeletal injuries suggestive of or consistent with abusive situations, imaging techniques may sometimes over or under diagnose some of these injuries. Taking this fact into consideration, in fatal child abuse situations, disarticulation and removal of the entire costal grid, followed by a maceration process for a non-traumatic soft tissue removal may be very useful for an adequate documentation of any skeletal fractures (ribs and sternum) with minimal artifact formation.

Methods: Internal examination begins with the incision of the scalp, either through a bi-mastoid incision, or a posterior approach. A "stem-to-stem" double Y incision at both the anterior and posterior aspects of the trunk is a fine approach to initiate internal examination of neck, thoracic, and abdominal structures. Incisions performed in cases of fatal child abuse should allow for optimal visualization of the underlying structures and eventual lesions, without causing, however, a great negative visual impact. All major cavities, cranium, thorax, and abdomen, should be examined and dissected "layer by layer" and whenever is necessary, special autopsy procedures should be applied, such as eye and middle ear removal. Removal of the entire

thoracic cage includes the spine, from C5 to L2, clavicles, the sternum, and all ribs, keeping all the bony structures completely articulated between them. Soft tissue elimination and disarticulation of the bony elements is achieved through a maceration process with enzymatic detergent. Careful reconstruction of thorax morphology with prosthetic devices followed by proper suture of all incisions allows the performance of this technique without causing, however, a negative visual impact on the body.

Results and Conclusions: The implemented procedure allows a neat observation in order to rule out recent and non-recent fractures with minimal artifact formation due to instrumentation otherwise caused by standard autopsy techniques and without causing a negative visual impact on the body.

Child Abuse, Skeletal Trauma, Autopsy

G56 "Hot Shots": A Forensic Approach to Allegations Surrounding Fatal Consequences of Injected Substances of Abuse

Rebecca A. Irvine, MD, Dept of Forensic Medicine, 50 Parramatta Rd, Glebe, New South Wales, AUSTRALIA*

After attending this presentation, attendees will have an awareness of the pervasive and variable concept of "hot shot" in the non-forensic community. A working definition for forensic scientists is suggested. Attendees will also be able to describe an approach to autopsy that will optimize the potential to refute or support the allegation or at least demonstrate that all due consideration has been afforded the possibility.

This presentation will impact the forensic science community by highlighting the lay concept of "hot shot" and how pathologists can address the allegation.

The term "hot shot" is variably defined and is well-ensconced in the public consciousness. Although it may encompass accidental death due to an unexpectedly high drug concentration, it more commonly implies malicious involvement of another and homicidal intent. Even a brief perusal of lay websites reveals awareness that benzodiazepines will potentiate opiates, and creative and alarming suggestions to make injections painful or fatal. Typical perceived victims are informers, fellow addicts (for robbery or revenge), or targets of organized crime. The concept appears regularly as a plot device in popular media, in the news, and as propaganda.

The concept has been neglected in forensic literature. Although the pathologist is rarely able to support or refute it, there is a need to acknowledge and define it, develop an approach to examination, and establish an academic data base. Complacency may result in distress for families, dissatisfaction on the part of law enforcement/prosecuting attorneys, public concern, embarrassment, and fostering of conspiracy theories.

A search of the database of DOFM Glebe revealed no cases of injected drug toxicity or detected adulterants that would reasonably represent homicide. Cases have gone to inquest on such allegations, but none appear to have had sufficient evidence to support taking the matter to trial. Law enforcement and the media in this district nevertheless regularly assert that a "hot shot" has occurred.

It has been suggested that a threatened victim would sustain obvious defense injuries; the usual scenario proffered, however, is a non-naive intravenous drug user unaware of the danger. A past history of drug abuse tends to suggest recidivism rather than homicide.

The first step in allaying concerns is to elicit what the concept means to the individual raising the assertion. The following is a suggested forensic definition of "hot shot": The *deliberate* injection or provision of materials for injection of an *abused substance* that is known to *likely be lethal* due to extreme purity, increased concentration, or adulteration by a known poison.

Although allegations may be misguided, the truth is that street drugs are invariably adulterated to "cut" the active substance, improve the appearance of the product, and introduce toxicological "distractions" (i.e., local anaesthetics). Drug substitution may occur (i.e., heroin for cocaine). There have been outbreaks of acute reactions to pharmaceutical adulterants (i.e., clenbuterol/scopolamine). There may be contaminants, including bacteria (with outbreaks of anthrax and Clostridial disease) and heavy metals (i.e., lead). Adulterants may have deleterious effects that contribute to death, including drug toxicity, non-drug poisoning, sepsis, and allergic reactions.

Identification and medicolegal verification of a "hot shot" is predicated on a thorough investigation, ideally with information regarding the nature of the presumed fatal injection. It also requires the collaboration of a toxicologist, possibly with the task of identifying an unusual substance.

In cases of alleged "hot shot" prior to autopsy, an examination that is arguably more thorough than the usual "overdose" case should be considered; the goal is to gain as much information as possible as to the causes and circumstances of death, bearing in mind that even negative findings of violence may help to clarify the situation. The allegation is usually predicated on the assumption that death occurred quickly, so evidence of a survival time may be important. Features of past drug abuse may be significant in some situations. A list of autopsy procedures for consideration in such situations will be presented.

Forensic pathologists need to be honest with law enforcement, prosecutors, and families about the limitations of autopsy in these cases, but acknowledge the possibility of homicide and approach the autopsy with thoroughness and an open mind.

Hot Shot, Drugs of Abuse, Homicide

G57 Sudden Cardiac Death of a High-Performance Skater

Oscar A. Plaza, MD, Calle 4B No 36-01, Calle 12B No 59-31, Cali, COLOMBIA*

After attending this presentation, attendees will understand how the misuse of Over the Counter (OTC) anabolics alter the cardiac architecture, and is a predisposing factor for sudden death. Another important fact is that the investigation of prior history associated with an autopsy-oriented procedure led to establishing an association between inappropriate use of these drugs with a viral infection, which led the deceased into a lethal pathophysiologic event that could happen again under the same circumstances. Since sudden deaths of athletes commonly involve drug abuse, a toxicology screening was ordered for fluids like blood or urine of the deceased, with negative results. The histopathology results were reviewed by departmental forensic pathologists and academic peers of an associated teaching hospital. It is believed that this case of accidental death was never reported.

This presentation will impact the forensic science community by understanding how multidisciplinary research collaboration involving the drug manufacturer and the system of distribution, toxicologists, and forensic medical team was able to reconstruct the chain of events in an appropriate manner. Determining the factors that influenced this unusual death was difficult at first, but the main purpose in determining the manner of death was because it created a controversy between the authorities who removed the corpse from the scene, the family, and the forensic pathologists because the absence of significant medical history, even the use of narcotics or anabolic illegally manufactured were considered. So far, the manner of death has not been determined. The products involved are OTC and do not require a medical prescription for sale. Health systems in Colombia, through an entity called the INVIMA regulator for the distribution of drugs (equivalent to the FDA), have not been given a decision on

restrictions on the use and sale of such anabolic in gyms, pharmacies, and sports shops.

Another sudden cardiac death case was reported in a high-performance skater who suddenly collapsed during a training session. This report examines the medical history, the chain of events, and pathogenetic mechanisms leading to death. Medicolegal aspects of the case are discussed after available literature is reviewed. There are a number of articles reporting many cases of sudden cardiac death in athletes who use performance-enhancing drugs, but there are no reports regarding this type of death where the use of OTC anabolics is involved as a contributing factor to death.

The last unusual sudden death case presented is associated with the consumption of OTC anabolics. This case was studied and used as an example of the practical application of research and multidisciplinary collaboration for the discovery of an unusual death. It is recommended that forensic investigators are familiar with these types of drugs which are common among athletes and the pathogenesis of this way of death that may have involved an inadequate response from a heart changed because of a viral infection.

Sudden Death, Cardiomyopathy, Anabolic Steroids

G58 What Is That Little Yellow Fragment? Application of Confocal Raman Microscopy in the Identification of the Means in a Case of Murder by Blunt Object

Irene Riezzo, MD, PhD, and Natascha Pascale, MD, Univ of Foggia, Viale degli Aviatori 1, Foggia, ITALY; Dania De Carlo, MD, Ospedale Colonnello D'Avanzo, Foggia, ITALY; Carmela Fiore, MD, Viale Pinto 1, Foggia, ITALY; Margherita Neri, MD, PhD, Univ of Foggia, Dept of Forensic Pathology, Viale degli Aviatori 1, Foggia, ITALY; and Riccardo Tagliapietra, MS, Renishaw S.p.A. Via dei Prati 5, Pianezza, ITALY*

The goal of this presentation is to report a case of homicide on a 42-year-old man who was found dead in fields around Foggia, close to a blood-stained brick. After attending this presentation, attendees will understand, in order to identify the tool used in case of homicide, the importance of analyzing and integrating the data derived from a well-detailed crime investigation, autopsy examination, and subsequent histological investigations, as well as using a new spectroscopy technique applied to microscopy called confocal Raman.

This presentation will impact the forensic science community by demonstrating how investigation and research resulted in the conclusion that the tramma to the victim was caused by several weapons.

Finding compatibility between the cause of death and the tool used is a hard daily routine task for the forensic pathologist and not easy to achieve. Often the wounds found on the corpse may be compatible with several tools, so the crime scene data might not be instrumental for the identification of the tool used. A crime scene investigation was performed by a forensic pathologist and the police who found a 42-year-old Caucasian man dead in the fields around Foggia. The corpse was lying supine on the grass, with the head fully bloodstained and bloodstained banknotes in his mouth. The head and face showed numerous blunt wounds. Close to the head the grass was covered in blood, and near the corpse was a brick measuring 40x20x20cm, smeared with blood. Nothing else was found at the crime scene.

A multidisciplinary forensic approach, which included CT scan analysis, autopsy, histological investigation, and confocal Raman microscopy analysis was performed. The external examination revealed the presence of multiple lacerations of the scalp in the fronto-parieto-temporal, with several exposed fractures of the skull. Also, other lacerations of skin were shown in the face with a fracturative complex of bones. Furthermore, the neck presented multiple abrasions and purple bruises. The CT scan analysis of the head demonstrated multiple fractures of neurocranium and facial bones, in particular of the skull in the left fronto-parietal.

The autopsy examination confirmed the multiple fractures of the skull and the face, in the parieto-frontal side and the maxillary bone. The detailed examination of the skull fractures at the left fronto-parietal detected a little yellow fragment of unknown material which wasremoved for subsequent exam with confocal Raman microscopy directed to identify its molecular structure. In addition, the internal examination revealed multiple contusions of the brain, especially in the left parietal side and at frontal level. The examination of the neck revealed hemorrhagic area of sterno-cleido-mastoidei muscles, and also the fracture of the thyroid cartilage with contusion of thyroid, along with the presence of blood inside trachea. No other traumatic injuries were found. The microscopic findings were represented by polyvisceral stasis, widespread and extensive cerebral intraparenchymal hemorrhages, cytotoxic and vasogenic edema, massive pulmonary edema, acute emphysema and atelectasis, and blood aspiration. According to the crime scene data, autopsy, histological, and CT scan findings, the cause of death was attributed to multiple skull and face fractures with deep brain contusions, blood aspiration, and combined mechanism attributed to an external neck compression suggested by the fracture of the thyroid cartilage.

With regard to the blunt object used, the results of the forensic investigation pointed out that the lesions revealed on the corpse were linked to the brick found on the crime scene. However, the yellow fragment of unspecified nature, found in correspondence of the skull fracture in the left fronto-parietal, suggested that a tool other than the brick found on crime scene caused this lesion. Therefore, the fragment was analyzed with the confocal Raman microscope.

The Raman spectroscopy is a technique which enabled the discovery of to discover information on the molecular composition of materials and, then, to identify their nature. This technique is based on the diffusion of a monochromatic radiation incident on the surface of an object, which can be absorbed, reflected, or diffused, and it is an ideal tool for identifying and distinguishing between organic and inorganic molecules and crystals. Specifically, the theory behind the Raman Spectroscopy is based on the inelastic scattering of low-intensity, nondestructive laser light by solid, liquid, or gas sample. Confocal Raman microscopy combines the three-dimensional optical resolution of confocal microscopy and the sensitivity to molecular vibrations which characterizes Raman spectroscopy. In confocal Raman microscopy, the chemical composition of a sample can be imaged by recording the integrated intensity of characteristic Raman lines of the substances involved. Thus, one can investigate whether and to which degree mixtures of substances are homogeneous on the length scale of micrometers and above. Confocal Raman microscopy is a relatively new technique that allows chemical imaging without specific sample preparation. By integrating a sensitive Raman spectrometer within a state-of-the-art microscope, Raman microscopy with a spatial resolution down to 200nm laterally and 500nm vertically can be achieved using visible light excitation.

Confocal Raman Microscopy, Homicide, Blunt Object

G59 Gaze Deviation as Image Evidence of Staged Death Scene

William R. Oliver, MD, East Carolina Univ, Brody School of Medicine, Brody Medical Sciences Bldg, Greenville, NC 27834; and Erik K. Mont, MD, Nova Scotia ME Service, 5670 Spring Garden Rd, Ste 701, Halifax, NS B3J 1H7, CANADA*

After attending this presentation, attendees will understand the importance of postmortem gaze in scene analysis and its place in the evaluation of forensic imagery of death scenes.

This presentation will impact the forensic science community by providing a better tool for analyzing images of death scenes.

With the ubiquity of digital cameras, more and more images of forensic interest are obtained not by professional forensic

photographers, but as casual and found images taken by onlookers. In one recent case, a digital image of the scene of a possible homicide was obtained during a search of a house for a different reason. The purported victim was a person with outstanding warrants. The question arose as to whether or not this scene was, in fact, a death scene, or if the scene had been contrived in order to convince investigators to stop searching for the alleged victim. There were multiple issues with the scene involving multidisciplinary evaluation by experts in fields such as bloodstain pattern analysis, forensic pathology, crime scene, and others.

While the investigation is continuing, and the details of this particular scene may not be available at the time of presentation, a number of interesting questions arose involving the positioning and appearance of the body in the images. In particular, an examination of the metadata of the image and of the statistics of the image data suggested that the image had been modified. Content analysis revealed numerous incongruences, one of which was that the gaze of the decedent was directed sharply to the side, away from the camera. It has been the experience of the forensic pathologists involved that, in the absence of head trauma that deforms the geometry of the face, postmortem gaze has always been in neutral position. However, no quantitative data was available to support this conjecture.

To evaluate this, a series of measurements of gaze were performed, using a modification of the Hirschberg test. The Hirschberg test is a common and simple technique, used in ophthalmology to test for strabismus, in which a light is shined onto the cornea and the location of the specular highlight is noted. In patients with neutral gaze and without strabismus, the specular highlight will be minimally to the nasal side of the center of the pupil if the light is directly in front of the eyes. If the gaze is diverted, then the specular highlight will be off-center equally and, if there is strabismus, then one eye will be centered and the other off-centered. There are some logistical issues with performing this test in the autopsy suite. Ensuring proper lighting and camera alignment requires careful positioning of the camera, light, and body. Corneal clouding may be partially alleviated with the use of saline solution or glycerin. Changes in eye shape may occur after death that may make the measurements unreliable.

Preliminary results indicate minimal variation from neutral gaze. This result is not surprising. Numerous studies have been done evaluating changes of gaze with anesthesia; the loss of eye movement, papillary reflex, and neutral gaze are all indications of deep anesthesia (though there may be nystagmus in lighter anesthesia and occasional ventral rolling of the eyes at some levels of deeper anesthesia). It is, thus, not surprising that in death a similar relaxation to neutral position occurs. Gaze deviation of the purported victim in death scene imagery may, thus, provide an indication of staging.

Postmortem Gaze, Image Analysis, Scene Analysis

G60 Limitations of Metal Fragment Analysis on Postmortem Computed Tomography (CT)

Howard T. Harcke, MD, 3205 Coachman Rd, Wilmington, DE 19803; Reed Selwyn, PhD, USUHS, 4301 Jones Bridge Rd, Bethesda, MD 20814; and Charles Allen, and Edward Mazuchowski, MD, PhD, AFMES, 115 Purple Heart Dr, Dover AFB, DE 19902*

After this presentation, attendees will understand the technical limitations of extended scale Computed Tomography (CT) measurements of density Hounsfield Units (HU) as applied to metallic ballistic fragments.

This presentation will impact the forensic science community by stressing that as postmortem CT is incorporated into medicolegal death investigations it will become necessary to carefully define standards for determination of metal fragment characteristics. If extended scale CT is to be used to determine whether fragments in a body are of the same material or to predict the composition of metal fragments based on density (relative to samples of known composition), the influence of Region of Interest (ROI), size, and placement must be appreciated and standardized techniques developed.

A logical forensic application of postmortem CT is the characterization of ballistic fragments present in the body at the time of medicolegal death investigation. Density measure has the potential to determine if fragments in a body are of the same material and to predict the composition of metal fragments based on density relative to samples of known composition. The purpose of this study was to evaluate the application of standard ROI analysis to extended CT scale measurements of density HU. The goals were to determine the influence of ROI size and placement on the density measure of gunshot fragments.

Postmortem CT imaging of gunshot wound victims was performed on a CT scanner with extended scale. Analysis of imbedded metal fragments was made on a radiology workstation using the standard software tools for measuring HU's from regions of interest. ROI placement and size were varied in assessment of metal fragment density while in the body and repeated in air after recovery at autopsy. Sample rounds of known origin were scanned in water and air for comparison and effects of kVp and mA were evaluated.

Both recovered fragments and bullets of known composition showed highly variable estimates of density depending on ROI area and placement. Tested fragments ranged from 1,200 to 30,000 HU. Values were varied for ROI size and location whether a fragment was scanned longitudinally or transaxially. Fragment measurements in the body produced densities approximately 50% lower than values measured in air. Lower scan kVp produced higher HU values (air measurement). Because of the wide variation in extended scale HU measurements occurring within and between fragments it was not possible to conclude whether fragments, were from the same source material or to distinguish composition of higher density fragments such as lead, steel, and copper.

ROI size and placement affect the CT measurement of density (HU's) in metallic ballistic fragments to such a degree that extended scale determination of density should not be used in forensic analysis without further investigation. Scatter and beam hardening artifacts occurring with present CT algorithms are responsible for these variations. New algorithms or correction of existing algorithms should be considered.

Postmortem CT, Ballistic Fragments, Metal Analysis

G61 Postmortem Lung CT in Hypothermia — A Retrospective Age Sex Matched Study

Wolf Schweitzer, MD, Giannina Giugni, and Michael Thali, MD, Univ of Zurich, Winterthurerstrasse 190/52, Zurich, SWITZERLAND; and Sebastian Winklhofer, MD, Univ Hospital Zurich, Dept of Radiology, Raemistrasse 100, Zurich, SWITZERLAND*

After attending this presentation, attendees will have a better appreciation for the forensic pathologists use of postmortem scanning to investigate pulmonary anatomy and pathology.

This presentation will impact the forensic science community by adding a morphological clue to possible hypothermia cases. That finding is a low density of lung tissue in CT scans. This is a radiological correlate of acute emphysema or overinflation of the lungs. Pathophysiologically, this is possibly mediated by a shifted oxygen-hemoglobin dissociation curve in hypothermia.

Methods and Material: Since 2010, in the Institute of Forensic Medicine of the University of Zurich, all bodies undergo postmortem CT full body scanning before autopsy. Group H (hypothermia) was defined to contain all deceased between 2010 and April 2012 who died with the pathological diagnosis of hypothermia. Diagnosis of hypothermia had been based on a range of factors such as being plausible due to circumstances, gastric erosions, or a positive test for ketone bodies in urine and no radiological findings were used at the

time to suggest hypothermia. Control group C was selected by randomly selecting individuals from the same period, in a way that allowed for an age and sex match. Cases with intensive care treatment for hypothermia and with no hypothermia immediately preceding death were excluded. Group C was selected to not contain strangulation, drowning, and macroscopic lung injuries. Axial CT slice images containing the lungs were used for further analysis. Each lungs area was examined in two locations, one above and one below the hilus. The whole lung area up to around 5-10mm underneath the outline of the pulmonary parenchyma was manually marked using software. Hypostatic dense tissue or subpleural bullous emphysema was not marked. The average CT density (HU: Hounsfield units) was then obtained for the marked areas. Readings were obtained twice independently by two readers and subsequently averaged. CT scans were obtained on Siemens CT scanners (Siemens, Erlangen, Germany). SECTRA PACS software (Sectra Imtec AB, Linkoping, Sweden) was used to view the CT scans and obtain CT density measurements. Statistical evaluation was done using the R package (R Foundation for Statistical Computing, Vienna, Austria). Approval of the relevant bodies was obtained, ethical regulations were respected.

Results: Hypothermic bodies contained lungs with significantly lower CT density (-764 +/- 67 HU) compared to age and sex matched controls (-546 +/- 154 HU; Wilcoxon p <0.001). Keeping in mind the restricted scope of the control group (as we excluded a number of diagnoses), logistic regression would predict the hypothetic presence of hypothermia at exceeding 90% for CT lung densities under-780 HU.

Discussion: Hypothermic indivuals might exhibit pulmonary findings of suffocation such as the CT appearance of lower density, quite possibly indicating acute overinflation. This is not an unjustified assumption —at 20 – 22°C, the oxygen-hemoglobin dissociation curve resembles the curve found for carbonmonoxide poisoning with 60% carbon monoxide-hemoglobine blood levels. In hypothermia, ventricular fibrillation or asystole is preceded by a left shift of the hemoglobin-oxygen dissociation curve. Cold temperatures cause oxygen molecules to adhere to hemoglobin more. As a result, tissues cannot take up oxygen as well because hemoglobin does not release it that well. This in turn can cause a range of complications. One of these complications is that a left shift of the oxygen-hemoglobin curve in itself is a factor promoting metabolic alkalosis which in turn might entail hyperventilation but which appears to be counteracted, at least to a degree, by lactacidosis due to tissue hypoxia and by respiratory acidosis (reduced carbon dioxide exhalation). Shallow and slow breathing as well as progressive bradycardia seem to reflect an adapted response, but more likely in individuals whose metabolism has sufficiently slowed down as response to hypothermia. An increase in breathing volume, particularly while tissues and cells are not sufficiently cooled down themselves, might then explain our findings. With that, acute emphysema or overinflation of the lungs could indicate that internal suffocation and, in fact, increased and not decreased breathing volumes may play a role in hypothermic death. At any rate, low CT density of lungs in postmortem CT scans should be investigated as a possible clue for hypothermia.

CT Scanning, Radiology, Forensic Pathology

G62 Postmortem CT Angiography as a New Tool in Medical Education and Clinical Research

Jochen M. Grimm, MD, JD, Nussbaumstr. 20, Munich, GERMANY; Christine Chevallier, Patrice Mangin, MD, PhD, and Beat Riederer, PhD, University Center of Legal Medicine Lausanne, Rue du Bugnon 21, Lausane, SWITZERLAND; Valentin Djonov, PhD, Baltzerstrasse 3, Bern, SWITZERLAND; and Silke Grabherr, MD, University Center of Legal Medicine Lausanne, Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, SWITZERLAND*

After attending this presentation, attendees will understand the role of postmortem angiography in medical education, advanced medical training, and in clinical research as well as the need for close interdisciplinary collaborations of postmortem and clinical medicine.

This presentation will impact the forensic science community by showing how the performance of a postmortem CT angiography can increase the quality of medical teaching in anatomy and highlight the impact of postmortem perfusion on clinical research and advanced medical training.

In postmortem investigations, radiological cross sectional imaging techniques such as Multi-Detector Computed Tomography (MDCT) have already found a place in many medicolegal institutes. More complex methods such as Postmortem CT Angiography (PMCTA) have been introduced in the last years. In order to increase practicability and reproducibility of this kind of exam, a standardized technique called Multi-Phase Postmortem CT Angiography (MPCTA) has recently been developed. This technique consists of a native CT scan followed by three angiographic phases (arterial, venous, and dynamic phase). The vascular system is hereby investigated in a minimally invasive way by cannulating the femoral artery and vein of one side, connecting these cannulas to a perfusion device and injecting a mixture of paraffin oil and contrast agent before and during CT scanning. Adequate technology for performing this examination, including a specialized perfusion device and contrast agent, has recently been developed in Switzerland. The new technique has already been proofed as being a sensitive tool for detecting vascular lesions and to increase significantly the quality of postmortem investigation when it is combined with conventional CT.

But the need for a reliable radiological demonstration of the vascular system has also increased in the field of medical education and advanced medical training. The goal of this presentation is to show the interest of postmortem angiography as a new tool in medical teaching and clinical research and to underline the importance of close collaboration between postmortem disciplines (legal medicine, pathology, anatomy) and clinical research.

Anatomical education for medical students: Human bodies foreseen for anatomical preparation courses have been examined by native CT, magnetic resonance imaging, and PMCTA using the technique of MPCTA. Thanks to the installation of computer displays in the autopsy-room, medical students are now able to compare the radiological data of the investigated body with the topographic anatomy of the same body during dissection courses. As a rsesult PMCTA, the vascular topography can be studied in detail. After the dissection course, anatomical cross sectional preparations have been fabricated which can be compared to the cross sectional radiological images.

In the context of clinical anatomy, the same radiological techniques have been used in order to develop and validate new diagnostic methods and surgical techniques. In fact, for multiple clinical studies, the knowledge of the exact vascular anatomy which can be explored on human bodies by PMCTA is essential. For other studies, the establishment of a postmortem circulation is of interest. Such a circulation can be obtained by using the equipment which has been developed for medicolegal PMCTA. Once a postmortem circulation has been built up, different surgical techniques can be tested on bodies under nearly "*in-vivo* conditions." Even the

performance of interventional vascular examination becomes possible. Without vascular perfusion, such interventions are impractical due to a collapsed vascular system.

The actual development of postmortem imaging and clinical anatomy leads to an increasing demand of interdisciplinary collaboration between different medical fields. This presentation will point out this need and show possibilities for such collaborations. It also demonstrates that a technique, which has initially been developed for forensic purposes, can gain an important impact on teaching and clinical research.

Forensic Radiology, Medical Education, Clinical Research

G63 A New Application of the Multi-Phase Postmortem CT Angiography (MPMCTA) in Sudden Death Cases

Stefania C. Bello, MD, Natascha Pascale, MD, Giulio Zizzo, MD, Gianpaolo Grilli, MD, and Cristoforo Pomara, MD, PhD, Univ of Foggia, Viale degli Aviatori, 1, Foggia, ITALY*

The goal of this presentation is to examine a new approach to forensic autopsy by performing pre-autopsy Multi-Phase Postmortem CT Angiography (MPMCTA) presenting the results collected at the University of Foggia according to a standardized protocol actually used in an international multicenter study. The performance of the MPMCTA in cases of sudden death will be discussed, proposing a new application of that protocol in these cases.

This presentation will impact the forensic science community by providing information for the necessity of a postmortem radiological examination, also performing CT angiography, especially in cases of sudden and unexpected death.

The postmortem CT has become the most common imaging technique used in the last decade representing a routine approach in forensic investigation. Pre-autopsy radiological imaging can reveal different diseases and wounds, but above all it is a significant tool to explain the cause of death as well as to plan the following autopsy examination. However, in the last years, it was concluded that the CT scan without the injection of a contrast agent provides little information about organic lesions and the vascular system.

On one hand, the forensic pathologist needs to visualize the vascular system obtaining nice images, but on the other hand, it seems necessary to perform exact radiological interpretation by decreasing artifacts due to perfusion and by reaching a complete filling of the vascular system. MPMCTA should become a standardized technique. The technique consists of the performance of a native (without contrast-agent injection) CT scan, followed by at least three angiographic phases (arterial, venous, and dynamic phase).

The angiographic phases consist of the perfusion of the vascular system with an oily contrast-agent mixed with paraffin oil, through the accesses in the femoral artery and vein. Accordingly with this technique the vascular system of the head, thorax, and abdomen can be investigated in detail and in a minimally invasive way mimicking the angiographic study in live people. The three phases (arterial, venous, and dynamic) allow a complete opacification of the vascular system and they could show very little vascular lesions or abnormalities as the exact source of bleeding that could be missed during the autopsy. The examination of soft tissues (musculature, subcutaneous tissue) is also significantly increased.

For this research, angiographic exams performed were reviewed for cases of sudden and unexpected death focusing on cases of Thromboembolism. In these series of the cases, it was observed that the access through the femoral artery and vein according to the technique protocol exclude the visualization of the vascular system under the point of injection where the cannulas are positioned. Here a case of a 53-year-old farmer who suddenly died while working in the fields is presented. No particular disease was known by his relatives. Before the autopsy examination, a postmortem CT angiography was performed which showed a filling defect in the right pulmonary artery. This finding suggested the suspicion of a sudden death due to pulmonary thromboembolism. So in order to detect the origin of the embolus, more CT scan images of the limb where the cannulas were not positioned were taken; however, no abnormalities arose from them. In this way, the angiographic study was completed just with the detection of the filling in the left leg. In the course of the autopsy examination, an embolus was detected in the right pulmonary artery, as confirmed by subsequent histological investigations.

In the meantime, the research of the exact site of thrombosis in the peripheral vessels could provide histological data about the age of the embolus itself, to assess the chronological transformation of the thrombus and to determine the causal relationship with pulmonary thromboembolism as cause of death.

In the following cases of sudden and unexpected death, a new application of the protocol is proposed in which the forensic pathologist has to locate and prepare the axillary artery and the axillary vein on one side to insert the cannulas that are regularly connected to the tube system of the perfusion device. All the other parameters of the standardized protocol were not modified.

In conclusion, the postmortem CT angiography using this new protocol is a useful tool to investigate all the vascular system in the cases of sudden and unexpected death, and on suspicion of pulmonary thromboembolism, it can detect the exact origin of the embolus. At last, the native CT scan and PMCTA have to be followed by conventional autopsy and histological examination of the findings.

Postmortem CT Angiography, Thromboembolism, Sudden and Unexpected Death

G64 Efficacy and Efficiency of Multi-Phase Postmortem CT Angiography (MPMCTA) on Altered Bodies

Christine Chevallier, and Ludovic Perrin, MD, University Center of Legal Medicine Lausanne, Rue du Bugnon 21, Lausane, SWITZERLAND; Paul Vaucher, MSc, Univ of Geneva, Institute of Legal Medicine, Rue Michel-Servet 1, 1211 Geneva, SWITZERLAND; and Patrice Mangin, MD, PhD, and Silke Grabherr, MD, University Center of Legal Medicine Lausanne, Rue du Bugnon 21, Lausanne, SWITZERLAND*

After attending this presentation, attendees will understand the possibilities, advantages, and pitfalls of performing a postmortem CT angiography on alterated bodies.

This presentation will impact the forensic science community by demonstrating that altered bodies can undergo a Multi-Phase Postmortem CT Angiography (MPMCTA), no matter if they were victims of extensive multiple trauma or if they are altered due to putrefaction. The interpretation of the obtained images can be performed without difficulties as artifacts are easily identifiable.

Over the years, imaging techniques such as Multidetector Computed Tomography (MDCT) have become a routine in forensic investigations. In order to quantify the degree of decomposition and other forms of alteration on the radiological images, the “Radiological Alteration Index” (RAI) has recently been introduced. This index states the alteration of cadavers by quantifying the presence of gas in the body using postmortem MDCT imaging. This means that the RAI increases with growing presence of gas. High quantity of gas inside of the body can be due to multiple traumas or putrefaction.

During the last years, more sophisticated techniques of postmortem imaging have been developed. In order to assess the vascular system, postmortem CT angiography has been introduced. A recently developed technique called MPMCTA uses a standardized protocol and consists in the injection of an oily perfusate mixed with contrast agent. Consequently, the question arises if MPMCTA is still feasible on altered bodies presenting huge quantities of gas.

The goal of this study was: (1) to find out up to which RAI a body can still undergo the technique of MPMCTA; and, (2) which artifacts can be observed depending on increasing RAI.

From a database containing 270 cases on which an MPMCTA, has been performed, we selected those cases which showed an RAI ≥50 (group 1). In order to create a control group, we selected correlative cases showing same age, sex, and cause of death but with a RAI ≤10. The quality of the native CT scan and each phase of the MPMCTA were than evaluated by a radiologist without specific forensic imaging training and a forensic pathologist with special training in forensic imaging.

In group one, 14 cases of our database could be selected. (Mean RAI = 72.5, Min RAI = 50, Max RAI = 100). The control group (n=14) showed a mean RAI of 2.30 (Min RAI of 0, Max RAI of 9).

By comparing the results, we observed that several artifacts were correlated to the RAI index. In fact, while the control group presented artifacts which are already known for the technique of MPMCTA, we observed additional artifacts in group one. In cases where the RAI was related to multiple traumatic lesions, those artifacts were partial or non-opacification of cervical and intra-cranial vessels. These artifacts were related to major arterial or venous lesions at thoracic or abdominal levels such as rupture of the aorta or the superior or inferior vena cava.

More interesting were artifacts observed in cases where the RAI was increased due to cadaveric alteration (putrefaction). In fact, artifacts which had never been described before were detected. Such artifacts were slight extravasations of contrast agent in the juxtadural space of the medulla, in the orbits, the cortex of kidneys as well as peri-splenic extravasations. Also, in glandular structures such as the thyroid, prostate, and suprarenal glands extravasations were detected. In addition, enhancement of the myocardium could be observed which would be considered as pathologic in cases of fresh cadavers. On the other hand, artifacts due to remaining blood and postmortem blood clots which are observed regularly in cases of short postmortem delay seemed to appear less frequently in decomposed bodies. However, the appearance of gas bubbles in the vascular lumen even after contrast agent injection has been noticed to increase with higher RAI.

The performance of MPMCTA in altered bodies is still possible even with a maximum RAI of 100. The diagnostic value of such an investigation remains pertinent and the exam adds further information to the result of conventional autopsy; however, there are some specific artifacts which are related to RAI, especially in decomposed bodies, which are important to know in order to interpret the radiological data correctly.

Altered Bodies, Forensic Radiology, Angiography

G65 Postmortem Whole Body Computed Tomography of Heroin and Methadone Abusers: First Results

Sebastian Winklhofer, MD, Univ Hospital Zurich, Dept of Radiology, Raemistrasse 100, Zurich, SWITZERLAND; Thomas D. Ruder, MD, and Garyfalia Ampanozi, MD, Buehlstrasse 20, Bern, SWITZERLAND; and Michael Thali, MD, and Wolf Schweitzer, MD, Univ of Zurich, IRM/Forensic Institute, Winterthurerstrasse 190/52, Zurich, SWITZERLAND*

The goal of this presentation is to detect and to learn about characteristic findings in postmortem imaging in cases associated with heroin or methadone poisoning.

This presentation will impact the forensic science community by showing how Multi-Slice Computed Tomography (MSCT) implemented in the diagnostic work-up algorithm of deaths associated with consumption of heroin and methadone might be a helpful tool to improve the daily work of forensic pathologists.

Illegal drug consumption remains an important issue in forensic pathology. Abuse of and ultimately intoxication with heroin and methadone is a frequent cause of death in young adults. Postmortem CT imaging plays an increasing role in the diagnostic workup in forensic pathology.

The purpose of this study was to assess and to analyze the findings in postmortem, full-body MSCT in victims of deaths where heroin and methadone intoxication played a role.

Routinely performed whole-body MSCT scans of 32 cases of non-traumatic death (16 women; 16 men; median age 38 years; range 26-63 years) who tested positive for heroin or methadone consumption by toxicology were retrospectively evaluated. Whole-body MSCT data were analyzed for pathologic findings as well as the images of an age-and sex-matched control group (n=29, 16 women; 13 men; median age 37.5 years.

Nine of the 32 cases were associated with a consumption of heroin in combination with methadone. In six cases, methadone was found to be the only consumed drug. In four cases, heroin was the only detected drug. In a majority of the cases (56%), a mixture of heroin, methadone, benzodiazepines, cocaine, or amphetamines was found.

Most common findings in the drug cases were: pulmonary edema 22 (69%), distended urinary bladder 14 (44%), cerebral edema (9 cases, 28%), aspiration (7 cases, 23%), pulmonary infection (5 cases, 16%), pulmonary emphysema (5 cases, 16%).

In the control group, a remarkable lower number of the six most common findings detected by CT in the heroin and methadone group was found in pulmonary edema (28%), distended urinary bladder (14%), pulmonary infection (3%), and in pulmonary emphysema (3%). Findings of aspiration (21%) and cerebral edema (28%) were almost similar to the heroin/methadone group.

The combination of lung and brain edema with a full bladder was seen in the heroin/methadone group in six cases (19%), whereas this combination was found in the control group in only one case (3%).

This study demonstrates characteristic findings of postmortem whole body MSCT in cases of heroin and methadone abusers. Furthermore, the combination of MSCT findings of a distended urinary bladder, edema of brain and lungs appears to be more specific than originally assumed, however much not very sensitive. Their combination should raise suspicion of intoxication even though some of the cases contained, but were not judged to have died of, heroin and/or methadone. While this appears to be well known in forensic pathology, new synthetic drugs that might not show up on toxicology screening tests in conjunction with restricted resources for routine toxicology might put an additional burden on forensic pathologists to argue case angles of possible poisoning based on evidence.

These preliminary results are promising regarding the value of postmortem imaging in deceased persons associated with heroin or methadone consumption. A future step is to evaluate the number and types of findings in larger studies.

Forensic Radiology, Computed Tomography, Drug Abuse

G66 Comparative Evaluation of Radiolucent Projectile Components by Radiographs and Computed Tomography

Catherine R. Miller, MA, 944 21st Ave N, No 503, Nashville, TN 37208; Michael G. Haag, BS, 5929 Painted Pony Dr, NW, Albuquerque, NM 87120; Chandra Gerrard, and Gary M. Hatch, MD, Radiology-Pathology Center for Forensic Imaging, Univ of New Mexico, MSC 07 4040, 1101 Camino de Salud, NE, Albuquerque, NM 87102; Jamie Elifritz, MD, Michael C. Simmons, MD, and Sarah Lathrop, DVM, PhD, Univ of New Mexico, Dept of Radiology, Albuquerque, NM 87131; and Kurt B. Nolte, MD, Radiology-Pathology Center for Forensic Imaging, Univ of New Mexico, MSC07 4040, 1 Univ of New Mexico, Albuquerque, NM 87102*

After attending this presentation, attendees will understand the necessity and limitations of forensic imaging in autopsies of suspected gunshot victims. Attendees will gain an understanding of the

importance of recovery of traditionally radiolucent projectile components at autopsy and of the challenges presented in this pursuit by the use of postmortem radiography only as opposed to radiography supplemented with Computed Tomography (CT).

This presentation will impact the forensic science community by strengthening the validity and necessity of postmortem CT scanning for gunshot-related fatalities. These findings also have applications clinically, as missed radiolucent projectile components left in the body during surgery can lead to infection.

Projectile components that are traditionally radiolucent are important in determining weapon and projectile type and caliber, but these components are often not visualized on postmortem radiographs. It was hypothesized that these components would be better visualized by evaluation of CT scans compared to the forensic pathology practice standard of X-ray.

Thirty-two cartridges with projectiles that possessed a radiolucent component were both dismantled using an interia bullet puller and fired, either into a water tank or down an enclosed range, and the radiolucent components were recovered. These cartridges were comprised of a variety of centerfire handgun, shotgun, and rifle rounds. The components were embedded in disrupted zones of blocks of ballistic gelatin. Nine true negative areas of disruption were also created. The blocks were subjected to X-ray and CT scanning. The CT images were helically acquired and reconstructed in axial, coronal, and sagittal views at slice thicknesses of 1.0mm x 0.5mm, 3mm x 3mm, and 0.8mm x 0.4mm. The X-ray and CT images were evaluated by three blindfolded, board-certified radiologists (two with training in forensic radiology) for the presence/absence of projectile components. If a projectile component was present, the radiologists further described their observations.

Projectiles were broken into several categories for analysis: fired vs. unfired, X-ray vs. CT scan, and material type. The material type category was further delineated as plastics, metals, cardboard/fiber, and miscellaneous, which included rubber, styrofoam, paper, fabric, and nylon. In all instances concerning observers one and three, visualization of projectiles/projectile components was equal or better on CT scans when compared to X-ray. This was true for observer two in only the cases of unfired projectiles (0% difference), metals (0% difference), and miscellaneous projectiles (7.7% difference).

An unpaired one-tailed Student t-test ($p<0.05$) was performed to compare total numbers of projectiles/pojectile components identified correctly on X-ray versus CT scan for each observer. The null hypothesis, that there was no difference in observation of projectiles/projectile components on CT scan vs. X-ray, was rejected ($t_{crit} = 2.92$, $t = 17.022$).

Though inter-rater kappa values between the three observers were low in most instances, the percentage of projectiles identified of any material type was high. The kappa values for observers one and two were 0.075 overall, -0.019 for CT, and 0.721 for X-ray. For observers one and three, kappa values were 0.255 over all, 0.333 for CT, and 0.139 for X-ray. For observers two and three, kappa values were 0.841 overall, -0.037 for CT, and 0.104 for X-ray. Observer one identified 88.8% of projectiles correctly, with 78.6% on X-ray and 99% on CT, a 20.4% increase. Observer two identified 84.7% of projectiles correctly, with 89.8% on X-ray and 79.6% on CT, a 10.2% decrease. Observer three identified 96.9% of projectiles correctly, with 95.9% correct on X-ray and 98% correct on CT, a 2.1% increase.

Of the true negative zones created 70% were described by the radiologists. Of these, 55% were correctly identified as true negatives and the remainder as false positves. False positives were identified in 98 cases on X-ray (obvserver 1:2; 2:64; 3:32), and 87 false positives were identified on CT (observer 1:0; 2:80; 3:7).

Traditionally radiolucent projectiles/projectile components embedded in ballistic gelatin blocks were significantly better visualized with CT scans than X-ray. Though concordance between radiologists was low, the total percentages of projectiles identified by each radiologist in each modality were high. The disparities between radiologists' identification of false postives can be attributed to individual skill level and familiarity with projectiles. As gelatin blocks have densities similar to human soft tissues, CT would likely be a better modality to find these projectile components in people with fatal and non-fatal gunshot wounds.

Forensic Pathology, Wound Ballistics, Forensic Radiology

G67 Determination of Postmortem Interval Using Non-Invasive Magnetic Resonance Imaging Measurement of the Apparent Diffusion Coefficient and 1-Dimensional Spectroscopy

Chandra Gerrard, Gary M. Hatch, MD, and Kurt B. Nolte, MD, Radiology-Pathology Center for Forensic Imaging, Univ of New Mexico, MSC 07 4040, 1101 Camino de Salud, NE, Albuquerque, NM 87102; and Natalie L. Adolphi, PhD, Univ of New Mexico Health Sciences Center, Dept of Biochemistry and Molecular Biology, 915 Camino De Salud NE, Albuquerque, NM 87131*

After attending this presentation, attendees will: (1) understand the application of non-invasive magnetic resonance Imaging; (2) become familiarized with Magnetic Resonance Spectroscopic Imaging (MRSI); and, (3) understand what this advanced technology entails and how this technology will aid in the determination of postmortem interval.

This presentation will impact the forensic science community by showing how this rarely used technology in forensic investigation can potentially help address important forensic questions such as postmortem interval.

Postmortem Magnetic Resonance Imaging (MRI) with Diffusion Weighted Imaging (DWI) to produce an Apparent Diffusion Coefficient (ADC) map is being refined as a method for determining Postmortem Interval (PMI) over the 2-14 day range. DWI can be used to monitor decomposition, because tissue breakdown results in increased diffusivity of tissue water corresponding to an increased ADC value. It was hypothesized that the addition of Magnetic Resonance Spectroscopic Imaging (MRSI) will enable the decomposition mechanism (autolysis only vs. putrefaction) to be identified. Spectroscopy enables the identification of specific chemical species, in this case metabolites resulting from decomposition. Currently, these methods are being tested using mammal models with known PMI. In the future, the combination of ADC mapping and MRSI is expected to provide a non-invasive method of determining PMI in specimens or decedents whose time of death is not known.

Examination using MRI with ADC mapping is performed on a 1.5 T MRI scanner on *in situ* mammal brains over the period of two weeks. The mammal specimens decompose at room temperature. Five specimens have been imaged thus far. At each postmortem time point, six echo planar images are acquired with an increase in the diffusion weighting with b-values of 0, 500, 1,000, 1,500, 2,000 and 2,500 s/mm^2. B-values are a measure of the strength of the diffusion sensitizing gradients used during DWI. The individual pixel elements are plotted as a function of the b-value. The slope depicts the ADC in units of mm^2/s. All the ADC values from the six echo planar acquisitions are calculated together to create an ADC map. Regions of Interest (ROI) are obtained from common tissues within the brain; i.e., gray matter and white matter. The ADC values obtained from these ROI are plotted versus PMI, enabling the creation of standardized curves quantifying the continuous change in the ADC of the tissue with increasing PMI. Volume-selective 1D MRSI is currently being added to the above protocol to identify and quantify specific metabolites in the decomposing tissue.

Preliminary data from five specimens reflects two distinct ADC vs. PMI curves that were hypothesized and corresponded to decomposition by different mechanisms: autolysis and putrefaction. The autolyzed tissue follows a steady incremental incline in the ADC curve and levels off with a lower numeric ADC value ≈ 22 mm^2/s. The lower numeric value signifies the tissue has less fluid movement and is more intact. The putrefied tissue demonstrates a rapid incline in the

ADC curve and levels off at a higher numeric ADC value ≈ 37 mm^2/s. Putrefied tissue exhibits more diffusion, or water movement, due to more complete cellular breakdown of the tissue. Thus far, the five specimens studied follow one of the two curves described above, presumably based on the nature of decomposition. The identification of the two curves as "putrefaction" and "autolysis" is based on standard MR anatomic imaging of each specimen, which shows that the tissues that yield a higher ADC value also demonstrate more significant gross structural changes and more gas inclusions, highly suggestive of bacterial putrefaction.

To confirm these results, further ADC studies of mammal models are underway to create statistically significant and reproducible results. To elucidate the nature of the two different ADC vs. PMI curves observed, MRSI, a non-invasive method to chemically analyze tissues, is being added to the protocol to reveal if the tissue is undergoing bacterial decomposition or autolysis. The analysis of the spectral data obtained will focus on identifying metabolites that differentiate biotic from abiotic decomposition. The outcome of the spectral analysis is therefore expected to indicate which of the two observed ADC curves the tissue should follow, which will allow accurate interpretation of ADC values obtained from tissues with unknown PMI in future studies.

Forensic Radiology, Magnetic Resonance, Postmortem Interval

G68 Pseudo Searing of the Skin Around Contact Gunshot Wounds

Erin M. Carney, MD, and David R. Fowler, MD, OCME, 900 W Baltimore St, Baltimore, MD 21223*

The goals of this presentation are to challenge the assumption that blackened skin around contact gunshot wounds is due to heat and to offer an alternative explanation for the cause of the skin color change.

This presentation will impact the forensic science community by presenting new data to challenge the longstanding belief that the black area of skin around a contact gunshot wound is due to soot forced into the skin rather than burning of the skin (or searing) from heat.

Searing of the skin by hot gases from contact gunshot wounds has been long documented in the forensic pathology literature; however, it has not been reliably shown that hair on and around the skin of the wound is burned by the hot gases of combustion. If the heat of the combustion is high enough to burn the skin, then it should affect the hair in and around the skin as well. Burning requires enough heat energy be transferred to the tissue to cause injury. The muzzle flash and the hot gases expelled from the end of the barrel are very brief in duration, even though the temperature has been measured at 1700K to 2000K (1400°C to 1700°C). The effect on the hair is minimal as the heat energy is small. The hypothesis is that hair burns much more easily than skin. Simple flame tests were performed on hair-bearing skin and the effect of the heat and flame documented. The hair burned and was consumed without evidence of any visible damage to the underlying skin.

A retrospective review of color photographs of 270 cases of contact gunshot wounds to the head and chest that occurred from January 2010 to July 2012 was conducted to assess the condition of the hair around the wound. The finding of unaffected hair around the wounds suggests that the black area of skin around a contact gunshot wound is not due to heat applied to the skin by gases. The review cases showed a wide variety of calibers and power variation. The microscopic features described in the literature can potentially also be explained by the soot being pushed at high pressure into the tissues around the wound that have already been abraded by the passing of the projectile. The features are therefore a kinetic energy effect rather than a heat or burn effect. The disrupted appearance of the cells with soot ingrained into the area gives the appearance of searing. Microscopic sections of tests fired through donated cadaver scalp at different ranges from contact to distant using 9×19mm Parabellum ammunition will be presented showing the features of each range.

In 127 cases, the photographs reveal that the hair was not burned. The remaining cases did not have adequate photographs to assess the status of the hair, or the wound was in an area of the body with no surrounding hair.

The longstanding belief that skin is burned or seared during a contact gunshot holds no merit. The photographs from 127 cases reveal that the hair in and around the wound remains intact and, since hair is more susceptible to heat damage than skin, allows the previously documented theory of searing to be reasonably challenged.

Contact Gunshot, Searing, Hair

G69 Retinal Hemorrhages Associated With Partial Submersion (Near Drowning)

Stephen Lenfest, MD, Patrick E. Lantz, MD, Ryan T. Mott, MD, and Constance A. Stanton, MD, Wake Forest Univ School of Medicine, Medical Center Blvd, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn that retinal hemorrhages can occur in cases of partial submersion (near drowning) with cardiopulmonary resuscitation and should not be considered specific for abusive head trauma in young children.

This presentation will impact the forensic science community by illustrating that retinal hemorrhages in young children must be interpreted with caution, particularly in the setting of extended cardiopulmonary resuscitation.

Aggressive, prolonged Cardiopulmonary Resuscitation (CPR) often occurs in partial submersion (near drowning) in young children. A literature review did not reveal any reports of Retinal Hemorrhages (RHs) associated with partial submersion or drowning, and there have been only a few studies looking at RHs associated with resuscitation in children. Two cases of RHs in young children who died following partial submission (near drowning) were presented. In both cases the decedents received cardiopulmonary resuscitation and advanced life support.

Case 1: A 7-year-old male experienced a partial submersion (near drowning) incident at a hotel swimming pool. He was witnessed flailing, choking, and struggling to stay above water. His mother and another adult helped him to the side of the pool. Emergency Medical Services (EMS) arrived and reported that he was breathing spontaneously and was in normal sinus rhythm. During transport to the Emergency Department (ED), he became bradycardic and then asystolic. CPR was started and continued for 25 minutes after arrival at the ED before he recovered spontaneous circulation. Cranial Computed Tomography (CT) showed profound global hypoxic-ischemic injury with cerebral edema. He was in the hospital for two days during which time his neurological status continued to decline and a repeat CT showed worsening cerebral edema with transtentorial and tonsillar herniation. Clinical brain death was pronounced. No clinical fundal examination was documented in the medical record. At autopsy, Postmortem Monocular Indirect Ophthalmoscopy (PMIO) revealed 50-100 bilateral flame-shaped and dot-blot retinal hemorrhages extending over the posterior poles and focally abutting the ora serrata. No optic nerve sheath hemorrhages were identified. Neuropathological examination confirmed severe, diffuse hypoxic-ischemic brain injury with cerebral edema and cerebellar tonsillar herniation.

Case 2: A 6-year-old male was found submerged in a swimming pool at a campground. He was estimated to have been submerged for approximately ten minutes. Bystander CPR was performed at the scene and EMS was alerted. EMS reported that the decedent was cold, unresponsive, and asystolic upon arrival. CPR was continued and Pediatric Advanced Life Support (PALS) was initiated en route to the nearest hospital. Aggressive resuscitation was continued in the ED until a circulating rhythm was established. He was admitted to the

Pediatric Intensive Care Unit (PICU) with a preliminary diagnosis of anoxic brain injury. His temperature was normalized, but he remained comatose throughout this course in the PICU with a Glasgow Coma Score of three. His pupils were fixed, dilated, and nonreactive. He had no cough, corneal, gag, or deep tendon reflexes. A head CT showed diffuse edema with global hypoxic/ischemic injury, and a nuclear medicine brain scan showed no intracranial blood flow confirming brain death. No clinical fundal examination was documented in the medical record. At autopsy, PMIO revealed four flame-shaped retinal hemorrhages in the right eye, and no abnormalities in the left eye. No optic nerve sheath hemorrhages were identified. Other findings included acute bronchocentric pneumonia, pulmonary edema, and diffuse hypoxic-ischemic brain injury with cerebral edema and tonsillar herniation.

These two cases further expand the spectrum of retinal hemorrhages in children with cerebral edema. RHs in children have typically been viewed as a hallmark for abusive head trauma, but routine postmortem ocular examination has revealed increasing numbers of cases with RHs not associated with AHT. RHs have not been previously associated with partial submersion (near-drowning). The RHs in these two cases are most likely attributable to resuscitation efforts and ischemia-reperfusion injury, but further investigation is required to determine the cause of retinal hemorrhages following partial submersion (near-drowning) with resuscitation.

Retinal Hemorrhages, Near Drowning, Resuscitation

G70 Perimacular Retinal Folds Associated With Fatal Intra-Cranial Injuries in Adults From Same Height and Near Same Height Falls

Selly R. Strauch, MD, 803 Fairview St, Jackson, MS 39202; and Patrick E. Lantz, MD, Wake Forest Univ, School of Medicine, Medical Center Blvd, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn that Perimacular Retinal Folds (PRFs) can occur in adults who have fatal traumatic brain injuries from same height or near same height falls.

This presentation will impact the forensic science community by emphasizing the utility of postmortem monocular indirect ophthalmoscopy and highlighting the need for caution in attributing the mechanism of PRF formation to vitreo-retinal traction occurring during cycles of cranial and ocular acceleration-deceleration.

Perimacular retinal folds are considered virtually pathognomonic for Shaken Baby Syndrome (abusive head trauma). However, PRFs have not only been identified in accidental infant head trauma, but have been identified in adults with Terson syndrome. The proposed mechanism of the intra-ocular hemorrhage is a rapid increase in intracranial pressure. Four decedents presenting with perimacular retinal folds at autopsy associated with fatal intracranial injuries are described. They all had blunt force head trauma secondary to same height/near same height falls.

Case 1: A 55-year-old woman was found dead lying at the bottom of a staircase. An area of blood was on the staircase. She reportedly had consumed alcohol the night prior to her death.

Autopsy findings included a 130gm left acute subdural hematoma (SDH) with flattening of the left cerebral hemisphere and a left-to-right shift with transfalcine hermiation, a 4th rib fracture, and a right temporal scalp hematoma. She had bilateral optic nerve sheath nerve hemorrhages (left greater than right) and an 8 x 5mm, well-demarcated, premacular pre-retinal hemorrhage circumscribed by a PRF.

Case 2: A 54-year-old man with a past medical history of alcoholism and esophageal cancer fell off a porch while drinking. Family witnessed the fall and called emergency services. On arrival at the hospital he was comatose. Cranial imaging showed florid cerebral edema with generalized ischemic injury and brain stem herniation. Four days later he was pronounced dead. No clinical fundal examination was documented.

Autopsy findings included facial abrasions, hemorrhage involving the temporalis muscles, bilateral SDH, bilateral subarachnoid hemorrhage, marked cerebral edema, and microscopic findings consistent with hypoxic ischemic brain injury. Postmortem ocular examination revealed bilateral optic nerve sheath hemorrhages, multiple retinal RHs in the right globe, and peripapillary hemorrhage associated with subretinal hemorrhage in the left globe.

Case 3: A 37-year-old man was transported to the emergency room. He had been in a physical altercation and fell striking the back of his head. A cranial CT revealed a SDH with significant rightsided cerebral swelling. His brain injury was considered non-survivable and life support was discontinued. No clinical fundal examination was documented in the medical record.

Autopsy findings included trauma to the left inferior occipital region with complex basilar skull fractures, bilateral frontal SDHs, subarachnoid hemorrhages, transtentorial herniation, and intraparenchymal hemorrhages in the cortex and brainstem. Bilateral optic nerve sheath hemorrhages were identified, PRFs, multiple retinal hemorrhages (including premacular hemorrhages in both globes), rupture of hemorrhages into subhyaloid space and vitreous, shearing of outer segments of photoreceptors by dissecting retinal hemorrhages, and subretinal hemorrhage with retinal detachment.

Case 4: A 60-year-old woman had a past medical history of repeated altered mental status and polysubstance abuse. She was found unresponsive at home and transferred to the nearest medical center. Cranial computed tomography revealed bilateral SDHs. No clinical fundal examination was documented in the medical record.

Autopsy findings included a laceration of the posterior scalp, bilateral SDHs, cerebral edema, right parafalcine and uncal herniation, midbrain/pons Duret hemorrhages, bilateral optic nerve sheath hemorrhages, scattered RHs over the right posterior fundus, and a premacular hemorrhagic cyst with a PRF in the left eye.

These four adults with retinal hemorrhages and PRFs died from traumatic brain injuries due to same height/near same height falls and expands the number of conditions associated PRFs. Three of four decedents died following hospitalization; however, no clinical fundal examinations were documented in their medical records. The hemorrhagic retinopathy and PRFs were identified by postmortem monocular indirect ophthalmoscopy emphasizing the need for uniform and consistent ocular examination of decedents with fatal traumatic brain injuries.

Retinal Folds, Accident, Brain Injury

G71 Death Due to Excited Delirium Associated With Synthetic Marijuana Use: A Review of Two Recent Cases

Julia Shields, MD, Zabiullah Ali, MD, Ana Rubio, MD, PhD, Rebecca J. Phipps, PhD, and Barry S. Levine, PhD, OCME, 900 W Baltimore St, Baltimore, MD 21223; Suzanne Doyon, MD, Maryland Poison Center, Univ of Maryland School of Pharmacy, 220 Arch Pine St, Baltimore, MD 21201; and Mary G. Ripple, MD, and David R. Fowler, MD, OCME, 900 W Baltimore St, Baltimore, MD 21223*

After attending this presentation, attendees will understand the toxicity of synthetic cannabinoids, the literature regarding associated deaths, and a case series of the two deaths of excited delirium resulting from synthetic marijuana use.

The presentation will impact the forensic science community by describing excited delirium due to synthetic cannabinoids and elucidate the need for further regulation of these substances.

Subjects in excited delirium typically present with aggressive, agitated, bizarre, and combative behavior and display invulnerability to pain, hyperthermia, diaphoresis, tachycardia, a tendency to be under-clothed for the environment, and a propensity toward water,

lights, or glass. In fatal cases, the subject frequently has a history of a struggle, restraint or sedation, sudden cardiac arrest and death while in custody or at the hospital, positive drug screen, and no other anatomic cause of death identified at autopsy. The majority of cases involve stimulant abuse, predominantly cocaine, but also methamphetamine, Lysergic Acid Diethylamide (LSD), Phencyclidine (PCP), etc. Less commonly, the subject may have a psychiatric history with a sudden discontinuation of antipsychotic medications.

The use of synthetic marijuana is on the rise, and there have been reported cases of fatal outcome associated with consumption of these compounds. Synthetic marijuana is popular among young people and is the second-most-used drug by high school seniors nationwide. Synthetic marijuana is marketed as a mixture of traditionally used medicinal "herbal incense" with mild cannabis-effect and sold under many names, such as K2, Spice, legal phunk, etc. Synthetic cannabis is a mixture of plant ingredients blended with synthetic cannabinoids such as cannabicyclohexanol, JWH-210, JWH-018, JWH-073, HU-210, JWH 250, RCS-4, RCS-8, etc. Case reports have described acute psychosis, convulsions and seizures, and myocardial infarction occurring after synthetic cannabinoid use. There are reported cases of sudden death following synthetic cannabinoid and anecdotal reports of agitated and bizarre behavior related to use, however, the literature is lacking in reported cases of excited delirium fatality secondary to synthetic cannabinoid consumption.

Two recent fatal cases of excited delirium associated with the use of synthetic marijuana were reported. A similar series of events occurred for both individuals, in which both subjects were acting in a bizarre and agitated manner prompting a struggle between the subject and police, resulting in restraint of the subject's arms in handcuffs behind the back and restraint at the ankles. In both cases, the subjects were witnessed to become unresponsive while in custody, arrived at emergency medical care in cardiac arrest, and had hypoxic ischemic encephalopathy with cerebral edema and cerebellar tonsilar herniation at autopsy. A history of recent synthetic cannabinoid use was related for both subjects, and both subjects had positive hospital drug screens for cannabinoids during their hospital course. Routine postmortem toxicological screening on urine and whole blood were negative. Additional testing for synthetic cannabinoids was performed by NMS Labs (Willowgrove, PA) using a liquid-liquid extraction technique and liquid chromatography-positive ion electrospray ionization tandem mass spectrometry**.** Postmortem testing of the hospital admission blood of the first subject was positive for the synthetic cannabinoid JWH-210. Test results for additional illicit drugs, including bath salts were negative in both cases.

Two cases of fatal Excited Delirium (ED) due to synthetic cannabinoid use are described. The use of these drugs is on the rise, especially among younger individuals, and the presence of these drugs should be suspected in cases of ED when other drugs known to cause ED, such as cocaine, phencyclidine, and bath salts are negative.

Spice, Synthetic Marijuana, Excited Delirium

G72 Ruptured Intracerebral Arteriovenous Malformations, Hypertensive Cardiovascular Disease, and Acute Hypertensive Effects of Stimulants: Is There a Direct Link?

Dwayne A. Wolf, MD, PhD, Glenn Sandberg, MD, Sharon M. Derrick, PhD, and Sarah V. Kelly, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Tr, Houston, TX 77054*

The goal of this presentation is to provide an understanding of the relationship between hypertensive cardiovascular disease and rupture of intracerebral Arteriovenous Malformations (AVMs).

This presentation will impact the forensic science community by improving the understanding of the impact of hypertensive cardiovascular disease on the natural history of intracerebral AVMs. The relationship of AVM rupture with the acute hypertensive effects of drugs will also be explored.

Currently available data regarding natural history of AVMs is conflicting; clinical studies have been limited by small sample size, young age of patients (prior to peak incidence of hypertension), and lack of long term follow-up.[1-5] Accordingly, some have concluded that hypertension has no impact on rupture of AVMs, while other sources include hypertension as a major risk factor for AVM rupture.[4-6] Therefore, the risk of hypertensive cardiovascular disease on intracerebral AVMs is presently unclear. Whether rupture of an AVM may be precipitated by or associated with an acute hypertensive episode caused by substance abuse (e.g., cocaine, methamphetamine, and phencyclidine) has direct relevance for manner of death.

A retrospective cohort study was designed in which all autopsy case files between January 2005 and July 2012 were reviewed to identify adult decedents (age >18 years) in which an AVM was listed as a cause of death. Cases were excluded if the decedent had a remote history of neurosurgical intervention. Other types of intracranial fistulas (i.e., dural arteriovenous malformations) and nonfistulous malformations (i.e., cavernous hemangiomas) were excluded. One case of unruptured AVM was included.

A total of 11 cases were identified that met study criteria. Relevant biographical and historical information was collected. Gross autopsy and histopathological data were collected on each decedent to assess for the presence or absence of cardiomegaly, left ventricular hypertrophy, end organ (kidney) damage, and extent of involvement and chronicity of the AVM. Heart weights were compared to expected heart weights determined from a model described by Gaitskell *et al*. in 2011.[7]

Seven of the 11 cases (64%) were male and 4/11 (36%) were female, with an average age of 44 years (range 29 – 58 years). Average body weight was 177 pounds (range 118 – 248 pounds) and average height was 66.5 inches (range 62 – 70 inches). The average body mass index, characterized as overweight, was 28.2kg/m^2 (range 17.9 – 39.1kg/m^2). The cases comprised of mostly (91%) ruptured AVMs with associated hemorrhage: Subarachnoid (SAH) 8/10 (80%); subdural (SDH) 2/10 (20%), and intraparenchymal 5/10 (50%).

Autopsy heart weights averaged 422g (range 250 – 690g) with an average left ventricular wall thickness of 1.5 cm (range 1.0 – -2.0cm). Four of ten (40%) decedents with ruptured AVMs had both cardiomegaly and left ventricular hypertrophy (left ventricular thickness >1.4cm). Five of the ten (50%) ruptured cases had Left Ventricular Hypertrophy (LVH) and 3/4 (75%) of the cases with cardiomegaly and LVH also had evidence of hypertensive kidney disease (nephrosclerosis and arteriolosclerosis). Ultimately, six out of ten (60%) of the cases with ruptured AVMs had evidence of hypertensive disease as evidenced by one of the following: LVH, cardiomegaly, or hypertensive kidney disease. A clinical history of hypertension was identified in two of 11 (36%) of the cases (each confirmed by histopathology); one case was an unruptured AVM and one was a ruptured AVM. Finally, two of the ten (20%) decedents with ruptured AVMs also had acute cocaine toxicities; one had both hypertensive heart and kidney disease, the other had histopathologic evidence of hypertension. Each was classified as an accident.

Ultimately, it cannot be concluded from these data that hypertensive cardiovascular disease is a direct risk factor for rupture of intracerebral AVMs. However, the low percentage of hypertension in decedents with ruptured AVMs suggests the association is weak at best. This data would support a cautious approach when assigning manner of death to decedents who died from a ruptured AVM and also had stimulants detected during autopsy. Furthermore, whether to include underlying hypertension as a contributory cause of death is not clear. A major limitation of this study is the low number of study subjects.

Arteriovenous, Malformation (AVM), Hypertension

G73 Neonaticide: A Retrospective Analysis of Characteristics and Trends of 55 Cases

Emily J.H. Dennison, MD, 1715 Trevilian Way, Louisville, KY 40205; Tracey S. Corey, MD, OCME, 810 Barret Ave, 7th Fl, Louisville, KY 40204; and Joy L. Shelton, BA, and William H. Donaldson, BA, FBI, Behavorial Analysis Unit III, 1 Range Rd, Quantico, VA 22315*

After attending this presentation, attendees will learn: (1) common demographics of neonaticide victims, including circumstances surrounding the pregnancy, crime scene characteristics, method of discovery, and cause of death; (2) common characteristics of neonaticide offenders; and, (3) diagnostic tests and difficulties in neonaticide investigations.

This presentation will impact the forensic science community by increasing the awareness among criminal justice professionals and forensic pathologists of the potential investigative challenges in neonaticide cases and will provide recommended investigative techniques.

Neonaticide is frequently defined as the killing of a newborn, most commonly by the biological mother, within 24 hours of birth. While not uncommon, this crime is difficult for pathologists, investigators, and families alike to understand. This FBI retrospective study analyzes the largest known collection of neonaticide cases from 20 states between the years 1992 to 2009 in an effort to better understand this crime and how to recognize it at the time of autopsy. Fifty-four female offenders with 55 related infant deaths (one offender killed two infants in separate incidents) were identified through the FBI's internal databases, law enforcement partners and public-source information. The perpetrators' average age was 21.7 years. Thirty-three percent had other living biological children, while 43% had previously been pregnant (although not all resulted in live births). Most of the perpetrators (96%) were hiding the pregnancy from family members. While all offenders knew they were pregnant and confirmed this to a family member or friend, only 5% of these women had the pregnancy confirmed by a medical doctor. Regarding victims, male victims (55%) were slightly more common than female victims (45%). Caucasians (49%) made up the majority of victims, with Hispanic (18%), Bi-racial (15%), African American (9%), Native American (6%), and Asian (4%) victims being less common. Fifty-eight percent of victims were discovered in an indoor location, the offender's residence being the most common place of discovery (53%). Victims discovered at an outdoor location (33%) were usually found outside the perpetrator's residence in a trashcan, the backyard, or on the roof. Most commonly (38% of cases), the victims were discovered once police were dispatched to the home after the mother sought medical attention, was found to have recently given birth, and medical personnel contacted authorities. The time interval between birth and discovery was less than 24 hours in 77% of the cases where the time interval was recorded (13 cases). In 75% of cases, no decomposition of the victim was identified. Five percent had mild decomposition, 5% showed moderate decomposition, and 15% had severe decomposition. While only in 87% of cases did a forensic pathologist specifically list "live birth" on the autopsy report, all cases were presumed to be live births since the deaths were ruled as homicides. Most pathologists used a combination of methods to determine live birth (89% of cases), with the combination of the hydrostatic "float" test on the lungs, microscopic evaluation of the lungs and other tissues, and confirmation of air in the lungs and gastrointestinal tract via gross examination or X-ray being the most common combination of methods (27.5%). Forty-five percent of cases relied on the history to help determine live birth, with 16% of cases relying solely on history, as Cause of Death (COD) could not be determined. The COD was determined in 84% of cases, with asphyxia deaths (80%) being the most common cause. Of these, 62% were due to suffocation, 30% were due to drowning, and 8% were due to strangulation. Of those deaths where a single COD was identified, 13% were due to sharp force injuries, 7% were blunt force injuries and 7% were due to exposure. In 27% of cases, the pathologist ruled the COD as multifactorial, with suffocation and exposure being the most common combination (73%). In neonaticide, as in many other forensic pediatric deaths such as SUID and drowning, the COD is made on the totality of the circumstances. The pathologist must consider the historical information, scene investigation, and pathologic findings when rendering an opinion regarding cause and manner of death.

Neonaticide, Child Homicide, Pathology

G74 Jay Dix Memorial Bonus Day

Michael A. Graham, MD, Saint Louis Univ School of Med, Div of Forensic Pathology, 3556 Caroline, Rm C-305, St. Louis, MO 63104; Randy L. Hanzlick, MD, Fulton County, Medical Examiner Center, 430 Pryor St, SW, Atlanta, GA 30312; Joseph A. Prahlow, MD*, South Bend Medical Foundation, 530 N Lafayette Blvd, South Bend, IN 46601; Joyce L. DeJong, DO*, Sparrow Health Systems, Forensic Pathology, 1322 E Michigan Ave, Ste 118, Lansing, MI 48909; Jonathan Hayes, MD*, OCME, 520 1st Ave, New York, NY 10016; and J. Keith Pinckard, MD, PhD*, Southwest Inst of Forensic Sciences, 5230 Medical Center Dr, Dallas, TX 75235*

After attending this presentation, attendees will learn how and why deaths related to multitude of topics occur. Attendees will learn a systematic approach to the evaluation of such deaths that can easily be implemented in their daily practices.

This presentation will impact the forensic science community by receiving a comprehensive review of what causes and contributes to different types of deaths. Attendees will be able to systematically evaluate deaths in which the previously specified topics that may have played a role in their daily practices.

A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual series of discussions is intended to provide the non-forensic pathologist forensic scientist a comprehensive basic review of selected topics in forensic pathology in order to increase familiarity and understanding and enhance inter-discipline communication.

This year's presentations will discuss the investigation of infant deaths and deaths related to electrocution, asphyxia, sports and recreation, and suicide.

Electricity is a ubiquitous entity in our daily lives. Some of it is intentionally generated to provide power and some of it originates as a force of nature (lightning). Interaction between humans and electricity is common and typically has no untoward effects. However,

under some conditions this interaction may result in morbidity and/or mortality. Multiple causes, mechanisms, and contributory factors play a role in injury and deaths involving electricity. Understanding and evaluating injuries and deaths in which electricity may have played a role requires basic knowledge of electricity and how it affects various biological vital functions. Recognition of injuries and deaths caused by electricity is particularly important because of implications regarding the safety of others. This presentation will provide a comprehensive review of these issues.

Human life requires the uptake and utilization of oxygen along with the release of metabolic waste. Failure of these processes leads to asphyxia. There are numerous entities—mechanical and chemical—that can cause asphyxia through a variety of mechanisms, present in a wide range of scenarios and that can be associated with a broad range of physical findings. Proper evaluation of these deaths requires knowledge of the various entities that can cause asphyxia, mechanisms through which these agents affect physiological function, scenarios under which these deaths occur and factors that contribute to these deaths. This presentation will comprehensively discuss the investigation of death in which asphyxia may have played a role.

There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to participating in and, occasionally, while being a spectator at sporting or other recreational activities. Understanding these deaths requires understanding of the physical requirements to perform particular activities, susceptibility of particular diseases to stresses associated with particular activities, effects of various chemical and/or biological agents that may be taken to enhance performance and physical injuries associated with particular recreational activities. This presentation will provide a comprehensive review of these issues in the context of investigating deaths that occur in relation to sports/recreational events. Understanding factors that are involved in deaths occurring in these circumstances also helps in instituting appropriate safety measures to protect participants and spectators.

The intentional termination of one's own life, suicide, can be accomplished in many ways, some overt and others covert. The accurate recognition of suicide has important implications for the decedent's survivors, estate, and others such as law enforcement. Unlike most other manner of death determinations, an assertive determination of the decedent's intent is fundamental in certifying a death as suicide. In addition to accurately determining the cause and manner of death, the proper investigation of a suicidal death may offer insight into the motivation for the death and provide information in the development and implementation of preventive strategies. The investigation and interpretation of findings in suicidal deaths will be comprehensively discussed.

The death of an apparently healthy infant is a devastating event for the infant's survivors and is accorded significant attention by society. Infant death may be the caused by a wide variety of diseases and injuries, involve a variety of mechanisms, and can be natural, accidental, or homicidal. External and/or internal evidence of disease or injury may be lacking. Accurate recognition of the cause, mechanism and manner of death has important implications for the survivors, other interested investigative and health agencies and society in general. Recognition of factors involved in sudden unexpected infant deaths can help in enhancing the safety of other family members and serve as a basis for formulating death prevention strategies. The investigation and interpretation of findings in sudden unexpected deaths involving infants will be discussed.

Sudden Death, Death Investigation, Forensic Pathology

G75 Unusual Suicides Utilizing Chain Saws — Case Reports and Literature Review

Margaret A. Kaleuati, MS, Debra K. Kowal, MS, and Christopher B. Rogers, MD, County Dept of Coroner, 1104 N Mission Rd, Los Angeles, CA 90033; Michael T. Schmidt, DO, Cedars-Sinai Dept of Pathology and Laboratory Medicine, 8700 Beverly Blvd, Los Angeles, CA 90048; and Cynthia Bir, PhD, 818 W Hancock, Detroit, MI 48201*

After attending this presentation, attendees will understand what can be observed in an unconventional suicide such as one committed with a chain saw.

This presentation will impact the forensic science community by better preparing those conducting death investigations for the analysis of unconventional death scenes and autopsy results to help identify the manner of death in these unusual cases.

Purposeful application of a chainsaw to the human form is a rare event; however, it has been reported in the literature more frequently in the past several years in cases of self-mutilation, suicide attempts, and postmortem dismemberments. In this presentation, the only two cases of suicide by chainsaw that have occurred in Los Angeles County will be reviewed. The findings of the investigation including the initial death scene examination, autopsy results, and subsequent analysis of tool marks in bones will be discussed. The mechanisms of suicide utilizing a chainsaw in these case reports will be examined and compared to other cases reported in the literature.

Case 1: A 49-year-old male was found dead on the floor of a motel room. He had been a resident of a board and care facility for the mentally impaired for over six years, but was not known to be under a physician's care for psychiatric issues at the time of his death. He had checked into the motel the day before for a one-night stay. He was lying supine between the foot of the bed and a dresser and the electric chainsaw was laying on the bed. Nearby on a table were the decedent's driver's license, suicide note, receipt for the chain saw dated the day prior and other personal items laid out in an orderly fashion.

Autopsy findings: A single wound approximately 2¼ inches deep passing through the cervical vertebrae but not injuring the spinal cord extended from just posterior to the right ear inferiorly across the neck producing a wound approximately 7 inches long. The atlas (C1) vertebra revealed injuries compatible with the use of a large width cutting-edge instrument such as a chain saw, reinforced by the presence of chatter across the occipital bone.

Case 2: A 47-year-old female was found dead in her bedroom. She was considered disabled due to a brain injury but was not known to be under a physician's care for psychiatric issues. She was lying supine with her head at the foot of the bed. The electric chainsaw was present on the bed with the blade resting across the decedent's neck and her right hand still in the handle. The sheets she had covered the dressers with and the comforter on the bed were covered with blood spatter. A suicide note was taped to a wall of the bedroom.

Autopsy findings: There were two deep incised wounds, one of the anterior neck and one on the left shoulder. The wound of the neck measured approximately 6 inches long and extended from just inferior to the right submandibular angle to the left side of the neck and continued through to the posterior surface of the neck just left of the posterior cervical line. The wound to the left shoulder, which appeared to originate in the left shoulder articulation and terminate in the left clavicle, was approximately 2 inches in length. A study of the neck organs, cervical vertebrae, and clavicle revealed injuries compatible with the use of a large width cutting-edge instrument, such as a chain saw.

Commonalities among the two cases included: no history of suicide attempts or suicidal ideations, no defensive or hesitation wounds, and toxicological results indicating no drugs of abuse present at the time of death.

Suicides by chainsaw are rare but reported in the literature. There can be discrepancies between what is found at the death scene and autopsy of these unusual suicides and what is expected to be found in a conventional suicide. These cases were compared to the

literature in consideration of the commonalities between the two cases and the differences that make each of these cases unique in comparison to the current literature.

Chainsaw, Suicide, Forensic Pathology

G76 Accidental Injury Caused by a Handheld Circular Saw: An Unusual Industrial Accident

Oscar A. Plaza, MD, Medicina Legal, Calle 4B # 36-01, Calle 12 b No. 59-31, Cali, COLOMBIA*

After this presentation, the participants will understand how this fatal accident occurred as a result of improper use of a handheld circular saw, as well as how the scene investigation gave investigators some insights on how a tool designed to prevent fatal injuries was involved in an accident that caused serious lesions to the user.

This presentation will impact the forensic science community by showing how multidisciplinary investigations, with the participation of the tool manufacturer, occupational health and industrial safety staff, and medical examiners, were instrumental in reconstructing the chain of events in a unusual industrial accident.

Presented here is a case of death resulting from an unusual industrial accident caused by the laceration of internal thoracic and abdominal organs. The accident occurred when a carpenter fell on a handheld circular saw while he was cutting wood. This report analyzes the scene, the chain of events, and the pathogenetic mechanisms that caused the death of an individual who was in the process of performing an unauthorized activity. The forensic aspects of the case will be discussed. Upon reviewing the existing literature, a large number of cases where various types of saws were used in suicide attempts are reported, but no reports were found on this kind of accidental death due to this type of tool. Under normal conditions, the handheld saw is used by an operator who directs the sharp edge of the saw to a fixed wood fragment located below the saw. The cutting action should not cause any problems because the tool has a protection mechanism (cover). In the case reported, the operator did the opposite. He attached the saw to a table with the cutting edge facing upwards, removed the cover, and put the wood on the cutting edge of the saw. He tripped on the wires and fell on the saw. The operator suffered serious injuries that affected his vital structures of the chest and abdomen, which caused his death due to massive bleeding of the right lung, the heart, and the abdomen. When the scene was processed, it was documented how the saw was improperly attached to the table and how the industrial accident happened. Other saws in the factory were checked in order to determine the cause of the injuries. A case of this type of accidental death has never been reported in the literature.

This case will make an impression on the international forensic community, since it will show how multidisciplinary investigations, with the participation of the tool manufacturer, occupational health and industrial safety staff, and medical examiners, all of whom were instrumental in reconstructing the chain of events. The multidisciplinary team was able to determine the factors involved in this unusual industrial accident. At first it was difficult to determine the manner of death. There was disagreement between the authorities that processed the scene and the medical examiners. The tool involved in this fatality was examined by an expert who found that the expectations of the manufacturer were correct and concluded that the tool had been misused. The medical and psychiatric records of the deceased were reviewed for some kind of psychiatric disorder that could explain the fatality. Since occasionally labor accidents involve the use of drugs of abuse, a toxicology screening of the vital fluids was carried, with negative results.

A case will be presented where an unusual industrial accident with a handheld circular saw was examined. This is an example of the practical application of multidisciplinary investigations and cooperation in order to solve unusual deaths. Forensic investigators must become familiar with tools that are increasingly involved in suicide attempts and fatal accidents.

Industrial Accident, Fatal, Investigation

G77 Circular Saw: No Enigma?

Cristoforo Pomara, MD, PhD, Natascha Pascale, MD, and Gabriela Perilli, MD, Univ of Foggia, Viale Degli Aviatori 1, Ospedale D'Avanzo, Foggia, ITALY; Alessio Marangelli, PO, Prosecutor Office of Lucera, Lucera, ITALY; and Stefano Derrico, MD, Univ of Foggia, Viale Degli Aviatori 1, Foggia, ITALY*

The goal of this presentation is to present a fatal case with a sharp injury on the neck due to a rotating saw blade in a man with occupational experience with power saws. A detailed crime scene investigation, and a complete postmortem examination established the cause of death and excluded homicide and suicide.

This presentation will impact the forensic science community by emphasizing the importance of a careful crime scene investigation in order to differ between accidental, suicidal, or homicidal events when investigating injuries of the neck in cases involving a circular saw.

Fatal cases involving the use of power saws (band saws, circular saws, or chain saws) are rarely reported in literature. The injuries are most likely to be to the front of the trunk, head, or neck, but may be in any part of the body where there is a blood vessel large enough to give rise to rapidly fatal bleeding. Incised wounds of the neck can be accidental, homicidal, or suicidal. Accidental incised wounds are common and usually tend to be of a minor nature; hand injuries and distal fingertip amputations appear to be common among those using powered cutting equipment. Conversely, accidental fatalities due to working power tools are exceptionally rare. Suicidal incised wounds of the neck are typically multiple, often accompanied by a number of preliminary trial cuts (hesitation marks) and nearly all persons choosing this unusual manner of suicide suffer from psychosis or depression. In homicides the incision is single, extremely deep, and extends completely to the vertebral column. The scene of crime is suggestive of a struggle between victim and aggressor with disarray and blood everywhere.

The case presented concerns a 48-year-old man who was found dead in his own garage. The prosecutor's office was immediately alerted and a forensic pathology was involved in the crime scene investigation. The corpse was lying on the floor, and bloody stains were found everywhere around the cadaver. A circular saw with a smooth blade, 0.3cm thickness and 19.5cm diameter, was found on the cadaver and collected for examination. Evidence of a struggle in the garage was excluded as well as psychiatric disorders or unsuccessful suicide attempts in the past. A complete postmortem examination was performed a few days after death. At external examination, a wide, deep incised wound with regular margins was described crossing the anterior to the posterior side of the neck over and up the cervical bone's plane. Two superficial incised wounds were observed at the jaw and at the flexor surface of right forearm. Mild cerebral oedema was recorded at gross internal examination. Gross examination of the neck revealed massive hemorrhages in the subcutaneous tissues and muscles; left jugular vein, left common carotid artery, and left vagus nerve were isolated one by one and sectioned. A beautiful series of forensic autopsys pictures applied to the study of the face and the neck will be presented. The left thyroid lobe and left side of trachea showed lacerations. The paracervical muscles were hemorrhagic and a partial laceration of the fifth and sixth cervical vertebra was also detected. Examination of the heart and other organs was unremarkable except for a mild, white foam detected on the main bronchi. Small and big vessels were poor of blood. A complete histopathological study with Haematoxylin-Eosin (H&E) stain was performed. Hemorrhagic shock from transection of the left carotid artery and jugular vein was indicated as the cause of death.

The crime scene investigation and the distribution of lesions led us to conclude a rare case of accidental fatal injuries with circular saw. The peculiar technique used at autopsy to investigate injuries of the neck documented photographically will impact the forensic community and emphasize the importance of a careful crime scene investigation in order to differ between accidental, suicidal, or homicidal events.

Power Saw's Injuries, Crime Scene Investigation, Autopsy Technique

G78 Forensic Point of View in Manual Strangulation

Lucia Barrios, MD, CHU de Nantes, 1 Place Alexis Ricordeau, Nantes, FRANCE; and Renaud Clement, MD, 1 Rue Gaston Veil, Nantes, FRANCE*

After attending this presentation, attendees will understand some principles of danger to life in manual strangulation.

This presentation will impact the forensic science community by the fact that the cause of death in manual strangulation is not yet elucidated.

Strangulation accounts for 2.5% of traumatic deaths worldwide and up to 10% of all violent death in the United States. Many people who are strangled survive. Much of forensic analysis and knowledge on manual strangulation was based on homicide victims. Serious damage to the vital structures in the neck was specific. Assessment of life-threatening injuries could be characterized as malicious intent.

All studies involving life-threatening and non-life threatening manual strangulation were reviewed. Are there any specific findings in clinical forensic medicine or in radiological investigation between deceased and living victims? Is the assessment of danger to life based on cerebral hypoxia and or cardiac reflex?

Only five studies were found in international literature. Only one, performed by a Swiss team, was clinical, all remaining studies were radiological. Three of them focused on the criteria between life-threatening and non-life-threatening manual strangulation. One compared strangulation signs between autopsy findings and multislice computed tomography and with magnetic resonance imaging. The clinic study proposed the categorization of strangulation victims who survived in three degrees of assault intensity (light, moderate, severe). It was stated that the duration of the neck compression would be associated with a high probability of a reflex cardiac arrest. Signs of typical manual strangulation prove the length and the forcefulness of the accused man. In contrast, radiological studies state the danger of life.

The appropriateness of life-threatening manual strangulation is crucial for forensic pathologists. The degree of penalty for the offender depends on this forensic point of view. Assessment of intensity and duration of manual strangulation by the injuries is still controversial when the cause of death remains obscure. There are four mechanisms of strangulation leading to death: venous obstruction leading to cerebral stagnation, arterial spasm due to carotid pressure leading to low cerebral blood flow, vagal collapse caused by pressure to carotid sinuses, and increased parasympathetic tone and obstruction of the airway by pressure on throat skeleton (unremitting manual pressure on the throat during four minutes seems practically unattainable). Mechanisms of death could be mixed in manual strangulation. The role of cardiac reflex by pressure on the neck in manual strangulation is still a controversial subject in forensic medicine.

Because of this, assessing life-threatening injuries is still difficult. When exactly does manual strangulation become a danger to life?

The clinical study explains that the classification should be considered as a proposition and forensic assessment is still individual. Radiological studies demonstrate the added value to forensic assessment by offering visualization of internal neck findings in victim survival or death. Forensic radiology studies concluded that the value of inner neck injuries is necessary. Forensic evaluation of danger to life needs reference standards and the small number of cases limits the results.

Further studies of survivors of manual strangulation have to be done. Comparative studies between forensic autopsy and forensic radiology must include more cases.

Manual Strangulation, Cause of Death, Danger to Life

G79 Cardioinhibitory Reflex Cardiac Arrest (CiRCA): Is it Possible Without Contributory Factors?

Silvia Tambuscio, MD, Univ of Verona, Piazzale L.A. Scuro 10, Verona, Italy, ITALY; Andrea Galassi, MD, San Bortolo Vicenza Hospital, Unit of Legal Medicine, Via Rodolfi 37, Vicenza, ITALY; and Federica Alessandrini, PhD, Univ of Ancona, Via Conca 6 Torrette-Ancona, ITALY*

After attending this presentation, attendees will learn that a single, short neck trauma can lead rapidly to death stimulating the carotid sinus cardioinhibitory reflex, without any compressive effect on the carotid arterial flow or any mechanical asphyxia.

This presentation will impact the forensic science community by highlighting that, as reported in the literature, there is no evidence proving that carotid stimulation alone can determine death.[1] In fact, in the present case, cardioinhibitory reflex cardiac arrest (CiRCA) resulted in the interaction between mechanical carotid sinus stimulation and underlying pathological and toxicological contributive factors.

It is widely known, in cardiology, that compression of the neck can produce variations in cardiac rhythm with bradycardia, syncope, and, in some cases, circulatory collapse resulting from the activation of an arterial baroreflex.[2,3] Remarkable interindividual variability in cardiac response has been reported.[4]

This physiopathological mechanism has been cited even in forensic setting, as the questioned cause responsible for deaths in which no other clear explanation is found. Many case studies have been recently reviewed[1] highlighting that reflex cardiac arrhythmia by neck stimulation is able to provoke death mainly with the contribution of other preexisting factors, such as drug abuse, cardiac diseases, and physical and/or mental excitation.

A 22-year-old Bangladese male, while spending time with some friends and other guests drinking alcohol in a night club, was dragged into a brawl outside of the establishment. Circumstances were carefully described by five different witnesses, all concordantly reporting that the man was hit by a single very strong punch on the left side of the neck, just below the mandibular angle. After the blow, the young man had a syncope and fell down, unconscious and unresponsive to intensive care.

Clinical records were examined in detail, including electrocardiograms. A history of chronic alcohol abuse, with multiple visits to the emergency for ethanol overdoses, was noted; apart from that, pathological anamnesis was normal.

Autopsy showed a remarkable bruise in the neck subcutaneous tissues and in the upper tract of the left sternocleidomastoid muscle, close to the neurovascular bundle. Further pathological exam ruled out any relevant traumatic brain or neck injury and cardiac disease.

Toxicology on postmortem blood specimens gave negative results for the most common drugs of abuse, except for the detection of ethanol 3.53g/L. Such blood alcohol concentration was similar to *in vivo* toxicological data of the subject, assessed during previous acute ethanol intoxications.

Forensic genetics were carried out screening mutations in three main genes (KCNQ1, KCNH2, SCN5A) involved in the Long QT Syndrome (LQTS). The deceased was a carrier of two different mutations in exon 11 of the KCNH2 gene, codifying for an ion channel named "HERG," related to the LQTs type 2. One was a silent mutation, but the subject was eterozygous for a missense mutation in

A2690C, responsible for aminoacidic substitution (from lysine to threonine) at codone 897 (K897T).

In this reported case, death by CiRCA was highly probable, but it was mediated by contributive factors, like alcohol intoxication and possible arrhythmic diathesis genetically determined. In this case, the high postmortem blood alcohol concentration does not explain death itself. In fact, in the literature,[5] lethal overdoses refer levels above 4.0g/L. Furthermore, tolerance to high alcohol levels by the subject, prone to repeated acute intoxications, must also be considered. More probably death resulted by mechanical activation of cardioinhibitory reflex at the neck with consequent bradycardia and loss of consciousness; then ethanol-related cardioinhibitory effects and brain depression led to final cardiac arrest. Questions remain as to the contribution of the genetic factor. In fact, while the detected missense mutation of KCNH2 gene seems to produce *in vitro* electrophysiological changes in sodium channel permeability,[6-8] its pathological significance *in vivo* is still uncertain.

In conclusion, the reported case confirmed that CiRCA should be a diagnosis by exclusion. It must be designated to cases in which circumstances are directly witnessed, and it should be supported by modern pathological, genetical, and toxicological analyses, to rule out other possible mechanisms of sudden unexplained death.

CiRCA, Carotid Sinus, Neck Compression

G80 Spinal Cord Injury in Breech Labor

Orlando Solano, MD, Calle 66 A No. 1 A 11-04, Cali, COLOMBIA*

After attending this presentation, attendees will understand how inadequate care of a breech delivery caused a perinatal death. The autopsy sheds light on how death occurred when extracting the fetal head and not by perinatal asphyxia.

This presentation will impact the forensic science community by higlighting how a multidisciplinary research involving the collaboration of academic peers and a group of forensic scientists was able to reconstruct the chain of events in an appropriate manner and how the factors that influenced this perinatal death were determined.

This is a case in which spinal cord injury occurred during a breech labor. According to a statement from the mother on the filed report, the mother stated that she felt her baby's body is coming out, but the physician failed to remove the head, so she thinks her baby's neck was broken. After spending a considerable amount of time, the full-term newborn was delivered without vital signs. The fetus's body was sent out for a forensic autopsy revealing the body of a female fetus of 3760g, 55cm height with cyanosis of the face. The internal examination anterior dissection revealed right parieto-temporal-occipital subgaleal hematoma, right parieto-occipital epidural hematoma, cerebral edema, and dislocation of a cervical vertebra. Posterior dissection performed up to the cervical region revealed dislocation of a cervical vertebra, spinal epidural hematoma from the first to the sixth cervical vertebra. After that, the spinal cord was lifted and samples were sent out for a histopathological study that revealed perimedullary spinal bleeding, brain and cerebellum micro stroke, and subarachnoid microhemorrhage. It is believed that this case of accidental death has never been reported.

This was unusual at that time because, initially, there were difficulties determining the cause of death due to the controversy that was stirred up among the physicians who attended the birth and the forensic autopsy pathologists. The medical autopsy revealed the findings from traumatic injury during breech delivery which caused the death of the full-term fetus in the vaginal canal, overflowing into the possible liability for lack of opportunity to perform a surgical procedure based on the absence of a pediatrician, arguments by the anesthesiologist, and the probable lack of expertise from the obstetrician/gynecologist specialists in the care of such deliveries. It is recommended that forensic investigators are familiar with this type of death as it is increasingly difficult to attend a breech delivery by technological advances in the institutions.

A case of perinatal death caused by spinal cord injury in the birth canal due to breech presentation associated with the delay in performing a cesarean section was reported. This case report describes, through a forensic autopsy with special dissections and review of medical records, the chain of events and pathogenetic mechanisms leading to the death of a fetus during labor. Medicolegal aspects of the case are discussed because when reviewing the existing literature, reports were found of the complications inherent to perinatal death due to breech presentation such as retention of the head, facial paralysis, and other injuries; but no reports on this type of death were found involving medical staff's negligence in the delay in performing a cesarean section.

Breech Delivery, Medical Liability, Spinal Epidural

G81 Overkill: A Report of Eight Cases and a Review of the Literature

Biagio Solarino, PhD, Giovanna Punzi, MD, Giancarlo Di Vella, MD, PhD, and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, attendees will have a better knowledge of the overkill phenomenon and its significance from a forensic psychiatric rather than a forensic pathology standpoint.

This presentation will impact the forensic science community by emphasizing the need for a universally accepted definition of overkill, based on the importance of such an event from a criminalistic and juridical point of view.

It is not uncommon that homicides are perpetrated with multiple injuries inflicted when the victim has already died. This is indeed not sufficient for defining a case of overkill that deals with a peculiar manner of murder.

Only in a few articles or textbooks in forensic literature is the term overkill reported. In particular, some authors correlate overkill to sex-motivated homicides where injuries, generally stabbing, are directed to significant sexual parts of the body. These signs are consistent with

the psychodynamics of sexual sadism. Others refer to it as the infliction of massive injuries by a perpetrator far exceeding the extent necessary to kill the victim. This action involves a strong excitement of the offender who is possibly in deep personal conflicts with the victim.[1,2]

The psychopathic trait of a perpetrator is often evaluated in such cases, revealing some differences between "disorganized" and "organized" types of killers.

These peculiar features involve a careful scientific approach by the investigators in cases of suspected overkill. The medical examiner has the role of evaluating the body areas where the perpetrator inflicts injuries and the tool(s) used for wounding. Very importantly, the medical examiner may be able to ascertain if and when an offender understood the victim was already dead or received the ultimate lethal wound during an escalating fight. Hence, wound pattern analysis could be of a relevant significance in assessing the motive and intent of the offender in committing murder and overkill.

Forensic psychiatric consultation is of basilar importance for establishing the recurrence of the offender's psychopathy but also in helping resolve the manner of death. In cases of overkill, it is possible to face personality disorders as well as many forms of psychosis disease. Such an investigation allows one to understand the perpetrator's behavior at the moment of performing the criminal act, if they are mentally ill and require psychiatric hospitalization in custody, if they are dangerous for the general public, and, finally, for the assessment of juridical responsibility and related issues.

On these bases, eight cases of overkill were analyzed from both the medical examiner and forensic psychiatrist standpoint. Data about the victims (i.e., sex, age, occupation, cause, and manner of death) and the perpetrator (i.e., sex, age, occupation, relation to the victim) is provided and extensively discussed, as well as a criminological analysis of the motive and the historical setting of the homicides. The profiling of the perpetrators is enriched by the study of both the psychiatric history, before and upon the crime, and the legal history (psychiatric examination and sentence).

The data here collected will be discussed with regard to the elements from the crime scene and the postmortem, in an attempt to better understand the meaning of this peculiar *modus operandi*.

Overkill, Sex-Related Homicide, Forensic Medicine

G82 Extensive Hemorrhagic Retinopathy, Perimacular Retinal Fold, Retinoschisis, and Retinal Hemorrhage Progression Associated With a Fatal Spontaneous, Non-Traumatic, Intracranial Hemorrhage in an Infant

Patrick E. Lantz, MD, Joshua N. Carlson, MD, and Ryan T. Mott, MD, Wake Forest Univ School of Medicine, Medical Center Blvd, Winston Salem, NC 27157*

After attending this presentation, attendees will learn that severe hemorrhagic retinopathy, perimacular retinal folds, and retinoschisis can occur from a fatal spontaneous, non-traumatic, intracranial hemorrhage in an infant. Attendees will also learn that retinal hemorrhages can progress in an infant during the course of hospitalization.

This presentation will impact the forensic science community by increasing the attendees' awareness of conditions in infants associated with severe hemorrhagic retinopathy, perimacular folds, retinoschisis, and retinal hemorrhage progression.

A number of studies continue to claim that Abusive Head Trauma (AHT) can be diagnosed with confidence when extensive Retinal Hemorrhages (RHs) accompanied by perimacular folds and retinoschisis are found in association with an intracranial hemorrhage in an infant. The only exceptions noted to date are crushed head injuries, or traumatic brain injuries associated with motor vehicular collisions. Natural disease processes causing intracranial hemorrhage have not been previously associated with severe hemorrhagic retinopathy, perimacular folds, and retinoschisis. Advanced as the explanation for the hemorrhagic retinopathy associated with AHT or Shaken Baby Syndrome, the vitreo-retinal traction theory assumes the RHs coincide with the intracranial injury and do not progress during hospitalization. A case of an infant with a fatal, spontaneous, non-traumatic intracranial hemorrhage associated with severe hemorrhagic retinopathy, retinoschisis, a perimacular fold, and RH progression was reported.

Case Report: A 2-month-old infant awoke from a nap fussy. Her mother changed her diaper and began preparing a bottle. Her father placed the infant over his shoulder and attempted to soothe her. A few minutes later he and the infant's aunt noticed that she was unresponsive. The paternal grandmother began cardiopulmonary resuscitation and on arrival of emergency medical services, the baby was apneic but had a palpable pulse. On presentation to the emergency department, she was hypotensive and started on a dopamine infusion. A cranial computed tomography scan demonstrated a large basilar subarachnoid hemorrhage occupying the supra-sellar cistern considered secondary to an aneurysm, arteriovenous malformation, or tumor. Blood was within the cerebral ventricles but because of the diffuse nature of the hemorrhage, the pediatric neuroradiologist could not rule out the possibility of non-accidental trauma. She was admitted to the pediatric intensive care unit and an osseous survey initially was interpreted as no evidence of acute or healing fractures, or other evidence of non-accidental trauma; however, on review of the skeletal survey remote healing/remodeling fractures involved the anterior left seventh and eighth ribs near the costochondral junction. A clinical examination consistent with brain death was confirmed by a negative cerebral blood flow study. Subsequently, an ophthalmology consultation with RetCam™ photo-documentation disclosed extensive multilayered RHs and a perimacular fold on the left, but no hemorrhages within the right fundus.

She had no external injuries and her autopsy was significant for severe cranial sutural diastasis, a large basilar subarachnoid hemorrhage, intraventricular hemorrhage, a right subdural hematoma, and severe anoxic ischemic brain injury, and cerebral edema. The spontaneous intracranial hemorrhage arose from an arteriovenous malformation of the choroid plexus adjacent to the hippocampus and inferior horn of the right lateral ventricle. Besides bilateral optic nerve sheath hemorrhages, she had diffuse multilayered RHs carpeting the left fundus to the ora serrata. A large premacular hemorrhagic cyst and perimacular fold with retinoschisis was present on the left, as well as vitreous hemorrhage. Although no RHs involved the right fundus during the first 21 hrs of hospitalization, she had subsequently developed multiple RHs over the right posterior pole while in the intensive care unit following a clinical brain death examination and negative cerebral blood flow study. Histologically, the healing fractures of the left ribs appeared at least four to six weeks of age.

This case describes severe hemorrhagic retinopathy with a perimacular fold and retinoschisis associated with a fatal spontaneous, non-traumatic, intracranial hemorrhage arising from an arteriovenous malformation of the choroid plexus. Also of significance, this infant had no RHs documented by a clinical ophthalmology examination and RetCam™ imaging while in the pediatric intensive care unit, but subsequently developed multiple multilayered RHs over the right posterior pole extending past the equator.

Although many authors consider that severe hemorrhagic retinopathy, retinoschisis, and perimacular folds are virtually pathognomonic of abusive head trauma, this case highlights the need for caution in attributing these ocular findings as diagnostically specific

for AHT. This case also emphasizes that RH progression can occur in infants during hospitalization.

Retinal Hemorrhage, Retinal Fold, Child Abuse

G83 Smartphone Image Acquisition During Postmortem Monocular Indirect Ophthalmoscopy

Patrick E. Lantz, MD, Dept of Pathology, Wake Forest Univ School of Medicine, Medical Center Blvd, Winston Salem, NC 27157-1072*

After attending this presentation, attendees will learn how to use a smartphone to capture still and video images of projected aerial images produced during postmortem indirect ophthalmoscopy.

This presentation will impact the forensic science community by providing an overview of smartphone still and video image acquisition during postmortem monocular indirect ophthalmoscopy.

Postmortem Monocular Indirect Ophthalmoscopy (PMIO) permits examination of a decedent's posterior fundus facilitating detection of retinal abnormalities including Retinal Hemorrhages (RHs). The required equipment necessary for PMIO is relatively inexpensive; however, image acquisition of the projected aerial image typically requires a handheld fundal camera, which is prohibitively expensive for most medical examiner's offices. However, most smartphones have the capability of capturing the projected aerial image formed during PMIO. Smartphone image acquisition uses the smartphone's focal light source along with an aspheric convex indirect condensing lens. The light source of most smartphones can serve as the source of illumination if it is co-axial to the optical path of the camera's lens. Securing the smartphone on an adjustable mini-tripod permits the examiner to stabilize the condensing lens with both hands. Current aspheric lenses range from +14 to +40 diopters and come in different diameters permitting a field of view of 35 to 50 degrees. The condensing lens is pulled back slowly to image the fundus. High-quality still and video digital images of the projected aerial image are readily captured using this technique.

Various smartphone camera applications (apps) include tap screen focusing, zoom, voice or sound activated shutter release, and video recording, which facilitate high-resolution image acquisition. With the smartphone set on "camera" and the light source set to "on" for constant illumination, position the slider so the camera icon is activated. Position the condensing lens in front of the decedent's cornea making sure the lens, decedent's posterior retina, and camera are parallel. Slowly pull the lens toward the camera lens and light source to image the fundus. Since the projected aerial image is located near the focal point of the lens, it is necessary to tap-focus on areas of the thumb or index finger to bring the projected aerial image into clear focus. The camera's shutter is activated either by touching a screen icon or by a voice or sound shutter-release app.

To zoom in on an aspect of the image (up to 5x), pinch and drag to activate the zoom feature (put thumb and index finger together on the screen and drag them apart toward opposite ends of the screen). This will zoom in on the projected aerial image and reveal a slide bar at the edge of the image with a minus (-) on one end and a plus (+) on the other end. Zoom in or out for optimal composition by using the slide bar or pinch and drag.

Most smartphone cameras can also record video at up to 1080p HD. To change from taking still images to video, move the slider so that the button is under the movie camera icon and the camera will switch to video mode. To begin recording video, tap the button with the red circle in it. When recording, the red button will blink and a timer will appear onscreen. To stop recording, tap the button again.

Once recording of the projected aerial image is complete, the still images can be saved or the video images can be captured and edited from the video sequence. Various application programs enable users to upload still images or video sequences from the smartphone camera that is connected directly to a computer or network. Video editing software permits editing of images and video clips for documentation of the fundal findings. Still and video image acquisition using a smartphone during PMIO will be demonstrated. This technique has the potential to facilitate more widespread use of PMIO for fundus examination by forensic pathologists. Clinical application of the technique may permit telemedicine consultation, especially in poor resource settings.

Smartphone, Fundoscopy, Retinal Hemorrhages

G84 Airbag Injuries in Transportation Pathology

Enrico A. Risso, MD, via Alfredo Catalani 10/26, Genoa, ITALY; and Dragan Primorac, MD, PhD, 471 Wolcott Ln, Orange, CT 06477*

After attending this presentation, attendees will achieve a better understanding of the injuries and the mechanisms of injuries related to airbag deployment.

This presentation will impact the forensic science community by highlighting how airbag injuries can be lethal and, sometimes, they are the only injuries responsible for death.

Airbags were invented more than 40 years ago. The goal of this presentation is to provide a better understanding of the injuries and the mechanisms of injuries related to airbag deployment. Airbags have proved to be a vital restraining device which is able to reduce morbidity and deaths associated with car crashes. The effectiveness of airbags in reducing fatalities and serious injuries is well established. However, due to the dynamic nature of airbag deployment, airbags are themselves a potential source of injuries and it has been estimated that more than 40% of airbag deployments result in a minimum of one airbag-related injury. Unlike other safety devices, airbags increase the amount of energy released during a car crash, thus they have always been regarded to be potentially dangerous to restrained and unrestrained occupants. Once considered very uncommon, airbag injuries are now reported more often, and the industry came to the conclusion that the airbag itself might be harmful and even potentially life threatening. The number of airbag-related injuries has proportionally increased with the number of vehicles equipped with airbags.

The expected pattern of injuries at autopsy can be complicated by airbag deployment. Airbags are intended to cushion the impact between the occupant and the interior structures of the vehicle (steering wheel or dashboard). Lateral airbags protect passengers from impact against side panels. The function of the airbag is to act as a "deformable object" in order to dissipate the greatest amount of kinetic energy possible. The majority of crashes in which airbag injuries occur are those of minor to moderate severity. During these events the seatbelt is regarded as providing a sufficient and adequate occupant protection. However, the unrestrained occupant might be exposed to forces which are greater than 18G.

The "bag slap" caused by the airbag deployment might be more harmful than the vehicular collision itself, especially in belted occupants. Recent studies have suggested a great reduction of fatality risk in belted drivers. However, other studies have linked the causation of some injuries—sometimes fatal—solely to airbag deployment.

Airbags rapidly reach their maximum pressure and dimensions by triggering a pyrotechnic device that inflates the bag in about 0.005 to 0.01 seconds. During deployment the airbag is propelled into the car compartment at a speed ranging between 157 to 338km/h. European airbags, which are designed to protect belted occupants, inflate to a volume of about 30 – 40 liters. They are smaller and deploy with much less force than American airbags, which are designed to protect both belted and unbelted passengers. American airbags deploy much more violently and inflate to a volume of 60 – 70 liters of gas.

All the constituents of the airbag module have been proved to be potentially harmful, comprising the airbag propellant capsule, the chemicals involved in the deployment, the inflating bag, and its

covering. The majority of injures are caused by the shearing forces following the rapid deployment of the bag, and are therefore related to blunt force trauma. As a consequence of the "punch out" of the inflating balloon, also known as "bag slap," the occupants may suffer fatal injuries such as skull fractures, fracture/dislocation of the cervical spine, lacerations of the liver, and severe chest trauma.

Airbag Injuries, Transportation Pathology, Road Traffic Fatalities

G85 Suicide by Double Gunshot Wounds From a Pen Gun: A Case Report

Isabelle Sec, MD, Institut Médico-Légal, 2 Place Mazas, Paris, FRANCE; Alain Miras, PhD, 49 Cours Vitton, Lyon, FRANCE; and Isabelle Plu, MD, PhD, and Marc Taccoen, MD, Institut Médico-Légal, 2 Place Mazas, FRANCE*

After attending this presentation, attendees will be able to recognize a pen or a homemade gun as a firearm, to identify entrance wounds as a 0.22 long rifle bullet, and will understand how a low-energy bullet can be lethal.

This presentation will impact the forensic science community by exploring how an unusual firearm was used in a double-gunshot wound suicide.

In firearm museums, you can find ingenious systems like "pen guns" or "cane guns" that are known to be used for espionage. They are single-shot firearms.

Pen guns were primarily designed for the purpose of self defense or giving a signal. It is actually a homemade gun, adapted from an old-style cartridge pen or made by any competent machinist. But, harmless as it may seem, this is a device with deadly firepower. It is made for a personal use like self defense or criminal activity. It could be a surprising weapon with many accidents described in literature.

The design of the pen gun consisted of a housing looking like a writing pen, containing a spring-loaded firing mechanism. The ammunition used is a 0.22 long rifle manufactured cartridge.

Reported is a case of lethal injuries inflicted with a pen gun. This case represents an unusual firearm fatality reported to a weapon made to look innocuous.

A 49-year-old-man was found dead lying on his back on a mattress. To the right side of the body there was a pen on the floor. Inside the pen was a metallic cylinder, housing a spring-loaded metal rod; the chamber contained an empty 0.22 long rifle cartridge. Another empty 0.22 long rifle cartridge was found in the house, far from the body, on the stairs, with blood spatters on the walls. A letter was found close to the corpse. Standard X-rays showed two bullets in the left side of the chest. The external examination revealed the beginning state of decay. Upper extremities presented desiccation. There were two entrance wounds of 4mm in diameter surrounded by soot deposit. They were located on the chest 5cm to 6cm medial to the left nipple.

At autopsy, the first wound tract stopped in the abdominal musculature. It was a short tract, without bone, vascular, or visceral lesion. A non-deformed 0.22 long rifle bullet was found in the muscle. The second wound tract passed through the sixth left rib, through the pericardia and left ventricle, the trough inferior lobe of the left lung, and through the eighth intercostal space at the back. Autopsy found a hemopneumothorax, a hemopericardium, a left ventricle wound. A non-deformed 0.22 long rifle bullet was found in the musculature. The cause of death was massive bleeding. The manner of death was ruled as suicidal.

Primarily designed for self-defense, pen guns can be converted to weapons by simple means. Pen guns were not designed as assassination weapons. They would fail miserably in this role. They were conceived as clandestine escape weapons, not likely to be found during an initial search. It is surprising to observe fatal firearm injuries caused by pen guns. A 0.22 long rifle bullet is known to have low velocity and energy and their wounding capacity is consequently low. Generally, the projectile does not exit the body and the entrance wound is surrounded by a large amount of soot. The lethal potential of pen guns is real when fired at close range.

Pen Gun, Suicide, Chest

G86 Causes of Death in Hanging: A Review of Physiopathological Hypotheses From 1970 to 2010

Renaud Clement, MD, 1 Rue Gaston Veil, Nantes, FRANCE; and Lelie Meresse, MD, Chu de Nantes 1 Rue Gaston Veil, Nantes, FRANCE*

After attending this presentation, attendees will understand some principles of hanging physiopathological theories.

This presentation will impact the forensic science community by the fact that hanging knowledges are based on historic experimentations and few clinical observations

Filmed hangings have been used as a powerful tool in understanding the pathophysiology of human asphyxia. Before these new developments, most of our contemporary body of knowledge was in fact based on old writings from the end of the 19th-century and beginning of the 20th-century. In the present communication, the literature from 1970 to 2010 will be reviewed. It is important to understand the origin of our current theories and the models that were used to develop them and to inquire as to their validity. The exact mechanism of death has yet to be elucidated. For this study, medicolegal textbooks written in English and French were reviewed. The reading focused on the pathophysiological hypothesis accepted or rejected by contemporary authors: occlusion of the trachea, occlusion of vessels, and pneumogastric nerve stimulation. Experiments supporting the this studies positions were compiled, as well as their clinical observations. Thirteen medicolegal textbooks with a specific chapter of hanging were eligible. For each author, the principal mechanism of hanging death proceed to vascular occlusion. They base their positions on historic experimentations performed by Brouardel, Hofmann, and Minovici (for example). Polson and Di Maio reported their own observations to implicate vascular occlusion leading to death in hanging. Respiratory asphyxia could be mixed in as a possible mechanism of death, but it plays a minor role for all authors. Cardiac inhibition caused by the stimulation of pericarotid nerves during hanging is a theory that is accepted by seven authors as a possible cause of death. One author suspects this mechanism as a contributive role of death and five reject it. Nine authors provide a clinical description of hanging, and describe the loss of consciousness, convulsions, and apparent death. The onset of the loss of consciousness occurs earlier than 10 seconds. For all authors, the delay to convulsions is evocated without precision. The time of apparent death varied from three to five and ten to twenty minutes. The timing of three phases is not well estimated by authors. The description of convulsions and respiratory movements are lacking in evidence in all medicolegal textbooks. This historical review supports the fundamental scientific principle that just because a theory is accepted does not guarantee that it reflects the truth. In hanging deaths, respiratory asphyxia by occlusion of the airway was considered the principal cause of death for several decades before the theories of vascular occlusion and cardiac inhibition were gradually accepted. Current studies being carried out on filmed suicidal and autoerotic hangings demonstrate that respiratory obstruction is not the primary pathophysiologic phenomenon leading to death. Despite a long history of being investigated, the pathophysiology of hanging still needs to be revisited and studied in the 21st-century.

Hanging, Respiratory Asphyxia, Occlusion of Neck

G87 John Hunter's Treatise on Gunshot Wounds

Victor W. Weedn, MD, JD, George Washington Univ, 2100 Foxhall Rd, NW, Somer's Hall, Lower Level, L-12, Washington, DC 20007*

After attending this presentation, attendees will gain an appreciation of the state of knowledge of wound ballistics as published in the literature approximately one decade after the American Revolution.

This presentation will impact the forensic science community by explaining the earliest underpinnings of the foundational science of wound ballistics.

The first significant description of gunshot wounds in the medical literature was by the famed London surgeon, John Hunter, in his 1794 *Treatise on the Blood, Inflammation, and Gun-Shot Wounds*.

John Hunter is generally regarded as the "founder of scientific surgery" and is recognized as among the greatest medical pioneers in the history of medicine. He wrote four books and left many lectures and notes. His last book, *A Treatise on the Blood, Inflammation, and Gun-Shot Wounds*, is considered to be his most important. This masterwork was published in 1794, a year after his death at age 65. The *Treatise* is known as the first scientific study of wound healing, but it may also be the first publication on wound ballistics. The introduction and first three parts of the book discuss healing and inflammation and 63 pages of the fourth part are devoted to gunshot wounds and their treatment. He declared: "Little has been written on this subject [gunshot wound healing], although, perhaps, when we take every circumstance into consideration, it requires particular discussion; and what has been written is so superficial, that it deserves little attention." His discussions are the result of observations made in 1761 – 1763, from the age of 33, as Staff Surgeon during the Seven Years War (the French and Indian War); first, on the French Island of Belle Ile during the siege and capture of the French Belle Isle and second, in Lisbon during the defense of Portugal against the Spanish, as well as 30 years of study thereafter. He saw gunshot wounds as different from other wounds: "Gun-shot wounds are made by the projection of hard obtuse bodies, the greatest number of which are musket-balls; for cannon-balls, pieces of shells and stones from ramparts in sieges, or splinters of wood, etc. when on board of a ship in an engagement at sea, can hardly have their effects ranked among gun-shot wounds, they will come in more properly with wounds in general." Hunter advised against the prevailing desire to explore the wounds, but instead advocated against opening the wounds, recommending they be treated conservatively. Hunter believed that infection was a treatment failure and not an unavoidable stage of healing, as did his contemporaries. It was not until after Joseph Lister published his successful trials on antisepsis in 1867 that Hunter's radical views become accepted. Hunterian scholars have not previously commented on his discussions of wound ballistics. Hunter categorized gunshot wounds into simple and compound—the former when the missile passes through "soft parts only" and the latter with fractures of the bone, lacerations of the arteries, or penetration of the body cavities to include injury of vital organs. Hunter also described the effect of the velocity of the musket balls on wounds, to include the effect on the path of the bullet, the amount of damage, the rapidity of healing, and the fracture pattern of bones. Forensic pathologists will relate well when he writes in a section entitled *Of the Strange Course of Some Balls*: "The difficulty of finding balls, I have just observed, often arises from the irregular course they take. The regularity of the course of the passage of a ball will in general be in proportion to its velocity, and want of resistance; …"

The earliest description of gunshot wounds in the medical literature was published in the post-American Revolutionary period and was based upon clinical observations of musket balls during warfare.

Gunshot Wounds, Wound Ballistics, Forensic Pathology

G88 Determination of Genetic Profile After Visualization of Fingerprint Marks With Dactyloscopic Powders

Pamela Tozzo, MD, Alice Giuliodori, PhD, Daniele Rodriguez, and Luciana Caenazzo, Univ of Padua, Via Falloppio 50, Padova, ITALY*

After attending this presentation, attendees will learn the potential of DNA techniques to the analysis of latent fingerprints after visualization with dactyloscopic powder as an important application in forensic caseworks.

This presentation will impact the forensic science community by providing a new perspective of DNA analysis in forensic investigations.

With modern PCR-based technologies, it is possible to obtain a genetic profile from very small amounts of DNA. Due to this, intensive research has opened many new sources for forensic genetic investigation.

Since their introduction in forensic investigations, latent fingerprints recovery and analysis are still maintaining their importance, and the search and archiving of fingerprints is still one of the most important procedures during criminalist investigation. The powdering method is often used for visualization because it is easy, inexpensive, and gives immediate results. The technique relies on the mechanical adherence of fingerprint powder to the moisture and oily components of the skin ridge deposits. Unfortunately, sometimes it happens that the curve and loop patterns are unclear/incomplete, so the fingerprint may not be useful for identification purposes.

Today, latent fingerprints are not commonly used for DNA typing even if they could be considered useful DNA sources, as reported in previous publications which have demonstrated that even a single skin contact can transfer enough DNA for successful STR typing and that fingerprints are a possible DNA source for forensic DNA investigation.

The amount of DNA contained in a latent fingerprint was found to be independent of handling time, dependent on the individual handler and the substrate's characteristics. The success rate in obtaining a genetic profile (partial or complete) from a latent fingerprint will depend on the individual who has touched the surface (good or bad shedder), the activities of the individual prior to touching the substrate, and the nature of the substrates. In forensic casework, neither the shedding nature of the individual nor the activities of the individual prior to touching the object are usually known.

To help address these aspects, a study was conducted on the effect of fingerprint enhancement methods on subsequent STR profiling.

First, a systematic study typing blood traces deposited on five different surfaces, both porous and non-porous, treated with eight types of dactyloscopic powders was performed. Three different DNA extraction methods were used.

In the second part of the study, the possibility of obtaining DNA profiles from latent fingerprints on the same five surfaces enhanced with the eight different powders used in the first part of the study was analyzed. On fragments of the cotton swabs used for recovering DNA from latent fingerprints, extraction procedures with two methods were performed. In order to obtain the greatest number of interpretable profiles, they adopted strategies in the extraction step, using techniques that would guarantee the more purified eluted DNA as possible, and in the amplification reaction, improving its sensitivity compared to the small amount of isolated DNA. Considering the low amount of DNA contained in latent fingerprints, all PCR reactions were carried out three times to obtain a consensus genetic profile.

The work in this study has demonstrated that DNA profiling can be performed on fingerprints left on different substrates and the nature of the substrate will affect the amount of DNA that can be recovered for DNA typing analysis.

In the first phase of the study, a profile was obtained in 92% of the 120 samples analyzed, with the percentage of full profiles of 60%; in the second part, in 55% of the 80 samples analyzed the authors

obtained a profile, complete in 32.5% of cases. The substrates that have led to the largest number of profiles have been the metal and the glass, probably due to the lower adhesion of the powders to these surfaces.

From the results obtained, it seems that the powders used in latent fingerprints enhancement, rather than having a direct inhibitory effect on extraction and amplification of DNA, may cause partial degradation of DNA, thereby reducing the efficiency of amplification reaction.

Genetic Profile, Latent Fingerprints, Dactyloscopic Powder

G89 Medications Error: Easy and Frequent Occurrences of Events but Difficult Reconstruction and Demonstration

Federica Colosimo, MD, Luca Gallelli, and Giulio Di Mizio, PhD, MD, Magna Graecia Univ, Viale Europa Loc. Germaneto, Catanzaro, ITALY*

The goal of this presentation is to show how medication errors represent preventable incidents occurring at any point in a chain of events beginning with prescription writing and continuing on to both drug dispensation and administration.

This presentation will impact the forensic science community by serving as a key aspect during drug dispensing; in fact, it is possible that a better counseling could reduce the risk to develop adverse events.

Several data have been published regarding this problem. In fact, it has been estimated that medication errors account for about 78% of serious medical errors in intensive care units; it is important to underline that a medication error can involve drug-related problems during the homecare setting. In particular, a recent paper has estimated that up to 30% of homecare patients experience a potential medication error, happening during preparation and administration of drugs. Medication errors can also induce a decrease in patient health status with an increase in health-care costs and occurs at every stage of the drug delivery process, i.e., prescribing, transcribing, dispensing, and administering.

However, the risk of the development of a serious disease induced by a medication error could be related to three factors: polytherapy, age of patient, and the therapeutic index. In fact, polytherapy could induce the development of drug-drug interaction; elderly patients present a physiological decrease of drug metabolism and drug excretion, responsible for drug accumulation; finally, the therapeutic index represents the safety of each drug; therefore, a medication error related to the administration of a drug with a very low therapeutic index (e.g., digoxin, theophylline, or anticancer drugs) could easily induce a decrease in health status.

Cases of personal observation will be presented in which medication errors have caused damage to the patients, or even death. They also perform the analysis of organizational remedies feasible with good clinical practice of risk management. Finally, the possible consequences of trial relating to these events, both in criminal court and in the compensation of damages, will be addressed. Therefore, it becomes an important aspect during the discussion on the methodology of forensic evaluation of the damage, for which it is crucial to establish a causal link between incorrect drug dosage and development of damage. The forensic criteriology based on Italian legal doctrine provides an adequate response to the need to perform, in such cases, assessments based on both strict survey methodology and laboratory protocols scientifically validated. The above methods could reduce the maximum margin of error and allow rule out other causes of disease. The medicolegal criteria that should be demonstrated to establish a causal connection between medication error and damage involve four major criteria: *anamnestic* criterion (e.g., the history of the patient), *clinical* criterion (e.g., clinical signs or symptoms and biochemical markers of disease), *anatomo pathological* criterion (usually performed on a cadaver, aimed at macroscopic and microscopic morphological recognition of specific target of organs and tissues due to drugs), and, finally, *toxicological* criterion (that is an "objective criterion" involving the identification and isolation of the substance given).

Medication Error, Clinical Risk Management, Clinical Pharmacology

G90 CT Multislice Guided Autopsy Methodology in a Fatal Body Packing Case

Marta Sozzi, MD, Francesca Castelli, MD, Laura Re, MD, and Luisa Andrello, MD, Univ of Insurbia, Via Guicciardini, 9/bis, Varese, ITALY; Gianfranco Foglia, Emilio Scossa Baggi, and Patrizia Roncoroni, MD, Canton Ticino Scientific Police, Via ferriere, Giubiasco, SWITZERLAND; and Antonio M.M. Osculati, MD, Via Meraviglia 22, Lainate, Milan, ITALY*

The goal of this presentation is to provide information to show how acknowledged cases of body packing are quite rare and the phenomenon often goes unrecognized. Fatal cases are even more infrequent, despite the fact that drug abuse is a growing social phenomenon definitely worthy of notice. That's why further study of this subject is necessary in order to be able to recognize and adequately treat the specific case should the need arise. When presented with unexpected deaths of young persons coming from specific areas, we should actually take into account the possibility of drugs being transported, in order to perform preliminary instrumental examinations that may be helpful for a proper autopsy execution.

This presentation will impact the forensic science community by showing how instrumental examination, such as X-ray, CT scan, and RMN can be very useful as a complementary survey to the autopsy. These techniques of investigation should also be more important in specific and difficult cases, such as in advanced decomposition of bodies.

Objectives: Within the field of forensic medicine, acknowledged cases of body packing are quite rare and the phenomenon often goes unrecognized. Fatal cases are even more infrequent, despite the fact that drug abuse is a growing social phenomenon definitely worthy of notice. That's why further study of this subject is necessary in order to be able to recognize and adequately treat the specific case should the need arise. When presented with unexpected deaths of young persons coming from specific areas, we should actually take into account the possibility of drugs being transported, in order to perform preliminary instrumental examinations that may be helpful for a proper autopsy execution.

Case: In the autumn of 2012, a young Black man coming from Tanzania was found dead in his hotel room. The man had been rescued at a train station for symptoms compatible with opiates poisoning and treated with Naloxone. His health rapidly improved, so he refused further medical exams and left the hospital, against the will of doctors. Before the autopsy, a multi-slice total-body CT scan exam was performed, which showed the presence of a lot of ovoid-shaped objects distributed across the man's whole gastrointestinal tract, from his stomach down to his rectum. The gastrointestinal tract dissection revealed 87 ovoid packets, which were extracted and handed over to the police for further forensic analysis.

Materials and Methods: A CT Somaton 16 Slices was used to perform a Computed Tomography (CT) scan with a 3D reconstruction. Gas Chromatography/Mass Spectrometry (GC/MS) was used to perform biochemical analysis on the packets' contents. GC/MS, High Performance Liquid Chromatography with Diode Array Detector (HPLC-DAD), and Headspace Gas Chromatography Flame Ionization Detector (HS-GC-FID) were used to quantify free heroin and other drugs in blood and fluids.

Then histological preparations with seven micron sections were performed and, after that, stained with Haematoxylin and Eosin.

Results: After the autopsy findings, in the local Scientific Police Station, detailed biochemical analysis were performed in order to find out the content of the 87 ovoid packets. Each of these packets contained approximately 15g of light brown powder, which proved the subsequent analysis contained heroin, at the medium concentration of 14.8%. It was found, therefore, that the degree of purity of this substance was much lower compared with literature data. In fact, in drug smuggling, publications made by authors of different countries all over the world show degrees of purity of heroin in the range of 50 – 90%. A drug screen conducted on specimens of blood, received from the autopsy, found lethal values of opiates (in the urine there was a total morphine concentration of 45000µg/l and a codeine concentration of 3700µg/l; in blood samples there was a total morphine concentration of 220µg/l and a codeine concentration of 22µg/l). The toxicological analyses also revealed the presence of acetaminophen in the urine and caffeine in the blood. In conclusion, these evidences show that the man died as a result of heroin intoxication.

Conclusions: In this case report, the preliminary execution of CT scan, performed before the autopsy, was very helpfull in substantiating that the man was a drug smuggler and showed exactly where to find the ovoid packets in the body, so as to guide the forensic pathologist during the autopsy, also facilitating the preservation and collection of the packets. This technique has been underutilized and poorly reported in literature, especially the 3D reconstruction, which has been so helpfull in this particular case report. Instrumental examination, such as X-ray, CT scan and RMN, can be very useful as complementary survey to the autopsy. These techniques of investigation should be more important in specific and difficult cases, such as in advanced decomposition of bodies.

Body Packer, Heroin, CT Multislice

G91 How to Scan Hot Stuffs: Scanning Electron Microscopy Applied to Forensic Investigations

Petra R. Basso, MD, Viale Borri, 57, Varese, ITALY; Terenzio Congiu, PhD, Via Monte Generoso, 2, Varese, ITALY; Luisa Andrello, MD, Viale Borri, 57, Varese, ITALY; and Antonio M.M. Osculati, MD, Via Meraviglia 22, Lainate, Milan, ITALY*

After attending this presentation, attendees will discover that scanning electron microscopy has a wide number of possible applications in forensic investigations. Attendees will also have a general understanding of the advantages of scanning electron microscopy in forensic analysis. They will be shown that the Scanning Electron Microscope (SEM) is not only a mere tool, but is an actual method of forensic investigation which requires operators to see the possibility of performing this analysis at the time of autopsy and/or when samples are collected.

This presentation will impact the forensic science community by demonstrating various methods in which organic and inorganic samples may be analyzed with an SEM and by providing elements to better understand the evolution and application of this technology to forensic cases.

Since it is a vesatile instrument, the SEM is widely used in forensic investigations. It is used to study a large variety of specimens in forensic investigations such as the analysis of gunshot residue, bullet fingerprints, bullet wipe or patterns around the bullet hole, environmental dusts, fibers (both natural and artificial), and ink and paper analysis.

In this presentation, a selected number of investigations are shown, to illustrate through specific cases, general purpose applications: SEM has the ability of providing both panoramic and highly magnified views of the same sample, giving an almost 3D view of the specimen. It is the ideal *trait d union* between macroscopic information collected during autoptic or investigative activity and microscopic information obtained with the light microscope. Above all, the SEM is an instrument that allows to perform a progressive and targeted microdissection of the sample, possibly at the time of autopsy and/or the collection of the sample.

This presentation will focus on the experience gained over the past four years by the Forensic Laboratory, a multi-discipline unit of the University of Insubria. At the Human Anatomy Laboratory, the sample, collected during the forensic investigation, is reduced, when necessary, to an appropriate size to fit in the specimen chamber, then prepared to be observed under the scanning electron microscope (FEI Philips XL-30 FEG-SEM microscope).

After a preliminary analysis, usually made by both secondary electrons detection (which shows the morphology of the sample surface) and detection of backscattered electrons (since high atomic number elements backscatter electrons more strongly than low atomic number elements, back scattered electron images show areas with different chemical composition as zones of different brightness over the sample), the sample is prepared once again: it is subjected to a osmium tetroxide maceration post fixation process in order to enhance membrane contrast and to better visualize intracellular structures and/or it is prepared by NaOH 1N maceration, when a better evidence of connective tissue stroma is desired. In these cases, the specimens are mounted on adhesive films applied on standard aluminium stubs, gold coated in an Emitech K550 sputter coater (Emitech Products Inc.) and then observed under the scanning electron microscope.

When the situation requires it, energy dispersive X-ray spectroscopy and X-ray mapping of specimens are performed, to identify the elemental composition of the whole sample or small area of interest on the sample.

SEM, EDS Microanalysis, Bloodstains

G92 A Singular Case of Asphyxia by Choking With a Handkerchief: Accidental Event or Suicide to "Shut-Up" Spirits?

Antonio De Donno, PhD, Pasquale Beltempo, MS, Maricla Marrone, MD, Sergio Lubelli, MS, Valeria Santoro, PhD, and Francesco Introna, MD, Univ of Bari, Piazza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, attendees will understand the importance of integrating circumstantial data, clinical history, and autoptic results in the differential diagnosis between homicidal, suicidal, or accidental death by choking.

This presentation will impact the forensic science community by providing key information that can help to correctly evaluate rare asphyxia cases.

Suicide accounts for 3% of deaths in the world's population. The SUPRE Project (Suicide Prevention Project - OMS) estimates that from 1950 to 1995 the percentage of deaths by suicide has increased globally by 60% and is currently growing, especially among the younger age groups.

In Italy, every year there are between 3,500 and 4,000 suicides; most of these are made by patients with psychiatric disorders. These numbers rise if a psycho-pathological state is associated with the abuse of substances such as alcohol and drugs. Among the psychiatric disorders, subjects with schizophrenia are particularly at risk.

Individuals with schizophrenia have many basic functions compromised, which include perceiving, thinking, language, emotions, will, initiative, and attention. The impairment is likely to lead to serious problems of adaptation in social or occupational functions, and it influences the decision-making capacity, pushing patients to take extreme acts.

Severe psychotic symptoms, such as delusions or hallucinations, and pathological personality traits, such as impulsivity and excessive suspiciousness, are additional factors that can determine an increase in the number of suicide attempts and in fatality.

Suicide by choking is extremely rare. The case presented appeared remarkable for the way in which it was set in place by the victim, the reasons why the victim attempted suicide, and doubts about the nature of the act.

In January 2010, a 60-year-old woman was found dead in her home with a handkerchief down her throat. The victim a had longstanding history of psychiatric illness (residual chronic schizophrenic psychosis in partially effective neuroleptic treatment). The victim had been under investigation by prosecutors for fraud for selling her services as a "sorceress." The son also reported previous suicide attempts made by his mother, even in his presence, guided by evil spirits' voices coming from inside her body. In order to "shut-up" the spirits, she tried to suffocate them with her hands or by self garroting with a belt. The external examination of the body showed abundant red wine hypostasis localized on face, neck, and upper chest. Autopsy showed petechiae in visceral pleura and epicardium, and visceral congestion. The absence of the upper left canine and lower left premolar with no traumatic lesions of the labial mucosa was also noted. There was no other sign of internal or external trauma. Internal organ sections showed hemorrhagic infiltration at the soft palate and at the soft tissues of the upper portion of the larynx. The histological examination confirmed multi-organ congestion and subpleural emphysema. Toxicological findings denoted and quantified clozapine overdose with a consumption over three times the prescribed dose (300mg/day).

Suicide by choking is difficult to accomplish and can easily be confused with accidental or homicidal choking. The psychotic factor is an important variable to consider in the suicidal behavior, especially for the hallucinatory component, which most likely induces some patients to perform acts motivated by a distorted view of reality

In the case presented, there were two possible scenarios, the first in which the patient, suffering from a psychotic delirium characterized by voices coming from inside, decided to end it by suffocating and purposefully placing tissues down the pharynx. In the second scenario, the patient placed a handkerchief in the mouth on the upper left canine to buffer the bleeding, but being under the influence of the clozapine (side effects: drowsiness, mental confusion, agitation, respiratory depression), airways were fatally blocked, causing a violent mechanical asphyxia.

Choking, Clozapine, Handkerchief

G93 Suicides Due to Substance Overdose in Tarrant County, Texas

Yoshiyuki Kikuchi, DO, Scott & White Memorial Hospital, Dept of Pathology, 2401 S 31st St, Temple, TX 76508; Ahmet Hilal, MD, Cukurova Univ, School of Medicine, Forensic Medicine Dept, Adana, TURKEY; and Ronald L. Singer, MS, Tarrant County MEO, 200 Feliks Gwozdz Pl, Fort Worth, TX 76104-4919*

After attending this presentation, attendees will learn the incidence of suicides due to substance overdose in Tarrant County, Texas, from January of 2006 to December of 2010, and its comparison to larger studies.

This presentation will impact the forensic science community by increasing awareness that prescription drugs are the leading substance type used among individuals who died by suicide due to substance overdose and that cautious prescribing practices are essential.

Introduction: Suicide is the 11th leading cause of death of all ages in the United States and more than 34,000 people end their lives every year. Suicide is found in every age, racial, and ethnic group. Center for Disease Control and Prevention (CDC) reports that substance overdose is the third-leading method of suicide, following firearm and hanging/strangulation. The vast majority of substance overdose suicides are related to prescription drugs. The purpose of this study was to summarize and demonstrate the characteristics of suicide deaths due to substance overdose in Tarrant County, Texas.

Material and Methods: This study included all suicide cases due to substance overdose in Tarrant County, Texas, from January of 2006 to December of 2010. Data were collected from the Tarrant County Medical Examiner Office records retrospectively. The substance was grouped into prescription drugs (benzodiazepines, opioid analgesics, antidepressants, and others), over-the-counter drugs, illicit drugs, ethanol, and other substances. The data were analyzed according to the age group, gender, race, and numbers and types of drugs.

Results: There were 90 eligible suicide cases (48 males, 42 females) due to substance overdose out of 733 substance-related deaths. The eligible cases represent 10% of all suicide cases (90 out of 891) during the same period. The majority of cases were Caucasians. The highest suicide rate (37%) was observed between ages 45 and 54, with the most cases (78%) falling between ages 25 and 54. Prescription drugs (75%) were the leading substance type used, with antidepressants the most popular. Thirty-eight percent ingested only one type of substance and 62% ingested two or more types of substances. There was no considerable difference between males and females in a total number of the suicide cases; however, the majority (79%) of females, compared to about half (48%) of males, ingested more than one type of substance.

Conclusions and Discussions: Suicide is a serious public health concern and substance overdose accounts for numbers of suicides. This study demonstrates an increasing problem with suicide deaths due to fatal overdose of prescription drugs in Tarrant County, Texas, a finding similar to other larger studies. However, more individuals (62%) ingested two or more types of substances in Tarrant County compared to a recent CDC report (25%). Many of these deaths can be prevented by controlling access to poisonous substances, and many of the substances used in suicides are commonly prescribed. Physicians and other clinicians should strictly follow guidelines for prescribing drugs with a high abuse potential. Surveillance systems designed to prevent illicit use of prescription drugs need to be implemented. Effective drug therapy is necessary for physical and mental health conditions; however, health care providers, patients, and their family members should be aware of the associated risk these substances pose.

Drugs, Overdose, Suicide

G94 Age Estimation Using T-Cell Receptor Excision Circles (TRECs) in Forensics

Soong Deok Lee, PhD, Hye Young Lee, BS, and Sohee Cho, MS, Seoul National Univ, Dept of Forensic Medicine, 103 Daehak-Ro, Jongjo-Gu, Seoul, KOREA*

After attending this presentation, attendees will understand the basic principle of formation of T-Cell Receptor Excision Circles (TRECs) and its change during a lifetime. The feasibility of its use in forensic practice and ethnic difference, if it ever exists, will be discussed and compared with previous reports.

This presentation will impact the forensic science community by providing evidence or techniques using the relationship between TRECs levels and age.

Age estimation using biological remains is one of the hottest topics in forensics. Many different approaches have been tried up to now, and the age estimation using TRECs is gaining interest.

The central role of thymus in the production of T-cells and the generation of T-cell receptors (TCRs) including TCR gene rearrangement is well established, together with thymic changes with time such as thymic involution. During the rearrangement of TCR gene segments, some regions which were not selected to form the parts of TCRs are spliced out as ring-shaped DNA. This exists in naïve T-cells immediately after development and maturation in thymus. Signal-Joint T-cell Receptor Excision Circle (sjTREC), which is one of the by-products of the rearrangement of gene segments encoding the variable parts of T-cell receptor α and β chains, not only

replicates during cellular proliferation in the periphery, but also is diluted with each round of cell division. Therefore, it is supposed that the content of these episomal DNA per total number of T-cells or level of constant genes would decrease with aging. In forensic cases, this biological phenomenon could be useful for providing evidence using the relationship between quantitative sjTRECs level and age.

For a long time, measurement of thymic output was indirect, mainly based on the phenotypic markers on naïve T-cells. However, since it is essential to detect the level of TRECs in the peripheral blood precisely and sensitively, it is necessary to utilize the sequence-specific DNA detection method. One of the most promising candidates is real-time quantitative PCR assay. Primers were designed to detect TRECs by targeting only the excised sequences after TCR gene rearrangement. Furthermore, TREC fragment-cloned plasmid was obtained, which is necessary for positive control and quantification using a standard curve. Using this plasmid sensitivity of the test was confirmed. Meanwhile, the immunological conditions such as blood volume or number of T-cells affected by immunological diseases or virus infections vary per person. These conditions also influence the relative level of TRECs in periphery blood. To normalize their level, it was observed that some genes can reflect these conditions or are expressed constantly, such as human serum albumin known to exist in blood plasma, or TCR alpha chain known to be a constant region of T-cell receptor. If it is necessary, various analysis methods which were utilized in other reports will be introduced.

This method is based on an immunologic principle, so the results would be variable depending on different ethnicities. After obtaining ethics committee approval, DNA samples from random Koreans of varying age groups would be tested for the above method. These results would be compared with others previously reported for different populations.

Age Estimation, TRECs, Forensics

G95 When Sadistic Fantasies Are Turned Into Reality

Francesco Vinci, MD, Felice F. Carabellese, MD, Maricla Marrone, MD, Chiara Candelli, MD, PhD, Francesco Rodriguez, and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, attendees will understand the extreme variability of the psychological drives of perpetrators of heinous sexual crimes.

This presentation will impact the forensic science community by connecting the relationship between sexuality and aggressiveness.

A case of murder of an 89-year-old woman, found dead in her home, is reported. The woman's body was prone and partially naked (from the lower half of the trunk down), with legs apart, pelvis and groin resting on the edge of the bed and a nightdress wound around her neck as a noose.

Examination of the body allowed many bruised areas of various shapes and sizes located in different parts, as well as protrusion of the tongue to be identified. Examination of the vulva highlighted the presence of a small, oval tear in the vicinity of the frenulum of the labia majora and along the median line. The hymen was infiltrated with blood and on the skin around the anal sphincter there were other bleeding tears.

In addition to infiltrated deep bleeding at some of the ecchymotic areas above described, the autopsy revealed the presence of blood infiltrates of the internal structures of the neck (sternocleidomastoid, root of the tongue, pharynx, and larynx, right jugular vein, and left carotid artery), fracture of the greater horn of the right hyoid bone with hemorrhagic infiltration of the carotid artery intima, that was fissured. These signs are all compatible with compression of the neck and death by asphyxia. Confirming this hypothesis, there was blood within the vascular tree, congestion of the viscera, emphysema, and pulmonary edema, as well as rare, small ecchymoses of serous membranes. The cause of death was therefore defined as asphyxia due to violent mechanical acute strangulation.

On the body of the victim, there were also numerous injuries, some of which were correlated to generic trauma and others to sexual assault. As regards the former, they suggested a prior altercation with her assailant, whereas the injuries orienting toward a sexual assault were clear signs of both vaginal and anal penetration, as well as bruises and abrasions present on the lower limbs. This hypothesis was supported by the finding of sperm inside the rectum. The evidence concluded that the elderly woman was the victim of a violent anal assault while she was forcibly held prone, probably in the same position as she was later found dead.

Considering that the anal lesions were made while the woman was alive, it could be assumed that the strangulation had occurred after the coitus; moreover, the particular position of the knot and of the ends of the noose (at the victim's nape) suggested that the assailant was behind the victim. As no sperm was found in the vagina, the presence of a bleeding hymen and a small laceration of the labia majora led us to the supposition that there had been vaginal penetration only in the early stages of the rape, which was then ended in the rectum.

Thanks to the finding of shoe prints on the wall of the victim's home, the subsequent investigations quickly led to the arrest of a 22-year-old who admitted responsibility but was unable to provide any plausible motivation for the criminal conduct and violent assault.

Through a dynamic reconstruction of the crime and clinical analysis of the aggressor's personality, the role of sexuality when conceiving the crime was reconsidered. Despite appearances, it became clear that the sexual violence was the expression of aggressiveness. This aggressive behavior aimed against the elderly woman was performed in the form of destructive violence and sexual desecration. These considerations became the foundation of a close psychiatric and forensic evaluation from which it emerged that, in this case, there were no detectable elements linked to a mental disease, even temporary, but only expressions of a disturbed personality in which an altered affectivity played a significant role.

Sadistic Fantasies, Homicide, Forensic Evaluation

G96 A Review on Italian Mafia Homicides: "Men of Honor" and Ritual Crimes

Benedetta Di Battista, MD, Sara Vita, MD, Marco Savito, MD, and Furio Patete, MD Univ of Foggia, Viale Degli Aviatori 1, Ospedale Col. D'Avanzo, Foggia, ITALY; and Stefano D Errico, MD, PhD, Via Montegrotto 77, Abano Terme, ITALY*

The goal of this presentation is to present typical homicide modalities practiced by organized crime syndicates in Italy. The killing styles operated by prominent criminal organizations vary from one group to the next, and it could be argued that different cultures, dependent upon geographical location, affect criminal behavior. Some forms of homicide are quite particular and their significance is still very often misunderstood.

This presentation will impact the forensic science community by influencing the judicial history of Italy through illustrating scenarios relating to Italian Mafia murders and a unique collection of images.

Homicides perpetrated by organized criminal groups are typically very brutal in nature. They often involve "special rituals" charged with symbolic meaning, which may be more or less explicit, depending on the chosen manner of execution and on the victim. Throughout the world, the term "mafia" is associated with organized criminal groups of Italian origin; these hierarchically arranged family groups are controlled by high-ranking members who make the decisions which are then passed down the hierarchy to other members of the family. The Mafia is not a single group or gang but it is made up of many families that have, at times, fought each other in bitter, bloody gang wars. At other times, they have cooperated in the interest of greater profits, sometimes even serving on a "Commission" responsible for

making decisions that affect all the families. It could be argued that Italian organized crime is not comparable to any other existing forms of criminal activity. Criminal associations such as the *Camorra,* originating from the region of Campania, *Cosa Nostra* based in Sicily, the *Ndrangheta* of Calabria, and the *Sacra Corona Unita* whose native land is the region of Puglia, are largely responsible for the development of different kinds of organized crime, not only in Italy, but with tentacles reaching outside the country. The culture and traditions of the different regions of origin affect the chosen modes of execution. This study moves through a preliminary narrative of the history and origins of each criminal organization, their main illegal activities, and finally onto some of the typical homicidal modalities, amply documented with a rich and varied collection of photographic material gathered during the investigation of crime scenes and from autopsies.

A specific case of a Calabrian mafia-related homicide is execution perpetrated by a single shotgun shot to the head followed by the deliberate concealment of the victims body, or the use of caustic substances to erase or modify features (facial), thus rendering the cadaver unrecognizable. In the cases presented, cadavers wore gloves to preserve fingerprints to aid in identification. The Apulian Mafia (the *Sacra Corona Unita*) has a similar operating technique; after shooting their victims, the corpse is buried in an abandoned area. This study looks at the case of four decomposed corpses discovered in cars plunged into ravines. In other cases, shooting is followed by charring of the body, making it impossible to recognize the victim without the use of genetic investigation. Radiological investigations (X-rays, MSCT) performed before autopsies are indispensable for the detection of bullets. Multiple cases of *incaprettamen*to (homicidal ligature strangulation) are also presented in this study. This particular ritual can be considered the hallmark of the Sicilian Mafia (*Cosa Nostra*). The victims wrists and ankles are pulled together behind his back, and an additional rope is tied around the neck and attached to the bindings in such a way that any attempt to free himself from this unnatural, contorted position will eventually provoke death by self-strangulation. One of the reasons for this homicidal mode is for the ease of transporting the corpse, which is often found inside the trunk of the car used for transportation.

Murder techniques used by the local mafia in the Gargano, a geographical area in the north of Apulia were also described. Here the manner of execution is characterized by the explosion of multiple shots from firearms (shotguns), some of which exploded in the face, serving the double purpose of killing the victim and simultaneously scarring the body, which would later be seen by relatives.

Italian Mafia, Homicide Modalities, Lupara Bianca

G97 Hantavirus Pulmonary Syndrome: A Case Report

Mario Rascon, MD, Univ of New Mexico, 1101 Camino de Salud, NE, MSC07 4040, Albuquerque, NM 87102; and Andre Barthelemy, 1 Univ of New Mexico MS4, Albuquerque, NM 87131*

After this presentation, attendees will be able to describe the geographical distribution of Hantavirus, its host, routes transmission,detail the pathogenesis and symptomatology infection, and characterize the Hantavirus Pulmonary Syndrome (HPS), and describe expected autopsy findings

This presentation will impact the forensic science community by familiarizing its audience with the features of the HPS, its clinical presentation, autopsy findings, and pertinent postmortem ancillary testing

Hantaviruses include a related group of RNA viruses of the Bunyaviridae family. It is transmitted by rodent hosts, mainly via aerosolized feces and urine, causing only incidental disease in humans. HPS, however rare, is a serious life-threateninig condition that needs early diagnosis and support therapy, since symptoms can develop very rapidly (within 24 hours).

Presented is the case of a 20-year-old woman with no significant past medical history who complained of having headache, cough, muscle and stomach aches, fever, and shortness of breath for several days. She was seen at a clinic and treated as an outpatient with ciprofloxacin. Two days later, she was taken to an urgent care facility due to acute onset of shortness of breath. She was admitted to the Intensive Care Unit (ICU) and died shortly after her admission. The admission Computed Tomography (CT) scan showed extensive bilateral pleural effusions.

Autopsy revealed marked lung edema and large bilateral straw-colored pleural effusions (right, 850mL; left, 550mL). Microscopically, the lungs showed extensive areas of intra-alveolar fluid, with fibrin depositiona and focal hyaline membrane formation. Anterstitial mononuclear cell infiltrate with immunoblasts was identified in the lungs, liver, and spleen. A serum assay was positive for *Sin Nobre* Hantavirus antibodies.

While the incidence of Hantavirus infections has been relatively low (551 cases reported in the United States between 1993 and 2011), the mortality rate is alarmingly high (about 35%). This is due to a virus-induced vigorous immune response within vascular epithelium leading to vascular instability, especially within the lungs. Capillary dilation and leakage lead to the more severe manifestations of disease: shock and respiratory failure.

Without an intermediate host, each rodent host serves as both the primary host and reservoir in nature, transmitted via saliva, respiratory tract secretions, feces, and urine, causing chronic infection in rodents and only incidental disease in humans, generally by inhalation of aerosols of these body fluids or of virus-laden dust. Other means of infection include bites from infected animals, contamination of cutaneous wounds or mucous membranes, or ingestion of contaminated food. With the exception of the Andes virus of Argentina, the virus is not transmitted between humans.

At particular risk are individuals living or working in small, dark spaces with poor ventilation and known rodent presence, perhaps following a period of environmental conditions favorable to rodent reproduction. A classic case might describe exposure following cleaning of a shed, vacation home, or livestock feed container.

The natural history of disease of HPS generally includes three phases that follow an incubation period that lasts from two to four weeks: prodrome—characterized by sudden onset of nonspecific fever, malaise, myalgia, headache, chills, nausea, or diarrhea, and lasting about three to five days; cardiopulmonary—with nonproductive cough and varying degrees of shortness of breath, with associated tachypnea and mild hypotension and, laboratory evaluation—will reveal hemoconcentration (elevated hemoglobin/hematocrit), thrombocytopenia, neutrophilic leukocytosis with left shift, and reactive lymphocytes. At this stage, the patient is at the most risk for massive fluid shifts and pulmonary edema. The patients who die usually succumb to progressive cardiac insufficiency. If this phase is contained, the convalescence—or diuretic phase—begins, with usually little significant long-term sequela, though exertional dyspnea may persist for up to three months.

Considering the speed with which Hantavirus can overwhelm its victims, rapid diagnosis is essential in the clinical setting. In the postmortem setting, this is no less true, as a quickly recognized and diagnosed Hantavirus infection can allow medical investigators to identify family or coworkers at risk of a similar decline.

Serology remains the most common means of Hantavirus diagnosis, with IgM-capture ELISA providing a presumptive diagnosis. This can be performed in the postmortem setting, but the authors recommend making every effort to get an antemortem sample, since serum extraction in postmortem samples can become difficult. Detection of hantaviral antigen in tissue biopsy or other autopsy specimens can also be pursued. Other diagnostic modalities include viral RT-PCR from blood or fixed tissue or immunohistochemical demonstration of viral antigen in fixed tissue.

Hantavirus, *Sin Nombre* Virus, Pulmonary Syndrome

G98 Workplace Fatalities: A Case Example of Asphyxia Due to Occupational Exposure to Airborne Chemicals

Meredith H. Frame, MD, and Cynthia A. Schandl, MD, PhD, Medical Univ of South Carolina, Dept of Pathology, 171 Ashley Ave, Charleston, SC 29425*

After attending this presentation, attendees will understand the types of fatal occupational injuries, the demographics of the victims, and the trends in fatalities nationwide.

This presentation will impact the forensic science community by increasing awareness of workplace fatalities, detailing the various injuries, associated occupations, and personal risk factors.

Although worker injury and fatalities have decreased since adoption of the Occupational Safety and Health Act (OSHA) in 1970, they remain an important safety issue.[1] In 2010, 4,690 workers were killed at work, which averages nearly 13 deaths per day.[2] The United States Bureau of Labor Statistics calculates the number of fatal occupational injuries by detailed event or exposure, with transportation incidents being the number one cause (40%) of work-related fatalities nationwide. Other major types of fatal injury include assaults and violent acts (18%), contact with objects and equipment (16%), falls (14%), exposure to harmful substances or environments (9%), and fires and explosions (4%).[3]

Presented will be the case of a 27-year-old white male who was found unresponsive in a chemical dryer at an industrial plant where he and his coworkers had been pressure washing the containers. He had entered the container in order to rescue a coworker who had lost consciousness. After lifting his coworker to safety, he was overwhelmed with the chemical fumes and became unresponsive. Resuscitation efforts were unsuccessful. Toxicological analysis did not reveal an etiology, but possible exposures included cyanuric chloride, cyanuric acid, or high concentrations of nitrogen. As a result of this incident, the company was fined by OSHA for serious violations including failure to post danger signs, lack of a ventilation procedure in confined spaces during cleaning, and failure to develop emergency rescue procedures. [4]

Discussed will be several notable trends in the last several decades, both in the types of injuries and the occupations associated with the fatalities. These include decreases in workplace homicide and work-related highway incidents, but increases in fatalities from fires and explosions, exposure to harmful substances or environments, and falls. The occupation with the highest number of fatalities is construction, but the highest rate of fatalities per 100,000 full-time equivalent workers is in agriculture, forestry, fishing, and hunting.[3]

Additionally, other personal risk factors such as age, gender, chronic disease, smoking, and alcohol and drug use have been implicated in workforce health and safety.[5] Examined will be the differences in types of workplace fatalities in male and female workers, as well as the disproportionate number of fatal injuries involving men.[3] Other significant populations considered include workers over the age of 55 and workers born outside of the United Sates.

Explored using this case example will be the role of the forensic pathologist in the investigation of workplace deaths as a joint effort with police, the district attorney, and OSHA.[6] The function of OSHA, including the standards set and penalty for violation of these standards, will also be reviewed. Finally discussed will be the future of occupational safety and the current improvements brought about by such incidents.

Workplace, Fatalities, Asphyxia

G99 Exotic Aortic Dissection Treated With Formalin: Macroscopic and Microscopic Findings — A Case Report

Frederic Savall, MD, and Fabrice F. Dedouit, MD, Hopital de Rangueil, Service de Médecine Légale, 1 Ave Professeur Jean Poulhès, Toulouse, FRANCE; Marie-Dominique Piercecchi-Marti, PhD, and Georges Leonetti, PhD, 264 Rue St Pierre, Marseille, FRANCE; and Daniel Rouge, MD, and Norbert Telmon, MD, PhD, Centre Hospitalier Univ Rangueil, 1 Ave du Professeur Jean Poulhes, Toulouse, FRANCE*

After attending this presentation, attendees will have a better understanding of macroscopic and microscopic aspects of acute aortic dissection.

This presentation will impact the forensic science community by providing an example of sudden death with poisoning suspicion from which a medicolegal autopsy was performed 15 days after death and after embalming.

Aortic diseases contribute to the high overall cardio-vascular mortality. The prevalence of aortic dissection is 0.5 to 2.95/100,000/yr. The diagnosis of aortic dissection has been missed in up to 38% of patients on initial evaluation. In up to 28% of patients, the diagnosis has been first established at the postmortem examination. The mechanisms of disease have been well established. Aortic dissection can result from intimal rupture followed by cleavage formation and propagation of the dissection into the media, or from intramural hemorrhage and hematoma formation in the media subsequently followed by perforation of the intima. Men are more frequently affected and chronic systemic hypertension is the most common predisposing factor. Cocaine use has been suggested as a possible cause of aortic dissection. The classifications classically used were Stanford and De Bakey classifications, which respectively subdivided aortic dissection in two (A and B) and three (I, II and III) groups according to the dissection location (ascending or descending aorta). Svensson *et al*. proposed a new classification in five classes in 1999 according to the intramural hemorrhage, intramural hematoma, aortic ulcers, or iatrogenic and traumatic dissection. Reported is a case of unexpected death of a man in a suspicious context of poisoning and discuss the autopsy and histopathological findings.

A 58-year-old French man died suddenly in Madagascar. He had lived in Madagascar for six years and, according to the police officers in charge of investigation, his wife could have poisoned him. His past medical history was not known but he had consulted a doctor who had performed an Electrocardiogram (ECG) and laboratory tests a few times before the death. The ECG showed a sinusal rhythm with no abnormality and the results of the laboratory tests were in normal range. The public prosecutor of Toulouse, France, ordered a medicolegal autopsy. The body had been embalmed and placed in a hermetic coffin during the flight from Madagascar to Toulouse. Two board-certified forensic pathologists performed an autopsy fifteen days after the death. All three body cavities (cranium, thorax, and

abdomen) were examined. Pathological examination was performed after fixation in 10% formalin.

The body was of strong build, length 170cm and weight 85kg. Two bleus hematomas were visible on the anterior face of the left forearm and on the posterior face of the left hand. No other external traumatic injuries were noted.

All the organs were well conserved because of formalin conservation. Examination of the thoracic cavity revealed a haemopericardium with 214cc of blood clot with formalin. The heart was enlarged and heavy (566g) with the appearance of dilated cardiomyopathy. An important aortic dissection was noted from the aortic root to the right and left common iliac artery. The intimal tear was found on the ascending aorta under the aortic arch. A widely intramural hemorrhage was also noted at the right coronary artery attesting to a retrograde dissection. These findings corresponded to a Stanford class A or De Bakey type I.

Microscopic studies confirmed the existence of aortic dissection with a widely intramural hemorrhage. The large false lumen affected the ascending aorta, aortic arch, right common carotid artery and subclavian artery, descending aorta, and both common iliac arteries. Histopathological examination also confirmed the existence of retrograde dissection to the right coronary artery. The dissection reduced 90% of the true lumen of the right coronary artery due to the compressive false lumen. The intimal tear was located 2cm above the aortic cusps. Examination of the kidneys revealed nephroangiosclerosis lesions due to a medical history of chronic systemic hypertension. Microscopic studies found signs of prolonged circulatory failure like acute cardiac liver, renal ischemia, and a fibrin clot formation. The forensic experts concluded that the cardiac tamponade was sufficient to explain the cardiovascular arrest and death of the man.

Cardiovascular diseases are the major cause of death in the majority of the developed countries and in many developing countries. Furthermore, due to the high mortality of aortic dissection in the acute stage, the survival rate is very low. Up to 20% of patients die before reaching the hospital. Thus, aortic dissection was the subject of many of necropsy studies. In a series of 150 postmortem tomographic examinations of non-traumatic death, Shiotani *et al*. noted 23 cases of aortic dissection. At the institute of Legal Medicine of the Hanover Medical School, 30 cases of aortic dissecting aneurysms were examined histologically between 2006 and 2009. The cause of death was a rupture into the pericardial sac in 28 cases (93%). The forensic experts performed an autopsy fifteen days after death and after embalming. They found the cause of death and excluded the suspicion of homicide. Some authors studied cases of autopsies realized with delay. Karger *et al*. retrospectively analyzed 155 forensic exhumations. In this study, postmortem interval ranged from eight days to eight years. Major discrepancies between cause of death as stated on death certificate and as diagnosed after autopsy existed in 57 cases (37%). The large majority of exhumation autopsies were successful and the cause of death was clearly determined in 66.5% of cases. One case was reported of an autopsy realized nine days after the death and after burial and exhumation. The circumstances of death were unclear but, at the autopsy, forensic experts noted a massive hemoperitoneum secondary to hepatic artery rupture due to infectious arteritis. Classically, aortic dissection occurs in individuals with hypertension and individuals with genetic disorders of collagen formation such as Marfan's and Ehlers-Danlos syndrome. Men are more frequently affected, and the peak age for the occurrence of proximal dissection is between 50 and 55 years of age. Many studies have been reported of aortic dissection associated with cocaine or methamphetamine use. Cases of dissecting aneurysm or aneurysm rupture have also been reported in pregnancy and the postpartum period. In this case, the toxicological analyses were not performed, but according to sex, age, and nephroangiosclerosis, it was a classic case of sudden natural death in a 58-year-old man with cardiovascular risk factors. The medicolegal autopsy was necessary to find the precise cause of death and exclude homicide. Obviously, in cases where the cause of death is unclear, its determination by autopsy even some time after the death, can remove suspicion and allow the family of the deceased to mourn.

Aortic Dissection, Embalming, Medicolegal Autopsy

G100 Effect of Concealment on Necrophagous Flies Access

Damien Charabidze, PhD, Didier Gosset, MD, PhD, and Valéry Hedouin, PhD, Univ Lille Norde de France, Institut de Medecine Legale, Faculte de Medecine, Lille, FRANCE*

After attending this presentation, attendees will understand how different combinations of accessibility and odor diffusion affect the access of bait by calliphorids necrophagous flies. Such results are needed in forensic entomology to estimate the Pre-Appearance Interval (PAI: delay before first insect arrival), especially regarding indoor cases.

This presentation will impact the forensic science community by providing, for the first time, data on flies' abundance and PAI depending on odor diffusion and accessibility.

Forensic entomology is used to estimate the age of the insects sampled on cadavers, and subsequently to estimate the time of death. However, flies do not always colonize corpses immediately after death. If the corpse is difficult to reach, especially in the case of wrapping, concealment, or burying, access by necrophagous insects may be delayed. Such a delay in insect arrival (PAI) is also observed with bodies discovered inside dwellings or vehicles.

It may seem obvious that the less accessible a corpse is, the later and fewer flies there will be; however, no known detailed experimental evidences have been obtained. Furthermore, a delayed/altered insect access on concealed or indoor corpses could actually result from two different processes: first, the difficulty for the insects to detect a corpse due to potentially low odor diffusion, and, second, the inherent difficulty in accessing concealed corpses. Thus, two different parameters overlap in insect "accessibility," the escape of gases and the surface allowing insects to enter. It was hypothesized that these two parameters both influence the colonization process, and therefore, must be considered together.

Two possible consequences of the low accessibility of a corpse could be: (1) an increase in the pre-appearance interval (i.e., the time before first insect arrival); and, (2) a decrease in the total number of flies accessing the corpse. Both can impact the decomposition timeline and, in a forensic context, the PMI estimation. To answer this question, experiments were performed under controlled (laboratory) and field conditions. Baited traps were used to test how different combinations of accessibility and odor diffusion affect the access of bait by calliphorids necrophagous flies. Although such experimental designs were not directly connected to "real" forensic cases, they covered a large range of possible scenarios and thus bring general information on the behavior of necrophagous flies.

During laboratory experiments, 30 *Lucilia sericata* gravid females were kept in a cupboard with one of the traps. The most efficient trap caught a mean of 24.6±3.4 flies per run. The less efficient one had the largest odor diffusion surface (99cm²) combined with the lowest accessibility (one 1cm² entrance hole). It caught a mean of 5±3.7 flies per run, and significantly differed from the other. Overall, the results indicate that: (1) *Lucilia sericata* can enter in barely accessible traps; and, (2) odor diffusion and accessibility both affect the number of flies entering the traps.

Field experiments were performed with the same trap designs. For these experiments, all the traps were placed together outdoors in the same place and at the same time. The trap with the larger entrance (ten 9cm² holes) caught the most flies (55.6% to 99.4% of the total number of flies caught during a single run). On the contrary, only a few flies entered the other traps. None of these traps exceeded 29% of the total number of flies caught during a single run. A delayed access of the less open (odor diffusion and accessibility) traps was finally noted. Major conclusions of field experiments are: (1) traps

with low accessibility took longer to be accessed by flies; (2) larger odour diffusion surfaces increased fly attraction; and, (3) flies more readily accessed traps through larger holes than through an equivalent surface area made up of smaller holes.

In a forensic-entomology context, results suggest that both accessibility and odor effusion should be considered together to assess the possible time that might elapse between death and first arrival by flies.

Entomology, PMI Estimation, Indoor Cases

G101 Traumatic Renal Artery Rupture Following a Fall: A Fatal Occupational Accident

Lucia Tattoli, PhD, Eloisa Maselli, MD, Giancarlo Di Vella, MD, PhD, and Biagio Solarino, PhD, Univ of Bari, Piazza Giulio Cesare 11, Bari, ITALY*

After attending this presentation, attendees will understand the importance of full forensic investigations in establishing the manner of death in occupational deaths. Circumstantial data and autopsy findings, together with a detailed workplace investigation, also are fundamental for the identification of legal responsibilities.

This presentation will impact the forensic science community by emphasizing the fact that, in some circumstances, the forensics have to take into account the traumatic involvement of vascular structures, even without external major injuries. From this perspective, the autopsy is crucial, mainly if death occurred at the time of the accident or immediately after and other causes (natural death, drug or alcohol abuse) must be evaluated.

Presented is a case of an occupational death due to rupture of the left renal artery in closed thoracic-abdominal trauma, after a fall from a height. Blunt renal artery injury is a relatively rare finding. The literature demonstrates an incidence of 0.08% of all blunt abdominal traumas, occurring in 1% to 4% of patients with renal injury. The most common cause is motor vehicle accidents; other causes include a direct blow to the chest or abdomen and a fall from a height. All of these mechanisms result in sudden deceleration or crush injuries, affecting the renal parenchyma or the vascular pedicle. Moreover, a traumatic ruptured renal artery, without grossly demonstrable kidney damage, is also unusual.

In the case presented, a 47-year-old man accidentally fell from a height of 2.5 meters while he was working on a scaffold. The worker was taken to the local hospital, but he remained unconsciousness and unresponsive. A rounded bruise of the left thoracic wall was noticed. At echocardiography, a hematoma was observed at the upper left abdominal quadrant. The patient was intubated and, despite the cardio-pulmonary resuscitation, he died 30 minutes later. With the goal of better understanding the dynamics of the event, a medicolegal autopsy and crime scene investigation was performed.

The shirt he wore showed a soft rounded mark on the left side of the chest. The external examination of the body showed only a rounded bruise of seven centimeters in diameter on the left hypochondrium. At autopsy, fractures of eight ribs were found (the majority to the left), with perilesional hemorrhages with nearly 100cc of fresh blood in pleural cavities. The abdominal cavity displayed two litres of fresh blood and clots. A complete rupture of the left renal artery was found at one centimeter from the origin from the abdominal aorta. No alcohol or drugs of abuse were found in the fluids collected at autopsy. The cause of death was identified as hemorrhagic shock due to the laceration of the left renal artery.

Frames of the surveillance cameras were acquired, showing the man sliding off the scaffold (made of metallic beams and wooden traverses) and falling on the left side of the body, without displaying where he landed.

At the workplace investigation, a footprint on the external side of the scaffold was found, where the victim was working; the footprint matched shoes worn by the worker. On the grassy ground below, was a metallic pedestrian gate with a 1-meter-high hinge post placed just below the side of the scaffold, 2.52 meters from the footprint. The final reconstruction of the fatal accident concluded the man had fallen onto the gate hinge post, hitting the left side of the thorax; the blunt injury caused the rib fractures and the laceration of the left renal artery without any other injury of internal organs.

This report of isolated renal artery rupture represents an unusual finding, extremely rare following blunt abdominal trauma, and accounts for less than 0.1% of all trauma patients. Moreover, traumatic renovascular injuries occur most often in multiple injury patients. In the presented case, the preliminary reconstruction of the work-related fatality was not clear before the autopsy as there were no major external lesions. Therefore, the autopsy detected the cause of the death, allowing the real traumatic mechanism to be traced.

Traumatic Artery, Occupational Fatality, Workplace Investigation

G102 Forensic Pathology Considerations in the Transgender Population

Rebecca A. Irvine, MD, Dept of Forensic Medicine, 50 Parramatta Rd, Glebe, New South Wales, AUSTRALIA*

After attending this presentation, attendees will be able to describe the possibilities of cause/manner of death in the transgender population based on their reported marginalization and lifestyle risk factors. Attendees will be aware of the increased proportion of viral disease, and the importance of variable medical and/or surgical transition features.

This presentation will impact the forensic science community by increasing awareness of the challenges of postmortem examination of transgender individuals.

Transgender (TG) refers to individuals who express their gender differently than expected by society based on their natal sexual anatomy, with a range of gender variant identities. A minority have undergone “full” surgical sexual transition. Their lifestyle risk factors, as reported primarily in a large study with greater than 7,000 respondents, apply to all TGs. It is important to recognize persons who identified as transgender as there are likely to be a number of possibilities and factors contributing to death. Forensic pathologists should be aware that information about sexual identity may not be specifically sought or provided, and changes may not be obvious upon examination.

There are only a few somewhat sensational case reports on TGs in the forensic literature. Studies are logistically difficult, and there are few cohort studies.

TGs face significant barriers to medical care. For those few with insurance, it is unlikely to cover expanded recommendations for health care, or the costs of medical/surgical transgender affirmation interventions. Disturbingly, in medical settings, 19% have been refused care, 28% reported harassment, 2% have been the recipients of violence, and 50% reported that their physicians lacked treatment knowledge. Many eschew health care, and natural conditions may be neglected.

Routine health care maintenance is not simple, because they require surveillance for conditions affecting both the natal and surgically-created sex organs, as well as conditions secondary to hormone use (the effects of which remain unclear). Up to 50% of TGs have used “illegitimate” source hormones. Some inject foreign substances for cosmesis, with possible systemic complications. Self-mutilation is common.

Rates of substance abuse (alcohol, drugs, tobacco) and psychiatric illness are significantly greater among TGs.

Almost all report bias, discrimination, “transphobia,” and frequently assault. The homicide rate is unknown, although there have been prominent cases in the media (and in film). The U.S. Hate Crimes Prevention Act was expanded to include a victim’s actual or perceived gender or orientation.

Analysis was performed on 33 TG individuals who presented to DOFM, Glebe, between 1993 and the present. Although this number

is too small for formal epidemiological analysis, descriptive examination shows features that generally reflect the reported lifestyle risk factors.

Where known, the risk factor frequencies are cited in narrative or brackets. Fifteen percent of the deceased group had "complete" surgical transition (penectomy +/- vaginoplasty), representing 15% of the MTF group (20%) and none of the FTM group (2%). Thirty-nine percent of the deaths were due to alcohol and/or drug toxicity; 26% reported use to "cope," up to 36% in individuals involved in "underground economies" (i.e., prostitution). Fifty-one percent of the deceased group had a history of substance abuse. The suicide rate was 18% (with an astounding 41% of the surveyed group reporting suicide attempts, 25X that of the general population). Four of the group (12%) were infected with HIV, all having been routinely tested; the expected rate is 4X the national US. average, or 3.76%. Twenty-seven percent were infected with hepatitis C virus. One death, of the 27% natural deaths, was directly due to HIV disease. Seventy-two percent of the deaths occurred under the age of 50. None were homicides. The rate of unnatural death was slightly greater than 75%.

One death depicts the unusual situation of a late complication of TG surgery as a possible contributing factor to death. The deceased had thromboembolic disease on a background of unknown current estrogen use, colorectal carcinoma *in situ,* and chronic ethanolism; there was also acute and chronic cystitis/prostatitis, the latter almost certainly due to the specific anatomy of the genitalia. This case illustrates the need to identify and examine every TG case in terms of their specifically altered anatomy and physiology, as well as an awareness of their substantial lifestyle risk factors.

Transgender, Lifestyle Risks, Postmortem

G103 Exogenous Lipoid Pneumonia: An Uncommon Incidental Autopsy Finding

Pauline Saint-Martin, MD, Sebastien Prat, MD, and Camille Rerolle, MD, CHRU de Tours, Hopital Trousseau, Service de Medecine Legale, Tours, 37000, FRANCE; Marc Deveaux, MD, Laboratoire Toxlab, 7 Rue Jacques Cartier, Paris, FRANCE; and François Paraf, PhD, CHU Dupuytren, Service de Médecine Légale, Limoges, FRANCE*

After attending this presentation, attendees will learn about lipoid pneumonia, a rare condition that may be incidentally found during postmortem investigation. Knowledge of the characteristics of this condition may allow revealing various risk factors that are helpful in the determination of cause of death.

This presentation will impact the forensic science community by highlighting an uncommon finding during autopsy. Basic knowledge of the characteristics of lipoid pneumonia may be helpful in the determination of cause of death.

Postmortem investigation often leads to incidentally revealing various conditions, which may or may not have played a part in the death of an individual. Lipoid pneumonia is a rare disease that is not necessarily involved in the occurrence of death, even as a contributory factor, but knowledge of the predisposing factors may be helpful in the determination of the cause of death of an individual.

Reported was a case of a 32-year-old woman who was found dead in her bed by her husband. According to him, she had taken methadone and cannabis the day before. She had a long history of drug abuse and was treated with buprenorphine in a drug addiction treatment center for six months. She also suffered from anorexia during her teen years, and had a history of suicide attempts.

External examination showed no traumatic injuries and no signs of intraveinous injection. At autopsy, a diffuse pulmonary edema (left lung: 816g; right lung: 998g) and congestion of lungs, brain, liver, and spleen were noted. The autopsy was otherwise unremarkable.

Toxicology revealed the presence of methadone (0.77µg/mL) and EDDP, its major metabolite (0.17µg/mL), buprenorphine (1.4ng/mL), amitriptyline (0.24µg/mL), olanzapine (0.20µg/mL), tropatepine (0.01µg/mL), nitrazepam (<0.01µg/mL), clonazepam (<0.01µg/mL) and 7-aminoclonazepam (0.06µg/mL), and zopiclone and tetrahydrocannabinolic acid (3.6ng/mL).

Miscroscopic examination of the lungs showed a diffuse interstitial fibrosis, with multiple intra-alveolar and interstitial foamy macrophages, and extracellular fat droplets with multiple polynuclear giant cells. Areas of subpleural emphysema were also seen. The brain, heart, and other organs were unremarkable. A diagnosis of lipoid pneumonia was made.

The medical record of this woman was studied and it was learned that, one year before she died, she had been hospitalized in a pneumology department. She was complaining of a moderate dyspnea and weight loss. A chest X-ray showed an opacity of the right lung. A thoracic CT scan revealed multiple ground-glass opacities and pulmonary emphysema. A bronchoalveolar lavage was performed, showing the presence of multiple macrophages and lipidosis. A diagnosis of exogenous lipoid pneumonia was made. The main risk factor was found to be a chronic intranasal use of various susbtances.

Lipoid pneumonia is an uncommon entity with the characteristic radiograph features and histologic findings of alveoli filled with vacuolated, lipid-laden histiocytes. It can be either exogenous or endogenous in cause based on the source of the lipid. Exogenous lipoid pneumonia usually results from aspiration or inhalation of fat-like material, such as mineral oil or petroleum-based lubricants and decongestants, resulting in pulmonary inflammatory reactions. The clinical findings may vary from the absence of symptoms to chronic cough, fever, hemoptysis, and dyspnea. Abnormalities are usually seen on chest X-rays, as an area of homogenous dense consolidation, or presence of nodules. CT scan can reveal areas of fat attenuation and ground-glass opacities. Endogenous lipoid pneumonia is an obstructive pneumonitis. It can be associated with non-small lung cancers but also can occur as a manifestation of infection and other diseases. It can also appear with fat emboli, pulmonary alveolar proteinosis, and lipid storage disorders. Polarized light microscopy after staining with sulfuric acid and acetic acid usually reveals cholesterol crystals, a finding diagnostic of endogenous lipoid pneumonia.

In this case, death was attributed to acute poly drug intoxication. As microscopic examination had revealed severe pulmonary lesions, lipoid pneumonia and pulmonary emphysema were considered as conditions contributing to the cause of death.

Forensic Pathology, Lipoid Pneumonia, Drug Intoxication

G104 A Comparison Study on the Performance of STR Typing Kits With Improved Buffer Systems

Sze-Wah Lin, MPhil, Chi-yuen Ip, MD, Christina Li, MS, and Kam-Ming Lai, MD, Ho Man Tin Govt Offices, Government Laboraotry, 88 Chung Hau St, Kowloon, Hong Kong, PEOPLE'S REPUBLIC OF CHINA*

After attending this presentation, attendees will gain information regarding STR typing kits with improved buffer systems which offer better tolerance to inhibitors commonly encountered in forensic casework samples.

This presentation will impact the forensic science community by discussing how studies showed the improved buffer systems in these newly developed kits are promising and could be employed for DNA typing of challenging samples.

DNA fingerprinting, since its introduction in the 1980s, has frequently been employed by forensic scientists to assist in the identification of individuals. Analysis of Short Tandem Repeats (STR) using Polymerase Chain Reaction (PCR) technique, which enables minute quantities of DNA to be detected, has replaced the Restricted Fragment Length Analysis (RFLP) technique since the mid 1990s. Though powerful in assisting forensic investigations, DNA fingerprinting is not straightforward.

One of the challenges of DNA fingerprinting is that, in many forensic cases, the DNA samples are far from pristine. Amplification of compromised samples can result in poor or no genotyping results, whereas amplification in the presence of inhibitors can even lead to loss in signals. The first issue has been overcome by the introduction of the analysis of STR with shortened amplicons, which are optimized for genotyping degraded samples. Meanwhile, several new STR typing kits with modified buffer systems claiming improved tolerance to inhibitors commonly encountered in forensic casework samples have been introduced to the market in recent years.

To study if these newly developed kits will perform better than the one currently being used in the laboratory (which has been on the market since 2001), three newly developed kits, A, B, and C from three companies,were selected and their performance compared in the following aspects: (1) detection sensitivity; (2) PHR, (3) stutter ratio; (4) intra-/inter-color balance; (5) concordance of typing results; (6) tolerance to inhibition by hematin and humic acid; and, (7) performance for challenging samples. A total of 35 samples were employed in this study, and were amplified according to the conditions as suggested by the respective manufacturers. The amplified products were injected into a genetic analyzer commonly used in forensic DNA analysis, and the data were analyzed with the software provided.

In summary, as compared to the STR kit currently used in the laboratory, all three tested kits demonstrated improved detection sensitivity with comparable PHR in various amounts of input DNA (0.125, 0.25, 0.5, and 1ng). They exhibited better tolerance to inhibition by hematin and humic acid, and showed obvious improvement in the analysis of challenging samples. In addition, full concordance was observed in a total of 375 STR allele calls in the analyses. Among the three kits, kit A displayed the best intra-/inter-color balance, the highest tolerance to inhibition by hematin and humic acid, and the greatest improvement in the analysis of challenging samples. It is noteworthy to mention that, although kits B and C (with increased PCR cycle numbers) showed greater enhancement in sensitivity, the stutter ratios of these kits were also elevated as compared with kit A. To conclude, studies showed that with the modified buffer systems, the performance of all these newly developed kits are comparable and even better than the currently used STR typing kit. In addition, they demonstrated improved performance in the analysis of challenging samples. Therefore, all are suitable candidates for the selection of the next generation STR typing kit in the laboratory.

STR, Inhibition, Tolerance

G105 Preconception Diagnostic Approach: Case Report

Mete K. Gulmen, PhD, MD, Burak E. Celik, MD, Kenan Kaya, MD, Kemal C. Yildirim, MD, Necmi Cekin, MD, and Ahmet Hilal, MD, Cukurova Univ, School of Medicine, Dept of Forensic Medicine, Adana, TURKEY*

After attending this presentation, attendees will see the results of the preconception diagnostic approach that can lead to death and the importance of detailed examination.

This presentation will impact the forensic science community by increasing awareness that preconception diagnosis approaches cause negativities at patient's treatment and follow up and the best approach is detailed examination and laboratory investigation.

Sudden unexpected deaths constitute a large part of forensic medicine's daily work and are mostly caused by cardiovascular system disorders. It was noted that acute myocardial infarction and coronary artery disease are mostly seen, but sudden deaths due to aortic dissection and rupture are less seen.[1]

Aortic dissection occurs by the rupturing of intima layer and, passing blood to the middle and two-thirds part of the media. This situation occurs mostly at the ascending aorta and mostly has a transverse course. Aortic dissection is a life-threating disease which is characterized by sudden chest and/or waist pain. The disease is seen most commonly in men.[2] Compensation mechanisms are not enough because aortic rupture cases are too severe and progress very rapidly. It was seen that of the 85.4% of cases located in the thorax, aneurysm was at the ascending aorta with 70% of them at the opening to the pericardium.[3] Despite the improvements of noninvasive diagnostic methods, acute aortic dissection's mortality is still high. Delaying the diagnosis affects hourly mortality by an increase of 1%. A rapid and correct diagnosis can place the mortality rate under 50%. Mortality rate of the disease was 1% per hour in 24 hours, especially at dissections, on the ascending aorta. This rate rises to 75% at the end of second week. When considered from this point, early diagnosis is an important factor which positively affects the prognosis.[4]

Introduction: The most important usage area of the pesticides is in agriculture as pest control. In 1985, organochlorine pesticide usage was forbidden except endosulfan and toxaphene.[5] Endosulfan (a neurotoxin) poisoning may cause neurologic symptoms like tonic clonic seizures, tremor, headache, dizziness, ataxia. The treatment approach is symptomatic, seizures can be controlled by benzodiazepine and if needed by phenobarbital.[6]

Case: It was detected that a 25-year-old male fainted while spraying his garden and was brought to hospital. He was unconscious, his pupils were dilated, and there was no light reflex. He was intubated due to shallow respiration and, right after cardiac arrest occured, he was resuscitated with cardiac massage and medical theraphy. It was thought that he was poisoned by endosulphane pesticide, so gastric lavage was done by using nasogastric tube. He was comatose and continuously having seizures. Benzodiazepine was used at his treatment. During his medical theraphy he was arrested and atropinized; defibrillation was performed, but he expired, not responding to resuscitation. At his autopsy, heart was weighted as 380g, 400cc bloody fluid was detected at his pericardial sac, there was 2cm dissection at his aortic knob, he was died because of pericardial tamponade which caused by aortic dissection. At his toxicological report, 143ng/ml active substance was found in his blood which belongs to benzodiazepine family and an antidepressive drug (diazepam).

Conclusion: There may be a few possibilities which caused undetected endosulfan level at his toxicology report. The first possibility is atropine which was used at treatment and not reported pralidoxime smooth the excretion of endosulfan. Another alternative is incorrect laboratory testing results. And the last and most important alternative is misdiagnosis. It was important that physicians consider endosulfan poisoning at the differential diagnosis instead of cardiac events for a patient who had central nervous system toxicity symptoms and signs with undefined etiology and who came from countryside. But this hospital and other healthcare organizations don't have required conditions for this kind of considerations. This is a dead end and also every condition of the country about this area must be used in situations like that.

Noted in the physicians logs or notes; mistakes were made because of misdiagnosis due to general assessments. Because of this, the best approach is to make the decision after a detailed examination and appropriate laboratory investigations.[7]

Diagnose, Autopsy, Aneurysm

G106 A Fatal Case of Human Herpes Virus 6 Fulminant Pneumonia in a Young Immunocompetent Woman

Lucia Tattoli, PhD, Eloisa Maselli, MD, and Biagio Solarino, PhD, Univ of Bari, Sezione di Medicina Legale, Piazza Giulio Cesare, 11, Bari, ITALY; Paola Frati, PhD, Univ of Rome, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, ITALY; and Alessandro Dell'Erba, PhD, Teaching Hospital of Bari, Risk Management Unit, Piazza Giulio Cesare 11, Bari, ITALY*

After attending this presentation, attendees will understand the importance of a complete forensic approach, through autopsy, histological, and virological examinations, in an uncommon case of lethal fulminant hemorrhagic pneumonia in a young immunocompetent woman and in determining Human Herpes Virus 6 (HHV 6) infection as the cause of death.

This presentation will impact the forensic science community by showing that acute HHV6 infections can occur in adults suffering a variety of syndromes, from non-specific to severe in both immunosuppressed and healthy patients.

Primary HHV6 infection causes *exanthema subitum*, a common febrile disease of infancy, whose clinical course is generally benign and self-limited. HHV6 is usually acquired at a young age and remains latent in the salivary glands and central nervous system of healthy subjects. Reactivation of latent HHV6 is common and can cause, in immunocompromised hosts, severe complications including encephalitis/encephalopathy, pneumonitis, hepatitis, thrombocytopenia, hemophagocytic syndrome, and myocarditis.

Pneumonia associated with HHV6 infection is interstitial, and it has been repeatedly reported in the literature in patients after allogenic stem cell transplant or with HIV infection. The clinical findings vary from mild to severe, requiring mechanical respiratory support attributable to Acute Respiratory Distress Syndrome (ARDS).

The case of a 27-year-old woman who was admitted to the emergency room complaining of cough, dyspnea, hemoptysis, and fever was reported. The clinical history of the patient was silent for any disease. A chest CT scan showed multiple foci of pneumonia of the right lung, with epato-splenomegaly, and mediastinal lymphadenomegaly. The blood exams showed severe decreases of leukocytes, platelets, and lymphocytes, and pseudo Pelger-Huet anomaly of neutrophils at peripheral blood smear. As the patient worsened, she was intubated with blood leaking from the airways. Despite medical resuscitation, the woman died eight hours after the admission. Due to the lack of previous medical history, a medicolegal autopsy was performed.

The external examination of the body was completely negative. The autopsy revealed hemorrhagic pleural effusion (1200cc total), pulmonary edema with hemorrhage, and epato-splenomegaly.

The histological examination revealed bilateral pneumonia with interstitial lymphocytic infiltrates and diffuse alveolar damage (ARDS-hyaline membranes). No alcohol or drugs of abuse were found in the blood and urine collected at autopsy.

Microbiological analysis was negative. Virological examinations of the pleural effusion and blood showed HHV6 pneumonia with low levels of Human Herpes Virus 7 (HHV7) and Epstein-Barr Virus (EBV), demonstrative for a co-infection.

The cause of death was HHV6—haemorrhagic pneumonia (with co-infection of HHV7 and EBV) that evolved into ARDS.

Some studies have identified co-infections with HHV6 and other viruses in a surprising number of HHV6-associated pneumonias. In fact, HHV6 and HHV7 are ubiquitous in the adult population and can reactivate periodically and cause several manifestations reported to occur at high frequency when the functions of cell immunity are impaired.

In this case, the young patient was not immunodepressed, without other pathologies, and developed a fatal pulmonary failure attributable to HHV6 pneumonia, evolving into ARDS. According to the literature, ARDS caused by HHV6 is extremely rare, and is described mainly in immunodeficient persons.

The evidence of a detectable viraemia has a key role in the diagnosis of the infection, which has to be identified and treated with specific antiviral drugs, as soon as possible. Nevertheless, virological exams, based on the quantification of viral load in bodily fluids, are available but need to be improved and standardized. Although no systematic evaluation of treatment regimens is available, coincidental administration of antiviral drugs can not result in clinical improvement.

Autopsy, Human Herpes Virus 6, Pneumonia

G107 Deaths in Custody: A Northern Portuguese Analysis From 2000–2010

Paulo Madureira, MSc, Comando Metropolitano do Porto, Largo 1 de Dezembro, Sem Número, Porto, PORTUGAL; and Katerina Puentes, MD, and Agostinho Santos, MD, PhD, Univ of Porto, Jardim Carrilho Videira ao Carregal, Porto, PORTUGAL*

After attending this presentation, attendees will have a better and clearer perception of the northern Portuguese situation on the topic of deaths in custody from a medicolegal perspective.

This presentation will impact the forensic science community by presenting the first Portuguese retrospective study of deaths in custody from a medicolegal point of view, analyzing important issues, such as demonstrating the cause of death, as well as circumstances and manner of death.

Deaths occurring while individuals are in custody, given their peculiarities, are quite tragic and distressing for the individuals' families and friends, police enforcement agencies, and the institutions where they occur. The same applies in a broader perspective to society, especially with those cases in which death happens in a sudden, unexpected, and violent manner. The suspicion of excessive force or violence against the arrested decedent on behalf of the police agents within jails and penitentiaries is always the subject of extensive media coverage, often even without true knowledge of the real facts. Thus, "deaths in custody" are of undeniable forensic interest, considering the demonstration of the cause of death, as well as the circumstances and manner of death. In Portugal, there are very few studies on this matter and none of them from a medicolegal point of view since the approach to this subject has been quite infrequent. Moreover, the studies published in the international reference forensic

literature relate to economic and socio-cultural realities which, in most cases, are rather different from the Portuguese one.

This study intends to analyze and characterize, from a medicolegal perspective, all deaths which occurred in the north of Portugal between 2000 and 2010 as a result of police vs. citizen interaction, when the decedent was under the responsibility of any police enforcement agency or security service. This study was based on data obtained from different police enforcement agencies and security services, autopsy reports, and criminal investigation process files. A total of 228 individual cases of prisoners in 13 different penitentiaries were analyzed, as well as 130 autopsy reports and 10 criminal investigation process files in different courts of law.

During the timeframe covered by this study, 237 fatalities were found that met the criteria for "death in custody." Of those 237 deaths, 55.3% underwent a forensic autopsy. "Deaths in custody" occurred in 225 cases under the jurisdiction of penitentiaries and correctional facilities, in seven cases under the jurisdiction of the PSP (Public Security Police), and in five cases under GNR (National Republican Guard) jurisdiction. The most common profile in these fatalities, according to the collected data, corresponds to male individual (98.3%), single (56.5%), aged between 25 and 44 (61.1%), with low level education (36.3%), resident in the Porto District (67.5%), and suspected of or convicted for crimes against personal or public property (31.6%). From a medicolegal etiology point of view, death from natural cause was the more frequent etiology (59.5%), followed by suicide (25.7%), accidental causes (8.9%), and homicide (4.2%). HIV infection/AIDS were responsible for 17.7% of the death cases studied. Hanging was the most frequently used method for suicide in jails (24.5%). There were ten homicides, two of which resulted from physical assaults between inmates and eight resulted from the police enforcement agent's action at the moment of approach/detention.

Death in Custody, Police Enforcement, Cause of Death

G108 Correlation Between Thyroid Disease and Sudden Thromboembolic Death: Case Report

Silvia Boca, MD, Isabella Aquila, MD*, Francesca Pepe, MD, Carol Pileggi, MD, Debora De Bartolo, Ciro Di Nunzio, PhD, Santo Gratteri, MD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand how thyroid disease can be related to sudden thromboembolic death in young people.

This presentation will impact the forensic science community by underlining the possibility of a sudden death caused by thromboembolism, consequent to thyroid disease.

Venous thrombosis is the third most common cardiovascular disease after myocardial infarction and stroke. The incidence rates for VT (1 – 3/1.000) vary between person/years.[1-3] The case fatality rate of profound venous thrombosis, mainly due to massive pulmonary embolism, varies from 1% in young patients to 10% in older patients. Often the diagnosis of pulmonary thromboembolism is discovered during autopsy.[4,5] In the United States, pulmonary embolism causes about 50,000 deaths per year.[6] In general, the thromboembolism determined a sudden death, especially in young people, and it is not always preceded by prodromal symptoms.

The literature suggests a moderate association between hyperthyroidism and acute venous thrombosis. In particular, the role of thyrotoxicosis is a common disorder with an incidence between 0.5% to 2.5% in the world. It causes large effects on the heart, reversible changes such as: increased prothrombotic VIII factor and von Willebrand factor; an increase of clots most resistant to fibrinolysis.[7-11]

The purpose of this study is to detect a possible association between thyroid disease and sudden thromboembolic death.

The case study examined a 41-year-old woman, mother of two children, found dead in the bedroom of her lover. Investigation at the scene found that the corpse was naked on the bed. The police reported the woman had had sexual relations with the man. From the investigation interview her doctor did not suggest any disease and the woman had been in good health. The external inspection of the cadaver did not detect external signs of a struggle or other injuries. The TCMS postmortem showed an alteration of TC densitometry in correspondence of the right ventricle. The survey autopsy showed a massive thrombus-embolism without other evident internal signs. Histological examination revealed a pituitary adenoma with lymphocytic thyroiditis of Hashimoto disease. The histological finding, the absence of other diseases or other predisposing risk factors for thromboembolism were allowed to correlate the genesis of thromboembolic sudden death with thyroid disease, which the victim had.

The study has value for the scientific community because it focuses attention on the problem of sudden deaths in young people. In particular, it highlights the high risk of mortality, as demonstrated in the literature, for people with thyroid disease in the genesis of sudden deaths of thromboembolic death. The prevention of these diseases and the appropriate therapy in patients would help to avoid such events.

Sudden Death, Pulmonary Embolism, Thyroid Disease

G109 Varicose Vein Rupture: Crime Scene of Uncertain Non-Natural Death?

Isabella Aquila, MD, Ciro Di Nunzio, PhD, Silvia Boca, MD, Francesca Pepe, MD*, Umberto De Gennaro, MD, Santo Gratteri, MD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to evaluate the possible consequences of varicose vein rupture and the importance of an adequate scene investigation to understand causes of death.

This presentation will impact the forensic science community by discussing varicose vein rupture and its mortal complications.

One of the most commonly reported chronic medical conditions is represented by venous disease, including varicose veins and Chronic Venous Insufficiency (CVI). It is also a substantial source of morbidity in the United States and the Western world. Varicosis is found in 15% – 50% of the population. Clinically relevant classification of varicophlebitis appears useful: stage one includes varicophlebitis without involvement of the respective junctional valve in the groin or at the knee and deep veins; while in stage two, the proximal part of the thrombus has reached the respective junctional valves of the long or short sapheneous vein; in stage three, it has entered the deep veins by means of these valves; in stage four, the thrombus migrates via insufficient perforating veins into the deep system. Several risk factors associated with the development of varicose veins and chronic venous insufficiency or both are older age, female gender, family history, obesity, and a standing occupation. Small Arteriovenous Communications (AVCs) are an important etiology of varicose veins and stasis ulcers of the lower extremities. Hemorrhage from ruptured varicose veins of the legs can occur spontaneously or after a minor trauma. More frequent complications of varicosis include peripheral edema of the ankles, skin ulcers, and varicose eczema. On the contrary, in most forensic practices fatal hemorrhage from rupture of varicosis is a rare event.

The goal of this study is to analyze the importance of inspection and on-site forensic investigations to determine the cause of death when the crime scene is uncertain.

One case of varicose vein rupture is reported. An 80-year-old man was found dead in the bedroom of his apartment. Traces of blood were found in the intire room. The body showed typical signs of death due to exsanguination. A large pool of blood was found on the floor. The scene analysis allowed for the evaluation of the presence of small spatters of blood on the back of the left foot. An external examination of the victim showed a circular lesion linked to subcutaneous arteriovenous anastomoses. Blood spatter investigations and circumstantial data allowed for the detection of the cause of the breaking of the ulcer. In fact, the sock worn by the victim presented a circular blood crust that served as a “cap” on the skin lesion (ulcer).

Analysis of the collected data showed that the elderly man, removing the sock, tore out the crust (cap) from the lesion when removing the sock. Other traumatic lesions were not found. In particular, blood stain pattern analysis was performed in order to understand the origin and the location of venous and/or arterial bleeding. However, blood projected from ruptured varicose veins of the lower limbs may also result in a similar pattern of projected, disseminated fine bloodstains.

In this case, the cause of the hemorrhage was a small lesion of the skin of the left lower leg of the victim, linked to a small arteriovenous communication. At first sight, fatal hemorrhage, with massive traces of blood, may associate the death scene to a crime, with focus primarily on a non-natural death. This case demonstrated the central role of crime scene investigation in these cases. Further, this study showed the fundamental role of prevention in cases of varicose vein disease through adequate treatments.

Hemorrhage, BPA, Varicose Vein

G110 Postmortem Multi-Slice Computer Tomography in the Evaluation of Single Gunshot Injuries

Isabella Aquila, MD, Carmela Falcone, MD, Ciro Di Nunzio, MFS, PhD; Silvia Boca, MD, Ester De Luca, MD, Oscar Tamburrini, PhD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Catanzaro, 88100, ITALY*

After attending this presentation, attendees will understand the role of postmortem imaging in the evaluation of single gunshot injuries.

This presentation will impact the forensic science community by discussing the usefulness of Multi-Slice/Computer Tomography (MSCT) in the description of gunshot injuries in relation to entrance and exit wounds and bullet paths, as well as in 3D reconstructions.

Postmortem MSCT is a new approach in forensic pathology for helping investigations. Gunshot injuries are one of the foremost fields of postmortem forensic radiology. MSCT is performed to locate the projectile, to identify entrance and exit wounds, to detect bullets and bullet fragments in the body, to show the bullet course, and other, inflicted injuries. Also it is possible to do 3D reconstruction of the soft tissue and skeletal injuries.

The purpose of this study is to determine the role of postmortem multislice computer tomography in characterization of gunshot injury to reconstruct the site gunshot entrance wound and the direction of the bullet path.

In this study three cases of death due to single gunshot injury are reported. In the first case, an 80-year-old man was found dead in the bedroom of his apartment with a gun in the right hand. An external examination of the victim showed devastating head injuries. In the second case, an 81-year-old man was found dead in his apartment. He did not have any gun in his hand because it was removed by the police. In this case an external examination showed the anatomical site of gunshot injuries. In the third case, a 56-year-old man was found dead on the road near the center of the city. Postmortem radiological investigation (MSCT) and autopsy examination were performed in these three cases. The determination of entrance and exit wounds was reconstructed from the characteristic fracture pattern with inward or outward bevelling of the bone respectively.

In this study, MSCT showed an overvalued internal hemorrhage and a precise detection of skeletal injuries and skull fractures. Circumstantial data and autopsy investigation showed cause and modality of death. For this reason radiological approach is very important for reconstruction of gunshot injuries but it does not give any information about modality of death.

In some countries, the use of imaging techniques such as computerized tomography and magnetic resonance is becoming a routine procedure before the autopsy, or even, in some cases, investigations carried out in place of the autopsy. Other advantages of this investigation are: presenting clear and objective information to the court as forensic evidence, 3D documentation of the investigation, and quality assurance through the digital data filling and transfer. The documentation and analysis of postmortem reports identified by MSTC, a non-invasive method, will lead over time to qualitative improvements in forensic pathology investigations. The methodological operative combination between the two disciplines (radiology and forensic pathology) has begun to define common objectives, especially through the use of methods such as MSCT, which are:

- Determination of the cause and modality of death.
- Evaluation of vital signs depends on the presence of anatomical damaged structures.
- Developing a forensic reconstruction based on various reports.

Currently, MSTC is a method increasingly used for forensic purposes so as to have the potential to enhance today’s formal procedures. Apart from the accuracy and three-dimensionality, this method allows the corpse to be re-examined even after some time. In fact, it is believed that this virtual approach, non-invasive or minimally invasive, will improve forensic pathology tools in the near future.

Gunshot, Virtopsy, Autopsy

G111 Automated Reporting System Increases Referral and Donors

Jeffrey M. Jentzen, MD, Univ of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109; and Steven C. Clark, PhD, 124 Elm St, Big Rapids, MI 49307*

The goal of this presentation is to alert medical examiners, coroners, and organ procurement agencies of the benefits of automated reporting of potiential donors to local organ procurement agencies. This system saves time and organs.

This presentation will impact the forensic science community by increasing organs for possible donation, complying with state statutes on reporting potential donors, and improving overall efficiency for medical examiners' and coroner's offices. This encourages improved data exchange between agencies which elevates the professional status of the forensic community.

As the number of accessible organs and tissues continues to remain insufficient to supply the current demand, deaths investigated by medical examiners' and coroners' offices may prove to be a significant source of viable organs and tissues; however, tighter budgets and increases in mandated reporting requirements have caused friction between many medical examiners'/coroners' offices and some organ procurement organizations. The need for collaboration and timely communication between these agencies is essential if each is to fulfill their responsibilities to the public and others who rely on their services. Although most states require medical examiners and coroners to report all deaths to the local organ procurement agency, many viable organs and tissues expire due to needless delays in notification, recovery, and procurement tasks. Although medical examiners' and coroners' offices have spent hundreds of thousands of dollars on "state of the art" case management systems, most are antiquated before they "work," and rarely do these systems allow (or are capable of) communication with other data systems. Reporting and information exchange regarding potential organ and tissue donors is time consuming, inefficient, and typically done—by telephone—daily.

The Washtenaw County medical examiner office in Ann Arbor, Michigan, along with Occupational Research and Assessment (ORA) and Gift of Life Michigan, recently collaborated in the development of an automated reporting system for organ and tissue referrals. Washtenaw County uses the MDILog® web-based software service (developed by ORA) for its case management, both hospital (University of Michigan) and non-hospital medical examiner cases are entered in the system as they occur. Gift of Life traditionally contacts the Washtenaw medical examiner's office each morning to inquire about recent cases and their potential for referral. The goal of the system was to reduce medical examiner staff time in fulfilling the mandated reporting requirement and increase the number of referrals to Gift of Life Michigan and the number of cases that resulted in actual donated organs and tissue. In addition, the resulting data transfer protocol (schema) could be shared with anyone wishing to replicate the data exchange process with their own case management system and the state/local organ procurement organization they are required to report cases to.

The concept is simple: using the investigative data set, the Organ Procurement Organization (OPO) (in this study Michigan Gift of Life) identifies which case criteria are essential to initiate a case for procurement. If the investigators have the correct hardware (laptop/tablet with cellular connection), they are able to connect to the case management system and start processing the case immediately on arrival at the scene. Once (and if) OPO case data thresholds are met and saved, the data flows seamlessly (without humans in the loop) to the Gift of Life computer center where case screeners review case details (only essential data is viewable to OPO staff) and provide feedback to the investigator (hold or release), allowing medical examiner staff to coordinate timely release of the body to funeral directors or tissue procurement agencies. If the suspected cause and manner of death require additional forensic investigation and autopsy, the investigator simply checks a box informing the OPO of a medical examiner "hold" on the referred case.

In the first six months since going "live," the automated data exporting system has processed 56 totally automated referrals resulting in 8 additional tissue donors. Gift of Life concluded that: implementation of the program required a review of internal case processing procedures and that it is likely that two of the cases resulting in donation would have otherwise been lost due to unnecessary time delays. Automated data exchanging avoids duplication of effort, human error, and saves time and tissue.

Tissue Donors, Automated Reporting, Organ Procurment

G112 A Retrospective Study of Non-Criminal Autopsy Cases in the Central Part of China From 2001–2010

Liang Liu, PhD, Huazhong University of Science and Technology, Tongji Medical College, 13 Hangkong Rd, Wuhan, PEOPLES REPUBLIC OF CHINA; and Luo Zhuo, MD*, and Ling Li, MD, OCME, 111 Penn St, Baltimore, MD 21201*

After attending this presentation, attendees will gain knowledge about the medicolegal death investigation system in China and common causes of sudden unexpected death, accidental death, and suicides in central part of China.

This presentation will impact the forensic science community by showing the importance of forensic autopsy in the medicolegal death investigation. The understanding of deaths due to allergic reaction to antibiotics caused by medical malpractice could lead to the prevention of such deaths.

Medicolegal death investigations in China are conducted by forensic medical experts, mainly within five relatively independent agencies: (1) the police departments; (2) the prosecutors' offices; (3) forensic medicine/science institutes in medical colleges and universities; (4) Institute of Forensic Science in the Ministry of Justice; and, (5) the government or private forensic societies. Approximately 300 forensic medical experts are distributed in 33 of 150 medical colleges, four universities of political science and law, and nine colleges of police or criminal police. The forensic medical experts/forensic pathologists in the medical colleges and universities are primarily responsible for the medicolegal examination of sudden unexpected deaths, accidental deaths, and suicidal deaths.

Wuhan is the capital city of Hubei province in central China with a population of 9,785,392. Forensic pathologists at Tongji Forensic Medicine Center of Huazhong University of Science and Technology (TFMC) are primarily responsible for the forensic examination of the sudden unexpected deaths, accidental deaths, and suicide cases in Wuhan. A retrospective study of forensic autopsy cases was conducted at the TFMC from 2001 to 2010. A total of 854 autopsy cases were performed by the forensic pathologists at TFMC in Wuhan city during the ten-year period. Of these deaths, 799 cases were determined to be non-criminal deaths. The age of individuals ranged from 0 to 82 years with the majority of subjects in the ages of 21 to 60 years (560 cases, 70.1%) and the mean age of 33.79±19.17 years. As regards to gender, there was a male preponderance (male: female = 1.87:1). More than 60% of deaths were due to natural diseases (488 cases), 213 cases (26.7%) were from accidents, and 28 (3.5%) were suicide. Of the 799 cases, the cause and manner of death could not be determined in 70 cases (8.8%) after thorough death investigation and autopsy examination. Of the natural deaths, 209 subjects (26.2%) died of atherosclerotic cardiovascular diseases and 31 subjects (3.9%) died of intracranial hemorrhage. There were 113 cases (14.14%) involveding infant deaths. Asphyxia due to amniotic fluid aspiration was the most common cause of death in newborn babies. Interstitial pneumonia was the most common cause of death in infancy. Sudden Infant Death Syndrome (SIDS) was a very uncommon diagnosed cause of death in infants. The study also showed that massive bleeding after delivery was the major cause of

death in the perinatal women. Of the 799 cases, 213 cases were accidental deaths. Of the 213 accidental deaths, 42 deaths were due to motor vehicle accident, 22 deaths were due to adverse drug reaction caused by medical malpractice, most of which resulted from allergic reaction to antibiotics. There were five cases from anesthesia accidents.

In summary, this report focuses on the characteristics of the non-criminal deaths occurring in central China. Presented data indicate that atherosclerotic cardiovascular disease is the number one cause of sudden unexpected natural deaths in Wuhan, followed by intracranial hemorrhages. Interstitial pneumonia was the leading cause of death in infants. Deaths due to allergic reaction to antibiotics caused by medical negligence remain a serious health problem in China.

Forensic Autopsy, Cause of Death, Drug Reaction

G113 Pathologic Study of 125 Autopsied Cases Where Subjects Died in Custody

Xinshan Chen, PhD, Cheng Lv, MS, Kaiyi Liu, MS, and Jie Yan, PhD, Tongji Medical College, 13 Hongkong Rd, Wuhan, PEOPLE'S REPUBLIC OF CHINA*

After attending this presentation, attendees will understand relative information about death in custody in China and the fact that most of these deaths are natural without homicide and illegal factors.

This presentation will impact the forensice science community by discussing impressions of Chinese prison law enforcement.

In recent years, the people who have died in custody or during the law enforcement practices have extensively attracted public concern. The possibility of violation of human power or illegal practices by police officers and other law enforcement officers have been frequently questioned. For this reason, a retrospective study was performed on the 125 cases that died in different sites such as prison, custody, detention centers, drug addiction treatment places, interrogation rooms, detention rooms, as well as during arrest and other enforcement processes of the public security bureau, prosecutors, courts, and other units. The 125 cases were selected from the Department of Forensic Pathology, Tongji Medical College, Huazhong University of Science and Technology from 1999 to 2009. For all of the cases, a comprehensive autopsy and histo-pathological examination were performed, some of them with laboratory tests such as toxicological analysis or biochemical examination of blood. Results: (1) the cases who died in the above-mentioned sites accounted for 4.42% of cases in 11 years, and showed a declining tendency in the past four years; (2) gender and age: men (123 cases, 98.40%) obviously more than women (2 cases, 1.60%), aged between 15 and 77 years old, with young and adult male from 20 to 49 years old occupied 103 cases (82.4%), the two female cases were 23 and 42-years-old; (3) occupation: 72 cases (57.6%) were farmers; 30 cases unemployed; worker, cadre, student, and self-employed, were four, three, two, and one cases, respectively; and the remaining 13 cases were occupation unknown; (4) Duration in detention: from zero hours to five years and seven months, mostly less than one month (68 cases, 54.4%), 99 cases in six months (79.2%); (5) Interval time between death and autopsy: five hours to 209 days, of which 60 cases were within 48 hours (48%); (6) the place of death: hospital, prisons, detention centers, interrogation rooms, drug addiction treatment places, arrest and elsewhere were 79, 14, 12, 8, 3, 2, and 7 cases respectively, with the majority (63.2%) dying in hospital; (7) Cause of death: among 118 known cases, 86 died of diseases; 16 cases, mechanical asphyxia; 13 cases, mechanical injury; three cases, poisoning; (8) manner of death: 86 cases were natural deaths; 25 suicide; seven accidental death; seven unknown; and no homicide cases; and, (9) classification of diseases: in 86 cases death of of disease, 41 were from cardiovascular diseases; 17 from respiratory system diseases; nine, central nervous system diseases; eight, digestive systems diseases, and 11 cases, other diseases. This data is consistant with the facts that most criminal offenders are young and adult men, the majority of deaths are natural except for a small number of suicides and accidental deaths, and their were no homicidal cases. It is suggested that all police and law enforcement units should further strengthen education, management, and disease prevention in order to prevent suicide, accidents, and illnesses.

Forensic Pathology, Regulatory Sites, Analysis of Death

G114 When Is a Murder Not a Murder? When It's a Non-Suspicious Death!

Stuart J. Hamilton, FRCPath, Leicester Royal Infirmary, East Midlands Forensic Pathology Unit, Level 3, Robert Kilpatrick Building, Leicester, UNITED KINGDOM*

After attending this presentation, attendees will understand the problems faced by forensic pathologists in the United Kingdom (U.K.) resulting from the distinction between "suspicious" and "non-suspicious" deaths, and the steps that can be taken to reduce the risks of homicides "slipping through the net."

This presentation will impact the forensic science community by highlighting the importance of educating all professionals involved in the medicolegal investigation of death regarding the importance of suspicion that a death may be related to criminal activity at the earliest stage of an investigation.

Unlike most jurisdictions, the U.K. divides autopsy practice into "suspicious" and "non-suspicious" deaths. As a result of this, the vast majority of medicolegal autopsies undertaken in England and Wales are performed by pathologists with limited, or in many cases no experience of the appropriate approach to potentially homicidal deaths and indeed many have never even observed a "suspicious death" autopsy. Furthermore, there is a likelihood that if a death is referred for autopsy as non-suspicious, then the pathologist is falsely reassured that there is "nothing to worry about."

Of course, some potential homicides are not identified as a result of the initial investigations, and are referred for a "routine coroner's autopsy." At the very least, this can lead to compromise of forensic evidence as the scene is not preserved and the body is not transported in a manner that preserves trace evidence. The forensic autopsy may be more challenging if an autopsy has already been commenced or even completed before the death is recognized as one that may require a more detailed examination than usual.

To demonstrate the potential pitfalls of this approach to autopsy and the difficulties it causes for the forensic pathologist and the wider aspects of a criminal investigation, three relevant cases will be discussed.

In the first case, a man with a history of alcohol abuse was found dead in a moderately advanced state of decomposition with a significant postmortem interval. The death was referred for a routine autopsy and, as there were no close relatives, after the examination the body was frozen awaiting the funeral. However, as the estate was being settled, it came to light that money had been taken from the deceased's account and benefits claimed for a considerable period after he was believed to have died. A suspect for this fraud was developed but a forensic autopsy was requested to exclude "foul play" in the death as well as after it.

The second case involves a body recovered from a river. The case was investigated by a junior police officer and deemed to be non-suspicious despite external injuries that were considered to be "unexplained but not suspicious." External examination by a general pathologist apparently revealed no marks or injuries to cause concern, but on commencing the internal examination the pathologist was faced with a situation he had not considered and a forensic examination was only requested a week after discovery of the body.

The final case revolves around an unexpected death in a nursing home. On commencement of the initial autopsy, the pathologist became very concerned and asked for assistance from a forensic pathologist who was able to confirm that the death was almost certainly the result of an assault and triggered a criminal investigation.

Finally, this presentation will address the ways in which these problems can be alleviated and how the East Midlands Forensic Pathology Unit (EMFPU) in Leicester is attempting to minimize the issues by education of all the relevant professionals, from police officers to trainee general pathologists. This approach should benefit the interests of justice and prevent pathologists who are inexperienced in forensic pathology from being exposed to an adversarial justice system for which their training leaves them unprepared.

Homicide, Suspicious Death, Education

G115 The Temporal Dynamics of Autopsies and Their Impact on System Efficiency: Do Autopsies Really Come in Threes?

Carmen K. Steigman, MD, Univ of Arkansas for Medical Sciences, Dept of Pathology, 4301 W Markham St, Slot 517, Little Rock, AR 72205*

After attending this presentation, attendees will understand the temporal fluctuations in the rate of autopsies, the accordion effect as it applies to pipeline processes, and how these impact efficiencies in the practice of pathology, both forensic and hospital-based.

This presentation will impact the forensic science community by: (1) providing insight into the forces internal and external to a laboratory which affect its processes and systems; and, (2) providing a framework for developing strategies to mitigate those effects and increase departmental productivity.

Barring mass disasters or epidemics, patients for autopsy generally arrive in both forensic and hospital-based pathology departments randomly over time. Within this random framework, however, there is a definite propensity for temporal clustering of autopsies, lending credence to informal observations by pathology residents that "autopsies seem to come in threes."

This temporal clustering provides a practical example of the "accordion effect." The accordion effect is well known in traffic science, foot marching, and bicycle racing, and it can affect processes in a pipeline in general. Similar to fluid dynamics in physics, the accordion effect creates fluctuations in sequential or pipeline work processes, creating disruptions in the flow of processes following it. Using traffic as an example, say a driver changes lanes suddenly. This sudden interruption in flow, followed by many cars applying brakes, creates a so-called "stop wave," which can travel backward to delay all the cars that follow.

Autopsy pathology is generally conducted as a series of processes in a pipeline fashion, making it susceptible to the accordion effect. A typical autopsy pipeline looks like this: the autopsy is performed, tissues are submitted to a single department for histology, microscopic slides are returned to the same pathologist, who provides information to clerical personnel, who return the work to the pathologist for final revision, culminating in the issuance of a completed report. A slowdown anywhere in the system has a direct "downstream" effect on every process that follows it, similar to the backward traveling wave of delay on the highway.

When the federal government mandated prospective payment systems for Medicare reimbursement in 1983, medicine began to experience a cultural shift. Facing serious fiscal cutbacks, hospitals needed to find ways operate more efficiently to survive. For the first time, health care delivery systems began to assess efficiency and quality in medical care using tools traditionally used in industry, such as time-motion studies and total quality management techniques. Although not the recipients of Medicare funding, most forensic pathology departments are government-based and operate with limited fiscal resources and staffing. Both hospitals and forensic laboratories face substantial challenges to system efficiency, cost-effectiveness, and quality.

A historical prospective study of autopsy frequency in a university hospital pathology department between the years 2001 – 2010 was conducted. The number of autopsies varied from 63 to 107 per year. The average number of autopsies performed each month within a given year ranged from six to eight, with a range of zero to nineteen per month.

An empirical analysis of autopsy clustering, factors potentially creating ebbs and flows in the autopsy process, and how the information may help guide institutional strategies for process improvement will be presented.

Autopsies, Accordion Effect, Efficiency

G116 Till Death Do We Dye?

Sharon Rose Crowley, MN, 122 Emeline Ave, Santa Cruz, CA 95060*

The goal of this presentation is to determine a meaningful consensus on reliability and validity of this adjunct, in order to better evaluate current practice.

This presentation will impact the forensic science community by showing: (1) improved outcome in service for victims of gender-based violence, a recognized public health issue (CDC, 2009); (2) improved examination methodology, greater diagnostic acumen, more accurate documentation, and better communication between homicide investigation teams and forensic science and public health communities; and, (3) increased transparency, efficiency, communication, and reduced health disparities for marginalized groups of victims, e.g., prostitutes, victims of human trafficking, and undocumented immigrant women.

The interpretation of genital findings in the deceased is both timely and pivotal. Gender-based violence is both a domestic and global issue. The focus of the present discussion is to discuss the use of 1% aqueous toluidine blue dye as an adjunct to the evaluation of the sexual assault victim. This discussion is based on a review of the literature of toluidine blue dye in *living* sexual assault victims *and* results of dye application as part of an exploratory study on fatal sexual violence against women, using a cross-sectional, prospective design and a convenience sample of 74 females: 46 from the Body Donation Program at University of California, Davis Medical school; 18 coroner's cases; and ten homicide cases, ranging in age from 24 months to 75 years.

Toluidine blue dye, a nuclear stain, has been widely recommended, adopted as a practice standard, and often recommended in local, regional, national, and international guidelines for sexual assault victims, including the Department of Justice (DOJ), Agency for Healthcare Research & Quality (AHRQ), American College of Emergency Physicians (ACEP), New England Journal of Medicine (NEJM), World Health Organization (WHO), and the International Association of Forensic Nurses (IAFN).

With increasing frequency, new studies on genital injury in *living s*exual assault victims incorporate dye in their methodology. Each new study builds upon the assumption that both reliability and validity of the dye have been recognized. Most of these authors cite original, well-regarded studies, including Richart,[1] Collins,[2] and Lauber & Souma,[3] as foundational cornerstones. As the yield of studies expands, it may be useful to ask questions germane to accurate interpretation: Have the reliability and validity of toluidine blue dye for application on various sites of the anogenital anatomy been sufficiently studied to warrant the current recommendations and practice guidelines for examination of sexual assault victims? In this *Fatal Sexual Violence Against Women* study, most of the 46 cases from the Body Donation Program were examined with both colposcopy at 7.5X and 15X magnification and a 35mm Single Lens Reflex (SLR) digital camera.

Dye was applied to 30/46 subjects, with 100% false-positive dye uptake. Richart[1] and Collins[2] noted 23 benign conditions that caused false-positive results in their samples. Current studies often question the admissibility of evidence, e.g., reliability of colposcopy, citing *Daubert and Federal Rules of Evidence,*[4] *versus Kelly-Frye*.[5] Colposcopy is a modality of binocular microscopy, with the capacity for magnified digital, film, and/or video photographs.

Are colposcopes photographs inherently different types of physical evidence? If reliability and validity is well established for both film and digital imaging, does this transfer to images viewed through colposcopic optics and captured by cameras? Toluidine blue dye is far less costly than colposcopy. As a quality indicator, what level of influence does this have on outcome? Another consideration is an examiner's expertise. Detailed information on sexual anatomy, even in living victims, is still a young field, especially when contrasted with other forensic specialties. Less experienced examiners may benefit from methods that include magnified photographs, whether colposcopy, or other digital systems.

- In a review of the original, core, studies on toluidine blue, the following issues were found to be germane: Dye requires meticulous technique; decolorization is more important than application.
- Interpretation of findings is subjective. Richart,[1] Collins,[2] and Lauber & Souma,[3] all used *qualitative* terms, such as *deep royal blue*, (positive), or *diffuse and/or patchy uptake* (non-specific), to describe patterns of dye uptake; these are *descriptive*, but also non-specific and subjective.
- Original study findings were *confirmed by biopsy*. The majority of subsequent studies on genital injury in adult/adolescent female subjects did not incorporate *follow-up* examinations, even when acute trauma was present.

Follow-up would effectively use the victim or study subjects as their own control.

Much has been learned about sexual anatomy and injury in female sexual assault victims. Concomitantly, the capacity to compare and contrast *normal* with various other cohorts increased. Toluidine blue dye was included in the initial iteration of the *sequential methodology for postmortem genital examinations*.[6] After further study, recommendations for dye application were removed from later iterations and publication.[7] A review and consensus by subject matter experts could evaluate the pivotal issues of reliability and validity. Such a panel could also facilitate the comparison and contrast of "cornerstone" results to those of recent studies. Individual anatomic sites could be reviewed for histological similarities/differences, to help determine appropriateness, applicability, and generalizability.

The ultimate goal of this endeavor is to improve the understanding of what is *normal*, *and what is not*, for the anogenital anatomy during the postmortem interval. The astute examiner must perform these examinations with optimal expertise and chronicle vital data. In this manner, the capacity to understand fatal sexual violence against women will continue to grow.

Gender-Based Violence, Toluidine Blue Dye, Colposcopy

G117 An Unusual Mechanism of Bladder Fluid Absorption With Fatal Fluid Overload in "Predisposed" Patient

Valentina Bugelli, MD, Univ of Pisa, Via Roma 55, Pisa, ITALY; Benedetta Guidi, MD, Hospital of Lucca, Operative Unit of Legal Medicine, Via Santa Dorotea 1, Pescia, ITALY; and Marco Di Paolo, MD, Univ of Pisa, Via Roma 55, Pisa, ITALY*

After this presentation, attendees will be aware of the possible clinical and legal implications following urothelial damage and fluid absorption

This presentation will impact the forensic science community by showing an unknown mechanism of fluid absorption with remarkable risk of complications due to fluid overload in "predisposed" patients.

An 85-year-old man had been undergoing hemodialysis treatments three times a week for the past three years. He was a water-controlled patient, not self feeding. One day he presented hematuria and the doctors decided to perform a continuous bladder irrigation. During the first day of irrigation, the patient did not have any problems and underwent his hemodialysis treatment as usual. Twenty-four to thirty-six hours after hemodialysis, while still undergoing irrigation, the patient gained 7.4kg. His wife said that the fluid introduced by bladder irrigation was not expelled, so the only explanation of this weight gain was the bladder irrigation procedure. Blood test results were as follows: Na^{+} 130 ↓ *(vn 130-148 mEq, intermedial data T1: 111, T2: 116, T3: 126),* $HCO3^{-}$ 19,8 ↓ *(vn 23-25 mEq, intermedial data T1: 16,2, T2: 17,8, T3: 22,5);* Ph 7.36 ↓ *(vn 7.35-7.45, intermedial data T1: 7.23, T2: 7.34, T3: 7.38),* PCO_2 98 *(VN 38-42 mmHg).* These data show a mixed acidosis due to hypervolemia, responsible for the reduction of sodium and HCO3- and for the development of pulmonary edema which led to an alteration of the ventilation and a CO_2 increase. Unfortunately, the clinical situation deteriorated rapidly and the patient died. The autopsy revealed hypertensive heart disease with increase in weight (660g); the lungs weighed 790g (right) and 590g (left) and were congested and edematous. There was a presence of coagulated blood and heavily congested mucosa in the bladder.

Histological examination of the bladder revealed the absence of the urothelium, with tunica propria affected by a series of alterations likely to be explained in the context of an erosive inflammation (necrotizing). Correct functionality of urothelium is fundamental because it is impermeable to fluid, thus being an effective barrier against the passage of osmotic fluid from blood into urine, and has the capacity to adapt to the bladder volume. Damage or loss of the epithelial surface by chemical, mechanical, or other mechanisms implies a reduction or total loss of this important insulation function provided by an intact urothelium.

A condition of abnormal resorption at the vesico-urethral level can occur during TURP: transurethral incision may determine vascular lesions, creating conditions for the absorption into the circulation of the liquid used for washing during surgery. Resorption can determine the onset of actual pathological syndrome, even a serious one, defined precisely as TURP syndrome.

In conclusion, the loss of the urothelium led to an alteration in the permeability of the bladder and to an abnormal resorption of fluid resulting in hypervolemia. This was the cause of mixed acidosis and massive pulmonary edema which led to *exitus*.

Bladder Absorption, Hypervolemia, Acidosis

G118 Fatal "Shaken Adult" Syndrome? A Case Report of an Elderly Patient

Pierre-Antoine Peyron, MD, Service de Médecine Légale, CHU Lapeyronie, 371 Ave Doyen Gaston Giraud, Montpellier, FRANCE; Cécile Bonnafoux, MD, Unité Médico-Judiciaire, CHU Carémau, Place du Professeur Robert Debré, Nîmes, FRANCE; and Anne Dorandeu, MD, Céline Leconte, MD, Philippe Cathala, MD, and Eric Baccino, MD, CHU Lapeyronie, 371 Ave Doyen Gaston Giraud, Montpellier, FRANCE*

After attending this presentation, attendees will be aware that shaking an elderly person's head might be fatal, causing brain damage in a way similar to shaken infants, and that a subdural hematoma of unknown origin in the elderly should raise the possibility of abuse.

This presentation will impact the forensic science community by raising awareness of the possibility of the existence of a new forensic pathology entity which might be called "Shaken Granny Syndrome." This will participate in a more global goal which is to increase the awareness of prevalence of elder abuse, clearly underestimated, in the forensic community.

An 81-year-old man suddenly lost consciousness and collapsed after a 45 minute quarrel with his wife and her lover, who reported to the police that they shook him back and forth several times, by grabbing his clothing, his shoulders and arms, without any blow to the head. Despite swift rescue action, he was pronounced dead at the scene.

He had been prescribed anticoagulants for a pulmonary embolism for years and an MRI, taken six months before death for behavior and memory disorders, showed extensive grey matter atrophy.

The autopsy performed the next day showed only recent bruising of the anterior chest and upper limbs. There was no hematoma of the inner aspect of the scalp, no fracture of the skull. A "fresh" subdural hematoma of eighty milliliters, non-adherent to the dura matter and located in the left hemisphere, was found without brain contusion at the macroscopic exam. Besides a non-occlusive coronary atherosclerosis, the other internal organs were unremarkable. Toxicology was negative (presence of treatments at therapeutic levels).

Basic histological examination showed a neutrophilic infiltrate of the bruising, thus considered as peri-mortem. The subdural hematoma was mainly composed of non-lysed red blood cells, which was consistent with an acute and recent onset. A minor subarachnoid hemorrhage and some cortical "flame-shaped" hemorrhages were found, suggesting that the subdural bleeding was traumatic. There was, however, no focal contusion of the brain and, therefore, no argument in favor of a direct trauma of the head. Histological examination of the other organs was noncontributory.

Selected brain sections were prepared for complementary immunohistochemical examination using β Amyloid Precursor Protein (β-APP) antibody, showing Diffuse Axonal Injury (DAI) scattered in different brain areas. Eyeball collection not being (so far) a routine procedure in adults, was impossible to check for retinal hemorrhages (the interest of which will be discussed during the presentation, focusing on specificity concerns). Cause of death was classified as "traumatic brain lesions and hemorrhage," and manner of death as "homicide."

In this case, trauma was considered the result of acceleration-deceleration forces due to brutal movements of the head secondary to violent shaking.

The Shaken Baby Syndrome is well known, but a literature review showed that the "Shaken Adult Syndrome" is still to be described. Only one case of a young adult who died from brain damage after his head was violently shaken during police custody was found during this study.[1] In the absence of the research of DAI, this case was questioned.[2]

Because of anticoagulant prescriptions, weakness of cervical muscles and some extra space between the brain and the cranial bone due to cerebral atrophy (with tensioning of the bridging veins within the subdural space), this case shows some similarities with the conditions found in the physiopathology of the "Shaken Baby Syndrome".

These conditions being often met in the oldest patients, the concept of "Shaken Elderly or Granny (rather than adult) Syndrome" might be relevant. This is of special interest when one considers that in some series, 10% of subdural hematomas of the elderly are "spontaneous", i.e., of unknown origin, the hypothesis of physical abuse being then exceptionally (or never) raised in the publications.[3]

Further studies are needed to better characterize the prevalence of subdural hematoma in elder abuse and the percentage of cases related to "shaking."

Subdural Hematoma, Elder Abuse, Shaking

G119 Autonomic Nervous System and Sudden Death

Enrico A. Risso, MD, Via Alfredo Catalani 10/26, Genoa, ITALY; and Dragan Primorac, MD, PhD, 471 Wolcott Ln, Orange, CT 06477*

After attending this presentation, attendees will improve their understanding about "unexplained" sudden deaths with negative autopsy findings caused by the activation of the utonomic nervous system, as well as cardiac deaths following injuries to other organs and related to the effects of the autonomic nervous system.

This presentation will impact the forensic science community by providing detailed knowledge about the most common mechanisms of death following activation of the autonomic nervous system.

Although the cardiovascular system is often considered a unique physiological entity, the evidence of a link between sudden cardiac death and autonomic nervous system is compelling. It is in fact well recognized that physical and emotional stress (such as anxiety or anger) may lead to sudden death as a result of arrhythmias, myocardial ischaemia, and infarction. Experimental evidence from human and animal models proves that stimulation of certain brain areas (mainly the insular cortex, the infralimbic cortex, and the amygdala) or sympathetic efferent fibers to the heart can produce fatal abnormaities of the heart rhythm. Psychiatric diseases are also known to cause sudden cardiac death. There is integration between the limbic system and the cortical autonomic "control sites." Circuitry between these areas might result in abnormal electrical stimulation to the SA node resulting in sudden death.

This catastrophic event is known to be responsible for more than 300,000 sudden cardiac deaths every year in the United States. The majority of victims are thought to have suffered ventricular tachycardia or ventricular fibrillation. Several clinical and experimental studies suggest that heart rate variability and baroreflex sensitivity are the most reliable predicting factors for possible future cardiac events.

Central autonomic dysfunctions causing cardiovascular complications such as ECG changes, cardiac arrhythmias, ischaemic damage to the myocardial muscle, and disturbances of blood pressure regulation might often occur as a result of brain injuries or acute cerebrovascular disease. These often life-threatening complications are thought to be due to increased sympathetic tone with subsequent elevation of circulating catecholamines. Several experimental and human studies have suggested that the most

arrhythmogenic areas, if injured, are the prefrontal areas or the insula. These brain structures might also give rise to further cardiac complications involving heart rate variability and possible heart failure. Although head trauma-induced heart rate variability has been recently studied with modern techniques, cardiac complications following brain disease are now being redefined.

The ECG changes following brain damage or ischaemia can often mimic myocardial ischaemia. The most commonly described abnormalities are regarded to be ST segment depression, flat or inverted T waves, prolonged QT intervals, and U waves. These phenomena have been proved to be due to autonomic nervous system reaction to the brain disease, and are not related to any kind of heart or coronary artery disease. In comparison with cardiac related ECG changes, these seem to appear later, with a peak about two days later from the cerebrovascular event (or trauma) and revertion within two weeks. It is interesting that, although in the majority of cases the ECG changes do not reflect real myocardial damage, sometimes macroscopic and microscopic changes to the myocardium have been observed at autopsy without coronary artery disease. These changes were observed to be myocardial necrosis with histiocytic infiltration, subendocardial hemorrhage, and myofibrillar degeneration.

Sudden Death, ANS, Forensic Autopsy

G120 Plaque Morphology in Subjects With Coronary Disease Who Suddenly Died

Emiliano Maresi, Francesca Portelli, MD*, Francesco P. Busardo, MD*, Nicola Gesualdo Patti, MD, Cettina Sortino, MD, Eluisa La Franca, MD, and Antonina Argo, MD, Univ of Palermo, Via Del Vespro 127, Palermo, ITALY*

After attending this presentation, attendees will be able to better understand the main pathological features of atherosclerotic plaque and pathogenesis of artery thrombosis in coronary sudden death.

This presentation will impact the forensic science community by increasing awareness that Sudden Coronary Death (SCD) depends frequently on active atherosclerotic lesions.

Most of Acute Coronary Syndromes (ACS) are precipitated by luminal thrombi, which arise from three different plaque morphologies: rupture, erosion and calcified nodules. Of these, plaque rupture is the most frequent, accounting for 60 – 75% of cases. The purpose of the present study was to determine the frequency of active and inactive coronary lesions and Myocardial Infarction (MI) in people with SCD.

SCD is defined as a sudden unexpected death within one hour of onset of acute symptoms from a stable medical condition or the death of a person who had been seen in stable condition less than 24 hours antemortem. No other potentially lethal cardiac or noncardiac cause of death could be present, including toxicology screening. The presence of acute thrombosis (collections of platelets, fibrin, and trapped erythrocytes and white blood cells) and disrupted coronary plaques (disruption of the luminal fibrous cap with fissure or rupture into a lipid core) was noted. An active coronary lesion was defined by the presence of a disrupted coronary plaque, luminal thrombus, or both (luminal thrombus in the area of a ruptured plaque). An inactive lesion had a luminal stenosis ≥75%, but lacked both plaque disruption and thrombus. Organized thrombi consisted of granulation tissue and recannalized channels within the arterial lumen with or without fibrin. Healed MI was identified by focal macroscopic replacement of the myocardium by scarring, with histological confirmation. Acute MI was diagnosed by the presence of coagulation necrosis with or without an associated inflammatory infiltrate.

The distribution of coronary lesions for the entire group of hearts (166 cases) was: acute thrombosis in 87 (53%), disrupted coronary plaque (with or without acute thrombosis) in 54 (32%), and organized thrombus in 25 (15%). There were also active coronary lesions in 49 cases (30%). The association of thrombosis and disrupted coronary plaque was as follows: acute thrombosis with plaque disruption in 49 cases (30%) and acute thrombosis without plaque disruption in 38 (23%). Disrupted plaque without acute thrombosis was identified in 5 cases (3%) among the 72 coronary lesions with ≥75% luminal stenosis. Plaque hemorrhage of any size was present in 96 cases (58%); of these, plaque hemorrhage occupying ≥25% of total plaque area was identified in 89 (54%). Thus, SCD could be attributed to active coronary lesions (thrombus, disrupted plaque, or both) in 141 cases (85%). There were 22 cases (13%) without an active coronary lesion which had an acute (two cases) or healed (20 cases) MI. In the 34 cases without an acute or a healed MI, 17 (50%) had only inactive coronary artery lesions such as severe atherosclerosis without acute coronary thrombosis or plaque disruption. The examination of the myocardium revealed acute MI only in 16 hearts (10%), both acute and healed MI in 18 (11%), healed MI in 68 (41%), and the absence of MI in 63 (38%). In hearts with acute MI, the infarct was identified macroscopically in 9 of 27 cases. Of these 27, there was a transmural infarct in 20 cases and subendocardial in seven cases. Platelet-fibrin emboli in small intramyocardial coronary arteries were found in 13 cases (8%) and only in cases with an acute coronary thrombosis.

Acute changes in coronary plaque morphology (thrombus, plaque disruption, or both) were found in 85% of SCD cases. In hearts with myocardial scars and no acute infarction, active coronary lesions were identified in 31 (46%) cases. Neither myocardial infarction (acute or healed) nor active coronary lesion was present in 38 (53%) cases.

Sudden Death, Atheroscler Plaque, Myocardial Infarction

G121 Aneurysms of the Coronary Arteries and Sudden Death: Three Case Reports

Francesca Portelli, MD, Francesco P. Busardo, MD, Paola Pugnetti, MD, Alessandra Maltese, MD, Giuseppina Garozzo, MD, and Emiliano Maresi, Univ of Palermo, Via Dei Nebrodi 64, Palermo, ITALY*

After attending this presentation, attendees will be able to better understand the main pathological features and pathogenesis of Coronary Artery Aneurysms (CAAs) in atherosclerotic—one case, and Kawasaki Disease (KD)—2 cases.

This presentation will impact the forensic science community by increasing the awareness that CAAs bear a significant risk of sudden cardiac death and that their development depends on transmural vascular inflammation.

CAAs are rare with an incidence of 0.02% to 0.04% in the general population. They are most commonly associated with the male gender and hyperlipidaemia. The proximal right coronary artery seems to be predominantly altered. About one-fourth of these patients have multiple coronary aneurysms. CAAs most commonly develop secondary to atherosclerotic coronary artery disease. Some CAAs are described as congenital and are linked to KD. Other circumstances are rather exceptional (trauma and dissection, infectious, scleroderma, connective tissue disorders such Marfan or Ehlers-Danlos syndromes and lupus, neurofibromatosis, periartheritis nodosa, and Takayasu's arteritis). Intraluminal (parietal or occlusive) acute thrombosis is found in 75% of the aneurysms with possible development of myocardial ischaemia and Sudden Death (SD). SD may also occur subsequently after rupture of CAAs and cardiac tamponade.

The first case regards a 3-month-old Italian male baby who, three days after the compulsory vaccination and antipyretic administration to calm the feverish condition, gradually showed eyelid conjunctival and lip erythema, diffuse cutaneous exanthema, and pharingo-tonsillitis associated to staring episodes. At admission, his temperature was 39°C and the hemato-chemical data were: erythrocytes $3.51x10^6$/uL; leukocytes $9.92x10^3$/uL; platelets $626x10^3$/uL; alcaline phosphatase 334 IU/l, PCR 7.85mg/dl; ALT 49IU/l. An echocardiogram showed a diffused hyperechogenic right coronary, dilated in the proximal tract with a 4mm aneurismal margin; hyperechogenic left coronary, dilated at the level of the common trunk,

with an aneurysmatic aspect at the level of the first tract of the anterior interventricular septum; moderate pericardial effusion; well preserved myocardial contractility. Death suddenly occurred nine days after admission. The autopsy revealed that death was due to cardiac tamponade subsequent to aneurysm rupture of the anterior descending coronary, the wall of which showed active transmural lymphomonocytic inflammation. The second case regards a 2-month-old male Indian infant. The infant showed signs of rhinitis and coughing associated with conjunctival hyperemia and allergic exanthema on the chest and arms. Laboratory analyses showed: leukocytosis (15.370/mm^3), elevated sedimentation rate; positive C-reactive protein, and thrombocytosis (476.000/mm^3). Klebsiella pneumoniae was isolated from the urine and an antibiotic therapy was started. Coughing, rhinitis, exanthema, and conjunctivitis progressively decreased until they disappeared, while laboratory tests showed an increase in phlogosis indices. Death came suddenly and unexpectedly on the seventh day of recovery. The autopsy revealed that death was due to cardiac tamponade subsequent to aneurysm rupture of the anterior descending coronary, the wall of which showed active transmural lymphomonocytic inflammation.

The third case concerns a 66-year-old man with a history of ischaemic heart disease and stroke cerebri, who entered the emergency area in a stupor state. The patient became comatose (Glasgow Coma Scale: 5) and the brain CT scan demonstrated a hyperdense right middle cerebral artery with a flattening of the cortical sulci along with signs of a suffering chronic hypoxia and after effects of an extensive malacic bilateral frontal area. The death occurred four hours after recovery. The autopsy showed a diffuse fibro-atheromasic thickening of the walls of the subepicardial coronary arteries which appeared focally aneurysmatic along with occlusive endoluminal thrombosis and chronic transmural flogosis.

The pathomechanism of CAAs remains a controversial topic of discussion. Weakened media of the coronary wall with a diminution of its elastic elements in areas of severe atherosclerotic plaques, and intraluminal pressure against the defective vessel wall, allow the vessel to dilate progressively. Not only does the chronic transmural inflammation destroy the media which represents the pathomechanism of CAAs in KD, but also makes an analogous possible pathway in atherosclerotic aneurysms. Our cases show that CAAs are an independent predictor of mortality because their development depends on the possible transmural extent of intimal (in atherosclerotic disease) and adventitial in KD inflammation. MRI represents the best diagnostic tool for identifying this rare pathological evolution.

Coronary Aneurysms, Atheroscler Disease, Kawasaki Disease

G122 Sudden Cardiac Death Due to Acute Coronary Artery Dissection Following Exercise-Related Blunt Chest Trauma: A Case Report

Marie Barbesier, MD, Catherine Boval, MD, Jacques Desfeux, MD, Catherine Lebreton, MD, Georges Leonetti, PhD, and Marie-Dominique Piercecchi-Marti, PhD, CHU La Timone, Service de Médecine Légale, 264, Rue Saint Pierre, Marseille, FRANCE*

After attending this presentation, attendees will learn about an unusual case of unexpected cardiac death during sports activities due to an acute coronary artery dissection following blunt chest trauma.

This presentation will impact the forensic science community by increasing awareness of sudden cardiac death following a blunt chest trauma occurring during sports activities.

The case is presented of a healthy 43-year-old man who suddenly collapsed ten minutes after the beginning of his sporting activity, kung fu. Despite resuscitation efforts by paramedics, the patient never regained a cardiac rhythm and expired. Review of the decedent's hospital records revealed that he had no specific past medical history. A forensic autopsy was performed 48 hours after death. At the external examination, the body showed embalming. There were also some contusions on the upper limbs, and one contusion on the left lateral chest area. Area of hemorrhage were found next to the left lateral fourth, fifth, and sixth intercostal spaces and anterior to the left second. The aortic arch and the descending aorta was normal and without coarctation. The heart weighed 410g which was within the normal reference range, and it had unremarkable myocardium and cardiac valves. The coronary arteries were present in a normal distribution with a right dominant pattern. An area of hemorrhage next to the proximal segment of the left anterior descending artery was observed. The other coronary arteries were without abnormalities. The lungs were edematous and their cut surfaces were congested. The gross examination of the left anterior descending artery showed a thick, recent adventitial hemorrhage surrounding the proximal segment with luminal obstruction by hemorrhage. Histological examination of the left anterior descending coronary artery revealed an acute dissection between the inner four-fifths and outer one-fifth of the media with collapse of the lumen due to blood in the false channel. Histologic examination revealed no evidence of inflammation, medial degeneration, or vasculitis. The arterial wall not involved by the dissection was otherwise unremarkable. An elastic stain showed essentially normal elastic fibers. In addition, the postmortem toxicological screening was negative. The death was attributed to an acute dissection of the left anterior descending artery resulting in an acute myocardial ischemia.

The heart's position between the sternum and vertebral column makes it vulnerable to injury from blunt chest trauma. Cardiac injuries after blunt chest trauma are various, including myocardial contusion or hemorrhage, arrhythmia, cardiac rupture, valvular injury, and acute myocardial infarction. Road traffic accidents are mainly responsible for blunt chest trauma and heart injury. Coronary artery dissection following blunt chest trauma is rare and is even less common in the setting of a contact sport such as kung fu. Coronary artery dissection following blunt chest trauma typically involves the left anterior descending artery; the probable explanation is its vulnerable anatomic position on the anterior part of the heart. The second most commonly affected artery is the right coronary artery. Although rare, left circumflex coronary artery involvement has also been reported. Shearing forces during the traumatic episode probably cause intimal tears of the most vulnerable part of the left anterior descending artery, which subsequently initiates the process of thrombus formation. Cases of coronary artery dissection have been described after practicing rugby, soccer, basketball and water-skiing. It is assumed that this is the first report of acute coronary artery dissection leading to sudden death following the practice of martial arts. The martial arts are considered relatively safe compared to many other sports, including football, basketball, and wrestling, and most martial arts injuries reported in the literature are minor. Indeed, the most common types of martial arts injury are sprains, strains, and contusions, and the less common injuries include fractures, dislocations, and dental injuries.

In conclusion, the forensic pathologist may be aware of the possibility of sudden cardiac death in a context of martial arts practice, and that martial arts are mistakenly considered safer than most.

Coronary Dissection, Sports, Blunt Chest Trauma

G123 Evaluation of Prevalent Ischemic Damage at the Right Ventricle Compared to the Left One: Improvement of a Diagnostic Tool for the Diagnosis of Fatal Pulmonary Fat Embolism?

Tony Fracasso, MD, CMU-Centre Univ, Romand de Medecine Legale, Rue Michel-Servet 1, Geneva, SWITZERLAND; Sara Sabatasso, MD, Univ Center of Legal Medicine, Univ Hospitals of Geneva, 9, Ave de Champel, Geneva, SWITZERLAND; Bettina Schrag, MD, Hopital du Valais, Institut Central, Medecine Legale, Ave du Grand-Champsec 86, Sion, SWITZERLAND; and Patrice Mangin, MD, PhD, Centre Univ, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, SWITZERLAND*

After attending this presentation, attendees will improve their knowledge on the physiopathology and pathology of cardiac damage after pulmonary Fat Embolism (FE). They will learn how immunohistochemistry can be helpful in the diagnosis of fresh ischemic cardiac changes and they will learn how to interpet right ventricular ischemia in cases of pulmonary FE.

This presentation will impact the forensic science community by providing a useful tool for a better diagnosis of fatal pulmonary fat embolism.

FE is a common complication of blunt force injuries occurring in major traumas, especially if fractures of long bones are present. In cases of fulminating FE, the sudden massive obstruction of the pulmonary circle determines a rapid and often lethal increase in the impendence to right ventricular ejection with subsequent right heart ischemia and failure.

Recently proposed was a method to evaluate the occurrence of prevalent right ventricular ischemia determining acute right heart failure in cases of severe pulmonary FE. This method allows the morphological diagnosis of primary right heart failure due to acute persistent pulmonary obstruction. The major limits of this work are bound to its retrospective character: in relatively few cases of pulmonary FE, immunohistochemical investigations were performed on available paraffin-embedded blocks of cardiac tissue, collected at autopsy on the basis of a routine sampling protocol without an extensive systematic investigation of different anatomical regions. The study presented here has different goals. First, the preliminary study was investigated to show a more consistent number of cases in a prospective protocol. Another area of intrest was to study whether right ventricular damage is homogeneously distributed in the different regions of the right ventricle in cases of severe fatal FE. Finally, the question of the role of this method as a potential tool in the improvement of the medicolegal diagnosis of fatal pulmonary embolism was addressed during this study.

In a prospective study 220 consecutive autopsy cases performed at the University center of legal medicine in Geneva (Switzerland) between July 2010 and March 2012 were investigated. In each case, eight cardiac regions (anterior, lateral and posterior wall of the right and the left ventricle, anterior and posterior part of the interventricular septum) were sampled and standard histology staining (hematoxylin and eosin, Masson's trichrome) were performed. Moreover, immunohistochemical reactions with the antibodies against Fibronectin and the terminal complement complex C5b-9 were performed. FE was determined by means of frozen sections of the lungs (one sample from each lobe was collected and investigated), the central nervous system (one sample from the cerebral and cerebellar cortex and from the pituitary gland was collected and investigated), and the kidneys (one sample from each organ). The frozen sections were stained by oil red O staining.

The slides were investigated by two different observers with final consensual evaluation. In case of discord, a third forensic pathologist gave his advice and was allowed the final decision. Classical histology signs of fresh cardiac damage such as hypereosinophilia, presence of contraction bands, myocytolysis, fragmentation of the cardiomyocytes, interstitial bleeding, and inflammatory infiltrates were systematically searched and classified into four degrees (abstent, weak, moderate, and severe). Similarly, the immunohistochemical reactions against the antibodies Fibronectin and C5b-9 were classified into four degrees (negative reaction, single cell reaction, group cell reaction, and diffuse reaction). The degree of FE was determined following the method proposed by Falzi.

In this presentation, the results of this study will be presented and the implications for the routine medicolegal investigations will be discussed.

Fat Embolism, Right Ventricle, Ischemia

G124 Acute Eosinophilic Myocarditis in a Churg-Strauss Syndrome Case Treated With Montelukast: Immunohistochemical Study to Explain Pathophysiology

Irene Riezzo, MD, PhD, Dania De Carlo, MD, Benedetta Di Battista, MD, Gabriela Perilli, MD, and Emanuela Turillazzi, MD, PhD, Univ of Foggia, Viale degli Aviatori 1, Foggia, ITALY*

The goal of this presentation is to present an uncommon fatal case of acute eosinophilic myocarditis in a 18-year-old man with Churg-Strauss Syndrome (CSS) treated with Montelukast. A complete methodological forensic approach by means of autopsy, histological, and immunohistochemical examinations led us to the conclusion of for a CSS with massive cardiac involvement.

This presentation will impact the forensic science community by showing how the absence of specific symptoms of cardiac involvement in a multiorganic CSS in active phase can make an early diagnosis difficult. This case report illustrates the importance of early diagnosis of CSS and underlines the possible relationship between LRA and CSS and its etiopathogenetic mechanism.

CSS is a systemic vasculitis with multiorganic involvement and represents a rare disorder with an incidence between 1.3 and 6.8 cases per 1,000,000 patients per year. It evolves through a prodromal phase characterised by asthma and atopic allergies (rhinitis) and eosinophilic infiltrative disease, a second phase with eosinophilic infiltration of tissues, and a third phase (vasculitic) characterized by systemic vasculitis. Three main histological features characterize it: necrotizing vasculitis, tissue infiltration by eosinophils, and extravascular granulomas. All organs may be involved (peripheral nerves, lungs, skin), but severe gastrointestinal, renal, cardiac, and central nervous system manifestations are associated with a poor prognosis. The heart is the major target (16% – 50% of cases) and its involvement is the major cause of death in CSS (48%), usually associated with an ANCA-negative status. Cardiac disease includes myocarditis, coronary vasculitis, valvular heart abnormalities, congestive heart failure, and pericarditis. The aetiology and pathogenesis of eosinophilia and tissue damage is unknown. On a cellular level, a strong shift toward a Th2-like response with massive T-cell activation and IL-4, IL-13, IL-10, and IL-5 production is evident. CSS patients usually have high serum levels of IgE. In the active phase, high levels of eotaxin-3 (a chemokine-involved organ damage) were found. The diagnosis of CSS is problematic, because none of the disease features are themselves pathognomonic and the numerous findings may have presented and evolved over a period of years. There are six clinical criteria proposed by the American College of Rheumatology (asthma, blood eosinophilia greater than 10% on differential white blood cell count, mono or poly neuropathy, migratory or transient pulmonary infiltrates detected radiographically, paranasal sinus abnormality, biopsy containing a blood vessel with extravascular eosinophils) with four being necessary for CSS to be diagnosed. However, these criteria are not pathognomonic in the absence of histologically proven vasculitis (eosinophil-rich and granulomatous inflammation involving the respiratory tract and

necrotizing vasculitis associated with asthma and eosinophilia). There are two different phenotypes, one "vasculitic," with manifestations due to small-vessel vasculitis (purpura, mononeuritis multiplex, glomerulonephritis), and one "eosinophilic," in which organ damage mainly results from tissue eosinophilic infiltration (pulmonary infiltrates, cardiomyopathy). ANCA positive patients usually show a more vasculitic phenotype. Although CSS is a rare disease, the number of reports increased in the last two decades after Leukotriene Receptor Antagonists (LRA) became available. In fact, in recent years several studies have reported the possible relationship between use of LRA and CSS expression. However, whether these drugs have a direct pathogenic role remains controversial.

Reported is a case of an 18-year-old man who was found lifeless at home in the bathroom by his parents. During the night he presented sweats, pain, and numbness in the leg. The extended family hadn't a history of sudden death or atopic disease. Two years before rhinitis, sinusitis, eosinophilia, and, above all, asthma were compared and treated with corticosteroids, antibiotic and antileucotrienic therapy (montelukast). The prick tests were negative. Serologic and PCR tests were negative for respiratory viruses and for *Legionella*, *Chlamydia,* and *Mycoplasma*. ANCA blood test was negative; the serum concentration of IgE was high. The last CT scan revealed bilateral ground-glass nodular lung opacities.

A complete postmortem examination was performed. The internal examination revealed only a polivisceral congestion and pulmonary edema. The surface of the heart showed opacity of the epicardium. The heart had a normal shape, size, and weight. The coronary arteries were normal and without significant stenosis or thrombotic occlusion. The valves were not thickened. The myocardium was flabby and pale with scattered patches of red and yellow-gray discoloration. The histological examination of the heart revealed diffuse and extensive infiltration by eosinophils with extensive loss of myocardial cells, pericarditis, necrotizing eosinophilic vasculitis, including small and epicardial coronary arteries, and colliquative myocytolysis.

The lungs showed eosinophilic pneumonia, necrotizing vasculitis with intimal and medial infiltration by eosinophils and extravascular granulomas, consisted of epithelioid macrophages and giant cells around large necrotic centers in a densely packed area of eosinophils with presence of the specific granules and nuclear debris. These granulomas were surrounded by eosinophils. The kidneys showed scattered necrotizing vasculitis and infiltration by eosinophils. Other organs, including the brain, showed no lesions.

An immunohistochemical examination of heart, lung, and kidneys samples with antibody anti CD4, CD8, CD45, EMBP (eosinophil major basic protein), IL10, TNF-alfa, and anti eotaxin-3 was performed to confirm diagnosis. The death was attributed to acute heart failure due to acute eosinophilic myocarditis in CSS.

Churg-Strauss Syndrome, Eosinophilic Myocarditis, Montelukast Therapy

G125 Sudden Unexpected Death of a Teenager Due to Peripheral T-Cell Lymphoma

Evan Himchak, BS, and Valerie A. Fitzhugh, MD , Univ of Medicine and Dentistry of New Jersey, 150 Bergen St, Newark, NJ 07101; and James B. Conway, and Abraham T. Philip, MD, Regional MEO, 325 Norfolk St, Newark, NJ 07103*

After attending this presentation, attendees will learn of an unusual hematological malignancy that caused the sudden and unexpected death of a 13-year-old girl, who had no prior clinical history or diagnosis of the condition.

This presentation will impact the forensic science community by highlighting a previously unreported cause of sudden, unexpected death of a teenager. This presentation will include a brief review of the classification schemata currently used by hematologists and oncologists for these type of malignancies and cluster differentiation markers used to establish the diagnosis.

The decedent, a 13-year-old female, was having a sleepover at the home of friends, whom she and her parents knew from church. At 2:00 a.m., she reportedly complained of chest and back pains and began to vomit. She requested the host family call her parents, as she wished to go home. Her mother and stepfather rushed to the place where she had her night out with friends. By the time her parents made the 12.5-mile 25 min trip, she had vomited several times and had become unresponsive. She was rushed to the hospital, where she was pronounced dead. During an in-depth forensic investigator interview, it was later revealed that she had complained of episodic chest pains for approximately two months. The pains were described as spasmodic chest and back pains, which started and resolved spontaneously. She was otherwise a normal child coping with scholastic challenges and playing soccer as part of her athletic curriculum. Her older male sibling had a childhood heart murmur, details unknown, which had resolved with age. Her biological father also had a heart murmur, not otherwise specified.

At autopsy, the decedent was of appropriate build and nutrition. Her heart at initial dissection revealed a thickened aorta when it was cut proximal to the arch. On further examination, the aorta was thickened at its origin, with extreme narrowing of the coronary ostia. The thickening also involved the pulmonary artery and the left atrium. Within the left atrium, the tumor had eroded the myocardium creating a 1cm defect in the anterior leaflet of the mitral valve, near the valve annulus. Histological sections revealed sheets of small-to intermediate-sized blue cells encasing the aorta, parts of the pulmonary artery, the left auricle and the mitral valve. The initial differential diagnosis suggested a Ewing sarcoma/primitive neuroectodermal tumor, lymphoma, or a rhabdomyosarcoma. The blue cells were strongly reactive to CD 45 and CD 3 with focal reactivity to CD 20, CD 99, and BCl-2. The tumor was diagnosed as a Peripheral T-Cell Lymphoma (PTCL).

The sudden, unexpected, death of an apparently healthy teenager is always tragic. Epidemiological studies on deaths in children under 20 years of age has a bimodal distribution with a large cluster under the age of 4 years and another large cluster in the 14 to 20-year-age groups. Much has been published about the causes of death in these two groups. A preliminary search of the English language literature revealed no cases of sudden, unexpected deaths due to hematological malignancy in the 6 to 14-year-age groups. In the United States, of the malignant lymphomas, the T-cell sub types are much fewer than those bearing B-cell markers. A British survey based on the tumor registries of England, Scotland, and Wales over a 20 year period identified 25 cases of T-cell lymphomas, comprising 1.6% on Non-Hodgkin's lymphoma registrations. PTCLs are extremely rare in children and very little is known about their natural history, therapeutic options, or prognostic indicators.

Sudden Death, Teenagers, Lymphoma

G126 Motor Vehicle Crash Involving an Elderly Woman With Undiagnosed Giant Cell Myocarditis

Jerri McLemore, MD, Wake Forest Univ, Medical Center, Dept of Pathology, Medical Center Blvd, Winston-Salem, NC 27157*

After attending this presentation, attendees will be able to debate proposed National Association of Medical Examiners (NAME) standards for investigations of motor vehicle crash fatalities and be able to identify the histologic pattern of giant cell myocarditis.

This presentation will impact the forensic science community by discussing some of the controversy surrounding creation of autopsy performance standards for investigation of motor vehicle crashes.

A 92-year-old woman was traveling down a residential street when her vehicle impacted a maintenance vehicle on railroad tracks

that crossed perpendicular to the road. No evasive action or braking was noted. Externally, she had obvious long bone fractures of the lower leg and forearm, but no other potentially lethal external trauma was noted.

With recent proposed changes to autopsy performance standards from NAME regarding autopsies of drivers of motor vehicle crashes where no external trauma to account for death is present, an autopsy was conducted. At autopsy, internal exam revealed a large pericardial sac laceration and a right atrial laceration with an associated 1200ml. right hemothorax and right-sided rib fractures. Medical disease apparent on gross examination was significant only for mild coronary arterial atherosclerosis and no acute gross anatomical findings to account for death other than the injuries.

Per recent proposed changes for the NAME histological examination autopsy performance standard recommending histological exam when no cause of death is forthcoming on gross or toxicological exam or based on circumstantial evidence, submission of tissue for microscopic examination would not have been necessary. Because of the academic nature of this institution; however, histology is routinely performed on all major organs including the heart in the vast majority of autopsies. Unexpectedly, histological examination of the heart revealed a diffuse, multifocal, mononuclear inflammatory infiltrate with abundant eosinophils and rare, poorly formed granulomas with multinucleated giant cells within the interstitium, focally migrating into the surrounding myofibrils within the interventricular septum and left ventricle. Conversations with the next of kin disclosed that the decedent had been diagnosed with myasthenia gravis within the preceding few years. The histologic and circumstantial evidence was consistent with giant cell myocarditis.

Mononuclear and granulomatous myocarditis is a subset of inflammatory ailments of the heart that includes but is not inclusive of toxic myocarditis, infectious etiologies including tuberculosis, fungal and parasitic etiologies, sarcoidosis, autoimmune disorders, and hypersensitivity reactions.[1] In particular, giant cell myocarditis has been associated with intractable ventricular tachycardia and other arrhythmias and tends to occur in younger people with an average age of onset of 42.6 years +/-12.7 years.[2,3] A very extensive review study of granulomatous inflammatory disorders of the heart at autopsy uncovered the importance of giant cell myocarditis in the medicolegal arena in cases of apparent sudden death, especially in a younger age group.[4] Giant cell myocarditis is often associated with numerous autoimmune disorders including type 1 diabetes, systemic lupus, rheumatoid arthritis, alopecia totalis, and myasthenia gravis often associated with thymomas.[1,5-7] Giant cell myocarditis tends to have more eosinophils with myocardial fiber necrosis and poorly formed granulomas compared with the histologic pattern of sarcoidosis while sarcoidosis tends to have prominent granulomas and more fibrosis.[4,8]

This presentation will impact the forensic science community by discussing some of the controversy surrounding creation of autopsy performance standards for investigation of motor vehicle crashes. The recent proposal by NAME regarding autopsies of decedents in motor vehicle crashes has not been without some controversy especially when adherence to a revised standard may diminish the coroners/medical examiners/pathologists' discretion in triaging cases. Similarly, the suggested changes in the NAME standard for histological examination of tissues have also generated much discussion. As this case demonstrated, even adherence to the most comprehensively worded standards may miss rare findings.

G127 Fulminant Myocarditis in Disseminated Mucormycosis: A Rare Cause of Death From a Snake Bite

Prashantha Bhagavath, MD, Shaila Bhat, DNB, Narayan Dabas, MBBS, Francis N.P. Monteiro, MD, and Pradeep K. Gouda, MD, Manipal Univ, Kasturba Medical Coll, Manipal, INDIA*

After attending this presentation, attendees will be able to identify an uncommon case of death due to mucormycosis myocarditis as a complication of viperine snake bite in an adult man. A complete forensic approach was performed through autopsy, and histological examination, and correlation with the clinical findings revealed that the cause of death was due to complication arising from disseminated mucormycosis, a rare complication seen in snake bite victims.

This presentation will impact the forensic science community by showing that disseminated systemic mucormycosis is a dreaded complication which can arise in many conditions, and can cause mortality, if left untreated.

Fungal infections are an important cause of morbidity and mortality. Mucormycosis is a ubiquitous filamentous saprophyte found in farms, gardens, forests, etc. and, unlike Candida and Aspergillus, it is generally not found in a hospital environment. The common portals of entry are respiratory, gastrointestinal tracts and skin. The outcome of mucormycosis is poor with 95% – 100% mortality in disseminated mucormycosis. Diabetes mellitus, especially diabetic ketoacidosis, high dose steroid exposure, neutropenia, degree of immunosuppression, renal failure, and poor hygienic conditions are some of the causative factors. Rarely, the disease has been reported in healthy people. Disseminated mucormycosis can produce fatal complications if it involves the cardiovascular system. Acute fulminant myocarditis is a critical clinical condition with sudden onset of severe congestive heart failure followed by severe hemodynamic deterioration. The case of a patient who developed acute fulminant myocarditis in the setting of disseminated mucormycosis secondary to snake bite envenomation is presented.

A 45-year-old male was bitten by a Russell's viper snake near the ankle of right leg while working in corn fields. He was transported to the hospital for treatment. In the hospital, he developed gangrene and compartmental syndrome in the region of snake bite, and wound debridement and fasciotomy was done as a part of management. He was treated with antibiotics as per the culture and sensitivity test reports. He developed acute arrhythmias and ST segment elevation was observed on continuous ECG monitoring. A 12-lead ECG showed concave ST elevation in almost all leads. The echocardiogram showed a normal left ventricular cavity without hypertrophy and preserved systolic function, no valvar vegetations, no pulmonary hypertension, and no significant pericardial effusion. He

succumbed due to irreversible cardiac arrest 19 days after admission, while under treatment at the hospital.

Postmortem examination revealed infected fasciotomy and debridement wounds with foul-smelling exudates. Multiple reddish circular haemorrhagic skin lesions of varying sizes from 5 – 11cm in diameter were present over the front and back of the trunk limbs. Epicardial and sub-endocardial hemorrhage was present involving the entire heart. Coronaries were patent. Hemorrhagic lesions were present in the greater omentum. An eroded necrotic area measuring 9cm x 8cm was present in the greater curvature of stomach. Hemorrhagic areas were present over the small and large intestines, kidneys, liver, and pancreas. Histopathological examination of the heart, kidneys, liver, and lungs showed irregularly shaped, non-septate hyphae with right angle branching with evidence of arterial invasion.

The cause of death was concluded as complications secondary to disseminated mucormycosis in a case of snake bite. Fatal fungal infections like disseminated mucormycosis can occur following snake bite envenomation. The physician should always keep this as a differential diagnosis and anticipate the fatal complications. Instituting early left ventricular support may improve outcome and result in better long-term survival. The forensic pathologist should differentiate the hemorrhagic cutaneous lesions from contusions and see evidence of fungal infections and their fatal affects during autopsies.

Myocarditis, Mucormycosis, Snake Bite

G128 A Sudden Death in a Fatal Case of Pneumococcal Overwhelming Postsplenectomy Infection Syndrome

Cristoforo Pomara, MD, PhD, Benedetta Di Battista, MD, Stefania C. Bello, MD, Margherita Neri, MD, PhD, and Irene Riezzo, MD, PhD, Univ of Foggia, Viale Degli Aviatori 1, Ospedale D'Avanzo, Foggia, ITALY*

The goal of this presentation is to show how Overwhelming Postsplenectomy Infection (OPSI) syndrome is a rare condition, associated with high mortality. Gross examination, histological and immunohistochemical staining, and microbiological investigation are complementary to correctly gain a diagnosis.

This presentation will impact the forensic science community by showing the rarity of a pathological condition related to a post-traumatic splenectomy in a young man as well as the difficulty of gaining a complete study such as the one proposed. Autopsy, second-level histopathological and immunohistochemical studies, and microbiological tests helped forensic pathologists diagnose the pathological condition and exactly investigate cause of death.

OPSI is a rare condition and is a low-incidence entity with a high mortality rate despite aggressive therapy. Although initial symptoms may be mild and nonspecific, it can progress rapidly to Waterhouse-Friderichsen syndrome with full-blown septic shock and Disseminated Intravascular Coagulation (DIC). The incidence of serious infections after splenectomy remains low, with the incidence of fulminant OPSI ranging from 0.1% to 8.5%. Splenectomized patients are a significant infection risk, because the spleen has the largest accumulation of lymphoid tissue in the body. The initial presentation may be mild and non-specific but may rapidly progress to septic shock with DIC and Waterhouse-Friderichsen Syndrome (WFS). The mortality rate for OPSI has been estimated as approximately 50% to 70%, despite aggressive therapy. Of those patients who die, greater than 50% die within the first 48 hours of hospital admission. The mechanism that connects splenectomy to WFS is unknown but OPSI possible causes are loss of splenic phagocitary function, the decreasing IgM serum levels, a possible suppression of lymphocytes sensibility, and changes of opsonine's system. In this system, shocks irreversibility caused by endotoxin-like phenomenon of Sanerelli–Shwartzman. A case of rapidly progressive fatal overwhelming pneumococcal septicaemia and DIC with bilateral adrenal hemorrhages after splenectomy is reported.

Presented is a fatal case of a 32-year-old man admitted to the emergency department with a history of a few hours low-grade fever and non-specific symptoms (abdominal pain, diarrhea, nausea, and vomiting). On physical examination, not neurological, the body temperature was 39°C (orally recorded), blood pressure was 60/40mm Hg. A splenectomy after car crash was recommended. Tachypnea with oxygen saturation of 94% on room air was also recorded. He complained of mild abdominal tenderness and positive bowel sounds. Laboratory tests revealed leukopenia (WBC 2300), thrombocytopenia (PLT 66.000), metabolic acidosis, and disseminated intravascular coagulation with multiple organ failure. Chest X-ray showed emphasizing design bundling of bronco vascular pattern in the basal right pulmonary. Diagnosis of "abdominal colic" was performed. Death suddenly occurred less than five to six hours after admission. A complete postmortem examination was performed the day after death. Autopsy findings included widespread visceral petechiae, encephalic vascular congestion and cerebral oedema, pulmonary oedema with haematic fluid on the main bronchi. Bilateral acute hemorrhagic necrosis of the adrenal glands as like WFS was also detected. Alveolar necrosis, interstitial chronic phlogosis, hemosiderophages, and perivascular edema were detected at histopathological and immunohistochemical analysis as well as parenchymal complete apoplexy of adrenal glands. Postmortem microbiological investigation on blood, lungs, and vitreous humor were positive for Streptococcus pneumonia. Pneumococcal post-splenectomy infection syndrome rapidly overwhelming in septic shock and multiple organ failure in a young man affected with WFS was established as the cause of death.

OPSI, Waterhouse-Friderich, Splenectomy

G129 Fatal Progressive Disseminated Histoplasmosis Presenting as FUO in an Immunocompetent Italian Host

Alessandro Bonsignore, MD, Univ of Genoa, Dept of Legal & Forensic Medicine, Via de Toni 12, Genoa, ITALY; Giulio Fraternali Orcioni, MD, San Martino Hospital, Dept of Clinical Pathology, Largo Rosanna Benzi 10, Genoa, ITALY; Francesco De Stefano, MD, Univ of Genoa, Dept of Legal & Forensic Medicine, Via de Toni 12, Genoa, ITALY; Jean Louis Ravetti, MD, San Martino Hospital, Dept of Clinical Pathology, Largo Rosanna Benzi 10, Genoa, ITALY; and Francesco Ventura, MD, Univ of Genoa, Dept of Legal & Forensic Medicine, Via de Toni 12, Genoa, ITALY*

The goal of this presentation is to focus on a fatal case of undiagnosed disseminated histoplasmosis occurring in an immunocompetent Italian host. A forensic approach by means of autopsy, microscopic examination, and microbiological studies led to the conclusion that the cause of death was septic shock caused by *Hstoplasma capsulatum* with pulmonary origin and overlapping of other fungal species infection.

This presentation will impact the forensic science community by demonstrating how important a thorough forensic investigation is to reach the correct postmortem diagnosis as well as showing that histoplasmosis could be an emerging sporadic infection in Western countries which needs to be addressed in clinical differential diagnosis in order to avoid unexpected death.

Histoplasmosis is a relatively rare infectious disease endemic in certain moist areas, such as East Africa, eastern and central United States, western Mexico, central and South America, and is mainly related to contact with soil containing feces of birds and bats. Most cases (95%) are acute, self-limited, and completely asymptomatic. Disseminated histoplasmosis has been described almost exclusively in immunocompromised hosts and in AIDS patients. Indeed, histoplasmosis is generally caused by a primary pulmonary lesion with a possible subsequent sporadic hematogenous dissemination.

Presented is a case of a 43-year-old Italian woman, previously splenectomized (due to the complications of a road accident) but

clinically immunocompetent, who was admitted to a regional hospital with a Fever of Unknown Origin (FUO) for several days. Two weeks later, in August, under suspicion of a lymphoproliferative disease, she underwent mediastinoscopy with incisional biopsy which revealed the absence of neoplastic lesions and specific granulomatous structures. Approximately one month later, following the appearance of hepatomegaly with altered indices of cholestasis (without jaundice) and the persistency of fever, the patient underwent liver biopsy with the sole evidence of a necrotizing granulomatous inflammation. Finally, ten days later, a bone marrow biopsy was suggestive for necrotizing inflammatory lesions of infectious etiology. Due to the rapid onset of sepsis, a sudden deterioration of general conditions occurred and the patient died.

A forensic autopsy was performed within 48 hours after death in order not only to find the real cause of death but also to investigate the hypothesis of medical liability (delay in diagnosis, lack of adequate therapy, and so on) of the clinician who had taken care of her.

On the basis of internal examination (sectioning the lung, an apparently capsulated blackish round lesion—1.5cm in diameter—appeared; also a reddish-brown focus with a yellowish central area was found. Other multiple dense spots in the pulmonary parenchyma were observed) and evaluation of histological specimens obtained from autoptic samples (jeweled oval cells of 1 – 5 microns in diameter), it was possible to formulate a diagnosis of histoplasmosis with polivisceral localization (lung, liver, brain, bone marrow), with overlapping—in the lungs—of other fungal species infection (Candida sp.) and arterial embolization of hyphae and pseudo-hyphae.

The diagnostic difficulties due to the inability to document a histoplasmosis in the early stages of the disease, more so in any clinical-radiological pictures which were not sufficiently specific and consequently clinically subtle, led to the accused clinicians being found not guilty of manslaughter. However, this case underlines the need to keep attention levels high in the clinical and forensic analysis of all the granulomatous lesions of unclear etiology which require histological and microbiological studies of blood and infected organs as well as detection of antigens in blood or urine samples by ELISA or PCR.

Fatal Histoplasmosis, Immunocompetent Host, Histopathology

G130 The Application of Forensic Microbiology in a Fatal Case of Transfusion-Transmitted *Yersinia Enterocolitica* Sepsis

Margherita Neri, MD, PhD, Mariantonietta Di Stefano, BS, Giuseppina Faleo, BS, Ruggero Parente, MD, Monica Salerno, MD, and Santina Cantatore, Univ of Foggia, Viale degli Aviatori 1, Foggia, ITALY*

The goal of this paper is to underline the usefulness of the use of forensic microbiological analysis to explain the cause of death in case of infective disease.

This presentation will impact the forensic science community by presenting the rare case of septic shock due to transfusion-transmitted *Yersinia enterocolitica*. The use of postmortem microbiological investigation on cadaveric blood gives support to the forensic pathologist to diagnose sepsis-related death. In this case, the forensic microbiological analysis allows the exact correspondence between the pathogen agent isolated from transfused Red Blood Cells (RBCs) and the etiological agent that determined the fatal sepsis, *Yersinia enterocolitica*.

This presentation concerns the fatal case of a woman infected by an RBCs transfusion bag contaminated with *Yersinia Enterocolitica*. *Yersinia enterocolitica* is a pleomorphic gram-negative bacillus that belongs to the family Enterobacteriaceae and causes mild disease, most frequently acute diarrhea, terminal ileitis, mesenteric lymphadenitis, and pseudoappendicitis. *Yersinia enterocolitica* most commonly affects young individuals, but whether this represents an increased susceptibility or a greater likelihood of developing symptomatic illness is unclear. Human yersiniosis is attributed to contaminated pork, milk, water, and tofu consumption, as well as blood transfusion. Bacterial sepsis has become the most frequent infectious complication of transfusion, but cases of transfusion-transmitted *Yersinia enterocolitica* sepsis with bacterial isolation are very rare in postmortem examination.

A 37-year-old woman, pregnant with her second child, was admitted to the gynecology and obstetrics unit with diagnosis of post-term pregnancy (41+3 weeks of pregnancy). The course of pregnancy was physiological. The fetus was in cephalic presentation, the amnio-chorial membranes were intact. On the third day of hospitalization labor was induced following amniorrhexis and, in the absence of contractile activity, the oxytocic perfusion was started. The patient responded positively to the oxytocic perfusion and gave birth to a female child with eutocic parturition. The prophylaxis of postpartum hemorrhage was made by administering of oxytocin and methylergometrine, and the suture of a vaginal laceration was performed. The woman, after the parturition, was affected by a hemorrhagic postpartum shock determined by trans-vaginal blood loss estimated at 1800ml during and after the parturition. Blood chemistry and blood count laboratory tests were performed and showed reduction of Hb, Hct (Hb 5.9, Hct 18.6) with a condition of acute anemia. On the fourth day of hospitalization (first postpartum day), the patient was transferred to the intensive care unit for the serious anemic condition; serial blood chemistry and blood count laboratory tests were performed and fresh frozen plasma and RBCs bags were transfused. The patient's clinical condition worsened and she showed a state of shock refractory to therapy, kidney failure, and CID; on the fifth day of hospitalization (second postpartum day), she was admitted to the operating room for an abdominal laparotomy and hysterectomy leaving uterine adnexa *in situs*. In the following days, the woman showed hemodynamic instability, respiratory distress despite the support with vasoactive amines, and mechanic ventilation. On the eighth day of hospitalization (fifth postpartum day), she died of septic shock. A complete postmortem examination was performed 24 hours after death and showed surgery outcomes of hysterectomy. Subpericardial and subpleural petechiae were detected. The other organs did not show specific alterations except for intense vascular congestion and generalized edema. Histological examination showed in lung specimens alveolar septa mildly thickened by edema and capillary congestion, alveolar edema, hyaline membranes lining the denuded alveolar walls, alveolar infiltrates of polymorphonuclear neutrophilic leukocytes, pigmented macrophages, monocytes and plasma cells, alveolar hemorrhages; in kidney specimens acute tubular necrosis and wide hemorrhages. In all organs, in particular in the lungs, small vessels contain fibrin thrombi. The cause of death was a fatal septic shock. On blood samples collected during the autopsy a microbiological analysis was performed using PCR to isolate pathogens responsible for septic shock. PCR analysis showed positive for *Yersinia Enterocolitica*. After the isolation of *Yersinia Enterocolitica* from the dead woman's blood sample, the infected transfused RBCs were identified. High titers of antibodies against *Yersinia Enterocolitica* were detected in the donor's plasma sample one month after blood donation. The donor had no clinical signs of intestinal infection at the time of donation.

Transfusion-Transmitted, Forensic Microbiology, Septic Shock

G131 Routine Postmortem Cultures in Infant Autopsies: A Four Year Experience

Kristin C. Escobar Alvarenga, MD, 4519 Stallion Brook, Spring, TX ; and Merrill O. Hines, MD, Mary L. Anzalone, MD, and Kathryn H. Haden-Pinneri, MD, Harris County Institute of Forensic Pathology, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will determine the value and effectiveness of learning routine postmortem cultures on infant autopsies and appreciate the importance of correlating postmortem culture results with gross and microscopic autopsy findings.

This presentation will impact the forensic science community by improving knowledge of the utility of postmortem cultures and by redefining roles of routine postmortem cultures on current protocols for infant autopsies.

A comprehensive infant autopsy not only includes an external and internal examination, but also many ancillary diagnostic tests including postmortem cultures, radiology, toxicology, histology, and metabolic studies. Each of these components may contribute to some degree in determining a cause of death. The purpose of this study is to specifically examine the relative contribution of routine postmortem cultures in establishing a cause of death in infant autopsies.

Postmortem cultures have long been regarded as an area of contention in the field of forensic/autopsy pathology and microbiology. There is no doubt that postmortem cultures not only provide epidemiological information for public health purposes but also play an integral role in helping to establish a specific cause of death in some cases. However, due to postmortem contamination, postmortem cultures can be difficult to interpret.

Bacterial cultures of blood, lung, spleen, and cerebrospinal fluid as well as viral cultures from the respiratory tract are routinely collected using sterile instruments on the majority of infant autopsies at the Harris County Institute of Forensic Sciences. The results of routine postmortem cultures from 304 infant autopsies ranging from 1 to 365 days of age over a four year period (2008 – 2012), presented with sudden unexpected deaths of previously healthy infants and without gross anatomic abnormalities or evidence of infection were analyzed. Data is available fpr 295 blood cultures, 299 lung cultures, 290 spleen cultures, 255 cultures of cerebrospinal fluid, and 238 viral cultures.

The data shows that the cause of death was determined to be infectious in 12 out of 304 pediatric autopsies (4%). In these autopsies with an infectious cause of death, eight of these cases had a positive postmortem culture and histologic correlation with the cultured organism; four had a negative postmortem culture with histologic evidence of infection. Out of autopsy cases with an infectious cause of death, five of the 12 viral cultures from the respiratory tract and none of the bacterial cultures of cerebrospinal fluid successfully isolated an organism that contributed to the cause of death.

Two hundred and twenty-one out of 304 pediatric autopsies (73%) were classified as sudden infant death syndrome or undetermined (co sleeping); 157 of these cases had a positive postmortem culture without histologic evidence of infection (postmortem contamination). The postmortem interval, like previous studies have shown, did not have a significant impact on the results of the postmortem cultures.

In conclusion, routine postmortem cultures will fail to identify a definitive cause of death in a significant proportion of pediatric autopsies that present with sudden unexpected deaths of previously healthy infants and with no gross anatomic abnormalities or evidence of infection at autopsy. Lastly, the high postmortem contamination rate complicates the interpretation of postmortem culture results.

Culture, Infant, Autopsy

G132 Vertebral-Medullary Trauma Death: When, Where, and How Was the Trauma?

Daniela R. Schillaci, Univ of Milan-Bicocca, Via Cadore 48, Monza, ITALY; Carmen Barbu, MD, Dept of Forensic Medicine, Covasna County, Bucharest, ROMANIA; and Musa Gashi, MD, and Arsim Gerxhaliu, MD, Pristina Hospital Circle, Ministry of Justice, Pristina, KOSOVO*

After attending this presentation, attendees will receive information on how to manage cases with minimal signs at autopsy and hospital information on how to reconstruct a traumatic event in order to clearly assign the responsibility of trauma. A careful evaluation of all the medical documents is the cornerstone to understanding the traumatic mechanism and timing of vertebral injury, especially when autopsy findings are minimalized because of a post-traumatic surviving interval.

This presentation will impact the forensic science community by understanding how the clinical information can be of relevant importance in cases of a trauma death with minimal autopsy signs.

A 45-year-old man died of sepsis secondary to quadriplegia due to complex multiple fractures of the lower cervical column (C4 - C7) after a three-week hospitalization in the intensive care unit.

The family, interviewed before performing the autopsy, declared that the man had been arrested for an alleged fight with a neighbor the day before. They reported that when the statement was taken in the police station, the police officer noticed a strange, irascible behavior and a neuropsychiatric consultation was requested.

The medical documentation shows that the man was hospitalized in the psychiatric unit and suddenly some neurological signs appeared. Then the patient was moved to the orthopedic unit and checked radiologically with a positive result of an instable C5 fracture, and a Philadelphia collar stabilizer was applied.

His condition rapidly worsened and he was transferred to the intensive care unit with respiratory arrest, peripheral and central cyanosis, and fixed and unreactive pupils (GCS=3). The blood pressure and oxygen's saturation were undetectable and the pulse was 40bpm. He was reanimated, intubated and a cardiotonic was administered; the patient recovered cardiorespiratory function (pulse 120 – 130bpm). Complex monitoring, sedation, and algotherapy with morphine followed.

After some days, an extensive CT scan of the head and neck was performed and no pathological or traumatic signs were found in the head, but multiple fractures from C4 to C7 (fractures of the spinous process of C4 and C5; fractures of the vertebral bodies of C5 (type III), C6 (type I), C7 (type I) were detected. After ten days of admission in the intensive care unit, the patient presented convulsion and fever (BT: 38.7°C).

During hospitalization the patient received fluid supply, human albumin 20%, mannitol 20%, antibiotic therapy according to antibiogram, antiaggregant, barbituric, analgesics, sedatives, antiacid and vitamins. Despite this intensive treatment his hemodynamic state was unstable and his fever rose to 40.9°C and biochemical signs of multiple organ failure appeared (leukocytosis $15x10^9$/L, AST 249 IU/L, ALT 580 IU/L, hypoalbuminemia, urea 11.2mmol/L, glucose 36mmol/L). The patient died after 23 days of intensive care with diagnose of sepsis.

At autopsy, the external examination revealed two decubitus areas, in the occipital and sacral area with skin necrosis, marks of defibrillation and no signs of trauma. The classical autopsy opening procedure was completed with a complete posterior neck dissection discovering a minimal, insignificant paravertebral blood infiltration on the C4 - C5 area, and the cervical column was taken away for further bone and spinal cord evaluation. The internal organs showed macroscopical signs of failure and sepsis. The spinal cord, fixed in formalin, presented macroscopically an external, light brownish discoloration investigated microscopically. The cervical vertebrae were prepared in order to observe the localization, type, and state of the fracture's repair process.

The forensic evaluation of the case confirmed a linear correlation between the vertebral-medullar injuries and the death. The CT images revealed clear, multiple complex fractures in the cervical area that could only be the result of a relevant neck trauma.

The localization of the multiple vertebral fractures in the lower cervical spine allows the existence of a free interval of neurological signs, and the instability due to the complexity of the fractures (C5) can explain the sudden deterioration of the neurological condition as the result of small, ordinary neck movements.

The big forensic questions to answer concern the moment and the mechanism of the vertebral trauma, because many different situations and persons could be involved in this case (the discussion/fight with the neighbor, abuse of force by the police, the event which occured in the psychiatric unit, fall, use of restraints,

altercation with another person) or a traumatic event before the arrest.

Spinal Cord Trauma, Forensic Pathology, Cervical Fractures

G133 A Single Case of Natural Death Due to Idiopathic Hypereosinophilic Syndrome Occurring in a Young Nigerian Prostitute

Francesco P. Busardo, MD, Univ of Palermo, Via Del Vespro, 129, Palermo, ITALY; Paola Mancarella, MD, Univ of Rome, Viale Regina Elena 336, Rome, ITALY; Francesca Portelli, MD, Via Dei Nebrodi 64, Palermo, ITALY; and Stefania Zerbo, MD, Paolo Procaccianti and Emiliano Maresi, Univ of Palermo, Via Del Vespro, N. 127, Palermo, ITALY*

After attending this presentation, attendees will be able to better understand the main pathological features of Hypereosinophilic Syndrome (HES) found at autopsy in a 21-year-old Nigerian prostitute.

This presentation will impact the forensic science community by discussing the possibilities of natural death caused by HES in a young prostitute. The place and circumstances in which she was found initially led to a supposition of a violent death.

In February 2012, early in the morning, a 21-year-old partially undressed Nigerian prostitute was found dead next to a rubbish bin, in a central square of Palermo, Italy.

After the external examination, rectal and vaginal swabs were taken for genetic analysis in order to find sperm. After a complete autopsy, organ samples were also taken for histopathological examination, using routine histological stainings, namely hematoxylin and eosin, Giemsa and PAS. Toxicological and serological investigations and hematological analysis were performed as well.

The external examination and autopsy didn't reveal any traumatic lesions or signs of sexual abuse as confirmed by the genetic investigation, which was negative in the research of spermatozoa. The serological analysis was also negative for viral and parasite infections and the toxicological investigation was negative for drugs and alcohol. The blood sample taken two hours after death showed that the white cell count was 9500/mm^3 with 2840 eosinophils/mm^3 (41%). The histopathological investigation showed: (1) lungs: marked eosinophils recruitment and degranulation with endovascular endothelial injury and formation of occluding platelet plugs; multi focal vasculitis with eosinophilic infiltrate and intimal myofibroblastic eccentric thickening; (2) heart: marked congestion and subendocardial myocytolysis and interstitial eosinophilic infiltration; (3) lymph nodes: normal structural organization with eosinophilic granulocyte infiltration of lymphatic sinuses; (4) liver: cloudy swelling of epatocytes which show granular cytoplasm; focal eosinophilic infiltration of fibrotic and thickening portal spaces; (5) kidneys: diffuse and marked vascular congestion and cloudy swelling of cortical convoluted tubules; marked and diffuse eosinophilic infiltration of renal pelvis; and, (6) bone marrow: normal hematopoietic components with prevalence of eosinophilic granulocytes in the myeloid series.

HES is a rare disorder characterized by a sustained overproduction of eosinophils, peripheral eosinophilia, and tissue eosinophilic infiltration. It commonly affects the heart, lung, skin, and central and peripheral nervous systems, and often causes impaired organ function.

Until the late 1990s, this disease had a bad prognosis with a median survival of less than one year with less than 20% of patients surviving two years, and with death usually occurring because of organ dysfunction. Current treatment has fortunately improved the prognosis.

In this case, however, because of the fact that this young prostitute lived *underground*, no information on the clinical development of the pathology which led to exitus exists and also the absence of any medical treatment didn't allow the course of the illness to be slowed down. As the hematological examination is from a single sampling which ran for approximately two hours after death, it is not possible to document the duration of this marked hypereosinophilia, the histopathological examination showed a reacutization of chronic eosinophilic vasculitis responsible for acute respiratory failure, the cause of death. In this case, the absence of a specific etiology has allowed us to define the HES as idiopathic.

Hypereosinophilia, Histophat Findings, Autopsy

G134 Medium-Chain Acyl-CoA Dehydrogenase Deficiency: A Differential Diagnosis in a Patient With Mental Status Changes Suspected of Drug Toxicity

Morgan Randall, BA, 260 Old Mount Tabor Rd, No 13, Lexington, KY 40502; Cristin M. Rolf, MD, and Stephanie K. Mayfield, MD, Univ of Kentucky, Central Laboratory Facility, 100 Sower Blvd, Ste 202, Frankfort, KY 40601-8272; Piero Rinaldo, MD, PhD, Mayo Medical School, 200 1st St SW, Rochester, MN 55905; and Gregory J. Davis, MD; Univ of Kentucky Medical Center, MS 117, 800 Rose St, Lexington, KY 40536-0298*

The goal of this presentation is to show how rare inborn errors of metabolism such as Medium-Chain Acyl-CoA deficiency can be present with symptoms commonly associated with drug toxicity.

This presentation will impact the forensic science community by showing how patients with nausea, vomiting, and acute mental status change in the setting of fasting should be tested for inborn errors of metabolism such as Medium-Chain Acyl-CoA deficiency if toxicology is negative. When recognized, family counseling can be initiated and additional lives potentially saved.

This case involves a 30-year-old white male coal miner who experienced nausea and vomiting with a 30-pound weight loss over the last three months of his life. He was admitted to the local hospital for a further evaluation of intractable vomiting and complaints of abdominal pain and scant hematemesis. Upon admission, the patient appeared to be in no acute distress and was alert and oriented to person, place, and time. Admission laboratory investigation demonstrated blood glucose of 71mg/dL (70 – 99), BUN 31mg/dL (7 – 18), Creatinine 2.0mg/dL (0.6 – 1.3), and an anion gap of 23.7mEq/L (10 – 20). Several hours into the admission, the patient became confused, anxious, and appeared to be hallucinating with bizarre manifestations, such as licking the air followed by self-injurious behaviors such as banging his head on the wall and trying to jump out a window. He was subsequently placed in soft restraints for his own and others' safety. Fifteen minutes later the patient became unresponsive and developed a rapid respiratory rate (40/min). In another 15 min, respirations and cardiac electrical activity suddenly ceased, and resuscitation attempts were unsuccessful. No ventricular fibrillation was observed during his hospitalization. Drug toxicity, specifically "bath salts," were suspected due to the patient's mental status changes, a history of remote drug abuse in the patient's past, and the prevalence of psychosis-inducing drugs in the community. Drug testing for synthetic stimulants such as mephedrone, MDPV, and methylone were all negative. The past medical history of this patient was unremarkable for previous mental status change. He furthermore had a sibling who had experienced a mild mental status change during a fast for colonoscopy, which was relieved with electrolyte drink and broth.

On autopsy, the patient was a well-developed male with features suggestive of recent weight loss (loose soft abdominal skin and striae). Findings included gross and microscopic microvesicular steatosis, mild cerebral edema, and subnuclear vacuoles of the renal cortical tubules. Autopsy urine and blood were negative for ketones. Postmortem screening of the blood, urine and vitreous were positive only for ethanol and promethazine prescribed in the hospital. Due to the odd presentation of fatty liver, negative drug screen, vomiting, and altered mental status, the forensic pathologist elected to request postmortem metabolic screening of the blood and bile, which was

positive. The patient was found to have died due to acute metabolic decompensation caused by Medium-chain acyl-CoA dehydrogenase deficiency, an inherited fatty acid oxidation disorder. Discussed will be the necessity of awareness of such entities as adult manifestation of inborn errors of metabolism in spite of their relative rarity.

MCAD Deficiency, Mental Status Change, Metabolic Disease

G135 Postmortem Distribution of 3-Beta-Hydroxybutyrate

Cristian Palmiere, MD, Centre Univ, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, SWITZERLAND; Patrice Mangin, MD, PhD, Centre Univ, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, SWITZERLAND; Dominique Werner, PhD, Lausanne Univ Hospital, Laboratory of Clinical Chemistry, Lausanne, SWITZERLAND*

After attending this presentation, attendees will understand how metabolic and biochemical disturbances existing at the time of death and potentially leading or contributing to death can be better characterized by 3-beta-hydroxybutyrate (3HB) determinations in blood and in biological fluids such as urine, vitreous, pericardial, and cerebrospinal fluids.

This presentation will impact the forensic science community by demonstrating how simultaneous determinations of 3HB in blood, urine, vitreous, pericardial, and cerebrospinal fluids may provide useful information pertaining to the duration of the death process. Indeed, the equilibrium between blood and other body compartment fluids (especially vitreous, pericardial, and cerebrospinal fluids) is established over time. The presence of comparable vitreous, pericardial, and cerebrospinal fluid 3HB values to blood 3HB values can thereby confirm that metabolic and biochemical disturbances and the death process developed over several hours. Additionally, this presentation will impact the forensic community by demonstrating that cerebrospinal fluid 3HB levels exceeding 2000µmol/l can be regarded as biochemical markers of concomitant, pathological blood 3HB increases, thus allowing metabolic and biochemical disturbances leading to death to be reliably diagnosed.

A total of 158 subjects were selected for this study. Case inclusion criteria were postmortem interval, circumstances of death, and availability of all biological fluids upon autopsy. After having performed postmortem investigations including native CT scan, autopsy, histology, biochemistry, and toxicology, 12 fatal diabetic ketoacidosis cases and eight free-ethanol hypothermia fatalities were identified. Furthermore, five other cases concerning sudden deaths in subjects presenting chronic alcohol abuse and no previous diagnosis of diabetes mellitus according to medical records were included, as well as 20 bodies presenting mild decompositional changes with all biological fluids upon autopsy. According to the medical records, all these cases were non-diabetics. All biological samples were transferred to the laboratories immediately after collection. When analyses were delayed, biological samples were stored at -20°C. Biochemical investigations including blood acetone, vitreous glucose, blood glycated hemoglobin as well as blood, vitreous, urine, pericardial and cerebrospinal fluid 3HB determinations were systematically performed.

The results of the study indicated that vitreous and pericardial fluid 3HB levels were reliable markers of underlying metabolic disturbances leading to death in diabetic ketoacidosis cases. In hypothermia fatalities, 3HB concentrations in pericardial fluid were the most representative compared to those in blood. In bodies presenting mild decompositional changes, vitreous and pericardial fluid 3HB levels were the closest to blood levels. Lastly, in sudden deaths related to chronic alcohol consumption, vitreous and pericardial fluid 3HB levels were the closest to blood 3HB concentrations.

Increases in blood 3HB concentrations seem to be reflected in parallel increases in pericardial fluid 3HB levels, irrespective of the cause of death. Vitreous humor can be considered a further, alternative, biological substrate for 3HB determination. Conversely, the interpretation of urine 3HB levels in diagnosing pathologically significant ketoacidosis requires more cautiousness. Lastly, markedly increased cerebrospinal fluid 3HB levels (over 2000µmol/l) can be considered a reliable indicator of underlying metabolic disturbances potentially leading to death and can be used to diagnose pathologically significant ketoacidosis.

Forensic Sciences, Distribution, Beta-Hydroxybutyrate

G136 A Rare Case of a Large and Bilateral Acute Cerebral Necrosis Following a Very Low Total Dose of Conventional Radiotherapy Treatment for Anaplastic Oligoastrocytoma

Cristoforo Pomara, MD, PhD, Stefania C. Bello, MD, Margherita Neri, MD, PhD, and Irene Riezzo, MD, PhD, Univ of Foggia, Viale Degli Aviatori 1, Ospedale D'Avanzo, Foggia, ITALY; and Cristian D'Ovidio, MD, PhD, Univ of Chieti-Pescara, Chieti, ITALY*

The goal of this presentation is to examine the histopathological aspects of an acute cerebral radionecrosis following conventional radiotherapy at subtherapeutic dosages associated with adjuvant chemotherapy. The adoption of adjuvant chemotherapy may therefore increase the incidence of radionecrosis due to its radiosensitization effect.

This presentation will impact the forensic science community by showing the necessity of a complete methodological forensic approach by means of autopsy, histological, and immunohistochemical examinations to diagnose an unusual early cerebral radionecrosis, due to a very low dosage of conventional radiotherapy and to differentiate from tumor recurrence.

Malignant gliomas are the most common primary brain tumors, and glioblastoma multiforme and anaplastic oligoastrocytoma comprise the greatest part of these. The actual standard protocol of treatment for these patients consists in maximal safe resection followed by radiotherapy and concomitant and adjuvant chemotherapy (temozolomide). However, even with treatment, outcomes are poor. The median survival for patients with glioblastoma multiforme is 10 – 12 months, whereas two-year survival rates for glioblastoma multiforme and anaplastic astrocytoma are only 9% and 44%, respectively.

Radiation doses in the region of 46 – 50 Gy are as efficacious as higher doses in the treatment of low-grade glioma, but doses of 60 Gy provide better outcomes for high-grade gliomas and are commonly prescribed for these tumors.

Radiation therapy for the brain, however, may often result in several episodes of acute and chronic damage, even if the total dose of radiation appears to be the most important risk factor for subsequent necrosis. Three distinct periods of radiation effect may be identified: acute (during the radiation itself), early delayed (at around 1.5 months after the radiation), and late delayed (between 4.7 and 7.6 months and for more than two years). More simply, radiation-induced effects are considered late effects if they occur after 90 days from the first day of radiotherapy. However, necrosis has been reported as early as three months and as late as 47 years after radiotherapy.

Reported is a rare case of large and bilateral acute cerebral necrosis following a very low total dose of conventional radiotherapy.

A 56-year-old female first presented epileptic attack associated with aphasia and paralysis. Magnetic Resonance (MR) imaging showed a lesion of 2cm in diameter in the left temporal lobe, without perilesional edema and gadolinium enhancement after perfusion. The tumor was totally excised via a left fronto-temporal approach. The histological examination of the mass confirmed the typical Anaplastic Oligoastrocytoma. Following the operation, a treatment with a total dose of 60 Gy conventional radiotherapy was programmed, in 1.80 Gy daily fractions, associated with steroids (desamethasone, 8mg each day) and chemotherapy (temozolomide, 100mg each day). After the

twentieth dose (a total dose of 36 Gy), she presented an epileptic attack associated with fever, tremor, confusion, aphasia, and recurrent focal deficit. MR imaging showed a mass with edema in the fronto-temporal lobes which suggested radiation-induced necrosis, without enhancement by gadolinium. In the following month, the woman died and the autopsy was effectuated.

The external examination was unremarkable. The examination of the brain, regular in size and weight, after fixation in buffered formalin revealed diffusely swollen cerebral hemispheres. On coronal sections, the cerebral frontal and temporal lobes revealed regions of necrosis and cortical hemorrhages.

The etiopathogenetic definition was outlined by histological examinations performed on brain tissue samples using Haematoxylin-Eosin (H&E) and Masson and it revealed the presence of diffuse and marked cytotoxic and vasogenic brain edema, and in samples taken from right and left fronto-temporal lobes foci of central necrosis and extensive cortical hemorrhages, marked stasis, and cerebral vessels surrounded by inflammatory cells, above all granulocytes. The immunohistochemical examination of the brain specimens was also conducted for antibodies anti-GFAP (glial fibrillary acidic protein), CD68, CD15, TNF-α, fibrinogen, HSP, cytokeratins, and TUNEL. The other organs showed signs of central dysregulation (pulmonary edema).

The exitus was attributed to an acute central dysregulation caused by edema and necrosis radiation-induced and relative complication with rapid increase of intracranial pressure.

In conclusion, according to scientific literature, the cerebral necrosis could appear in areas radiated to less than 50 Gy, but with daily fractions of 2.25 Gy. In this case, the cerebral necrosis was very large and it was caused by inferior dosage (36 Gy), so it corroborates that the adjuvant chemotherapy, temozolomide in particular, significantly increases the risk of cerebral necrosis by approximately fivefold. A review of the literature is presented

Cerebral Radionecrosis, Anaplastic Oligoastrocytoma, Immuhistochemistry

G137 Fatal Hemorrhage From a Tracheostomy Site in a Patient With Blue Rubber Bleb Nevus Syndrome: A Case Presentatio and Review of Literature

Marta A. Helenowski, MD, 2121 W Harrison St, Chicago, IL 60612*

After attending this presentation, attendees will understand the importance of a thorough examination of the viscera and soft tissues, especially in the head and neck region, and gain insight on potential complications including sudden death from the rupture of soft tissue vascular malformations due to emergency tracheostomies.

This presentation will impact the forensic science community by increasing the awareness of the rare Blue Rubber Bleb Nevus Syndrome (BRBNS)and the risk it presents for fatal hemorrhages depending on its location. A review of literature on the topic of fatalities linked with tracheostomies will be presented.

This case involves a 31-year-old Caucasian female with a medical history of multiple arteriovenous malformations on the right side of her body and a diagnosis of BRBNS. She went to the emergency room because of an infected tooth. Several years prior to her visit to the emergency room, she had had a single episode of bleeding-from-the-tongue-based AVM. Prior to extracting the tooth, she was injected with lidocaine and developed acute anaphylaxis with severe facial and airway swelling resulting in an obstructed airway. An emergency tracheostomy was performed, which was complicated by profuse hemorrhage from the adjacent ruptured soft tissue vascular malformation. Hemostasis could not be achieved by the Intensive Care Unit staff and the patient exsanguinated. The body was brought to the Office of the Cook County Medical Examiner for postmortem examination. An autopsy determined that the immediate cause of death was anaphylaxis due to a reaction to the anesthetic medication that was given prior to the tooth extraction; however, the condition, that significantly contributed to her death was hemorrhage due to a ruptured vascular malformation during the tracheostomy. The uncommon location of an exsanguinating vascular malformation in the neck region in a patient with BRBNS deserves a generous discussion.

Approximately 153 cases of BRBNS have been reported in the literature. What was possibly the first description of BRBNS appeared in 1860 in a paper by Dr. Gascoyne. Dr. Gascoyne described a nevus involving the parotid gland, which caused death from suffocation in a patient who displayed numerous nevi of the viscera. Dr. William Bean coined the name BRBNS in 1958 because of the rubbery, nipple-like texture of the cutaneous hemangiomas that tend to camouflage vascular malformations found in the viscera, and in this case, the neck region. BRBNS has since been reported in patients with numerous and varied types of cutaneous vascular nevi frequently associated with visceral malformations. Most commonly, these visceral malformations are located in the small and large intestines and cause death from hemorrhage. Reports of BRBNS associated with findings of hemorrhaging vascular malformations in the head and neck causing suffocation have also been reported. The association of BRBNS and hemorrhaging vascular malformations of the head and neck has led anesthesiologists to develop various techniques to manage the airway in these patients without disrupting the lesions. Although BRBNS is usually diagnosed in infancy, there are, unfortunately, cases of BRBNS which remain undetected until adulthood. A possible genetic inheritance pattern is currently being studied.

Cases describing prominent head and neck findings in patients with BRBNS emphasize that they often first present to an otolaryngologist or oral surgeon with the incidence of oral hemangiomas as high as 59% to 64%. None of these cases has discussed the risks and potential complications of emergency tracheostomy placement in these patients. This case is the first to discuss a patient with BRBNS who underwent a tracheostomy and developed a fatal hemorrhage due to this rare presentation.

Nevus, Tracheostomy, Hemangioma

G138 Toward Validating a Universal Equation for Estimating Postmortem Interval

David O. Carter, PhD, Div of Natural Sciences and Mathematics, Chaminade Univ of Honolulu, 3140 Waialae Ave, Honolulu, HI 96816; Amy E. Maile, BS, Univ of Nebraska-Lincoln, 102 Entomology Hall, Lincoln, NE 68583-0816; and, Larry Barksdale, MA, 575 South 10th St, Lincoln, NE 68508*

After attending this presentation, attendees will understand that it is possible to provide an accurate presumptive estimate of Postmortem Interval (PMI) within a few hours of attending a death scene.

This presentation will impact the forensic science community by demonstrating the use of a new method for medicolegal death investigators to gather information useful for making timely decisions on the scope of the investigation and the use of resources.

Estimating PMI is a critical step in every death investigation. During the initial interview process, a first responder/investigator will attempt to determine the time at which the deceased was last known to be alive. This information is not always helpful to establish a firm PMI. The information for a more reliable PMI can be critical to evaluate alibis, identify the deceased, establish a working hypothesis on the manner of death, lend weight to other information through corroboration, and corroborate the cause of death. Several methods have been developed to estimate PMI since the mid 19th-century, but the development of a universal method remains elusive. Two universal equations were recently proposed in the forensic science literature.[1] One of these equations was developed for above-ground death scenes and presents PMI as a function of soft tissue mass loss,

temperature, and relative humidity. In response to the need for validating this equation in other climates, we have begun the process of validating this equation in southeastern Nebraska, USA. This region is located in a cold climate characterized by hot summers and the lack of a dry season (climate code: Dfa).

Presented are the findings from three death investigations where the estimate generated by the above-ground PMI equation was used and compared to a known PMI. Temperature and relative humidity were measured at intervals of one minute with a datalogger placed as close as possible to the corpse. These measurements were collected for 90 to 150 minutes.

It is shown that this method has real time application for corroborating other information and thus making a more robust initial estimation of PMI. It is often the case that first responders and crime scene investigators need just one additional component of information to make a confident decision on the parameters of the investigation to confidently proceed with further investigative tasks such as interviewing witnesses. On the other hand, other information may not be available, or is unreliable, so that the method herein provides the primary information for estimating PMI. The current method is such that it can be taught easily to first responders and crime scene investigators. Supervisors and others who have an interest can easily check the data points by looking at digital images, collecting official weather data, and conducting the calculations of the method. This is a real-time viable tool that only awaits additional research and application.

The current results complement the universal equation for above-ground death scenes proposed in the recent literature. Results indicate that overall, the proposed equation was accurate in helping to narrow the time frame for an estimated PMI. Since the percentage of soft tissue loss is subjective, it is recommended that more than one individual observe the physical characteristics of the corpse to determine an average tissue loss. This procedure will allow for a more accurate range for tissue loss and minimize the error associated with estimating PMI.

G139 Using Interpolation to Estimate Postmortem Interval on the Condition of Various Ambient Temperature

Tiantong Yang, MD, 116 Lugu Rd, Shijingshan Dist, Beijing, PEOPLE'S REPUBLIC OF CHINA; Xinbiao Liao, MD, 3 Beijiaochang Cross Rd Yuexiu District, Guangzhou, PEOPLE'S REPUBLIC OF CHINA; Lin Chang, MD, Key Laboratory of Evidence Science, China Univ of Political Science and Law, Beijing, PEOPLE'S REPUBLIC OF CHINA; and Mary G. Ripple, MD, David R. Fowler, MD, Xiang Zhang, MD, and Ling Li, MD, OCME, 900 W Baltimore St, Baltimore, MD 21223*

After attending this presentation, attendees will learn how the ambient temperature influences the postmortem blood pH values and how to use interpolation to estimate Postmortem Interval (PMI) at various ambient temperatures.

This presentation will impact the forensic science community by enabling the forensic pathologists to better understand the correlation between blood pH values and various ambient temperatures at PMI. The relationship between blood pH values and ambient temperatures at different PMIs analyzed by interpolation function fitting provides another useful tool in the estimation of time since death.

The determination of the time since death is a primary task of medicolegal death investigation. Few accurate methods currently exist to evaluate the (PMI) at various ambient temperatures. Interpolation analysis was applied to study the correlation between blood pH values and ambient temperatures at different PMIs. A total of 48 rabbits were randomly divided into six groups and sacrificed by air embolism. Five mL of blood from the right ventricle were sampled immediately after death and then placed in sterile blood tubes. The blood specimens from each group were placed in water baths at 10°C, 15°C, 20°C, 25°C, 30°C. and 35°C temperatures, respectively. At different PMIs (once every four hours), the blood pH values were measured by meter electrochemical analyzer.

The results showed that there was a strong correlation between the blood pH values and PMI at various ambient temperatures. At different ambient temperatures, pH values decreased at different rate. Under temperatures of 10±0.05°C, it took 64h for the pH value to drop from 7.528±0.037 to 6.143±0.029. Under temperatures of 20±0.05°C, it took 38h for the pH value dropping from 7.528±0.037 to 6.141±0.035. Under temperatures of 30±0.05°C, it took 20h for the pH value to drop from 7.528±0.037 to 6.141±0.037. However, under temperatures of 35±0.05°C, it only took 14h for the pH value to drop from 7.528±0.037 to 6.143±0.031. The pH values decreased much more rapidly with increased PMI at higher temperature when compared with the values in the lower temperatures, which indicated that ambient temperatures play a significant role in estimating the PMI.

Regression analysis was performed for data obtained at different temperatures and PMIs. The PMIs and various pH values were used as variables, where x represented PMI and pH values as dependent variable y. The optimal regression function results showed that the R^2 value of the cubic curve-fitting equation was higher ranging from 0.974 to 0.982, suggesting that the degree of fitting was optimal, which indicated that there was strong correlation between the pH values and the PMI. The data also showed that postmortem changes were a dynamic process influenced by ambient temperature. A 3D surface equation was developed in estimation of PMI under various temperature conditions. Statistical analysis and curve-fitting of the data yielded cubic polynomial regression equations and a surface equation at different temperatures. The relationship among pH, PMI, and ambient temperature can be described by a three-variable fifth-degree equation. Interpolation analysis was applied to develop a 3D surface equation in estimation of PMI under various temperature conditions. The surface equation represented a 3D sculptured surface, indicating the relationship among pH, PMI, and ambient temperature could be descripted by a three-variable fifth-degree equation.

In conclusion, this study provides another useful tool of using interpolation analysis to estimate PMI at various ambient temperatures. The mathematical description using interpolation function fitting seems to be more suitable to cope with the complexity of PMI estimation in consideration of ambient temperatures.

pH, Postmortem Interval, Interpolation Analysis

G140 Postmortem Eye Temperature Measurement: A New Method of Time of Death Estimation?

Michal Kaliszan, PhD, Medical Univ of Gdansk, Debowa 23, Gdansk, POLAND*

After attending this presentation, attendees will be familiar with a process of body cooling after death. The knowledge of cooling rates of different body sites is of use estimating the Time of Death (TOD).

This presentation will impact the forensic science community by showing the possibility of estimation of the TOD, especially in the early postmortem period, by measuring the temperature in the eyes of human corpses.

Estimation of the TOD is an important issue for the forensic pathologist examining the body at the death scene. The TOD estimation methods actually used in practice, based on postmortem changes such as hypostasis, rigor mortis, rectal temperature, or different supra-vital reactions are still not of satisfactory precision.

Recent studies in pigs and humans have shown a possibility of significantly decreasing the TOD estimation error, in particular

regarding the very early postmortem period, by choosing the eye as the temperature measurement site.

The single eye, rectal, and ambient temperature measurements were taken at the scenes of death in 21 cases with known TOD (1h 35min to 5h 15min), using pin probes connected to a high-precision electronic thermometer (Dostmann-electronic). The measured eye temperatures ranged from 20.2°C to 33.1°C. Rectal temperatures were measured at the same time and ranged from 35.0°C to 37.4°C. Ambient temperatures (1°C to 24°C), environmental conditions (still air to light wind) and hair amount on the head were also recorded every time. TOD was calculated using a formula based on Newton's law of cooling previously successfully applied in comprehensive studies on pigs: $T = T_a + (T_0 - T_a)exp(—k_c t)$ (Eq. 1) where T is the temperature of the body site, T_a is the ambient temperature (assumed to be constant during the course of cooling until the time of the measurement), T_0 is the initial human eye temperature (assumed to be 34.9°C), k_c is a first order cooling rate constant, and t is the time since death. The mean value of k_c=-0.113h^{-1} had been previously determined in studies on the postmortem cooling process in pig eyeballs. Thanks to both the significantly faster postmortem decrease of eye temperature and the residual or lack of plateau effect in the eye, no influence of body mass, TOD in the human death cases using eq. 1 could be estimated with quite good accuracy. The maximum TOD estimation error during the postmortem intervals up to around 5h was 1h 28min in one case among 21, while for the rest of 20 cases it was not more than 53min, while mean error for all 21 cases was ± 49 min. However, this highest overestimating TOD error in one case may be explained by baldness of this one examined individual.

The results from 21 cases with known TOD show that the presented method of TOD estimation may be of satisfactory accuracy in the early postmortem period, particularly when applied to bodies found at room temperature and in normal environmental conditions (still air, normal humidity). The study is being continued and the model is going to be improved using the new results from successive cases.

Time of Death, Body Cooling, Eye Temperature

G141 Toxicology of the Exhumed Body: Challenges and Pitfalls

Enrico A. Risso, MD, Via Alfredo Catalani 10/26, Genoa, ITALY*

After attending this presentation, attendees will improve their understanding about the "nightmare" of postmortem drug redistribution.

This presentation will impact the forensic science community by providing results from several studies in a topic which is often underestimated in the textbooks. This presentation is a proposal of guidelines for toxicology sampling in case of exhumation, including the most important sampling steps which have to be performed at the locus.

The word exhumation derives from the Latin words *ex* and *humus*, the former meaning "out of" and the latter meaning "ground." These words mean "out of ground" and describe the legal and authorized procedure to retrieve the coffin and the body from a grave for postmortem examination after legitimate burial in a cemetery. This event represents a real crime scene and has to be approached by pathologists and police officers as such.

Although autopsy procedures on corpses buried for a long time and in an advanced state of decomposition were regarded to be useless, without being accepted by the scientific community until the end of the nineteenth century, recent studies have proved that many useful histological and toxicological findings can be identified after months or years of interment. In several countries exhumations are extremely rare. Therefore, even for the most experienced forensic pathologist, it might be very difficult to develop the appropriate knowledge and skills to approach a forensic exhumation with the particular interpretative problems that might arise during the analysis of the findings.

The most famous exhumations performed in the United Kingdom (U.K.) were the victims of Dr. Harold Shipman, an English General Practitioner who shocked the population of his nation by killing up to an estimated 220 – 240 of his patients with lethal doses of diamorphine. Recent famous exhumations were performed in Italy in 2007, when the bodies of Poliziano (1454 – 1494), a Florentine classical scholar and poet, and Pico della Mirandola (1463 – 1494), a Renaissance philosopher from Modena, were exhumed from St. Mark's Basilica in Florence. Toxicological analyses established that both had died as a result of arsenic poisoning. Another extremely interesting item of research was recently performed on Napoleon's hair in France. The toxicology result undermined the theory that the British poisoned him with arsenic and disclosed that the pattern of arsenic consumption was spread over a long period of time, reflecting a chronic exposure rather than an acute poisoning; therefore, if the cause of death was due to arsenic poisoning, the theory of conspiracy which implicates one of Napoleon's companions poisoning him only while on St Helena's island would not be possible.

Although it is well known that arsenic and other heavy metals (such as antimony, zinc, copper, lead, mercury, cadmium, and thallium) may normally be present in the soil, a higher concentration within the human tissue clearly excludes the possibility of passive diffusion from the earth into the corpse. Mercury can persist in bones for thousands of years and it has been isolated from prehistoric human remains. High aluminium levels in bone, brain, and liver are regarded to be the most likely cause of death in exhumed bodies of dialyzed patients.

Postmortem toxicology in case of exhumation, especially after several years of burial, is indeed a very challenging matter and, as mentioned above, a failure during the sampling may result in a wrong interpretation of the data even for an experienced forensic pathologist.

Toxicology, Exhumation, Sampling

G142 Body Packages in Spectral Imaging CT-Experimental Study to Distinguish Between Different Illicit Drugs *In Vitro* and in a Porcine Model

Jochen M. Grimm, MD, JD, Ludwig Maximilians Univ Hospital, Nussbaumstr. 20, Munich, GERMANY; Silke Grabherr, MD, Centre Univ Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, SWITZERLAND; and Edvard Ziegeler, MSc, Stefan Wirth, MD, PhD, and Michael Scherr, MD, Ludwig Maximilians Univ Hospital, Nussbaumstr. 20, Munich, GERMANY*

After attending this presentation, attendees will understand the impact of modern imaging methods on research and clinical handling of suspected body packers as well as the need for cooperation between forensic and clinical disciplines.

This presentation will impact the forensic science community by demonstrating how new imaging methods like dual energy spectral imaging CT scan alter existing algorithms and change clinical handling of suspects and patients, provided that specialists from the disciplines involved cooperate closely.

Bodypacking—meaning the transport of packed illicit drugs inside the human body—is a prevalent and increasing concern for modern societies with a major impact on the medicolegal and clinical field. The most feared complication of body packing is the rupture of one of the carried packs with potentially lethal drug intoxication (body packer syndrome). When suffering from symptoms of intoxication due to pack rupture, existing algorithms for the treatment of body packers suggest immediate abdominal surgery to remove the packs. Yet, in cases of heroin intoxication, a laparotomy with its high rate of complications could be avoided by administration of the antidote

Naloxone and intensive care supervision of the patient. Thus, the distinction of carried illicit drugs, especially between heroin and cocaine, can be crucial in clinical handling of body packers and influence medicolegal investigations. Our objective was to evaluate the differentiability between several substances in packages containing illicit drugs via Spectral Imaging CT (SICT) *in vitro* and in a porcine model.

Ten samples of illicit drugs (heroin, cocaine and hashish in different concentrations/compressions) packed in standardized ovoid plastic containers were examined *in vitro* and after placement in the rectum of a 121.5kg pig cadaver. Images were obtained using a 64-row CT unit (GE CT750 HD) in spectral imaging mode. The mean CT number in Hounsfield-Units (HU) representing radiation density was recorded for each sample. Spectral curves displaying radiation density of each sample in HU in relation to photon energy at keV-levels between 40 and 140 were obtained. Mean HU and standard deviation as well as the average slope (S) of the curve were evaluated for each sample. Statistical analysis was performed using Wilcoxon's test.

Mean HU of a substance was greatly affected by its concentration and the degree of compression and did not significantly differ between the investigated drug types. *In vitro*, the average slope of a substance's spectral curve did not significantly differ with varying density and concentration, but was characteristic for the investigated type of drug (i.e., heroin, cocaine, and hashish, respectively; all $p<0.001$). In the porcine model, differences were less pronounced than *in vitro* but still significant ($p<0.01$). Mean effective radiation dose for the scans was 9.4 mSv in the porcine model.

This presentation will demonstrate that interdisciplinary cooperation is important to evaluate potential applications and use the advantages of new imaging methods to their full extent. It will highlight the ability of new imaging methods to differentiate between various substances in general and different illicit drugs in particular. In contrast to hypotheses in the existing literature, the examinations *in vitro* and in a porcine model suggest that different illicit drugs cannot be identified by measuring their radiation density in HU at any given keV level. However, at a reasonable radiation dose, SICT may aid in the identification of incorporated substances in a body packer using the slope of the spectral HU curve. If confirmed in clinical studies, this information could alter the clinical handling of symptomatic body packers suffering from body packer syndrome due to pack rupture. Body packers carrying heroin could be treated conservatively instead of undergoing complicated abdominal surgery.

Body Packer, Illicit Drugs, Spectral Imaging CT

G143 Death Following Retrobulbar Injection of Desmopressin for the Treatment of Non-Arteritic Anterior Ischemic Optic Neuropathy: Which Implications of an Off-Label Use

Benedetta Guidi, MD, Hospital of Lucca, Via Santa Dorotea 1, Pescia, ITALY; and Marco Tuccori, MD, Stefania Fornaro, MD, and Marco Di Paolo, MD, Univ of Pisa, Via Roma 55, Pisa, ITALY*

After attending this presentation, attendees will be aware of the possible clinical and legal implications following off-label use of corticosteroids and desmopressin for the treatment of Non-Arteritic Ischemic Optic Neuropathy (NAION).

This presentation will impact the forensic science community by illustrating a case of fatal acute myocardial infarction after retrobulbar injection of synthetic replacement of vasopressin.

Since a standard treatment for NAION with proven efficacy is not available to date, most therapeutic approaches are empirical and include a wide range of agents presumed to act on thrombosis, on the blood vessels, on the disk edema, or presumed to have a neuroprotective effect. Among other proposed treatments retrobulbar injection of corticosteroid and desmopressin represents an invasive approach, with potential local and systemic complications. Which is believed to have never been documented before. The rationale for using desmopressin in the treatment of NAION is uncertain and probably consists in experimental findings demonstrating that desmopressin induces ciliary artery relaxation in dogs via V1-receptors through a mechanism which involves nitric oxide. In turn, this would enhance vascular permeability, thus facilitating the re-absorption of optic edema. A similar vasodilation effect can be attributed to corticosteroids.

A 60-year-old man, apparently healthy with negative history for cardiovascular diseases, was hospitalized because of a unilateral sudden and painless severe visual loss (20/200) on waking in the morning. The optic disc appeared hyperemic and edematous, with a focal severe swelling. Relative inferior altitudinal scotoma was present at visual field examination. The patient presented with erythrocyte sedimentation rate 20mm/h and normal levels of plasma fibrinogen and C-reactive protein. The diagnosis of NAION was made. Two separate and immediately consecutive injections of betamethasone (2mg/0.5ml) and desmopressin (2mcg/0.5ml) were performed in the retrobulbar space. The administration of any preoperative medication or cardiovascular examination is not documented. In the patient medical records, the total volume of the injections and the size of the needle used are not specified. The procedure was technically uncomplicated without any monitoring in progress during injections such as ECG, peripheral oxygen saturation, or blood pressure measurement. Fifteen minutes later, the patient suddenly developed cold sweat, dyspnea, thoracic pain and severe hypotension. ST segment elevation Acute Myocardial Infarction (AMI) was diagnosed by ECG. Intensive care support was initiated. However, despite cardiopulmonary resuscitation, the patient died of irreversible cardio-respiratory arrest. At autopsy, the heart presented with a normal shape and weight (350g); coronary arteries showed significant atherosclerotic luminal narrowing. Histological investigation showed a stenotic atherosclerotic plaque (95%) complicated by culprit thrombosis of the Left Anterior Descending (LAD) artery, 2cm after its origin. Examination of the other organs was unremarkable, except for mild pulmonary edema and polyvisceral stasis. There was no evidence of increased orbital volume or sign of vagal compression secondary to retrobulbar hemorrhage.

Professional autonomy in the health care decision-making process renders the physician free to prescribe a drug for purposes other than that which it has been approved, where it is considered both safe and effective according to his/her professional judgement.

The use of unlicensed and off-label medicines is a widely used medical practice mainly in certain clinical settings.

Physician's autonomy in healthcare decision making represents an instrument to guarantee the progress and evolution of scientific knowledge and to realize in the meantime the most effective safeguard of health protection and promotion.

Though off-label prescription is common and sometimes necessary for providing a pathway to clinical practice innovation, it presents significant risks. This practice may lack rigorous scientific scrutiny and there is little known about the degree of scientific evidence supporting it. According to the literature, a high percentage, around 73%, of off-label use had little or no scientific confirmation.

Unexpected, adverse effects represent a possible risk. Since the off-label practice may expose patients to avoidable risks, it is mandatory for doctors to follow the lawful direction and ethical recommendation.

This case is out of the ordinary for the forensic scientist because of the possible recognition of medical liability for personal injuries and murder when a patient has psycho-physical damage or dies as consequence of the administration of an off-label drug.

Desmopressin, Non-Arteritic Anterior, Off-Label Prescriptions

G144 A Case of Suicide by Nembutal: The Consequences of Free Trafficking Drug Online

Carmela Fiore, MD, Univ of Foggia, Viale Degli Aviatori 1, Foggia, ITALY; Agostino Pasqualini, BS, Policlinico Le Scotte, Siena, ITALY; Palmira Fortarezza, MTL, Ospedale Tatarella, Cerignola, ITALY; Maria Antonietta Sorrentini, MD, and Santina Cantatore, Univ of Foggia, Ospedale D'Avanzo, Viale Degli Aviatori 1, Foggia, ITALY; and Fabio Centini, BS, Policlinico Le Scotte, Siena, ITALY*

The goal of this presentation is to show a suicidal case of a veterinarian and/or human barbiturate euthanasia agent (Nembutal), purchased freely online. Postmortem findings with a complete histological and toxicological analysis of pentobarbital distribution in fluids and tissues are discussed.

This presentation will impact the forensic science community by showing the importance of an accurate anamnestic, circumstantial, histological, and toxicological investigation in all drug-related deaths. At the same time pointing out that pentobarbital is not available in pharmacies as a commercial preparation, but its online traffic is completely free for anyone.

Pentobarbital is a hypnotic belonging to the class of rapidly acting barbiturates. Sodium pentobarbital, which is also called "truth serum", was adjunct during narcoanalysis to allow increased interaction of catatonic and schizophrenic patients with therapists, particularly during the treatment of these patients during the 1930s and 1940s. Today it is commonly used in pharmaceutical preparations for the euthanasia of animals. On the one hand, accidental and volunteer overdose caused by short-acting barbitures in humans have become rare since these molecules became commercially unavailable as sleeping drugs/hypnotics. On the other hand, suicidal ingestion of a lethal dose of pentobarbital has increased because it is advocated by the "Exit" association. This association provides assistance to individuals wishing to commit suicide because of lasting painful disease or severe degradation of their physical condition. Even if the pentobarbital is not available in pharmacies as commercial preparations, it could be ordered with a medical prescription from local drug distributors; its online trafficking is completely free, as this case demonstrates.

A 24-year-old male was found dead in a bedroom of a bed and breakfast by an attendant. He was a fourth-year medical student who had supported a few tests, when, two years after the end of a relationship, he fell into depression. Followed by specialists, a "bipolar disorder" was diagnosed. In February 2012, his mother was aware that the young man had bought online from Mexico a drug used in veterinary medicine: Nembutal. Obtaining information about the shipment, the woman was able to seize the substance. Twenty days before his death, the mother had been informed by a friend about another online purchase of Nembutal from China. It arrived by mail but the parents were unable to seize the substance. On April 3, 2012, the young man pretending to sleep at a friends, reserved a room at a bed and breakfast, where he was found dead the following day at 1 p.m. The corpse was laying on the bed; and, next to him, an empty bottle of whisky and two packets of white dust (one empty and one full) were found.

A complete autopsy was performed 24 hours after death. The external examination revealed traumatic lesion. The internal examination revealed only polivisceral stasis and massive pulmonary and cerebral edema. Histological examinations showed, in the brain, cytotoxic and vasogenic edema and red neurons; in the myocardium, interstitial edema; in the lungs, massive endoalveolar edema; in the liver, sinusoidal stasis and macrovesicular steatosis. A comprehensive toxicological screening was performed on postmortem cardiac blood, urine, bile, gastric contents, and tissue homogenates (liver and kidney) using a combination of immunoassay and chromatographic techniques. In all the biological fluids and tissues, lethal concentrations of pentobarbital were confirmed (blood: 57,461mcg/mL; bile: 890,67mcg/mL; urine: 7.06mcg/mL; gastric contents: 13474,96mcg/mL; liver: 512,48mcg/mL, kidney: 361,77mcg/mL). Ethanol and volatile compounds in peripheral blood were sought by head-space-gas-chromatography equipped with flame iosination detection (HS-GC-FID); it showed a very high level of alcohol in the blood (1,2903g/l). The presence of pentobarbital was also confirmed by toxicological examination of the white dust.

According to the crime scene data, autopsy, histological, and toxicological findings death was attributed to acute pentobarbital intoxication.

Pentobarbital, Drug Online Trafficking, Toxicological Finding

G145 Income-Based Medicine and the Avastin Dilemma: How Italian Doctors Carry the Tangled Skein on Their Shoulders

Raffaello M. Bellino, MD, Univ of Bari, Section of Legal Medicine, Bari, ITALY; Maricla Marrone, MD, Policlinico Teaching Hospital of Bari, Risk Management Unit, Piazza Giulio Cesare, 11, Bari, ITALY; Lucia Tattoli, PhD, Univ of Bari, Sezione di Medicina Legale, Bari, ITALY; Cristiana Laculli, MD, Ospedali Riuniti Foggia, Foggia, ITALY; and Alessandro Dell'Erba, PhD, Policlinico Teaching Hospital of Bari, Risk Management Unit, Piazza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, attendees will learn about distributive justice concerns and their consequences on medical liability.

This presentation will impact the forensic science community by illustrating how evidence is not a value in itself, but needs to be interwoven with other societal values in a clear way.

The treatment of age-related macular degeneration has opened a wide-ranging discussion. Although ranibizumab (Lucentis) is a licensed and approved treatment, many ophthalmologists in Italy and worldwide continue to prescribe bevacizumab (Avastin), which is licensed for treatment of some metastatic cancers but not for the treatment of eye conditions. The off-label use of bevacizumab appears to produce comparable results, as shown by guidances of scientific societies worldwide and by the CATT Research Group, at a substantially lower cost than the licensed treatment of ranibizumab.

The practice of medicine is no doubt based on the appraisal of scientific evidence and, in such a sense, the drug licensing process plays a fundamental role. Nonetheless, the practice of medicine has long since shown universalistic attitudes.

The debate Lucentis-Aventis unveils the controversial dispute between the mere devotion to scientific evidence in clinical practice and the relative weights that some other elements (e.g., sensitive and cost-effectiveness analysis) play in medical decision-making. In the first hypothesis, the off-label use of drugs would be discouraged in favor of licensed drugs. This approach would have the side-effect of dramatically restricting the universalistic access to healthcare. In the second hypothesis, criticisms are grounded on the difficulty of balancing the role that empathy, cost-effectiveness, or other criteria should play in distributive justice. Given the need to prove the equivalence of therapeutic effect, pharmaceutical companies have not always demonstrated responsiveness to social and economic context, due to the profit loss subsequent to more cost-effective treatments. In addition, in the absence of clear guidances for the unlicensed or off-label use of drugs by regulatory authorities, it would be legitimate to doubt the universalistic attitude that inspires such controversial medical practice, as universalism is patently bounded to efficacy.

In both hypotheses, there is a small risk to subsume scientific evidence to profit maximization (income-*based medicine*), given that collection and appraisal of evidence risk to be conditioned by actual and prospective earnings of pharmaceutical companies without any referral to positive consequences for the health status of the society. In such a context, given that the responsability for the off-label use of drugs rests on the shoulders of prescribing doctors, the decision between the aforementioned hypotheses appears to be dependent on the individual professional person, directly bringing about unfair

inequalities. In addition, the legal protection for those clinicians who act cost-effectively appears to be lacking under the Italian laws, on the basis that incomplete scientific evidence could be given to prove one's diligence in case of off-label use of drugs. The controversy is relevant, because the relatively wide scientific evidence gathered in favor of the off-label use of bevacizumab is uncomparable with that available in other clinical settings (e.g., Neonatal Intensive Care Units), where the off-label use of drugs is nonetheless common, even though the information about the optimal dosage, specific pharmacokinetics characteristics, as well as potential adverse reactions, is insufficient.

Off-Label Drugs, Medical Liability, Ethics

G146 Fatal Sodium Nitrite Poisoning: A Case Report

Giancarlo Di Vella, MD, PhD, Maria Carolina Romanelli, MD, and Francesco Introna, PhD, Univ of Bari, Piazza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, attendees will learn about acute intoxication deaths resulting from unusual chemicals, representing a challenge for investigators and pathologists in charge of determining cause of death.

This presentation will impact the forensic science community by showing that only a collaborative and multidisciplinary approach involving public health officials, forensic pathologists, and toxicologists can properly lead a comprehensive investigation.

Sodium nitrite poisoning, usually due to accidental food and water contamination, is rarely recorded in the literature. Sodium nitrite is a white to slightly yellowish crystalline powder that is very soluble in water. Its main use is for the industrial production of organo-nitrogen compounds, but it is also used as a food additive because it inhibits growth of pathogenic microorganisms and is used as a taste and color preservative for certain meats. It can be toxic in high amounts for humans because it causes methemoglobinemia. Sodium nitrite's LDLo is 33-250mg/Kg, meaning a 60kg person would likely have to consume at least 2g to 15g to result in death.

Presented is a case of "iatrogenic" sodium nitrite poisoning that occurred during a medical examination and malabsorption test for three patients, resulting in the death of one of them. Three women performed a Sorbitol H2 Breath Test to detect specific sugar malabsorption. Acute-onset symptoms, consistent with chemical poisoning, occurred within minutes after consuming 5g of sorbitol dissolved in a glass of water. Symptoms included asthenia, lost of consciousness, myoclonic jerks, nausea, and retching. The emergency was immediately recognized, but unfortunately, one of the women died a few minutes later despite all efforts and administration of methylene blue in an attempt to revert methemoglobin to hemoglobin. The other two women were transported to the nearest emergency department where methylene blue was promptly administered. The two patients were later discharged without clinical sequelae after hospitalization in the Intensive Care Unit. Samples of the presumed sorbitol powder that had been administered to the women were collected by authorities in the private medical clinic where the breath test had been performed. Investigations revealed that sorbitol had been bought online (international website) and that it was the first time it had been used in this clinic. During the autopsy, the external examination of the cadaver revealed diffuse cyanosis and resuscitation signs. Postmortem findings (organ gross examination and histological analysis) confirmed a normal cardio-respiratory system apart from the evidence of multiorgan congestion and pulmonary intra-alveolar hemorrhagic edema. The gastrointestinal apparatus showed acute congestive and focal hemorrhagic findings of the visceral wall related to the contact with poison. The majority of organs also showed a bluish discoloration due to the intravenous infusion of methylene blue as a result of the attempt at resuscitation. Extensive toxicology testing was performed to determine the cause of the poisoning and a list of potential agents was developed by forensic toxicologists. Infrared spectroscopy and gas chromatography revealed that all the sorbitol recovered in the clinic was actually sodium nitrite at a concentration of 97 – 98%. Analyses of urine and blood collected at the time of autopsy were performed using gas chromatography and test for nitrites and nitrates; the presence of high concentrations of sodium nitrite was confirmed. The serum nitrite ion level was 0.97mcg/ml and this level is consistent with death from nitrite poisoning (lethal level >0.55mcg/ml). The small concentration of nitrite in urine suggested the occurrence of rapid death.

The health risk of purchasing drugs from online websites that are not official drug resellers of well-known companies will be debated.

Sodium Nitrite, Sorbitol Breath Test, Toxicity

G147 Postmortem Toxicological Review of Combined Drugs Toxicity Deaths Reported in the Republic of Ireland Involving the Detection of Bath Salts Headshop Products

Khalid Jaber, MD, Firebrigade Training Centre, Malahide Rd, Dublin, IRELAND*

The goal of this presentation is to share the Irish experience in identifying deaths caused by combined drug toxicity in which detection of headshop products, referred to as bath salts, has been identified.

This presentation will impact the forensic science community by sharing, for the first time, the Irish experience of chemical deaths caused by combined drugs toxicity that postmortem toxicoloigcal analysis detected as headshop products (drugs), referred to as bath salts. The human toxicology section of the state laboratory is a centalized toxicological analysis unit that handles all referred samples from the various coronial services operating in the Republic of Ireland.

Synthetic cathinones include drugs like mephedrone, MDPV, butylone, flephedrone, and methylone that form part of a larger group of illegal drugs encountered in Ireland and other countries as components of products sold in retail stores referred to as head shops.

In Ireland, prior to May/June 2011, a rapid growth of these commercial interests was noticed on the main streets in the capital of Dublin and in most other smaller cities and towns in Ireland. The public as well as the media have become alarmed with the proliferation of the head shop products. A national TV documentary program focusing on a downtown Dublin street recorded 18 customers that queued, over an interval of 15 minutes of filming, in front of a small hatch of one head shop. They were buying these products for cash. Ireland was experiencing a new epidemic of addiction craze of consumption of head shop products, which have been marketed as bath salts although marked "not for human consumption," with 24 hr availability and facility for home delivery to those requesting such service. These products for some time have been legally cleared by customs when imported by these business outlets. An owner who was interviewed articulated his position that he was selling bath salts and it was up to the buyers to use them the way they saw fit. For example, one gram of his bath salts could sell from 10 to 30 euros!

The consumers of these products (the customers of these shops) spanned a wide range of ages (technically, customers must be over 18 to buy anything from a head shop) and represented all social strata, both sexes, and marital status.

Users' clinical signs and symptoms such as hallucinations, anxiety panic attacks, and psychosis were increasingly observed and reported to health workers; the police force was monitoring the rise of this worrying trend. These drugs have become a convenient replacement to the hard drugs of abuse as consumers began to inject these drugs. In November 2009, the first fatality of combined drug toxicity that included mephedrone was strongly suspected initially and was subsequently confirmed in postmortem toxicological analysis. In

February 2010, the Department of Health placed certain substances on sale in head shops under the control of the Misuse of Drugs Act 1977, paving the way for these bath salts products to be outlawed. In the same month, an arson fire totally destroyed a head shop in Dublin. In March 2010, two pipe bombs were discovered by employees of two head shops separately. The Army Bomb Disposal Unit removed the weapons and deemed them to have been two viable improvised explosive devices. The following month, a petrol bomb attack was carried out on a head shop in a seaside town north of Dublin, leading to fire breaking out.

In May 2010, the Irish government announced a criminal ban with immediate effect on a list of head shop-based drugs, making it illegal to trade in mephedrone, spice products, and substances that exert biological effect like cannabis, cocaine, and ecstasy.

One month later, the Minister for Justice published the New Criminal Law, The Psychoactive Substances Bill, which made it illegal to sell hallucinogenic products. The bill granted power to Garda Siochana to seek a court order to close head shops suspected of selling drug-like products; the owners of these premises were required to prove they are not involved in such activities.

The state laboratory identified 33 postmortem toxicological analyses that showed positive head shop synthetic cathinones over a three year period between November 1, 2009 and November 30, 2011. Five cases were identified prior to the New Psychoactive Substances Bill while four cases were identified in June 2010 and the rest afterward. These cases comprise twenty-six males and six females.

An account of these cases, discussion of this epidemic, and the effectiveness of the national measures taken is presented.

Toxicology, Headshop, Drugs

G148 Cause of Death–Acute Alcohol Poisoning, Manner of Death–Suicide: A Case Study

George S. Behonick, PhD, and Kevin G. Shanks, BS, AIT Laboratories, 2265 Executive Dr, Indianapolis, IN 46241; Robert Kulhanek, 2422 North 7th St, Sheboygan, WI 53083; and Mark J. Witeck, MD, 6826-91st Ave, Kenosha, WI 53142-7651*

After attending this presentation, attendees will understand the importance of alternative or secondary specimens collected at autopsy for the toxicological analyses of volatile compounds, most notably, ethyl alcohol or ethanol. The case data represents exceptionally high alcohol concentrations in heart blood and vitreous humor within the context of the death scene investigation and autopsy findings. Interpretive considerations when evaluating unusually high blood and vitreous humor alcohol concentrations, with special attention directed to possible explanations for the findings based on the decedent's history and scene investigation, are included in the case study.

This presentation will impact the forensic science community by showing the significance and importance of a complete, competent medicolegal death investigation integrated within a diligent scene investigation, an autopsy with appropriate collection of primary and alternative specimens for toxicological study, and most importantly, the collaborative work effort of medical death investigators, forensic pathologists, and forensic toxicologists.

Acute alcohol poisoning is a frequent cause of death classification; however, it is rare when a decedent willingly and intentionally initiates a heavy bout of drinking with the sole purpose of consummating a life-ending act. The case is an 85-year-old male found deceased, sitting upright in a chair, in a ground floor room of his private residence. The witness, who reported the death, stated the decedent was sitting in the same manner two days before; the relative believed the man to be asleep and did not want to disturb him. The witness confirmed the decedent alive three days before but apparently in a state of distress; he also appeared to have been intoxicated and crying. His family history was notable for the death of his spouse approximately six weeks earlier. Investigation at the scene revealed a hand-written note simply stating "good bye." Further, two books found in the residence (*Final Exit* and *The Peaceful Pill Handbook*) extolling the practicalities of "self-deliverance" strongly suggested ideation on the part of the decedent. Additional evidence collected from the scene included a store receipt for a 1.75 liter bottle of vodka with a purchase date of three days prior to discovery of the body. Investigators discovered an empty vodka bottle under a bed in an upstairs room. External examination of the body indicated rigor, lividity, and skin slippage to be consistent with a postmortem interval of three days. Remarkable findings at autopsy included severe plaquing of the coronary arteries and aorta, a partially calcified aortic valve, moderate plaquing in the cerebral arteries within the Circle of Willis, notable cystic changes in the kidneys, and pulmonary edema. Autopsy noted moderate decomposition of the body along with an absence of significant injury capable of causing or contributing to death. Specimens for toxicological analyses collected at autopsy included heart blood and vitreous humour. The analyses consisted of volatile compounds by headspace gas chromatography in blood and vitreous humour and a comprehensive screen (more than 300 compounds) in blood by Ultra Performance Liquid Chromatography coupled to Time of Flight Mass Spectrometry (UPLC/ToF-MS). The results of the volatiles analyses indicated alcohol concentrations (weight by volume) of 1.605% and 0.893% in blood and vitreous humour, respectively.

Previous studies in cases involving unusually high alcohol concentrations demonstrated a mean blood alcohol concentration of 0.74%, with a range 0.42 – 1.77%. A report also indicates a 55-year-old male achieving a blood alcohol concentration of 1.13% (w/v) in a suicide gesture averted by supportive therapy.[1] This case study explores the plausibility of achieving the alcohol concentrations reported for heart blood and vitreous humor and includes discussion of other factors (diffusion, postmortem neo-formation secondary to decomposition) to consider when interpreting the results.

Ethanol, Poisoning, Suicide

G149 Decomposition Pattern of Human Heads as Related to Insect Activity

Yangseung Jeong, MA, 560 Prestwick Ridge Way, No 100, Knoxville, TN 37919*

After attending this presentation, attendees will understand how human heads decompose with the involvement of insects and the different way in which insect activity proceeds depending on whether a head is covered or uncovered.

This presentation will impact the forensic science community by studying the process by which human heads decompose through the activity of insects.

Despite the important role of insect activity in the process of human decomposition, decomposition pattern by insect activity has been an issue of little interest among forensic anthropologists as well as forensic entomologists. The goal of this study is to examine and compare the decomposition patterns of human heads in covered and uncovered conditions through the evidence of insect activity. Heads, as opposed to full cadavers, were chosen for this study because of their forensic significance. Blow flies tend to lay eggs in the head region first, and according to an unpublished preliminary study, the head revealed the most consistent decomposition pattern compared to other body parts.

This research was conducted at the Anthropology Research Facility at the University of Tennessee, Knoxville. A total of 60 donated

individuals (36 covered and 24 uncovered), donated between April 2011 and March 2012, were observed and photographed every day until no further taphonomic change was observed.

The results of this research indicate that covered heads were more likely to reach skeletonization than uncovered ones. Specifically, while about 78% (28 out of 36) of covered heads exposed more than half of cranial bones, only 25% (six out of 24) of uncovered heads reached the same degree of decomposition. This result is statistically significant (χ^2=16.33, p=.000). For both covered and uncovered heads, newly-hatched maggots tend to start feeding inside the orifices, among which the mouth and nose are most popular. Observations show that as the maggots grow, they move out of the holes, exposing bones around the T-zone of the face which connects eyes, nose, and mouth.

Further study observations demonstrate that when a head is covered by black plastic sheeting, maggots coming out from the mouth, nose, and eyes tend to congregate on relatively high portions of the head (i.e., the surface furthest from the ground). While some maggots travel on the outer skin, many pass through the narrow space between bones and inner skin, exiting through holes that they make. After conquering the high portion of the head, maggots consume soft tissues downwardly, resulting in the exposure of bones far from the ground first. Thus, for covered heads, any remaining, soft tissues closest to the ground are more likely to remain and dry out relative to tissues further from the ground.

Conversely, observations from the study show that when a head is not covered, maggots coming out from the holes tend to gather together toward the ground, which usually is a shaded area. Because they tend not to feed on the area directly under the sun, soft tissues facing the sky are likely to remain untouched and dry out. Thus, for uncovered heads, any remaining soft tissues close to the ground are more likely to be skeletonized, demonstrating an opposite pattern to that of the covered heads.

In summary, this research suggests that black plastic sheeting functions to block sunlight, which in turn provides maggots with a relatively comfortable environment to feed. Consequently, this particular environment significantly alters the decomposition pattern of heads. The information of this study is expected to be utilized during crime scene investigation when it is necessary to determine if a body was covered during the initial period of its decomposition and if the body was disturbed after its deposition.

Decomposition, Pattern, Insect Activity

G150 PMI Estimation in Burned Remains: Real Cases

Valentina Bugelli, MD, Luigi Papi, Stefania Fornaro, MD, Chiara Toni, MD, and Dominici Ranieri, Univ of Pisa, Via Roma 57, Pisa, ITALY; and Stefano Vanin, PhD, Univ of Huddersfield, Queensgate, Huddersfield, UNITED KINGDOM*

After attending this presentation, attendees will have novel information about the applicability of the Forensic Entomology (FE) approach for the Minimum Time of Death (mPMI) estimation in burned remains.

This presentation will impact the forensic science community by validating the entomological approach in the PMI estimation in burned bodies. The two reported cases, and the experiments carried in the same area, statistically confirm the applicability of the entomological approach based on the fly developmental rate for the PMI estimation.

Different methods can be used in order to destroy or hide a body or make its identification very difficult: mutilation, burning, burying, acid dissolution, and concealment into concrete blocks, among others. Burying and burning are perhaps the most common ones. Fire is also used in cases of self-inflicted injuries and suicide or suicide-homicide, but burned remains can also be found in several accidents of different origin (cars, aircraft crash, industries, domestic, etc.), and cases of burnt bodies found in different locations such as open fields, cars, and indoors have been reported by several authors.

In burnt bodies, arthropod specimens may be the only tool useful in the estimation of the mPMI. In fact, burning prevents the use of the classical thanato-chronological techniques (e.g.: livor, rigor, algor mortis, (K^+)) for mPMI estimation.

This work deals with the description of five burned bodies found during the summer 2011, in Central Italy. The studied cases can be grouped in two categories: homicide/suicide (three people) and aircraft crash (two people).

In July 2011, a mother killed herself, her daughter, and her son by administering a drug and setting fire, using gasoline, to the car in which they were located. The last time they had been seen alive was 3:08 p.m. Fire brigades were alerted at 3:38 p.m. When forensic pathologists arrived on the scene, the bodies were completely burned and colonized by fly eggs. Most of the colonization in the mother's body was at the abdomen and inside the skull, fractured by the heat. During the autopsy, performed the day after, the larval mass in the mother's abdomen had a temperature of 35°C, despite the bodies being stored in a refrigerator.

Colonization in the daughter's body was less important than in the other bodies. There was only a mass in the skull and the larval mass temperature was 5°C. In the body of the son, a mass in the chest (temperature was 19°C) and another mass in the abdomen (24°C) were observed. *Lucilia sericata* and Sarcophaga sp. larvae were collected from these masses. It is assumed that the fly oviposition and larviposition occurred immediately after the fire had been extinguished and before the bodies were recovered (two to four hours).

An air crash occured at 7:07 p.m. in July 2011. During the inspection at 8:00 p.m., the air temperature was 25°C. On the ground near the fuselage of the aircraft, firemen collected the broken airplane clock indicating seven hours, seven minutes, and 40 seconds, so the precise time of the impact and of the death (7:07 p.m. 40 seconds) was known. Two people died during the crash. The first body was only partially charred and did not present any fly colonization; the second one was almost completely charred and did present a colonization (eggs) in the lungs, heart, and liver. The fly oviposition (*Lucilia sericata*) occurred immediately after the fire had been extinguished and before the bodies were recovered (two to four hours)

These cases demonstrate that, in burned remains, the composition and the arrivals of the first insect colonization waves (Calliphoridae, Muscidae, Sarcophagidae) are the same as in the case of "fresh" bodies. In addition, the aircraft crash case indicates a faster colonization of the burned body compare to the other. This supports the application of the entomological approach, based on the developmental rate, for PMI estimation.

PMI Estimation, Forensic Entomology, Fire

G151 Initial Investigations of Hyperspectral Remote Sensing for Postmortem Interval Estimations in Forensic Entomology

Jodie A. Warren, MA, Simon Fraser Univ, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Margaret Kalacska, PhD, McGill Univ, Dept of Geography, Montreal, QC H3A-2K6, CANADA; and Gail S. Anderson, PhD, Simon Fraser Univ, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will be introduced to the initial applications of hyperspectral remote sensing to forensic entomology and understand its potential for increasing the precision of current immature blow fly age estimates and successively increasing the accuracy of postmortem interval estimates.

This presentation will impact the forensic science community by illustrating the opportunities offered by hyperspectral remote sensing into an entirely new area, entomology, and its possible future potential value in forensic or medicolegal entomology.

Current methods examining dipteran larval development to estimate minimum elapsed time since death are based on a minimum tenure of the insects on the body. Immature blow flies develop at a predictable rate and, based on the insect stage, a minimum postmortem interval is estimated. Unfortunately, in some instances, because some of the stages can be lengthy, only a crude estimate can be provided. This initial proof of concept investigation examines the use of hyperspectral remote sensing to reduce the estimate in the postmortem interval. The use of hyperspectral remote sensing in forensic entomology is unheard of, but remote sensing is successfully being applied to many other sciences including many forensic sciences. The objective of this investigation was to examine the use of hyperspectral remote sensing in increasing the precision of current blow fly (Diptera: Calliphoridae) age estimates and consequently increasing the accuracy of postmortem interval estimates

Daily spectral measurements of immature *Protophormia terraenovae* (R-D), a common blow fly, spanned the 325 – 1025nm range but the measurements were condensed to reduce excessive noise. Measurements were obtained using a handheld spectrometer once daily. Immature development was examined in two parts due to time constraints. Measurements were obtained from second instar to the pupal stage and from the beginning of the pupal stage until adult emergence. The adult colony was raised on milk powder, sugar, and water ad libitum. A CMP 4030 Conviron chamber was used to maintain the adult colony as well as the experimental animals. Development occurred at 25°C, a 14:10 (L:D) photoperiod of 20µmol of light and a relative humidity of 75%. The immature insects were raised on milk-fed veal liver in the Phytotron at McGill University, and then insects were transported daily to the spectrometer for measurement. Despite the transport, the average temperature recorded by a data logger remained at 24.6°C. Matlab R2011b and PRtools 4.1 were used to complete the spectral analysis. Also, a fourth order polynomial Satvitsky-Golay smoothing filter was applied. A forward feature selection was used to designate the top 25 discriminating bands.

This proof of concept investigation introduces a comparison of how the spectral signatures of *P. terraenovae* change from day to day within the immature stages. The results are more than promising and show a potential method for narrowing the original estimates and offering a better overall estimate of insect age, and therefore, postmortem interval estimation.

Protophormia Terraen, Hyperspectral Remote, Forensic Entomology

G152 Radiocarbon Analysis of Fly Pupal Cases to Estimate Date of Death

Joyce K. Stocking, MS, and Macarena D. Hevia, BA, Unidad De Identificacion Forense, Servicio Medico Legal, Avda. La Paz 1012, Independencia, Santiago, CHILE; and Douglas H. Ubelaker, PhD, Smithsonian Inst, Dept of Anthropology, NMNH-MRC 112, Washington, DC 20560*

After attending this presentation, attendees will understand the potential value of radiocarbon analysis of fly pupal cases associated with recovered human remains to estimate the date of death.

This presentation will impact the forensic science community by demonstrating how radiocarbon analysis of fly pupal cases can be used to estimate the date of death of the associated human remains, offering a less invasive sample alternative which yields more accurate results.

Beginning in the 1950s, atmospheric testing of thermonuclear devices produced elevated levels of artificial radiocarbon in the atmosphere that subsequently entered the food chain and were incorporated into the tissues of living organisms, including humans. These levels reached a peak in 1963 and, subsequently, have declined following the cessation of atmospheric testing. Research and casework have demonstrated how analysis of the radiocarbon content of human tissues can be used to estimate the date of death when compared to the documented values of the "bomb curve." Human soft tissues are especially useful in this regard since their radiocarbon values are relatively close to the atmospheric levels in comparison with skeletal tissues. Of course, following decomposition and skeletonization, soft tissues may not be available for analysis. Since fly larvae associated with decomposing human remains feed on the human soft tissues, the radiocarbon values of those soft tissues would be expected to be incorporated into the tissues of the larvae, including the puparial cases. The durable puparial cases can be found associated with human remains long after the adult insect emerged. Radiocarbon analysis of recovered puparial cases thus produce values consistent with the human soft tissues and can be used to estimate date of death.

Five human skeletons with preserved fly puparial cases and known death dates were located in the Human Rights Division of the Servicio Médico Legal in Santiago, Chile. Documented death dates were 1973, 1974, 1979, 1986, and 1986. Samples of puparial cases from each were submitted for radiocarbon analysis to an ISO 17025 accredited radiocarbon laboratory. The following summarizes the results for each of the five samples, listing the conventional radiocarbon age expressed in Percent Modern (pMC), the actual death date of the associated individual, and the date of intersect of the radiocarbon value and the bomb curve (using values from both the northern and southern hemisphere).

1. 131.2 pMC; death date of 1979; intersect dates 1978 – 1979
2. 140.3 pMC; death date of 1974; intersect dates of 1973 – 1974
3. 144.7 pMC; death date of 1973; intersect dates of 1972.5 – 1973
4. 122.5 pMC; death date of 1986; intersect dates of 1983 – 1985
5. 122.0 pMC; death date of 1986; intersect dates of 1983.5 – 1985

As indicated in the information presented above, radiocarbon analysis produced values that intersected the bomb curve either on the date of death or within one year of it.

When working with fly puparial cases associated with unidentified human remains, context and/or radiocarbon analysis of carefully selected human tissues can clarify if the puparia values relate to the earlier ascending aspect of the bomb curve or the later descending aspect. During recovery of skeletonized human remains, preserved fly puparia should be collected since they potentially provide valuable information on date of death of the associated individual.

Radiocarbon, Puparia, Remains

G153 Microbial Communities and Necrophilous Insects Associated With Cadaver Decomposition Islands in Southeast Louisiana

Danielle C. Levron, BS, and Erin J. Watson-Horzelski, PhD, Southeastern Louisiana Univ, Dept of Biological Sciences, Box 10736, Hammond, LA 70402*

The goal of this presentation is to provide attendees with knowledge of the microbial diversity and forensically important insects related to the five stages of decomposition.

This presentation will impact the forensic science community by demonstrating the importance of understanding biological and ecological aspects of both forensically important insects and microorganisms associated throughout the decay process.

Microorganisms in topsoil and forensically important insects are both pivotal in the decomposition of vertebrate carrion. Decomposition of vertebrate tissues results from both internal and external factors including autolysis, putrefaction, and diagensis, as well as scavenging of tissues by insects, vertebrates, and microorganisms. In forensic biology, there is limited information

available regarding the microbial communities associated with the decay of large vertebrates above-ground (*i.e*., cadaver decomposition islands). Most studies regarding microbial diversity and community structure are associated with profiling soil microbial populations, clandestine graves, or small-scale laboratory studies. However, the majority of decomposing remains of forensic interest (humans and poached wildlife) are recovered above-ground and often placed directly onto vegetation, leaf litter, soil surface, etc. Furthermore, soil microbes could be of particular forensic importance in later stages of decay when insect abundances have declined. From an investigative and evidentiary point of view, the more information one has, the stronger the case. Thus, this research was designed to produce a comprehensive database of microbial diversity, community structure, and succession using adult swine carcasses (i.e., human representative and reference model for forensic entomology research).

This study includes four series of seasonal experiments conducted in a woodland habitat in Hammond, LA, during the winter and summer seasons during 2010 – 13. The primary goals of this research are twofold: (1) to establish a microbial diversity database and successional patterns of soil microbes associated with cadaver decomposition islands in southeastern Louisiana; and, (2) to correlate the microbial soil profiles with the observed stages of decay and faunal succession patterns of necrophilous insects. Each seasonal experiment consisted of three adult swine carcasses (~60 – 160kg) placed directly on the leaf litter/soil surface. Each seasonal study was conducted for 12 months with sampling events and protocols varying for insect and soil core collections throughout the five stages of decay. Entomological data were collected both manually and using pitfall traps. Each sampling event included collection of insects both manually and using pitfall traps as well as two soil samples (~12cc each) collected beneath each carcass using a soil-coring device. Soil cores consisted predominantly of aerobic microorganisms associated with decaying detritus and organic-rich topsoil of the forest floor. Topsoil cores were also collected per sampling event at a control site approximately 15 meters away from the carcasses.

Processing of the soil samples included the following: soil characterization (soil texture, pH, total organic carbon, and total organic nitrogen), microbial enumeration, DNA extraction and purification, PCR amplification, T-RFLP analysis, and sequencing analysis. The primary sarcosaprophagous fly species associated with the swine carrion during the winter 2011 study were two Calliphoridae species (*Calliphora vicina* (Robineau-Desvoidy) and *Phormia regina* (Meigen)) and one Muscidae (*Hydrotaea leucostoma* (Wiedemann)). Data generated from this study will produce successional patterns of insects and microbes, which could potentially elucidate estimations of time since death for large vertebrate carcasses above-ground. More importantly, microbial topsoil diversity data will likely be more informative during later stages of decay such as advanced decay and putrid/dry remains. Data from the winter 2011 study (February 5, 2011 to December 6, 2011) will be presented.

Decomposition, Insects, Microbes

G154 Effects of Ketamine on the Development of *Chrysomya Megacephala* (F.) (Diptera: *Calliphoridae*)

Yaonan Mo, PhD, MD, Zhou Lü, PhD, MD, Zhai Xiandun, MD, Zhou Haimei, MD, Li Pu, MD, Ma Jinqi, MD, and Guan Ling, MD, Henan Univ of Science and Technology, Institute of Forensic Science, Luoyang, PEOPLES REPUBLIC OF CHINA; and Ling Li, MD, Univ of Maryland School of Medicine, 22 South Greene St, Baltimore, MD 21201*

After attending this presentation, attendees will gain the knowledge about how the presence of ketamine affects the development of larvae of necrophagous flies feeding on cadavers.

This presentation will impact the forensic science community by showing forensic entomologists and forensic pathologists the effects of ketamine, a drug commonly used as an anesthetic, on the development of larvae of the forensically important fly *Chrysomya megacephala* (Diptera: *Calliphoridae*). The understanding of the larval growth pattern of necrophagous flies feeding on cadavers in the presence of certain drugs could lead to a more reliable estimation of postmortem interval in drug-related deaths.

It is widely accepted that the presence of certain drugs or poisons can affect the development of larvae of necrophagous flies feeding on cadavers. These effects should be taken into consideration in estimation of the Postmortem Interval (PMI) of drug-related deaths. In recent years, it has been reported that many drugs and poisons within cadavers can affect the developmental duration of larvae or pupal stages of necrophagous flies, and then affect the accuracy of the PMI estimation. Ketamine, first synthesized in 1962, is an NMDA receptor antagonist and a derivative of Phencyclidine (PCP). Ketamine hydrochloride is used in intravenous anesthesia in clinical practice to replace PCP. Illicit drug abuse has risen to epidemic levels over the last decade in China because of the implementation of its open-door policies. Abuse of ketamine has recently gained popularity in China and an increased trend of deaths due to ketamine intoxication has been noted during the past decade in central China. It is not known if the effects of ketamine on the development of necrophagous flies have been reported.

This study investigated effects of ketamine, a drug commonly used as anesthetic, on the development of larvae of the forensically important fly *Chrysomya megacephala* (Diptera: *Calliphoridae*). Larvae of the *C. Megacephala* were divided equally into four groups and were reared on artificial diets containing different concentrations of ketamine: 0.25µg/g, 50µg/g and 100µg/g in an environmental chamber. Samples were collected every 12 hours. The body lengths, weights of each larva, and developmental durations of each stage were observed and measured. This study demonstrated that ketamine, low temperature, and their synergistic action significantly suppressed the larval growth of *C. megacephala* ($P<0.001$). The inhibiting effects of ketamine on the growth of larvae by length and weight were most significant before the larvae achieved their maximum length and weight when compared with a control group ($P<0.001$), especially in the 25µg/g ketamine-treated group at a temperature of 24°C. The time that the larvae achieved the maximum lengths and weights were significantly delayed in the ketamine-treated groups when compared with the control group ($P<0.05$), which resulted in prolonged duration of larval and prepupal stages while shortening the duration of pupal stages especially at low temperature. No significant differences were observed on the larval maximum length and weight between the control group and the ketamine-fed groups at the same temperature. No linear correlations were discovered between ketamine concentration and growth rate of larval body length and weight. In the deaths of suspected ketamine intoxication, the delayed growth effect should be taken into account when using regression against larval weight or length to estimate PMI.

In conclusion, ketamine can significantly delay larval development of *C. megacephala*. Knowledge of the effects of ketamine on larval development of *C. megacephala* can be useful in the estimation of PMI in suspected ketamine-related deaths. Further research is needed to observe the effects of ketamine on the development of more species of necrophagous flies as different species may have different responses to the same drug.

Forensic Entomology, Ketamine, Chrysomya Megacephala

G155 Heat Generation in Maggot Masses and Its Effect on Larval Development

Vivienne G. Heaton, MSc, Univ of Central Lancashire, School of Forensic and Investigative Science, JB Firth Bldg, Preston, Lancashire, UNITED KINGDOM*

After attending this presentation, attendees will understand the relationship between the size of a maggot mass and the temperature of its microclimate as well as how this mass-generated heat influences larval development.

This presentation will impact the forensic science community by highlighting the importance of incorporating mass temperatures into PMI estimates that are based on larval development.

Observed to arrive at a body within minutes of death, blowflies (Diptera: *Calliphoridae*) are frequently used as a biological clock in criminal investigations, aiding in the estimation of the Postmortem Interval (PMI). In forensic entomology, PMI is estimated based on the temperature-dependent developmental rates of known blow fly species. By combining temperatures recorded at the death scene with the known rates of development for larvae reared in temperature-controlled environments, it is possible to age individuals and, hence, estimate time of death. However, few studies take into consideration the mass-generated heat produced by larvae co-existing in an aggregation. This study investigates the relationship between the number of blow fly larvae in a mass and the amount of heat generated, as well as identifying the minimum mass size and elapsed time before any differences in accrued temperature achieve significance. This research also highlights the potential impact mass-generated heat may have on larval development rates and, hence, any subsequent PMI estimates.

Various sized larval masses (50 – 2,500 larvae) composed solely of *Lucilia sericata* (*Phaenicia sericata* in North America) were reared in the laboratory on racks of lamb ribs at a constant ambient temperature of 22°C. Using data loggers and a thermal imaging camera, mass temperatures were monitored and recorded at five-minute intervals for the duration of the feeding stage of development. Data was analyzed using the statistical package R (version 2.12.1). Results showed a strong positive relationship between mass size and the amount of heat generated by the aggregation, with temperatures rising as masses increased in size. A minimum mass size of 1,200 individuals was required for the microclimate temperature to increase significantly above ambient ($p \leq 0.05$), with aggregations composed of 2,500 larvae producing temperatures that exceeded ambient by as much as 14°C. Comparing Accumulated Degree Hours (ADH) for different-sized masses at specific times during development highlighted 26 hours as the point at which the 1,200 masses became significantly warmer than ambient ($p \leq 0.05$). Larger masses had ADH values that diverged from ambient after as little as ten hours into feeding and development. Preliminary data also suggests that larvae feeding in a mass experience two peaks in temperature, one shortly after reaching third instar, and a second, smaller peak immediately prior to the post-feeding phase of development.

In order to determine whether these differences in microclimate temperature affect rates of development, larvae were sampled from different-sized masses at hourly intervals. This allowed identification of the exact time at which individuals reached specific stages of development, primarily the point at which >50% larvae metamorphose from first to second instar, second to third instar, and then the onset of migration. Preliminary results suggest that there were significant differences ($p \leq 0.05$) when comparing the time (minutes) required for larvae from different-sized masses to reach these developmental junctures. Larger masses appeared to require less time to reach the third instar and post-feeding phase of development in comparison to smaller masses. However, there were no significant differences ($p > 0.05$) when comparing the ADH values for each of the aforementioned developmental points, with all larvae requiring similar levels of accrued heat energy to progress through each stage regardless of their mass size.

These results imply that the thermal output of a maggot mass is dependent on its size and has the potential to affect the rate at which larvae develop. Therefore, by incorporating maggot mass temperatures in the form of ADH values into current methods used to estimate larval age, it may be possible to increase accuracy for PMI estimates in criminal investigations. Further research is encouraged in this area in order to expand on the current understanding of maggot mass thermodynamics.

Maggot Mass, Heat, Larval Development

G156 The Pre-Colonization Gap: When Do Blow Flies First Lay Live Larvae on a Corpse?

David F. Cook, PhD, Sasha C. Voss, PhD, and Ian R. Dadour, PhD, Univ of Western Australia, Centre for Forensic Science, 35 Stirling Hwy, M420, Crawley, Western Australia, AUSTRALIA*

The goal of this presentation is to show how Postmortem Interval (PMI) determination remains the main focus of forensic entomology. However, minimum time frames are based on time of first colonization by the oldest immature found on the body. Following this presentation, attendees will have a better understanding about the question that has always eluded forensic entomologists, which is the period between death and colonization. However, this study also revealed that so-called secondary and tertiary species that visit a corpse are, in fact, primary.

This presentation will impact the forensic science community by determining how soon following death an exposed corpse is colonized by both oviparous and ovoviviparous adult flies, hopefully playing a major role in future PMI determinations.

Forensic entomology is the study of insects within a legal framework. The outstanding variable in determining an accurate PMI is the time that adult flies first lay live larvae or eggs onto a body. The “hinge pin” in forensic entomology is based on the predicted order of insects, typically blow flies and flesh flies, which are attracted to a decomposing corpse or cadaver. Many references have divided the predicted order into primary, secondary, and tertiary insects. This correlates with the process of decomposition and how it changes over time e.g., fresh, bloat, active decay, and skeletal stages. Blow flies generally arrive after death and recent research has shown that *Calliphora dubia*, *Calliphora varifrons,* and sarcophagid adults lay live larvae onto guinea pig carcasses within one hour of exposure. These flies are typically the primary visitors to a corpse. Very little is known about ovoviviparous blow flies, which are invariably the first blow flies to visit a corpse in southwestern Australia and are often the critical species in a PMI determination. New trials exposed 30 guinea pig carcasses throughout the day (0600 – 2000 hours) during spring and summer in bushland on each of five successive days. Replicate carcasses were set up randomly along a kilometer of bushland track and a carcass was removed every 0.5, 1.0, 2.0, 4.0, 8.0 hours throughout the day. Blow flies layed eggs onto carcasses within 30 minutes (33% of carcasses) and, on average, on all carcasses within 1.5 hours of death. Eight different oviparous (including *Lucilia sericata*, *Chrysomya rufifacies*, *Chrysomya varipes,* and *Australophyra rostrata*) and the ovivivparous fly species above deposited either eggs or live larvae onto the carcasses within six hours.

This study highlights the previously unknown rapidity with which blow fly species are able to commence laying onto carcasses and takes into account a large number of fly species, some of which are considered in the literature to be late colonizers of carcasses. A repeat exposure of carcasses again over five successive days in summer revealed five similar species of blow flies laid onto carcasses; however, extreme high temperatures significantly reduced overall blow fly activity. A further trial will be conducted in spring and summer to again evaluate this pre-colonization period. This research has many ramifications for the PMI calculation, especially if all flies

previously designated secondary and tertiary are, in fact, primary visitors to a corpse.

Postmortem Interval, Ovoviviparity, Blow Fly

G157 Characterization of Cypsela-Pappus Units in the Asteraceae: A New Tool for Forensic Botany

Gerard M. Courtin, PhD, and Louise Martin, BSc, Laurentian Univ, Dept of Forensic Science, 935 Ramsey Lake Rd, Sudbury, ON P3E 2C6, CANADA*

The goal of this presentation is to provide law enforcement personnel and botanists with a means to identify certain types of seeds and their appendages.

This presentation will impact the forensic science community by stressing the importance of forensic botany as a legimitate aspect of criminal investigation, where the smallest plant fragments may provide vital evidence that can help lead to a conviction. The field of forensic botany is slowly gaining recognition as an aspect of criminal investigation that can provide trace evidence previously overlooked either because its importance was not recognized or because investigators did not have the knowledge of how to recognize, seize, and preserve the material for later analysis.

Plant fragments may play a role either in linking a victim and perpetrator, locating a body if it has been moved to a site other than where the homicide took place, or linking either victim or perpetrator to a particular vehicle or location.

Two strategies for seed dispersal by plants are wind and animals. Seeds may be armed with hooks or have roughened seed coats that adhere readily to fur or clothing. Other seeds have tufts of fine bristles, termed a pappus, that aid in wind dispersal but also readily stick to fur or clothing. The daisy family, Asteraceae, is composed of many species that have evolved to use animals, including humans as a means of spreading their seeds, referred to as cypselae, far away from the parent plant. Furthermore, such plants are often found in droughty and nutrient-poor sites such as road sides and other waste places. It is in just such places to which, or across which, a body might be carried or dragged.

The present research explored 21, separate species of the daisy family growing in a single geographic region (Sudbury, Ontario, Canada) to determine if recognizable differences existed between seeds and their tufts of bristles and whether these differences were great enough to allow identification to species.

Cypselae and pappi were examined separately and systematically at increasing levels of magnification to distinguish cypselae and pappi from each other, first by eye, then with a dissecting microscope, followed by a compound microscope, and, finally, under Scanning Electron Microscopy (SEM). Cypselae were distinguished on the basis of size, shape, and surface texture. Under the dissecting microscope alone, it was possible to identify to the level of species in 12 of the 21 cypselae examined.

The pappus was removed from the seed and treated separately because it often becomes detached from the seed head when brushed up against and, therefore, might be the only evidence seized. Intact pappi were separated on the basis of shape, size, and number of bristles using the dissecting microscope. The tuft of bristles was mounted on a microscope slide using glycerin jelly and viewed both under dissecting and compound microscope as was dictated by the level of detail being examined. Bristles were observed in terms of length, bristle width and number of cells, shape of the bristle terminus, and ornamentation of the bristle, such as barbs or spurs. Examination of the pappus alone or its individual bristles made it possible to distinguish six species using the dissecting microscope and eleven species using the compound microscope. The two keys that were devised for separating both cypselae and pappi were submitted to a blind test by three individuals with no previous experience with the material to ensure that the keys were functional and unambiguous.

A small number of species could not be distinguished one from another even when examined under the compound microscope. This group was observed using SEM and an atlas of images made to allow comparisons with unknown specimens.

The field of forensic botany is slowly gaining recognition as an aspect of criminal investigation that can provide trace evidence previously overlooked, either because its importance was not recognized or because investigators did not have the knowledge of how to recognize, seize, and preserve the material for later analysis. The present work indicates that the smallest plant fragments may provide vital evidence that can help lead to a conviction.

Cypsela, Pappus, Asteraceae

G158 Insect Repellent and Insecticide Effects on Adult Insect Activity at Carrion in Northern Virginia

Diana Fleming, MFS, MA, and Elizabeth Richards, PhD*, Travis AFB, AFOSI 1 FIS, 721 Vandenberg Dr, CA 94535*

After attending this presentation, attendees will better understand the potential effects of insect repellents and insecticides on insect activity at carrion and, consequently, on the estimation of a Postmortem Interval (PMI) for human remains by a forensic entomologist. A comparison of the effects of two insect repellents and one insecticide on diptera and coleoptera activity on carrion and relative decomposition of that carrion will be presented.

This presentation will impact the forensic science community by raising awareness of the potential impact the presence of insect repellents and/or insecticides may have on insect activity associated with carrion. Understanding the potential influence such chemicals may have on insect activity and, in turn, decomposition, will be useful to forensic entomologists and the law enforcement community when estimating a PMI. Without understanding the ultimate effects insect repellents and/or insecticides may have, it is possible an approximation of time since death may be under- or over-estimated.

Many factors influence detection and colonization of carrion by necrophagous insects; some factors may accelerate, slow, or even act as barriers to insect activity. Some potential barriers to necrophagous insect activity are natural, man-imposed physical barriers, and man-imposed chemical barriers. This research study addressed three different man-imposed chemical barriers: two insect repellents (a natural oil-based repellent called EcoSmart and a 99% N,N-diethyl-3-methylbenzamide or DEET® spray and one insecticide (Raid®).

In this study, eight skinned, frozen rabbits were utilized. All eight rabbit specimens were of roughly the same size and weight. The specimens were secured inside cages and placed approximately six meters apart on a grassy residential lawn. The chemicals used in this study were EcoSmart®, DEET® spray, and Raid®. Two test groups were utilized: Group A and Group B. Group A tested the effects of the repellents and insecticide in open space. Group B tested the effects of the same three chemicals; however, the rabbit specimens were loosely covered in plastic. For each rabbit specimen in Group B, the outside layer of the plastic was sprayed with each of the three chemicals. All tests were run simultaneously, ensuring equal exposure to temperature changes, minimizing the variables affecting the results. The experiment was structured to test the effect of each chemical by comparing the number of adult flies and adult beetles collected next to each specimen by day. Collection of adult insects was facilitated by the use of sticky rodent traps. Only adult insects from the Diptera and Coleoptera orders were counted. The insects were identified only to order versus down to species and the identification was made visually for the purposes of counting total numbers of adult flies and beetles. Data analysis was conducted utilizing a quantitative versus a qualitative method. The collected data, namely numbers of flies and beetles by each specimen on each day of the experiment, was subsequently utilized to calculate mean values and standard deviation. Mean and standard deviation were

calculated for each rabbit specimen by day, group, type of insect, and combined insect count.

Based on the comparison of the collected data to the normal standard deviation range, significant results were identified for specimens treated with DEET® and Raid® in both groups.

This experiment was successful in demonstrating that DEET® and Raid® can have a significant effect on adult insect activity on carrion and, therefore, may affect the rate of decomposition. While some killers may apply methods to accelerate the rate of decomposition or to prevent a body from being found or recognized right away, altering the rate of decomposition through the application of insect repellents or insecticides could also have a significant impact on investigations. Delayed insect activity on a body could make it appear as if the body has been decomposing for a shorter amount of time than it actually has, thus possibly leading to an inaccurate time frame for events leading up to the discovery of human remains. Further studies are required to test the effect of different insecticides and insect repellents, specifically on necrophagous insect activity. Such studies would greatly benefit investigators and forensic entomologists when an accurate estimation of a minimum postmortem interval (mPMI) and a Period of Insect Activity (PIA) are needed.

Forensic Entomology, Insect Repellents, Insecticides

G159 Phenotypic Plasticity of *Cochliomyia Macellaria Fabricius* (Diptera: *Calliphoridae*) in Texas: How Intraspecific Variation Can Impact Forensic Entomology

Charity G. Owings, BS, Aaron Tarone, PhD, Clifford Spiegelman, PhD, and Jeffery K. Tomberlin, PhD, Texas A&M Univ, College Station, TX 77843*

After attending this presentation, attendees will be more familiar with the concept of phenotypic plasticity, different phenotypic responses of blow flies reared under the same environmental conditions, and ramifications such plasticity can have in death investigations.

This presentation will impact the forensic science community by emphasizing the inherent variability that exists within natural populations of forensically important arthropods.

Phenotypic plasticity, or the ability of a single genotype to produce multiple phenotypes under alternative stresses, has been documented in genetic and ecological literature and spans across many phyla.[1-2] Genotype by Environment interactions (GxE) may influence conspecific populations facing alternative conditions.[3] Given this, subpopulations of forensically relevant insects should also possess the ability to adapt to a shifting environment as exposure to distinct stresses increases. Recent literature in forensic entomology has focused on this phenomenon, particularly in relation to growth substrate and geographic distribution of blow flies (Diptera: Calliphoridae).[4-5] In these studies, development rates of conspecific blow fly subpopulations were significantly different from each other when reared in distinct environments. The implications of plasticity between conspecific blow fly populations lie in estimating the Time Of Colonization (TOC) with published developmental data. If conspecific blow fly populations do not exhibit similar biology but are treated as equals when forming this estimate, less accurate TOC and, thus, minimum Postmortem Interval (mPMI) estimates may be made. These errors may have drastic outcomes, such as a faulty verdict in a court of law.

This study was conducted at the Forensic Laboratory for Investigative Entomological Sciences (F.L.I.E.S.) Facility on the Texas A&M University campus, College Station, Texas. The goal of this research was to explore variable responses of three conspecific populations of the secondary screwworm, *Cochliomyia macellaria* (Diptera: *Calliphoridae*), in two distinct environments. Phenotypes measured include mean development time (divided into immature and pupal development time), and mean pupal and adult mass. In this research, three geographically distinct populations of *C. macellaria* were reared at 31°C, 70% RH and 21°C, 65% RH. Each temperature treatment contained 15 population replicates, with each replicate housing 100 fly larvae on 50g beef liver. All replicates were placed randomly within two growth chambers and were observed every twelve hours until the wandering third instar stage. At this time, observations were switched to every eight hours. All pupae were collected, weighed, and returned to the appropriate incubator to observe for adult eclosion. Adults were frozen at -20°C, dried at 55°C for 24 hours, sexed, and weighed. Data were not normally distributed and could not be appropriately transformed. Thus, Friedman ANOVA tests and Wilcoxon paired comparisons were used to determine differences between populations and temperature ($p<0.05$).

It was demonstrated that all three strains exhibited genetically different developmental responses for immature and pupal duration ($p<0.0001$). However, unlike the immature stage, responses in the pupal stage were not similar and, thus, showed evidence of adaptation of at least one population to a distinct environment. This is represented by a significant GxE interaction in pupal duration ($p<0.0001$) and pupal mass ($p=0.0232$).

In conclusion, this research demonstrates the importance of considering geographic distribution as a source of variability when estimating a TOC event. In order to comply with the last requirement of the *Daubert* statute (known error rate), the forensic entomologist must have some idea of the variation that a species can exhibit via phenotypic plasticity.[6]

G160 Analysis of the *De Novo* Transcriptome of Immature *Chrysomya Rufifacies* (Diptera: *Calliphoridae*) to Investigate Sexually Dimorphic Patterns of Gene Expression and Their Role in M-PMI Estimates With a Forensically Important Fly

Meaghan L. Pimsler, BS, Sing-Hoi Sze, PhD, Jeffery K. Tomberlin, PhD, and Aaron Tarone, PhD, Texas A&M Univ, College Station, TX 77843*

After attending this presentation, attendees will gain a better understanding of sexually dimorphic patterns of gene expression throughout the immature development of a blow fly of international forensic relevance. Furthermore, members will acquire insight into

the application of these data to the development of sex-specific growth development curves and molecular methods for estimating ages of immature blow flies.

This presentation will impact the forensic science community by adding to the body of molecular data available for forensically relevant species of flies, which will help in refining time of colonization estimations using insect evidence in immature stages. Currently, the pupal stage is one of the most difficult stages in which to make an estimate of age, due to its externally quiescent nature. While predictable developmental changes are occurring in pupae, a very detailed understanding of fly development is required to make even qualitative refinements of pupal age with morphological data alone. The application of these genomic tools will enable researchers to use gene expression profiles to estimate age more accurately and reliably.

Previous work has identified temporal patterns of gene expression throughout immature development in arthropods,[1] such as Diptera,[2-4] and there is a wealth of research demonstrating sex-specific patterns of gene expression.[5-9] Other work has suggested that, in addition to differences in temporal patterns of gene expression, the sexes of the blow fly *Lucilia sericata* may also develop at different rates (Picard, personal communication). As a result of this, it may be possible to investigate molecular mechanisms governing this plasticity and develop predictive models that incorporate sex, gene expression, and accumulated degree hour data. Though there is a well-annotated and manually curated database, "FlyBase,"[10] of gene expression profiles throughout development in *Drosophila* (Diptera: *Drosophilidae*), a greater breadth of temporal gene expression profiles across Diptera will help researchers to better understand the evolution of developmental pathways and patterns of conservation. Further development of sex-specific differences in temporal gene expression patterns should also prove informative. *Chrysomya rufifacies* (Diptera: *Calliphoridae*) (Macquart) is an especially tractable model organism for these kinds of questions as it exhibits monogenic sex determination with single-sex offspring clutches and homomorphic sex chromosomes.[11-13]

In this experiment, offspring from an isolated female *Ch. rufifacies* were collected and flash frozen. The sex of each larva sampled was determined once the remainder of the cohort had eclosed. For each sex (male and female) and time-point, samples from six separate cohorts were collected. RNA was extracted, sequenced with Illumina HiSeq, and assembled with custom software similar to ASplice.[14] Analysis of the transcriptomes yielded putative markers of the stages of interest. The most promising markers were verified by designing primers based on predicted transcripts and testing them via qPCR.

Many of the genes with homology to those found in other organisms exhibited differential expression profiles across immature stages in accordance with patterns identified in *Drosophila*, especially in highly conserved genes. However, there was greater homology with the more closely related *Lucilia sericata* transcriptome assembled in 2010.[15] The sex-specific markers from previous research were also observed in the immature stages.

In conclusion, genomic tools can be used to improve precision and accuracy of mPMI estimates derived from this species. In addition, this study demonstrated that this species of fly also has sexually dimorphic temporal patterns of gene expression throughout immature development, and that these genes share some homology with those found in other organisms. Furthermore, this work suggested that males develop slightly faster than females, and highlight a need for the inclusion of the sex of the individuals in creating developmental profiles. As the insects age, there is a concurrent increase in variation in terms of the relationship between size or length and time. The development of sex-specific growth curves would provide one additional explanation of that variation and, therefore, increase estimate precision.

Forensic Entomology, Transcriptome, mPMI Estimate

G161 Triple Primed PCR for SE33 Allele Sequence Determination

Kerry Mullaney, MFS, 2206 Alstead Ln, Bowie, MD 20716; Becky Hill, MS, National Institute of Standard and Technology, 100 Bureau Dr, MS8311, Gaithersburg, MD 20899; and Daniele S. Podini, PhD, George Washington Univ, Dept of Forensic Science, 2100 Foxhall Rd NW, Washington, DC 20007*

After attending this presentation, attendees will understand what the Triple Primed Polymerase Chain Reactiom (TP-PCR) method is, how it works, and how it can be used to sequence alleles of the SE33 locus. Attendees will also have a better understanding of the discrimination power of the SE33 locus.

This presentation will impact the forensic science community by presenting a new technique to determine allele sequences without Sanger sequencing. TP-PCR is an inexpensive, sensitive and fast alternative for allele sequencing. The application of this method will

enhance the discrimination power of the most polymorphic marker in current Short Tandem Repeat (STR) kits.

The locus SE33 is currently the most polymorphic STR in forensic DNA kits. The alleles of the SE33 locus are characterized by having a typical four base-pair (AAAG) length variation as well as an additional sequence polymorphism due to a single hexanucleotide (AAAAAG) insert that occurs once within the repeat region. This complex repeat pattern is represented as $[AAAG]_x$ AAAAAG $[AAAG]_y$. Because of this complexity, the 70 different length alleles can have up to 13 different sequence variations for a total of 171 alleles. But, the locus-specific primers (P1, P2) of the conventional Polymerase Chain Reaction (PCR) method utilized in forensic DNA typing can only distinguish length variation, limiting the discrimination power of this locus.

Previously, the only method to determine allele sequence was Sanger sequencing, an expensive and time-consuming process. This study demonstrates a novel method for allele sequence determination of locus SE33 using the TP-PCR. This method uses a triad of primers: a locus specific, fluorescently labeled flanking primer (P2), a primer with the repeat unit on the 3' end and a non-binding non-human DNA sequence on the 5' end (P4), and a paired primer of the same nonhuman tail sequence (P3).

During early amplification cycles, the P4 primer anneals directly to the repeat region, producing multiple fragments of varying length. But, the two additional adenine nucleotides of the hexanucleotide unit prevent the P4 primer from binding across this region. This interruption produces a 31 bp gap in the successively longer PCR fragments that correlates directly with the location of the hexanucleotide repeat within the sequence. In later cycles, the paired primer P3 and the fluorescently labeled flanking primer (P2) exponentially amplify the mixture of fragments produced by the P4 primer. This prevents a gradual shortening of the average PCR product due to the P4 primer annealing to sites within the sequences of products of earlier amplification cycles.

Each peak on the resulting electropherogram represents a specific number of repeat units within the SE33 allele. The smallest peak represents the 6 AAAG repeats present in the P4 primer and each successive peak an additional repeat unit. The 31bp gap between peaks separates the fragments produced from the P4 primer binding before and after the hexanucleotide repeat within the sequence. Consequently, by simply counting the peaks on each size of this gap the allele sequence is determined. This study establishes that this technique is powerful enough to differentiate the allele sequences of samples genotyped as homozygous with conventional STR kits. Furthermore, this technique deduced the correct sequence of the previously unpublished 16.2 and 17.2 alleles.

This study demonstrates that TP-PCR is a single reaction method that can be used to maximize the discrimination power of SE33 by allowing allele sequence determination without Sanger sequencing.

SE33, Allele Sequencing, Triple Prime PCR

G162 Application of the IPCRp Method for Genotyping of Male DNA Obtained by Pressure Cycling Differential Extraction

Pero Dimsoski, PhD, Florida Int'l Univ, Dept of Chemistry & Biochemistry, 11200 SW 8th St, Miami, FL 33199*

After attending this presentation, attendees will understand some principles and methods used in comprehensive approach to the problem of obtaining a male genotype from sexual assault evidence where the major issue is the mixture of body fluids from the victim and the suspect. Application of the standard methods on these mixtures often produces an incomprehensible genotype of the suspect.

This presentation will impact the forensic science community by providing attendees with a better understanding of how the small quantities of a male DNA material obtained by the pressure-cycling differential extraction method can be efficiently amplified and detected by IPCRp method (Isolation of PCR products).

The IPCRp method has been previously described to be a fast and efficent way to amplify the low copy number DNA. The method itself increases the sensitivity of the PCR reaction several-fold by highly concentrating a dye-labeled DNA target that is ready to be loaded on the genotyping platform. Therefore, only a few copies of the DNA are sufficient to obtain the genotype. The method utilizes the PCR reaction in which the reverse primer is labeled with biotin acting as a probe for capturing the fluorescently-labeled targeted DNA strand during the amplification. After the PCR, the biotin is attached to the streptavidin-coated plates. Following the washing step, the single-stranded dye-labeled targeted DNA is released by denaturation and loaded for detection on a genotyping instrument. Results are almost free of background noise due to the washing step, in which all of the unincorporated labeled and labeled primers, dNTP's, PCR-reaction buffer, and polymerase are separated and do not interfere with detection.

Control DNA samples prepared by mixing the epithelial and sperm cells and differentially extracted by using pressure cycling technology yielded small quantities of male genomic DNA. The pressure cycling technology followed by the DNA extraction manipulation resulted in a degradation of the female epithelial cells (female DNA). The male DNA was amplified by modified Y-STR and autosomal PCR-multiplex amplification kits. To increase the sensitivity of the PCR, the IPCRp method was applied. The isolation of the PCR products method required modification of the standard multiplex PCR genotyping kits. The amplification kits were designed with the forward and reverse primers fluorescently and biotin labeled, respectively. Following the PCR, performed under standard conditions, the amplified products were captured on the streptavidin-coated, 96-well plates and following the washing step of the unincorporated labeled and unlabeled primers, dNTP's, polymerase, and other material, only the fluorescently-labeled PCR-targeted products in a single stranded DNA configuration were released by denaturation, and loaded into a capillary electrophoresis instrument. Full profiles of the DNA samples were obtained by both kits, although the results from the modified Y-STR kit were with less background noise than the autosomal kit, presumably due to the combined effects of both differential extraction and differential PCR amplification (capturing).

This simple and robust approach of using the pressure cycling technology for differential extraction and decomposition of the epithelial cells, followed by the IPCRp amplification of the male DNA, can improve the genotyping of the male DNA obtained from the mixtures of body fluids from the victim and suspect. Although the IPCRp procedure requires modification of the standard DNA-identification kits, it added only a few extra steps (capturing and washing) to the standard post-PCR protocol which increased the additional time of the post-PCR manipulation by 20 minutes; this is an insignificant accommodation for the standard forensic laboratory practice compared to the benefits of obtaining a genotype of the suspect.

IPCRp, Pressure Cycling, Sexual Assault

G163 Comparative Analysis of Size Specific DNA Concentrators Following Organic DNA Extraction

Jennifer P. Cravo, MSFS, 47 Elmhurst Cir, West Hartford, CT 06110; Christian G. Westring, PhD, 2300 Stratford Ave, Willow Grove, PA 19090; and Heather E. Mazzanti, MSFS, 450 S Easton Rd, Glenside, PA 19038*

After attending this presentation, attendees will understand some principles of DNA analysis, the differences between Sartorius Stedim Vivacon and Millipore Amicon concentrators, and how the addition of PCR inhibitory substances influences the recovery of DNA following

PCIA organic extraction. Attendees will be introduced to principles behind organic DNA extraction methodologies, including the practical benefits of selecting function-specific DNA concentrators. The current study will demonstrate the efficiency of DNA recovery using four commercially available centrifugal DNA concentrators following PCIA organic DNA extraction of forensic type samples.

This presentation will impact the forensic science community by presenting data suggesting the practical benefit of size-specific DNA concentrators for the optimal recovery of DNA from forensic casework type samples. The results of this study demonstrate a significant difference in concentrator brands' abilities to recover nucleic acids, which may cause forensic laboratories to reconsider which concentrator units are currently being utilized.

The use of organic extractions followed by centrifugal concentrators for the purification of DNA is an important tool for forensic laboratories. Centrifugal concentrators both remove PCR inhibitory substances and concentrate the nucleic acid in a sample.[1,2] They are designed to speed up the evaporation of solvents from DNA samples so that purified DNA can be collected and further tested. The objective of the current study was to determine which centrifugal concentrator pore size would recover the most DNA by analyzing samples of whole blood dilutions in deionized water ranging in concentration from 0.2 - 40%. Internal Positive controls for all samples were compared in order to assess the efficiency with which each concentrator removed inhibitory substances.

The purpose of this study was to determine which DNA concentrator (filter and pore size) was better suited for organic extractions based on percent recovery and quality of profile generated. The two DNA concentrator brands under evaluation included Sartorius Stedim Vivacon 500 (size YM-50 and YM-100 Nominal Molecular Weight Limit in Daltons) (Goettingen, Germany) and Millipore Amicon® Ultra (size 50 and 100 NMWL) (Darmstad, Germany). The filter membranes of Amicons have a vertical design allowing for a greater membrane surface area, promising to provide fast sample processing and high sample recovery.[3] The Vivacon filters utilize a horizontal filter design which is equipped with the patented regenerated cellulose Hydrosart® membrane.[4]

In brief, compared to Vivacon filters, Amicon filters demonstrated reduced DNA recovery, on average recovering 52% less nucleic acids. Furthermore, the data indicated decreased amplification efficiency indicating a failure to remove all inhibitory substances. The use of Vivacon 100 NMWL concentrators following PCIA organic extraction has the practical benefit of optimum recovery of DNA and total removal of PCR inhibitory substances, which is particularly advantageous when dealing with forensic samples.

Forensic Science, DNA Analysis, Concentrator

G164 Evaluating Length Heteroplasmy in the Human Mitochondrial DNA Control Region

Susan M.R. Gurney, PhD, 6600 Lincoln Dr, Apt C3, Philadelhpia, PA; Lucy Forster, MD, Institute of Legal Medicine, Univ of Münster, Müenster, GERMANY; Peter Forster, PhD, Murray Edwards Coll, Univ of Cambridge, Downing Street, Cambridge, UNITED KINGDOM; Matthew Spencer, PhD, School of Environmental Sciences, Univ of Liverpool, Liverpool, UNITED KINGDOM; Christopher Huang, ScD, Murray Edwards Coll, Univ of Cambridge, Physiological Laboratory, Downing St, Cambridge, UNITED KINGDOM; Arne Röhl, PhD, Institute of Legal Medicine, Univ of Müenster, Müenster, GERMANY; and Bernd Brinkmann, MD, Roentgenstr. 23, Muenster, GERMANY*

After attending this presentation, attendees will have a better understanding of length heteroplasmy in the human mitochondrial DNA control region. The importance of point heteroplasmy in forensic casework is already known; what is less understood, but more commonly encountered, is length heteroplasmy. The purpose of this research was to examine the mechanisms and mutation rates of human mitochondrial DNA length heteroplasmy, to assist forensic practitioners to identify length heteroplasmy, and to use our guidelines to analyze data where heteroplasmy is present.

This presentation will impact the forensic science community by showing forensic scientists how to analyze mitochondrial DNA results that are complicated by exhibiting length heteroplasmy. Previously, these types of mtDNA results may have been disregarded due to the unknown mutation rate and mechanisms of length heteroplasmy. In this presentation, pedigree data from families in Kerala, India, have been analyzed to elucidate the mutation mechanism and the mutation rates of length heteroplasmy. For the application of length heteroplasmy to forensic science, these results demonstrate the importance of understanding heteroplasmy to be able to confirm maternal relationships, and shows that new point mutations are heteroplasmic in the first generation. Worked examples to assist the forensic practitioner will also be presented.

Examination of the mitochondrial DNA control region found that in more than five percent of mother-child pairs a mutation has occurred in at least one mtDNA C-stretch, blurring the biological relationship between the woman and her alleged child. How then should the forensic practitioner handle fast-mutating C-stretches? This problem was explored experimentally and statistically in five steps: (1) first, DNA samples were collected from 248 families (1,172 individuals) living in the most highly radioactive area in the world (Kerala, India). The natural radiation levels in coastal Kerala are about 10mSv and are, therefore, around ten times higher than normal. This provides an environment which speeds up the mutation rate and allows mutations to be observed as they happen and are transmitted to the children. DNA samples were collected from members of the family covering up to four generations, so mutations occurring between generations could be examined; (2) second, the presence of three known C-stretches and identified a fourth new C-stretch in the mtDNA have been confirmed. The mtDNA control region in humans is approximately 1,122-bp long and is comprised of regions with repetitive tracts of consecutive cytosines. Such "C-tracts" are prone to length heteroplasmy; in other words, one individual can have various mtDNA lengths in his or her cells which differ by the number of C's at these C-tracts; (3) third, a consistent classification of C-stretch status was developed based on the underlying biological process; (4) fourth, the mutation rate observed in the irradiated families was determined, the mutation rate being accelerated and therefore a highly conservative "worst-case" estimate for any situation likely to be encountered in a forensic mtDNA deficiency case context worldwide; and, (5) finally, based on the mutation rate that was calculated, a simple statistical treatment of C-stretch mutations, which will be demonstrated in a worked example is proposed.

Mitochondrial DNA, Heteroplasmy, Radioactivity

G165 An Unusual Case of Strychnine Poisoning

Sebastien Prat, MD, Service de Médecine Légale, Hospital Trousseau, CHRU Tours, Tours, FRANCE; Guillaume Hoizey, PhD, Toxlab, 7 Rue Jacques Cartier, Paris, FRANCE; Thierry Lefrancq, MD, Le Vauban, BP 549, 16 rue Clerget, Nevers, FRANCE; and Pauline Saint-Martin, MD, Service de Medecine Legale, Hospital Trousseau, CHRU Tours, Tours, FRANCE*

After attending this presentation, attendees will learn about strychnine (use and prohibition) and, particularly, strychinine poisoning, which is relatively rare because of its prohibition.

This presentation will impact the forensic science community by the histological and toxicological findings in this poisoning case, which police authorities concluded to be suicide , without finding the container.

Strychnine-related death has been described since the 19th-century. This alkaloid was discovered in 1818. Historically, strychnine was used by the Southeast Asian autochthones on arrows. After its discovery in the occidental countries, the substance was used to destroy animal predators. Synthesis has been possible since 1954. Two toxicity mechanisms are described: the tetanising activity and the paralysing action. It is also a part of curare poisons. Its production has been modified by legislation to protect people against accidental intoxications. In 1999, its use was prohibited in France; since this prohibition, strychnine-related death is rare. The most important issue is knowing the origin of the substance.

A 69-year-old man was found dead at home. A letter was found relating familial conflicts. A bailiff had to visit him because of familial conflicts. External examination found no signs of violence. During the autopsy, a pulmonary edema and a blue substance in the stomach were found. Toxicological analysis measured strychnine at 0.29µg/ml in the blood sample. The blue coloration evoked Taupicine®, a rodenticide countaining 10% strychnine. All these elements suggest a strychnine-related death; however, a specific source has not been found by the police. In the medical history, no previous psychiatric disorder was found. Some relatives spoke with him the morning of his death. He did not exhibit suicidal tendencies.

Strychnine induces seizures with normal counsciousness. Death is frequent without emergency care. Accidental, suicidal, and criminal contexts have been described. Strychnine poisoning in children has classically been accidental, whereas, in adults it has been suicidal. Criminal poisoning was described in the 19th-century by a serial killer. It is believed that strychnine could be employed to commit a terrorism attack. Because of its ability to increase pulmonary capacities, strychnine has been used in sports competitions with injections made during the physical activities. Most of the intoxication is secondary to ingestion or inhalation. Sometimes, strychnine is used as a cutting agent in cocaine products. Some topic intoxication is described, too. Various analyses have been developed for quantification such as GC/MS and HPLC.

This case is unusual. It shows a relatively low rate in comparison with the results given in the literature. Histological examination and toxicological findings have permitted the authors to conclude this was a strychnine poisoning. Circumstances of strychnine-related death must be studied because of the rarity of cases. Because of the prohibition in 1999, people cannot get strychnine-containing products. Most often, the products were acquired a few decades before. Also, it seems that strychnine is relatively stable and is active at least ten years or more. In this case, police authorities have concluded it was a suicide, even if there is no psychiatric history and the container of the alkaloid has not been found.

Forensic Pathology, Strychnine, Poisoning

G166 Accentuation of Asphyxial Death by the Background Effect of Chronic Liver Disease, Splenomegaly, and Abuse of Alcohol and Drugs

Khalid Jaber, MD, Firebrigade Training Centre, Malahide Rd, Marino, Dublin, IRELAND*

After attending this presentation, attendees will appreciate the difficulty encountered in finding a constellation of anatomical findings suspicious of asphxial death in a young person, found supine on the floor of the bedroom, with a history of important medical diseases.

This presentation will impact the forensic science community by highlighting the interplay between problematic scene findings and circumstantial history with important anatomical features. The latter present challenging constellations that could be ascribed to asphyxial death, but the decedent was also a person with established liver cirrhosis, alcoholism, and positive serology for HCV and HIV infections.

The decedent was a known drug abuser and a drug addict. He was placed on a methadone maintenance program. He was also a regular consumer/abuser of alcohol. He showed positive serology for Hepatitis C and HIV viral infections. He was diagnosed with liver cirrhosis and secondary splenomegaly. In addition, he was treated for schizophrenia and depression.

According to the female partner, she woke up partly due to his snoring and partly to step out of the bedroom for a brief interval, less than five minutes, leaving him in bed. Upon her return, he was found supine on the floor and in a collapsed state. His face was getting increasingly blue. She attempted CPR, getting instructions over the phone from a fire brigade officer who made sure she was on the phone carrying out his instructions until the arrival of the dispatched ambulance crew, which arrived within minutes.

The female partner was not trained previously in CPR and it would appear she was trying her best but realized that the deceased was slipping away. Although the ambulance crew sustained CPR until it was clear the decedent was not responding, the clinical impression of the crew was that the deceased was “dead” by the time they got to the scene. It must have been a traumatic experience to the young female partner who allegedly lost two previous male partners while in active relationships with them at different times. Review of a CCTV revealed that, approximately 36 hours prior to his collapse on the floor of the bedroom, the decedent was in an inebriated, drunken state, falling around, and being supported whenever possible by his female partner. A police car picked up both of them and drove them a short distance to the home of a relative less than three minutes away.

There are important anatomical findings identified in the autopsy mainly: florid petechial and punctate serosal; mucosal and intramuscular hemorrhages involving the face, neck, pleurae, lungs, heart, intercostal muscles, and back of the trunk; multiple external contusions that include bilateral peri-orbital contusions and other contusions identified on the head, back of the trunk, and upper and lower extremities; and, an incomplete, non-displaced, focal, small cricoid cartilage fracture, associated with overlying localized soft tissue hematoma, enlarged spleen weighing close to one kilogram, and patchy acute pulmonary pneumonia. In the neck, there were circumscribed, bilateral perivascular (adventitial and peri-carotid arterial hematoma), peri-neural (peri-vagal and peri-sympathetic ganglion hematomata), and intra-neural (intra-sympathetic ganglion and focal intra-vagal) hemorrhages seen. His postmortem blood toxicological analysis showed the following prescribed drug results: free Codeine: 0.17ug/ml, phenethylamine 0.01ug/ml, paracetamol: present, methadone: 0.37ug/ml, eddp (methadone metabolite): present, nordiazepam: present, mirtazapine: 0.08ug/ml and olanzapine: 0.05ug/ml. Ethanol analysis showed blood level of 71mg% and urine level of 168mg%.

The autopsy findings are concerning in that asphxial death, caused by neck and chest compressions, have been seriously considered, notwithstanding the probable underlying contribution and

effect of liver disease on bleeding tendencies that potentially underscores and accentuates the manifestations of impressive hemorrhages. Could the multitude of contusions influence the way the manner of death is considered in this case?

Asphyxia, Liver, Drugs

G167 A Unique Cause of Death in a Double Hot Tub Fatality: Electrocution by Implantable Cardioverter Defibrillator

Robert R. Pfalzgraf, MD, OCME, 70 Danley Dr, Dist 21, Fort Myers, FL 33907*

After attending this presentation, attendees will understand how to investigate deaths occurring in hot tubs and other closed environments, especially when more than one fatality occurs simultaneously. One must investigate all environmental hazards that might have impacted all of the victims.

This presentation will impact the forensic science community by exposing an environmental hazard that has not been previously reported to cause death.

Although deaths in hot tubs are not an infrequent occurrence, deaths of two or more people in a hot tub or any other closed environment raises suspicion that an external hazard has caused the deaths of these victims. Hazards include electrocution by faulty wiring or equipment, drugs, extreme temperatures, homicidal violence, and poisons such as carbon monoxide in the breathing environment. Examination of the surrounding environment in which the deaths occur as well as the equipment involved is vital in determining the cause of death. Full autopsies with postmortem toxicology are also necessary in determining the cause of death. Identifying hazards in an environment will also enable the removal of hazards and the prevention of further deaths and injuries.

Implantable cardioverter defibrillators are considered life-saving devices because of their ability to detect and then treat ventricular fibrillation by shocking the heart back into sinus rhythm. However, little is known about the effects of these shocks on other people in contact with these patients when their ICDs fire. In certain situations, it is probably hazardous to have skin-to-skin contact with people who are being shocked by their ICDs.

The case presented is that of two elderly people, a husband and wife, who had a daily habit of sitting in their hot tub and were found dead there by neighbors. Both decedents had a history of heart disease. Examination of the scene revealed the hot tub to be in an open area on the lanai behind their house. Inspection of the wiring and the equipment by medical examiner investigators, an electrical inspector, and an expert hired by the next of kin revealed no electrical hazards. The autopsies of the two decedents showed no injuries and both had severe heart disease. Toxicological studies of both victims were negative. At autopsy, the female decedent was found to have an implantable cardioverter defibrillator. It was removed and submitted for query. The query revealed that the woman developed ventricular fibrillation, and, over a short period of time, her ICD delivered four separate shocks without producing cardioversion. No external source of electrical current was detected by the ICD.

Based on the autopsy, circumstances, and scene investigation, it is the opinion that the cause of death of the woman was ventricular fibrillation due to her underlying heart disease. Since it is unlikely that the husband also died of natural causes simultaneously, it is also the opinion that the husband died from electrocution from his wife's ICD while trying to rescue her. Being in water containing an electrolyte solution greatly reduced the electrical resistance of skin-to-skin contact, making a shock from an ICD more hazardous.

In summary, the investigations of deaths occurring in hot tubs require full autopsies and toxicology along with examination of the environment and inspection of the equipment in use at the time of death. In cases involving ICDs, the device should be queried. People in contact with patients with these devices should be aware that they can also receive shocks that can be fatal in some circumstances.

ICD, Electrocution, Hot Tub

G168 The Shaken Baby Syndrome: How Doctors and Authors Can Support the Indefensible

Alain Miras, PhD, 49 Cours Vitton, Lyon, FRANCE; Stéphane Chapenoire, PhD, 23 rue Pierre De la Dime, Bordeaux, FRANCE; and Federic Dupuch, INPS- Rue Pierre Baronnier- BP 30169, Ecully, FRANCE*

After attending this presentation, attendees will recognize Shaken Baby Syndrome, and how it can occur in all socio-professions and economics even when the parents are doctors or if the babies are twins.

This presentation will impact the forensic science community by making attendees aware of Shaken Baby Syndrome because the impossible and unthinkable can happen at any time and in all socio-professional contexts.

Shaken Baby Syndrome is known worldwide. Prevention of Shaken Baby Syndrome is the responsibility of the hospital, private doctors, and the media, but also by information applied to diaper packages and baby formula. The perpetrators are usually in denial or find reasons that are refuted by scientific studies, national or international publications, and by common sense! Thus, the courts are becoming more severe against the perpetrators, even if they take into account family background, profession, social and psychological context.

Lesion descriptions are more and more precise and diagnosis requires very specific and powerful examinations (X-rays, radionuclide bone scanning, CT scan, and RMI) which explore organs such as the brain, the eyes, the skeleton, and the cervical cord. It is sometimes possible to date the injuries if they are multiple and spaced out.

The sad originality of this presentation is to present two cases of shaken babies. Detailed examinations of the lesions were performed in each case.

Case 1: A case concerning two-month old twins. It appeared that in the case of the twins, both had severe and multiple injuries from multiple incidences. But lesions were similar with a similar distribution, a comparable chronology, and a similar frequency. These characteristics indicate that the violence was made almost simultaneously in both babies. The progress of both children (each now one-year-old) is currently good, and it is likely that there will be no neurologic complications and abnormalities.

The lesions consisted of:

- bilateral rib fractures
- vertebral compression fractures (dorsal and lumbar)
- forearm bone fractures
- pelvic bone fractures
- lower limb bone fractures
- encephalic hemorrhagic lesions

Case 2: A case of a shaken 8-month-old baby who died from his injuries, which occurred within a professional medical family. In this case, the parents initially attributed responsibility to the 14-month-old brother as well as trivial actions such as changing diapers.

The lesions consisted of:

- bilateral retinal hemorrhage
- acute subdural hematoma (SDH) bilateral, 9mm thick
- diffuse cerebral edema major
- scalp contusions
- 40mm non-displaced skull fracture (occipital)

The adult present on site explained that the trauma occurred after a fall from his height (75cm) onto the floor. Both parents are medical practitioners.

After a review of the recent international literature and the consensus conference from the French National Health Authority in May 2011 about shaken baby and child abuse in general, a parallel is drawn between the lesions found in these babies and explanations will be given for this presentation.

In both cases, the first doctors who treated these children either did not agree on the diagnosis or raised the possibility, especially in the second case, that the accidental cause could not be eliminated.

It is obvious that the validity of the forensic hypothesis is dependent on the quality of the health practitioners, the first medical observations, the forensic pathologist experience and photographs. In these cases, the explanations for the injuries were inadequate and discrepant.

If assessment and investigation of suspected Shaken Baby Syndrome is a multidisciplinary task (health professionals, senior forensic pathologist, psychologist, social worker, police investigators, judges), it is necessary that doctors and health professionals that are in contact with children are aware that with the Shaken Baby Syndrome, and after considering all possible alternative explanations, the improbable, the impossible, and the unthinkable can happen at any time and in all socio-professional contexts.

Shaken Baby Syndrome, Death, Twins

G169 "The Killer B's" – A Case Series of Consumer Product Related Deaths in Young Children

Garth D. Warren, MD, 7056 South Dahlia St, Centennial, CO 80122; Dawn Holmes, MD, 2121 W Harrison St, Chicago, IL 60612; and John Carver, MD, JD, and Amy Martin, MD, OCME, 660 Bannock St, Denver, CO 80204*

After attending this presentation, attendees will have a better awareness of consumer product related deaths in young children.

This presentation will impact the forensic science community by presenting a case series of autopsy findings and circumstances related to consumer product deaths in young children (five-years-of-age) over the past 20 years (1992 – 2012) at the Denver Office of the Medical Examiner.

The U.S. Consumer Product Safety Commission (CPSC) estimates that nearly 30,000 deaths in the United States are related to consumer products annually. In 2010, there were an estimated 181,500 toy-related injuries and 17 toy-related deaths in children less than 15-years-of-age. Between 2006 – 2008, there were an estimated 101 nursery product related deaths annually in children less than five years of age.

The CPSC is responsible for protecting the public from serious injury or death from more than 15,000 types of consumer products sold in the United States. The Consumer Product Safety Improvement Act of 2008 was established with the intent of providing stringent oversight on product manufacturing and testing requirements, penalties for violations, whistleblower protections, and a database for product information and consumer reporting. Despite improvements in federal agency oversight, a significant number of deaths are still attributable to faulty or misused consumer products. The majority of these deaths will be, or should be, investigated by Coroner or Medical Examiner Offices.

Presented is a number of selected cases between 1992 and 2012 where the death of a young child (<5 years of age) was associated with a consumer product. The cases include: (1) a 6-month-old infant male who drowned when his Bumbo baby seat tipped over in an adult bathtub. The Bumbo baby seat was first recalled in 2007, and since then, the CPSC has learned of at least 50 incidents in which babies have fallen from Bumbo seats while they were being used on raised surfaces. In all, there have been over 20 reports of skull fractures to infants using the Bumbo baby seat. This has led to a second recent recall of the baby seat in August 2012; (2) a 3-month-old infant girl who drowned when her baby bathtub flipped over in an adult bathtub; (3) a 4-month-old infant male who aspirated a party balloon. According to the CPSC, balloons are the leading cause of asphyxial related deaths in young children. Accidents involving balloons tend to occur in two ways: some children have sucked uninflated balloons into their mouths, often while attempting to inflate them. Some deaths may have resulted when children swallow uninflated balloons they are sucking or chewing on; (4) an 8-month-old male who suffocated in a beanbag chair; (5) a 4 month-old-male wrapped in a "swaddling" blanket who smothered to death; and, 6) a 17-month-old infant male who strangulated to death while playing with a bead maze toy box.

The forensic community has the opportunity to take an active role in protecting the public from consumer product related injuries and deaths through proper reporting, documentation, and public awareness of tragic events resulting from unsafe or misused products.

Consumer Product, Childhood Deaths, Accidental Deaths

H1 The Temporal Degradation of Bone Collagen: A Histochemical Approach to Postmortem Interval Estimation

Amelia M. Boaks, MSc, 107 Neville Park Boulevard, Toronto, ON M4E3P7, CANADA*

After attending this presentation, attendees will gain knowledge regarding the development and application of a simple histological method that selectively stains collagenous and non-collagenous proteins to determine whether a predictive rate of collagen loss occurs over a scale of months and years.

This presentation will impact the forensic science community by providing a potentially useful technique for estimating the Postmortem Interval (PMI) of skeletonized remains over a range of months to years. As collagen degrades over time, the pattern of degradation may be used to predict the PMI of skeletonized remains in forensic cases. The relative simplicity of this procedure and its easily obtainable equipment (already available in many forensic laboratories) potentially allow for the future widespread use of this method in forensic anthropology.

Forensic anthropologists are currently unable to reliably estimate the PMI of skeletonized remains.[1,2] This pilot study was conducted to determine if bone collagen degrades at a predictable rate over time and if so, to determine if this pattern could contribute to the creation of a quantitative method for estimating the PMI. The sample used in this study consisted of one fresh pig long bone and an additional ten pig long bones from subjects with known PMIs ranging from two to twelve months. The method involved the use of a histochemical stain which, when applied to embedded sections of bone, selectively stained collagenous proteins pink and non-collagenous proteins green. Excess stain was rinsed from the section, and the remaining stain was eluted and analyzed using a spectrophotometer at optical density frequencies of 540°nm and 605°nm to yield an Optical Density (OD) value of each dye. A standard curve was created such that a given OD value at a specific frequency would correspond to a known concentration of collagenous or non-collagenous proteins in the unknown section. The ratios of these concentrations were then calculated and statistical analyses were conducted to determine if a significant change or degradation in the ratio of bone protein concentrations occurred over time. Correlation and regression analyses also were performed to determine if the bone protein ratios were significantly correlated with time and, if so, how much of the correlation (or variance in the sample) could be attributed to this correlation.

A statistically significant change took place, with the largest change occurring in the first two months. The Pearson's correlation analyses revealed a significant negative correlation between the ratios of protein concentrations and time; however, the results of the regression analyses yielded only a moderate R^2 value, indicating that while time has some predictive value in determining the age of a bone, additional factors also appear to have a significant effect in predicting the age of an unknown bone.

Via visual assessments of pre-eluted sections, it was evident that the first regions of a bone section to lose collagenous proteins and stain green were the endosteal and/or periosteal regions. The exception to this pattern was found in those bones whose structural integrity had failed and the cortical bone had cracked. In these cases, green staining appeared along the margins of the site of structural failure. Among the modern samples, there was a clear change in the ratio of the pink and green dyes ranging from almost entirely pink in the fresh sections to predominantly green in most of the 10- and 12-month sections.

In summation, while it is apparent that collagenous proteins are significantly correlated with time, other factors also clearly play a role in the rate and process of bone degradation, or diagenesis. As a result, PMI estimations cannot currently be made solely upon the ratio of remaining collagenous and non-collagenous proteins in bone. Rather, further research which monitors the rate and pattern of diagenesis with respect to time and extrinsic factors, such as soil pH values and microbial activity, should be conducted.

Bone Histology, Collagen, Postmortem Interval

H2 New Methodologies and Protocols of Forensic Identification by Craniofacial Superimposition

Eugenia Cunha, PhD, Univ of Coimbra, Life Sciences Dept, Forensic Sciences Center, Coimbra, 3000-056, PORTUGAL*

After attending this presentation, attendees will become familiar with the issues of Craniofacial Superimposition (CS).

This presentation will impact the forensic science community by showing how Methodologies and Protocols of forensic identification by Craniofacial Superimposition (MEPCROS) will be used by European scientific units; to promote and validate exchange of CS protocols among different European institutions.

One of the most important objectives of forensic anthropology is the determination of a victim's identity, a process that always requires a suspect in order to compare antemortom and postmortem data. Unfortunately, antemortem records are often unavailable and DNA may be impossible in circumstances where, for example, there aren't known relatives of the presumed victim. Moreover, there are situations where many individuals share the same biological profile (e.g., mass disasters, mass graves). In these situations, CS techniques (a forensic identification process where photographs of a suspected victim are superimposed over an unidentified skull in order to establish whether they belong to the same person) have been successfully applied to exclude or establish identity, particularly in Europe. However, no standards exist and forensic experts apply their own approach to the problem based on the available technology and their knowledge and expertise.

The new MEPROCS projects goal is to propose a common European Union (EU) framework to allow the extensive application of CS in practical forensic identification scenarios commonly tackled by European police units. This framework will include: (1) the implementation of an existing semi-automatic method to assist forensic experts in the application of the CS technique resulting in a simple, quick, and systematic approach; (2) the definition of standard protocols within Europe, leading to the objective application of the CS technique in different forensic identification scenarios; and, (3) the specification of a forensic science methodology to provide an objective evaluation of the forensic identification results achieved by CS, avoiding particular assumptions that could bias the process. Hence, the project clearly promotes the validation and exchange of CS protocols and methodologies among different organizations. The particular objectives

of this project concern supporting the development of a trustworthy CS methodological framework by fulfilling requirements covering educational, technical, economic, social, and security aspects.

MEPROCS is a two-year project founded by the EU commission with more than one million euros. It was launched in Mieres (Spain) on March 12, 2012. It is coordinated by the European Centre for Soft Computing. The multidisciplinary list of participant institutions of this network are: the European Centre for Soft Computing from Spain, the Consorzio Ricerca Sistemi ad Agenti (CORISA) from Italy, the European Council of Legal Medicine from Germany, the Physical Anthropology Lab of the University of Granada from Spain, the Israel National Police (Ministry of Public Security) from Isreal, the Forensic Sciences Centre of the University of Coimbra from Portugal, and the Guardia Civil (Ministry of Interior) from Spain. In addition, there are some other institutions, associations, and/or researchers taking part in the network either as associated partners or supporting institutions: Policía Judiciária (Portugal), Council of Forensic Medicine (Turkey), Forensic Anthropology Society of Europe, International Academy of Legal Medicine, International Association of Forensic Sciences, World Police Medical Officers, Department of Forensic Medicine (University of Copenhagen), Forensic Science Programme (Universiti Sains Malaysia), and Laboratory of Forensic Anthropology and Odontology (LABANOF, University of Milan).

The objectives of MEPROCS require bridging the gap between researchers in forensic anthropology and computer science by defining means to foster the dialogue between the different actors involved (technological partners, forensic anthropologists, and end users) across Europe. MEPROCS is an outstanding tool permitting the creation of a coordinated and connected series of activities in order to put the latter tasks into effect. The network is open to incorporate relevant researchers and/or institutions in the field of craniofacial identification in 2012 and early 2013.

Craniofacial, Superimposition, Forensic Anthropology

H3 Case Report of Facial Reconstruction Using the Cranial Forensic Database in Korea

U-Young Lee, MD, The Catholic University of Korea, Department of Anatomy, School of Medicine, 505, Banpo-dong, Seocho-gu, Seoul, 137701, KOREA; Dae-Kyoon Park, MD, PhD, Soonchunhyang University, Departmentt of Anatomy, School of Medicine, 366-1 Ssangyong-dong, Cheonan-si, Seoul 331946, KOREA; Yi-Suk Kim, MD, PhD, Ewha Womans University, Dept of Anatomy, School of Medicine, 911-1, Mok6-dong, Yangcheon-gu, Seoul, 158710, KOREA; Sang-Seob Lee, PhD, 331-1 Shinwol7dong, Yangcheon-gu, Seoul, 158-707, KOREA; Deog-Im Kim, PhD, Catholic University of Korea, Dept of Anatomy, School of Medicine, 222, Banpo-daero, Seocho-gu, Seoul, 137701, KOREA; Dong-Ho Kim, BS, 296-19, Pyeongchang-dong, Seoul, KOREA; and Seung-Ho Han, MD, PhD, The Catholic University of Korea, Dept of Anatomy, School of Medicine, 505, Banpo-dong, Seocho-gu, Seoul, 137701, KOREA*

The goal of this presentation is to report the first Korean casework application of the facial reconstruction method for human identification and to emphasize the importance developing a forensic database for various forensic applications.

This presentation will impact the forensic science community by demonstrating the utility of facial reconstruction methods in Korean casework as well as emphasizing the importance of developing databases for various forensic applications.

Facial reconstruction is a method to help verify the human identity by reconstructing a face from an unidentified skull. The scientific data for facial reconstruction can be classified broadly into two types: soft tissue thickness between bone and skin surface, and facial features such as eye, nose, mouth, and ear. From 2008 to 2011, the Catholic Institute for Applied anatomy constructed a forensic database including basic cranial measurements and facial soft tissue thickness acquired from 3D models of the cranium, mandible, and face using the computed tomography images of 732 Koreans.

This case report is the first attempt to utilize the aforementioned database to develop a facial reconstruction for a slightly putrefied body discovered naked near a mountain located in Yeowol-dong, Ojung-gu, Bucheon-si, on July 1, 2011. The initial examination of the body reported that the soft tissues of the face and left leg were removed and all phalanges were cut off. The autopsy record estimated that the loss of the soft tissues and the phalanges was due to postmortem animal attack and other trauma was not found. The cause of death was unknown. By forensic anthropologic examination, the body was estimated to be an approximately 40-year-old female. After autopsy, computed tomography of the body was taken, then a 3D model of the skull was produced. The soft tissue thickness at 13 midline landmarks and 21 lateral landmarks from females in their forties were selected from the forensic database. The morphology of the nose was estimated using a regression function to predict the location of pronasale and the size of the nose from the measurement of the bony nasal aperture. The other facial features such as the eyes, mouth, and ear were reconstructed by experience with facial reconstruction. Thirteen midline landmarks and 21 lateral landmarks were marked on the 3D model of the target skull using the 3D model modulating program. The guide bars reflecting the soft tissue thickness were added on the surface of each landmark in 3D spaces. The model of the skull with the guide bar was printed into a rapid prototyping model. According to the Neave technique, the expression muscles and the skin were reconstructed on the rapid prototyping model with clay. After clay work, the reconstructed face was scanned with a 3D laser scanner, then the details such as hair style, color of the iris, and texture of the skin were adjusted using the computer. Finally, several pictures of 3D facial reconstructed models were chosen and posted on mass media to find the family of the deceased. The police are now trying to find the family of the deceased using the reconstructed model.

Facial Reconstruction, Forensic Database, Korean

H4 Evaluation of Five Dental Calcification Formulas for Estimating Age in South Africans

Kyra E. Stull, MS, Univ of Pretoria, Dept of Anatomy, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; Herman Bernitz, PhD, Univ of Pretoria, Dept of Oral Pathology and Biology, Pretoria, 0001, SOUTH AFRICA; and Stephany Y. Van Der Walt, BA, Univ of Pretoria, of Anatomy, Private Bag x323, Arcadia, SOUTH AFRICA*

After attending this presentation, attendees will gain knowledge of the reliability and validity of five dental calcification correction factor formulas that are currently used to estimate age among South Africans.

This presentation will impact the forensic science community by providing information on the applicability of dental calcification correction factor formulas on South Africans and evaluating the reliability for scoring dental calcification.

Demirjian is a popular age-at-death method that examines calcification of seven teeth (I1 – M2) in the mandibular quadrant of 20th-century Canadian children.[1] The methodology is based on a dental maturity score which is derived from both the observed tooth stages and the corresponding weights assigned to each tooth. Using the provided percentiles, the maturity score is transformed into an age estimate. Despite some disadvantages, this method is often preferred to Moorrees which examines calcification per individual tooth rather than per quadrant.[2]

In two validation studies on South African children, the Demirjian formula has been shown to be consistently inaccurate.[1] In order to improve both accuracy and applicability, Phillips and Uys established South African correction factors based on the Demirjian methodology.[1,3,4] While these correction factor formula are currently used in South Africa, they have not been tested for either reliability or validity. The purpose of this study is to test both the reliability of the dental calcification method

and the accuracy of the correction factor formula on an independent sample of South African children.

Three hundred and sixty-three panoramic and radiographs (164 males; 199 females) of black, white, and colored groups aged 6 to 10 years were collected both from private dental practices in Pretoria, South Africa, and from the Red Cross War Memorial Children's Hospital in Cape Town, South Africa. Each mandible in the radiograph was scored according to the Demirjian methodology.[1] The Uys (UFBM and UFBF) and Phillips (P.Indian, P.Black, Tygerburg) correction factors were used to provide an age estimation. The Uys correction factors separated into sex groups but not ancestry, whereas the Phillips correction separated into ancestry but not sex.[3,4] Therefore, a total of five different age estimations inclusive or exclusive of either sex or ancestry were compared to true age in all cases.

Statistical analyses included error margin and bias to validate the technique and Analysis of Covariance (ANOVA) to explore differences between males and females. Error margin evaluated differences between estimated and true ages and bias examined whether the estimations were consistently over- or underestimating. For inter- and intra-observer error, ten images were randomly selected and scored by three observers of varying experience.

P.black had the smallest mean bias, mean error margin, and error margin range (-.27 years, .88 years, .006 years – 4.33 years), while P.Indian had the highest mean bias (.84 years), and UFBM had the highest mean error margin (1.1 years). No statistically significant sex differences in error margin or bias were noted for any of the five correction factors (all p-values >0.05). Inter- and intra-observer agreement ranged between 33% – 88% and 73 – 100%, respectively. The most common disagreement was between stages C (crown complete), D (dentine formation), G (root apex open), and H (root complete, apex closed). Low agreement was found with incisor roots; most likely due to poor visibility of these structures in the radiographic images.

While all five tested correction factors may be useful for estimating age in children, applicability of the methods is problematic, especially without known sex or ancestry. While sex was shown to not affect age estimations, ancestry presented with far more variability. P.Black demonstrated the lowest error margin and bias, which suggests this may be the best correction factor to employ.

Though several correction factors have been derived for South Africans none of the equations are predictive. Upon thorough evaluation of the methodologies, it is clear that none of the outputs are presented in a usable fashion; formula should result in an age estimation with associated standard deviations. Although these researchers have collected population-specific data which should yield better results than Demirjian, the data is not presented in a usable format.[1]

Error Margin, Bias, Validation

H5 Multi-Instrument Geophysical Surveys of Buried Human Remains in East Tennessee

Stephen J. Yerka, MA, Univ of Tennessee, 5723 Middlebrook Pike, Rm 237, Knoxville, TN 37923; Joanne B. Devlin, PhD, Univ of Tennessee, 250 S Stadium Hall, Dept of Anthropology, Knoxville, TN 37996; and Nicholas P. Herrmann, PhD, Mississippi State Univ, Dept of Anthropology, 206 Cobb Institute, Starkville, MS 39762*

The goal of this presentation is to provide crime scene investigators and physical anthropologists with innovative and comprehensive information on the identification of clandestine graves and associated evidence using advanced and readily available geophysical instrumentation. This presentation provides a review of current collection strategies and data processing techniques to present flexible and standardized protocols for the identification of this type of geophysical anomaly under controlled environmental conditions. Attendees will be provided with information to determine the utility and applicability of particular geophysical techniques in clandestine grave searches.

This presentation will impact the forensic science community by showing how the search for human remains must incorporate appropriate and methodical approaches that aim to identify evidence while not adversely affecting a crime scene. The methods of archaeology can provide critical tools for the crime scene investigator, particularly those involving the search for buried human remains and associated evidence. This project examines the application of several geophysical instruments to the detection of buried human remains drawing upon a long history of successful use in archaeological fieldwork. A comparative assessment of the use of Ground Penetrating Radar (GPR) and soil resistivity will be presented to demonstrate the most appropriate instrument given important variables of burial depth, time interval, and especially environmental conditions.

Geophysical survey data were collected on burials examined in both forensic and archaeological settings throughout areas of Tennessee. Three historic (and active) cemeteries in varying soil types and surface conditions were surveyed with multiple geophysical techniques including GPR, soil resistivity, and geo-magnetic survey. In addition, data were collected on four burials, created in 2010 at the University of Tennessee Anthropological Research Facility (ARF), that were subsequently excavated in 2012. The archaeological and forensic burials represent varied soil types, differing interment periods, and diverse pit attributes, thereby providing a unique opportunity to examine and compare data collected with several geophysical survey instruments. The resulting data were correlated with available information on the burials and include excavation records, body condition (before and after), time since death, soil properties, pit morphology, and recent weather and soil conditions to demonstrate critical factors and the most appropriate methods to incorporate in geophysical surveys.

East Tennessee has a variety of soil series and soil types, but clayey and loamy soils dominate. These clay-rich soils pose their own set of obstacles and opportunities for the application of geophysical techniques to locate buried targets. Moisture and porosity in these soils have a significant effect on the type of signal return, and these effects that confound geophysical detection can be systematically accounted for only through controlled studies over time. Geophysical data were collected in soils of differing moisture contents with the experimental burials surveyed twice prior to excavation, once under wet and rainy conditions, and again in dryer conditions. While the more recent experimental burials are consistently detected, the range of contrast at the targets was greatly affected by moisture levels. Shallow human burials in the clay-rich soils at the ARF appear as low-resistance anomalies in moist to saturated soils, while the GPR signal return is attenuated or scattered by the wet, clayey soils. When the soils are *saturated*, the GPR depth of penetration is hindered substantially, and this is true for both the 400MHz and the 200MHz systems that the researchers had access to for this study. Clay particles in general, especially when wet, charge differentially and can cause GPR signal

scatter and system noise such that the likelihood of detecting burials with GPR in saturated clay soils is reduced dramatically.

Burials both at the ARF and at historic cemeteries were surveyed using multiple instruments. The comparison of soil resistivity and GPR data in these soils provides further insight into the subsurface effect on radio-wave and electrical-resistance responses under similar conditions. The historic cemeteries provide a large sample of burial contexts spanning more than 200 years of use with varying depths, and accoutrements, and they provide a baseline of comparison for the experimental human burial contexts at the ARF.

In this research, factors of the environment that constrain when and how to use GPR and soil resistivity in a search for clandestine burials are identified. Fieldwork indicates that the incorporation of soil resistivity with the GPR return data (as a multiple-instrument survey) can dramatically increase the chances of characterizing a buried target.

Geophysics, Clandestine Graves, Buried Remains

H6 Bone Histomorphometrics and Sex Assessment

Lindsay H. Trammell, PhD, Pima County Medical Examiner's Office, 2825 E District St, Tucson, AZ 85714*

After attending this presentation, attendees will gain an understanding of bone histomorphometrics as it relates to partial estimation of the biological profile to identify unknown human remains from forensic settings. They will be introduced to the utility of histomorphometrics in the estimation of sex.

This presentation will impact the forensic science community by expanding the knowledge and scope of bone histology to include methodologies in addition to age-at-death estimation techniques thereby strengthening the overall accuracy of the biological profile and, consequently, the likelihood of positive identification.

Histological analyses have proven valuable in discerning fundamental age information about individuals. In fact, bone histology has been utilized to determine age-at-death for over forty years.[1-5] Histological analyses have not particularly focused on assessing sex as part of the biological profile; however, some research has demonstrated the need for sex-specific analyses when developing age-at-death regression equations.[6,7] Studies have also noted that the mean values of specific histological variables are significantly different between the sexes, possibly indicating different rates of bone modeling and remodeling.[6-8] Though past literature has not attempted to assess sex based on histomorphometrics, the finding that differences in bone remodeling do exist and that sex-specific equations to estimate age are potentially more reliable than sex-pooled equations indicate the utility of such methodologies.

This research was performed at the Department of Anthropology's Mineralized Tissue Histology Laboratory and the Forensic Anthropology Laboratory at the University of Tennessee Medical Center. Forty-eight white male and female decedents of known age, sex, and ancestry from the University of Tennessee Medical Center were sampled during autopsy to remove three one-by-one centimeter specimens from the sectioned margin of the left frontal, parietal, and temporal bones. An additional 50 left frontal bone samples were procured from males and females with known demographics from the Tennessee Medical Center. Complete medical histories were available, so retrospectively, if outliers demonstrate differential bone remodeling or atrophy, they could be excluded from analyses.

Bone samples were given a unique numeric, cleaned and dried, and embedded. Three thin-sections were cut for each sample and then ground and polished for analysis. A research light microscope and computer imaging software were used to examine slides at various magnifications; photographic series of the entirety of each thin-section was captured using a mounted digital camera attachment. Prepared thin-section slides were first examined to recognize cellular structures, evidence of remodeling, and the distribution of remodeling prior to quantification of the following histological features: external table thickness, number of secondary osteons, secondary osteon area, secondary osteon perimeter, secondary osteon maximum and minimum diameters, secondary osteon diameter ratios, secondary osteon Haversian canal area, secondary osteon Haversian canal perimeter, secondary osteon Haversian canal maximum and minimum diameters, secondary osteon Haversian canal diameter ratios, number of secondary osteon fragments, osteon population density, and osteon circularity.

This research created a discriminant function analysis based on the collected histomorphometrics to assess sex. A jack-knifed discriminant function analysis was run separately for the frontal, parietal, and temporal bones and then again to include all three bones to determine how accurate the histological features are at "discriminating" between subgroups and predicting which subgroup (male or female) each individual belongs to. Using only the frontal bone to assess sex resulted in a 67% correct classification, the parietal a 52% correct classification, and the temporal a 64% correct classification. When the discriminant function analysis utilized a combination of sub-variables from the frontal, parietal, and temporal to assess sex, it did so with 80% correct classification for females and 90% correct classification for males with an overall 86% correct classification. These results lend credibility to the prospect of using bone microstructure to assess sex.

In conclusion, bone histomorphometrics has potential in not only estimating age-at-death of unidentified individuals, it also contributes to assessment of sex.

Histomorphometrics, Sex Assessment, Forensic Anthropology

H7 Patterns in Worldwide Craniometric Sexual Dimorphism and Its Importance in Forensic Anthropology

Diana L. Messer, BS, 376 Newtown Turnpike, Redding, CT 06896; Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensic Sciences, Dept of Anthropology, 501 E 38th St, Erie, PA 16546; and Panya Tuamsuk, MD, Khon Kaen Univ, Dept of Anatomy, Faculty of Medicine, Khon Kaen 40002, THAILAND*

After attending this presentation, attendees will understand that differing degrees of craniometric sexual dimorphism among world populations can significantly impact sex estimation.

This presentation will impact the forensic science community by serving as a resource for understanding variation in worldwide craniometric sexual dimorphism and thus, considerations for more accurate sex estimation.

Forensic anthropologists frequently encounter individuals from a variety of ancestral backgrounds in American casework as well as global human rights cases and mass fatalities. The degree of craniometric sexual dimorphism varies among different populations and it is especially important for forensic anthropologists to keep these differing degrees of craniometric sexual dimorphism in mind when assessing sex. Guyomarc'h and Bruzek noted that applying Discriminant Function Analysis (DFA) from modern American craniometric data to a Thai sample resulted in poor classification accuracy.[1] The low classification accuracy in their Thai sample is likely a result of differing levels of craniometric sexual dimorphism between populations in addition to different population sex-specific means. Indeed, the sex-only function in FORDISC 2, which pooled samples of males and females from several groups, was removed in FORDISC 3 because Hispanic males were often misclassified as females.[1-3]

In order to analyze the differing degrees of craniometric sexual dimorphism among world populations, 13 measurements were analyzed from a modern Thai sample from Khon Kaen University Hospital (n=114), modern South African blacks from the University of Pretoria (n=84), and modern samples from the Forensic Data Bank (n=695), as well as 26 population samples that include both males and females from the W.W. Howells Data Set (n=2412). The statistical program R was used to run analyses of the craniometric data.[4] The pairwise Mahalanobis distance (D^2) was used as a measure of the difference between males and females within each group in order to isolate sex differences from ancestry differences, in contrast to pooling all groups in canonical variates analysis, where sex and ancestry influence the differences simultaneously. The classification percentages for males and females were calculated in FORDISC 3.1 for each group. The Easter Island group had the highest classification accuracy (96.5%) indicating a high degree of difference between males and females, making it easier to differentiate between the sexes. The Thai group had the lowest classification accuracy (72.8%), meaning that the males and females were more similar to one another and more difficult to differentiate. That is not generally true for all Asian populations, which are quite variable in the degree of craniometric sexual dimorphism. For example, the Ainu group had a classification percentage of 92.1% while the Atayal had a classification percentage of 74.5%.

The Thai and South African Black groups were the least sexually dimorphic in both the facial and vault measurements while the Easter Island sample was the most sexually dimorphic in both the facial and vault measurements. This shows that a small male from a group such as the Thai could easily be mistaken for a female of another group, such as Easter Island. In general, as the degree of sexual dimorphism in the face increased, the degree of sexual dimorphism in the cranial vault also increased.

The results of this paper further indicate that there are craniometric trends across nearly all samples from around the world. Using stepwise selection in FORDISC 3.1, the first three measurements of the 13 considered that were most important in the discrimination between males and females were related to cranial lengths (glabello-occipital length, nasio-occipital length) and facial width (bizygomatic breadth).

In conclusion, these findings confirm the importance of understanding that levels of sexual dimorphism vary between populations and this can help us interpret classification percentages in DFA and appreciate that sex assessment may be more difficult in those populations where males and females are more similar, such as the Thai, or where smaller males of one group may be confused for females of another group. With more investigations in many parts of the world, the challenge of population-specific methods becomes more important and this study functions as preliminary research into this question in order to formulate more accurate sex estimation in forensic anthropology.

Sexual Dimorphism, Craniometrics, Sex Estimation

H8 Sex Estimation Using Non-Metric Traits in Thai Crania With the Walker (2008) Method

Madeline Roth, BA, Merychurst Univ, Dept of Applied Forensic Sciences, 501 E 38th St, Erie, PA 16546; Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensic Sciences, Dept of Anthropology, 501 E 38th St, Erie, PA 16546; and Panya Tuamsuk, MD, Khon Kaen Univ, Dept of Anatomy, Faculty of Medicine, Khon Kaen, THAILAND*

After attending this presentation, attendees will: (1) be informed about the current research into sex estimation in the Thai; and, (2) understand the reasons why population-specific methods of non-metric sex estimation are important.

This presentation will impact the forensic science community by demonstrating that a commonly used North American method may not perform well when applied to other populations, and by furthering the research into sex estimation in the Thai.

Non-metric methods of sex estimation are widely used by forensic anthropologists across the world because of their ease of application and usefulness on fragmentary remains. Recently, statistical techniques such as discriminant function analysis have been applied to several well-established non-metric trait scoring systems in order to increase their classification accuracy and reliability, as well as make them admissible in court under the *Daubert* standards. It is also important that population-specific methods of sex estimation be developed, as patterns of sexual dimorphism vary extensively worldwide.[1-3] A method that accurately separates sex in one population may not be as effective in a population that is very different morphologically. There has been little effort to develop non-metric methods to estimate sex in the Thai or other Southeast Asian groups, and those that have been developed lack the integration of statistical methods necessary for reliability.

A non-metric method of estimating sex from crania that is commonly utilized in North America was published and developed using samples of African and European Americans, American Indians, and English.[4] In this study, Walker's method was applied to a sample of 70 males and 26 females from the Kohn Kaen University Hospital in Kohn Kaen, Thailand. Walker's reported logistic discriminant functions were applied to the Thai sample to test their performance. Next, in order to describe differences between the Thai sample and Walker's samples, the means of the samples were compared using Wilcoxon's rank-sum test, and the trait distributions of Walker's samples were compared to the Thai sample using the Freeman-Halton test. Univariate statistical analysis was run using each of Walker's five cranial traits to determine each trait's usefulness in estimating sex in Thais. The Thai sample was also classified through linear discriminant function analysis, using FORDISC 3.1.[5] Finally, the Thai sample was classified with logistic discriminant function analysis.

Results showed that Walker's method is not suitable for use in Thai populations. When Walker's logistic discriminant functions were applied to the Thai sample, their performance was very poor, exhibiting consistently low classification accuracies and high sex biases. In some cases, these functions produced classification accuracies of less than 50%, which is less accurate than random assignment of sex. Wilcoxon's test and the Freeman-Halton test indicated that there were significant differences in trait score means and distributions between the Thai

population and Walker's reference samples. In certain traits, the Thai male sample was significantly different from Walker's male samples, while not significantly different from Walker's female samples. When linear discriminant function analysis was used on the Thai sample, classification rates were consistently lower than those obtained in Walker's study. Using logistic regression derived from the Thai sample did not improve results. Throughout this study, no analysis produced a classification accuracy greater than 80% in the Thai sample.

Walker's method should not be used on the Thai, and must be used with great caution in untested populations as its results may be invalid. Patterns of sexual dimorphism in the Thai are different enough from those seen in Walker's samples that the equations developed by Walker do not effectively classify the Thai by sex. All analyses using Walker's traits performed poorly, even when newly calculated using the Thai as a reference sample; this indicates that Walker's system is not useful for estimating sex in the Thai, due to a lower degree of sexual dimorphism in these traits. New systems utilizing different traits should be explored in order to find those that may be the best for estimating sex from Thai crania.

Sex Estimation, Non-Metric Traits, Southeast Asia

H9 An Evaluation of the Hartnett-Fulginiti Method for Age-Estimation on an Independent Skeletal Sample

Andrew C. Seidel, MA, 1857 W Keating Ave, Mesa, AZ 85202*

After attending this presentation, attendees will learn about an evaluation of the Hartnett-Fulginiti (H-F) method for estimating age-at-death.[1-3]

This presentation will impact the forensic science community by providing data concerning the efficacy of this method when applied to a known-age skeletal collection differing from its reference sample. Validation using an independent sample is essential given that age-estimation techniques impose the age structure of their reference sample skeletal to the samples under investigation.[4-5]

Accurate estimation of age-at-death is crucial for the development of biological profiles and, therefore, a foundation of forensic anthropology. The H-F method revises two of the more widely used methods for age-estimation: the Suchey-Brooks (SB) method employing pubic symphyses and the Işcan and Loth (IL) method utilizing the sternal end of the fourth rib. These revisions were based upon a sample of elements from 630 individuals curated at the Maricopa County Forensic Science Center in Phoenix, Arizona. The sample is predominately of European ancestry, and ranges from 18 to 99 years of age. The current research aims to assess the utility of the H-F revisions on a skeletal sample independent of its reference sample as well as its efficacy on a subsample of individuals of African-American descent.

This research employs a random sample of 200 individuals of known age and ancestry from the Hamann-Todd collection curated at the Cleveland Museum of Natural History. The sample consists of 39 females and 161 males ranging between 19 to 87 years of age. Nearly half of the sample is of African-American descent (n=90). Rib ends were unobservable for some individuals and so the H-F rib method was evaluated on a subsample of 182 individuals. Age-at-death was estimated for each individual by examining the pubic symphyses and rib ends and assigning them to one of the seven H-F phases. Spearman's rank correlation coefficients were calculated between estimated and actual H-F phases and the percentages of individuals whose known ages fell within their estimated H-F phase or an adjacent phase were calculated.

Results suggest that the H-F method performs slightly better than the SB and IL methods. Higher correlations were recorded between estimated and actual H-F phases than for similar evaluations of the SB and IL methods (H-F pubic: Spearman's ρ=0.768, p-value <0.001; SB: Spearman's ρ=0.699, p-value <0.001; H-F ribs: Spearman's ρ=0.771, p-value <0.001; IL: Spearman's ρ=0.720, p-value <0.01).[1] The H-F method estimates the correct age phase for a similar percentage of individuals as the SB and IL methods (H-F pubic=41.5%, SB=44%; H-F ribs=41.2%, IL=35%) and it estimates the correct age within one phase on a moderately larger percentage of individuals (H-F pubic=92%, SB=83%; H-F ribs=90.7%, IL=79%).[1]

When the males from the sample are segregated by ancestry, a higher correlation exists between estimated and actual H-F phases for individuals of African-American ancestry than for those of European ancestry (African-American pubic Spearman's ρ=0.770, p-value <0.001, European pubic Spearman's ρ=0.651, p-value <0.001; African-American rib Spearman's ρ=0.812, p-value <0.01, European rib Spearman's ρ=0.625, p-value <0.01), suggesting that the H-F method performs well on individuals of African-American descent despite being developed from a primarily European sample. Data from the female subsample suggest a similar pattern, but sample sizes are too small to permit statistical verification.

Twenty individuals were selected for re-evaluation to assess the degree of intra-observer error. Correlations between first and second age estimates were very high (pubic: Spearman's ρ=0.934, p-value < 0.001; ribs: Spearman's ρ=0.975, p-value <0.001), exceeding those reported for similar tests of the SB and IL methods.[1]

The results of this evaluation of the H-F method for age-estimation suggest that it performs as well as or better than the widely accepted SB and IL methods. Its performance on a subsample of individuals of African-American ancestry indicates that it is unhindered by the primarily European composition of its reference sample. Lastly, the H-F method exhibits low intraobserver error rates. These observations suggest that the H-F method can be employed consistently and fruitfully by forensic anthropologists.

H10 A Re-Examination of Age-at-Death Estimation From the Human Sacrum

Kyle A. McCormick, MA, Dept of Anthropology, PO Box 6000, Binghamton, NY 13902-6000; Michael W. Kenyhercz, MS, PO Box 751845, Fairbanks, AK 99775; and Nicholas V. Passalacqua, PhD, 1559 Mount Vernon, East Lansing, MI 48823*

After attending this presentation, attendees will have a more comprehensive understanding of the human sacrum as an age indicator and statistical techniques used to assess age.

This presentation will impact the forensic science community by providing further investigation into traits and statistical techniques for estimating age-at-death from the human sacrum.

The goal of this presentation is to inform attendees about the performance of seven traits previously proposed as significant markers in the assessment of age at death from the human sacrum.[1]

Accurate age-at-death estimation from human skeletal remains is critical for establishing a comprehensive biological profile of an unknown individual, in order to facilitate the victim identification process. While many regions of the human skeleton have methods available to assess age at death, the sacrum has only recently been investigated.[1] The study builds on that previous work.

The primary aim of this study was to assess the performance of seven sacral traits, previously proposed to have utility in the assessment of age-at-death from human skeletal remains. These traits were: fusion of S1/S2, fusion of S2/S3, surface change, apical change, fusion of annular ring of S1, microporosity, and macroporosity. The study sample consisted of n=633 sacra from the Hamann-Todd (n=386) and Bass (n=247) collections. Individuals from the Hamann-Todd collection consisted of males and females, mainly of African and European ancestry, ranging in age-at-death from 10 to 96 years, and individuals from the Bass collection consisted of males and females of European ancestry, ranging in age-at-death from 16 to 97 years. Previous research found no significant sex or ancestry differences in regard to age changes in the sacrum.[1]

These traits develop over a continuum and each morphological character was scored according to multiple trait variants as described in Passalacqua (2009). In order to limit observer error; however, these traits were re-scored on a presence/absence or an unfused/fused scale. Age ranges were arbitrarily assigned into three broad age categories: young adult (<31 years), middle-aged adult (31 – 50 years), and old adult (51+ years). Each of these age ranges were treated as "populations" and subjected to multinomial regression analysis, random forest modeling, a naïve Bayesian model, and linear discriminant function analysis. Lastly, frequencies for each trait within each age group were tabulated and used to calculate Principal Component (PC) scores. The PCs were plotted against themselves to investigate the interplay of each trait in the estimation of age.

Each of these statistical methods for group membership had a similar correct classification rate, ranging from 69.8% correct using a naïve Bayesian analysis to 67.1% correct using discriminate function analysis. This trend, however, did not hold true for classifications of particular age ranges. By far, the most mis-aged age range was the middle-aged adults (31 – 50 years), with three of the four analyses correctly classifying 3.4% or less of this age range. Discriminate function analysis showed a much better ability to correctly classify middle-aged adults, with 38.1% of this group correctly classified.

Principal component analysis showed that the frequency distribution of these traits varied by age. Two principal components were derived from these data. The first PC showed the greatest loadings in the fusion of the S1 annular ring and then by the depression/resorption of the S1 annular ring, while PC2 demonstrated the greatest loading was macroporosity followed by surface changes. When plotted against themselves, the principal components showed a clear separation of each of the age ranges. On PC1, the decades moved in gradual order from youngest to oldest, while PC2 showed the <31-year group and 51+ years in a gradual order while 31 – 50-year group was separated.

Results demonstrated that treating age groups as populations yielded total correct classifications greater than pure chance. In each analysis, middle-aged adults misclassified most frequently. Conversely, the oldest age group (51+ years) demonstrated the highest classification accuracies. The principal components indicated that fusion of the S1 annular ring, depression/resorption of the S1 annular ring, macroporosity, and surface change accounted for the majority of variation present in the sample. Similar to other degenerative aging techniques, the sacrum predictably changes throughout life with younger and older individuals classifying correctly more often than middle-aged individuals.

Forensic Anthropology, Age-at-Death Estimation, Sacrum

H11 Multi-Isotope Study of Modern Human Dental Enamel From a Dutch Population

Gerard J.Q. van der Peijl, PhD, PO Box 24044, The Hague, 2490 AA, NETHERLANDS; Laura Font, PhD, Vrije Universiteit Amsterdam, Faculty of Earth and Life Sciences, De Boelelaan 1085, Amsterdam, Noord-Holland 1081HV, NETHERLANDS; Gareth R. Davies, PhD, Vrije Universiteit Amsterdam, Faculty of Earth and Life Sciences, De Boelelaan 1085, Amsterdam, 1081 HV, NETHERLANDS; Isis A. Van Wetten, MS, Hunzestraat 53II, 1079VT, Amsterdam, 1079VT, NETHERLANDS; and Tymour Forouzanfar, Watevliet 94, 2134 VV, Hoofddorp, Noord-Holland 2134 vv, NETHERLANDS*

After attending this presentation, attendees will understand the potential of combining isotope ratios for different elements in dental enamel to assist in estimating the origin of unidentified victims.

This presentation will impact the forensic science community by providing insight into the use of isotope ratios to assist in estimating the origin of unidentified victims.

Isotope ratio analyses (δ18O, Sr and Pb) have been carried out in wisdom teeth (third molars) from Dutch individuals that were born and lived in The Netherlands (30 individuals) and from individuals (five individuals) that were born abroad (South Africa, Surinam, Germany, Poland, Kenya), and moved into The Netherlands during childhood or adulthood. Also included are results for four front teeth (central and lateral incisors) from two young children (five to six years old), who were born and live in The Netherlands. Results demonstrate the use of isotope ratios for estimating the origin of unidentified human victims.

Variations in radiogenic isotopic systems (Sr and Pb) in wisdom teeth from the foreign individuals were compared to the variations of the Dutch population. The combination of δ18O stable isotope ratios with radiogenic isotope ratios, such as Sr and Pb provides provenance information from different perspectives: For isotopic studies of dental enamel, δ18O provides information on the isotope composition of waters ingested by the individual, the Sr isotope composition links the individual to the geological environment, and Pb isotopes reflect exposure of individuals to Pb sources present in the environment. The multi-isotope method has great potential application in forensic sciences.

The average δ18O isotope composition of dental enamel from the collection of third molars from modern Dutch individuals is 25.62 ± 0.41 (1σ) ‰. The individual from South Africa has a similar δ18O isotope composition compared to the Dutch dental enamel. This is in accordance with the information provided for the South African individual who moved to The Netherlands at two years of age, which is before the formation of third molars that begin to calcify at seven to nine-years-old.

From the δ18O isotope composition of dental enamel, the δ18O isotope composition of the water ingested by the individuals has been calculated using the equations of Daux et al.[+] and Chenery et al.[1,2] The calculated δ18O isotope compositions of the ingested water by the different individuals clearly indicated variable isotopic compositions that depended on the place of origin.[1,2]

Srontium isotope ratios in dental enamel show large variations (0.707 – 0.710) in teeth from Uganda and Surinam due to the different geology (tertiary sediments and volcanics to granitic metamorphic rocks, respectively) in these areas. The Sr isotope results in dental enamel from the Dutch population vary between 0.709 – 0.710, which is comparable to the Sr isotope values in scalp hair, water, and soils in The Netherlands. The combination of Sr isotopes with δ18O isotope composition show distinctive compositions related to place of origin. By only using one isotopic system; for instance δ18O in dental enamel from Uganda and Surinam or Sr isotopes in tooth enamel from Poland and

The Netherlands, the place of origin could not be distinguished. Similarly, Pb isotope results in dental enamel will be discussed.

H12 Analysis of Non-Human Skeletal Material Received in a Medical Examiner Setting

Katie N. Woods, BA, 1318 Commonwealth Ave, Unit 7, Allston, MA 02134; and James Pokines, PhD, Boston Univ School of Medicine, Dept Anatomy & Neurobiology, 72 E Concord St L1004, Boston, MA 02118*

After attending this presentation, attendees will gain new perspectives on the types of non-human skeletal material commonly received from law enforcement for forensic analysis in Massachusetts.

This presentation will impact the forensic science community by providing attendees with the species and taphonomic alterations common to this region and therefore the types of training which should be emphasized in these fields. Previously published documentation of types of non-human cases is sparse and is usually limited to general statements of what species are commonly examined. Forensic anthropologists have noted that commonly examined non-human remains throughout the U.S. are those related to food production such as deer, lamb, pig, cow, and chicken, as well as those from dog and horse. This study seeks to provide an organized and systematic analysis of a large sample of these cases.

Non-human skeletal elements were analyzed by the forensic anthropologist for Office of the Chief Medical Examiner. Cases were from the entire state of Massachusetts and the vast majority were found by members of the public and reported to law enforcement as potential human remains. Information was recorded on the different taxa present, the specific types of skeletal elements, and the different taphonomic processes affecting the bones (such as animal gnawing, weathering stage, and signs of peri-mortem butchery). Remains were analyzed through physical, macroscopic examination, and through photographs.

The most commonly analyzed non-human remains were those of white-tailed deer (*Odocoileus virginianus*), cattle (*Bos taurus*), and pig (*Sus scrofa*). Approximately 40% of the cases analyzed contained at least one skeletal element that showed signs of modern (machine) butchery. Most cases of machine butchery were skeletal elements from *O. virginianus*, *B. taurus*, and *S. scrofa*. This study validates the assessment of species related to food production being commonly presented by the public as potential forensic cases, while dog (*Canis familiaris*) remains were present in only 6% of cases and only one case involved definite horse (*Equus caballus*) remains. Only 5% of cases involved cranial elements, and most of these were fragmented. This most likely can be attributed to the general public's knowledge of the shape of the human skull as a popular symbol, making it difficult to confuse with a non-human cranium, and the active collection of non-human crania when encountered, leaving the more difficult to identify postcranial remains for later discovery. Gnaw marks were seen on 33% of the bones and were categorized as coming from large carnivore, small carnivore, undetermined carnivore, large rodent, or small rodent. Large rodent gnawing consisted of teeth marks left by North American porcupine (*Erethizon dorsatum*). Approximately half of the skeletal elements were at weathering stage 0, with some examples of weathering stage 1, but no cases were noted as being beyond that stage. Due to the state's extensive coastline, there also were cases involving skeletal elements from marine life including elements from dolphin (Delphinidae), seal (Phocidae), and unknown large fish species. Several of these elements had alterations typical of marine coastal environments, including rounding and bleaching.

The compilation of this information can help forensic anthropologists better understand what types of cases are being reported by the general public as potential forensic cases, and the skeletal recognition of which taxa in the North Atlantic region should be emphasized in forensic curricula.

Non-Human Remains, Forensic Anthropology, Taphonomy

H13 Sex Estimation in Modern African and Diaspora Populations

Meredith L. Tise, MA, Ashley L. Humphries, MA, and Erin H. Kimmerle, PhD, Univ of South Florida, Dept of Anthropology, 4202 E Fowler Ave, SOC 107, Tampa, FL 33820*

After attending this presentation, attendees will become familiar with cranial and postcranial metric sex estimation techniques in a modern African population and United States diaspora populations. Prior analysis looking at populations throughout Africa shows strong regional variation, especially concerning sexual dimorphism, which supports implications for using population-specific estimation parameters.

This presentation will impact the forensic science community by offering research into human skeletal variation among under-studied populations.

The estimation of sex is a significant component to the biological profile created by forensic anthropologists during casework. Many methods related to the biological profile have been developed based on skeletal collections in the United States. As forensic initiatives have increased throughout the continent of Africa, questions arise as to whether estimation parameters created from one population are appropriate for diverse groups. This presentation explores this question by using cranial and postcranial data collected at the Raymond A. Dart Skeletal Collection in Johannesburg, South Africa. For this research, a modern Botswanan sample was used containing 31 male and 31 female individuals. The age, sex, and population is known and confirmed for all of these individuals. As a preliminary analysis, by using these Botswanan individuals to create sex estimation techniques to be used in that region of Africa, comparisons can then be made to modern United States samples to assess the variation and determine whether population specific methods are needed.

Both cranial and postcranial measurements were used to create univariate and multivariate sex estimation techniques. All cranial data were collected with a Microscribe G2X digitizer. Seventeen measurements were used. Additionally, 31 postcranial measurements were taken from each individual. Multivariate analyses were performed on the cranial and postcranial measurements in SAS 9.1.3, consisting of a stepwise Discriminant Function Analysis (DFA) to determine which variables are the most accurate when estimating sex. From these variables, classification functions were created for multivariate sex estimation. A linear DFA allowed for sectioning points and cross-validation classification rates to be produced for the cranium and postcranial skeleton.

The multivariate results suggest that the femur's stepwise selected variables allow for a classification function with a total cross-validation rate of 90.53%, which is higher than any of the other classification rates, with the cranium (90.32%) and the humerus (88.89%) following closely behind. When considering only the univariate sectioning points of the postcranial skeleton, the top three total classification rates are measurements of the humerus, including humeral head diameter (88.89%), humerus epicondylar breadth (87.29%), and humerus proximal epiphyseal breadth (87.04%). When utilizing the Robert J. Terry Collection to represent an African diaspora sample, univariate maximum length measurements of the arm also consistently had the highest classification rates with ulna maximum length (83.71%) and humerus maximum length (82.03%). By comparing these resulting measurements and classification rates to African American samples,

insights can be obtained into human variation in Africa and other diaspora populations.

Human Identification, Sex Estimation, African Populations

H14 Evaluating Methods for Measuring the Ischiopubic Index for Determining Sex and Ancestry From the Human Skeleton

Caitlin C. Vogelsberg, MS, 1371 W Copper Creek Pl, Tucson, AZ 85737; and Stephen P. Nawrocki, PhD, Univ of Indianapolis, Archeology & Forensics Lab, 1400 E Hanna Ave, Indianapolis, IN 46227-3697*

After attending this presentation, attendees will better understand the validity and utility of recently proposed measurement techniques for both the ischium and pubis that differ from Washburn's original method, including several new measurements of the coxa designed by the authors.

This presentation will impact the forensic science community by helping to improve the way that the Ischio-Pubic (IP) Index is used in the determination of sex and ancestry of unidentified skeletal remains. Furthermore, it will illustrate the importance of carefully examining the sources of variance in a skeletal sample to tease out potential environmental effects.

Osteometric techniques employed in studies of the human pelvis are firmly rooted in the defining work of a few individuals, such as Washburn.[1] Unfortunately, Washburn's widely-used pubis and ischium lengths have increased potential for intra- and inter-observer measurement error because the fusion point of the three major elements of the os coxa (ischium, ilium, and pubis), from which ischial and pubic lengths are taken in adults, is often ambiguous. Few studies have attempted to alleviate this problem and those that have, such as Patriquin's recent work, lack validation.[2] Furthermore, few have simultaneously addressed ancestral variation in the anterior pelvis that could confuse the issue. The current research addresses these problems and suggests that a shift to a more precise method for calculating the IP index is warranted.

Six measurements consisting of three pairs of corresponding pubic and ischial lengths were taken using Washburn's, Patriquin's, and a newly developed technique that uses the very center of the acetabulum (the "acetabular point").[1,2] A sample of 220 identified skeletons was drawn from the collections at the University of Pretoria in South Africa and the University of Tennessee at Knoxville. Measurements were taken from males and females of "Black" and "White" ancestry born in both North America and Africa. "White" and "Black" are used in this context in the traditional sense, referring to individuals whose ancestors were previously derived from either indigenous European or indigenous African populations, respectively. All individuals were adults between the ages of 18 and 99 and free of pathological conditions and postmortem degradation.

Each index was calculated using the traditional formula ((pubis length/ischium length) x 100). A fully-factorial univariate Analysis of Covariance (ANCOVA) was applied to each of the three indices to determine whether any of the independent variables (sex, ancestry, age at death, and continent of origin) or their interactions have a significant effect on the variance of each index. Then the accuracy of each index was assessed by generating separate discriminant functions for sex and ancestry and resubstituting the entire sample into each equation, producing percentages of individuals correctly assigned by each method.

The results indicate that all three indices are significantly affected by sex, two are affected by ancestry, and none are affected by age at death. The newly-developed acetabular index has the best accuracy when predicting sex (87% correct) but the worst accuracy when predicting ancestry (53%), suggesting that its lack of sensitivity to ancestral variation allows it to hone in on sex differences more effectively. Patriquin's index had the best accuracy for predicting ancestry (64% correct) but the worst accuracy for predicting sex (78%). Continent of origin appears to have an independent influence on anterior pelvis morphology beyond the effects of sex or ancestry, suggesting that the environment is an important factor irrespective of genetics.

Ischio-Pubic Index, Sex Determination, Predicting Ancestry

H15 The Birds and the Bones: Differential Avian Scavenging Patterns in Determination of Postmortem Interval

Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007; and Jesus C. Villa, BA, 2354 W University Dr, #2162, Mesa, AZ 85201*

After attending this presentation, attendees will understand the importance of avian scavenging patterns in the taphonomic process and in determining postmortem interval, as well as recognizing a wider range of scavenging bird species and the marks they leave in skeletal material.

This presentation will impact the forensic science community by illustrating the presence and use of differential taphonomic markings left by avian scavenging, which will provide valuable information about postmortem interval and the taphonomic process.

Postmortem interval is measured largely by taphonomic processes, in many cases specifically by insect scavenging activity. Similarly, scavenging by mammals (most notably carnivores and rodents) and avians has been noted and studied in taphonomic and postmortem interval contexts. However, of the eight avian species known to scavenge on the carrion of large animals (including humans) in North America, only two species have had their scavenging patterns studied in-depth. Reeves studied "the accelerated rate of decomposition and the signature markings on the bones" of pig carcasses (*Sus scrofa*) that were scavenged upon by Turkey Vultures (*Cathartes aura*) and American Black Vultures (*Coragyps atratus*).[1]

This study investigates specifically the markings on bones left by the American Black Vulture, the Andean Condor (*Vultur gryphus*), the Bald Eagle (*Haliaeetus leucocephalus*), the Chihuahuan Raven (*Corvus cryptoleucus*), the Common Raven (*Corvus corax*), the Golden Eagle (*Aquila chrysaetos*), and the Turkey Vulture, all of which were housed at the Phoenix Zoo. The Phoenix Zoo does not display all eight species of known North American avian scavengers, including the American Crow (*Corvus brachyrhynchos*) and the California Condor (*Gymnogyps californianus*). Consequently, the results from the Andean Condor are assumed to be representative of the California Condor and the results from the two Raven species are assumed to be representative of the American Crow, due to similarities in their respective sizes, natural habitats, and diets. All of the species were kept in separate enclosures, with the exception of the Turkey and American Black Vultures, which share an enclosure. This ensured a controlled environment free of terrestrial and overlapping avian scavenging which could potentially confuse resulting data. Every species was represented by two birds, except for the Turkey/American Black Vulture population, which were represented by four Turkey Vultures and three American Black Vultures. Over a one-month period, the birds were first given ham hocks (*Sus scrofa*) for two weeks followed by pork ribs and beef ribs (*Bos primigenius taurus*) for two weeks. The specimens were left in the enclosure for several days until completely de-fleshed or until the next scheduled feeding (approximately every two to three days). The bones were then collected, macerated at the forensic anthropology and odontology laboratory, and examined grossly and microscopically.

No visible evidence of scavenging was found on the ham hock bones that were placed in the enclosures during the initial phase of the research. The pork and beef ribs, however, yielded multiple notable results. Grooves and scratches were noted among the specimens recovered from the Bald Eagle, Raven, and Turkey/American Black Vulture exhibits. None of the observed marks appeared to be consistent

with rodent scavenging, implying that only avian scavenging marks were present. The marks observed on the specimens provided to the Turkey and American Black Vulture population appear consistent with those described by Reeves.[1] Initial observations of the marks left on the specimens provided to the respective Bald Eagle and Raven populations appear macroscopically to be distinct in overall morphology (i.e., length and overall appearance), from those noted in the Vulture populations, and from those noted in Reeves.[1] Microscopically, however, all marks appeared to display a similar, rounded cross-section very similar to that of the aforementioned populations.

Because the ranges of these birds vary between species, especially due to seasonal migration, analysis of differential taphonomic markings left by avian scavenging will provide valuable information about postmortem interval and location of death (i.e., if the remains are moved postmortem). For example, Bald Eagles are normally only present in the Desert Southwest and the Midwest during the winter (with the exception of a small, year-round population in south-central Arizona).[2] Human skeletal remains found in non-winter months in these geographic regions and displaying marks that are consistent with Bald Eagle scavenging can then be inferred to have been exposed for at least a portion of one winter, further refining postmortem interval and taphonomic processes.[1]

Avian Scavenging, Postmortem Interval, Taphonomic Processes

H16 Stature Estimation in Modern Thais: Are Population-Specific Estimation Equations Necessary?

Ani N. Hatza, BA, Mercyhurst Univ, Dept of Applied Forensic Sciences, 501 E 38th St, Erie, PA 16546; Stephen D. Ousley, PhD, Mercyhurst Univ, Dept of Applied Forensic Sciences, Dept of Anthropology, 501 E 38th St, Erie, PA 16546; and Panya Tuamsuk, MD, Khon Kaen Univ, Dept of Anatomy, Faculty of Medicine, Khon Kaen, 40002, THAILAND*

After attending this presentation, attendees will understand why the development and use of separate stature estimation equations for different ancestral groups are necessary in forensic anthropology.

This presentation will impact the forensic science community by demonstrating that the stature estimation accuracy of linear regression equations developed for a given population declines when applied to a different population, in this case the Thai. Additionally, this presentation provides new stature estimation equations developed specifically for modern Thai individuals, a group that until recently has been largely overlooked with respect to stature estimation studies.

Stature estimation is one aspect of a biological profile utilized by forensic anthropologists to assist law enforcement with the identification of unknown human remains. The use of population-specific stature estimation equations by forensic anthropologists increases the precision and accuracy of stature estimations and of identifying an unknown individual who is thought to come from a particular population. The *Daubert* standard requires forensic anthropologists to demonstrate the scientific validity of their methodologies through empirical testing, peer review and publication, and calculating error rates. External validity must be tested and is a requirement when procedures based on one population are applied to another population. Modern Thai males and females exhibit average statures that are considerably smaller than those of American Blacks and Whites, and Hispanic males. Mean stature for Thai males is approximately 165cm, while that of American Black males is 175cm, American White males is 176cm, and Hispanic males is 170cm; Thai females have a mean stature of approximately 155cm, whereas the mean stature for American Black and White females is 164cm.[1] For this reason, the development of population-specific stature estimation linear regression equations appears necessary.

To date, two stature estimation studies have been published for the modern Thai.[2,3] The Mahakkanukrauh study was performed on a sample from Chiang Mai, Thailand, in the northwestern region of the country. The authors noted that their linear regression equations produced unusually high standard errors, particularly with respect to the female equations. The Pureepatpong study was based on a sample population from Bangkok, located in southern Thailand. The linear regressions proposed in the Bangkok study had lower standard errors and higher R^2 values than the Chiang Mai regressions; however, the Bangkok sample population exhibited lower mean statures and limb lengths than both the Chiang Mai sample and the current study's sample population.

The lengths of five long bones (femur, tibia, humerus, radius, and ulna) were collected from 106 modern Thai at the Khon Kaen University Hospital, Thailand. Outliers were removed and linear regression formula and prediction intervals for stature were calculated using *R*.[4] Additionally, regression equations in FORDISC 3.1 based on American White, American Black, and Hispanic populations were applied to the Thai sample.[1] Results showed that the femur is most highly correlated with stature in both males and females, as in other studies, and therefore provides the best single bone stature estimation equations. Compared to the results of the previous Thai stature studies, the results of the current study produced the lowest standard errors and highest R^2 values. 90% prediction intervals at the mean using bicondylar femur length and maximum femur length, respectively, were 160.3cm to 168.9cm for Khon Kaen males and 150.3cm to 161.1cm for Khon Kaen females.

Upon comparison, estimation of Thai stature using the FORDISC 3.1 linear regressions resulted in lower R^2 values, higher standard errors, and wider prediction intervals across the board. Black equations for males and females underestimated Thai stature overall, whereas the White and Hispanic equations tended to overestimate Thai stature. Larger prediction intervals sacrifice precision for greater accuracy; however, in a forensic context, accurate but imprecise stature estimations are not as useful to law enforcement officials. These findings indicate that although stature prediction equations that were intended for use on a different population will work, these estimates will contain greater error, especially when moving farther away from the sample mean.

H17 Online Pedagogical Methods in Forensic Anthropology: Effective Strategies for the Virtual Field and Lab

Misty A. Weitzel, PhD, 345 N Monmouth Ave, Monmouth, OR 97361*

After attending this presentation, attendees will become aware of online or e-learning alternatives for developing and disseminating curricula in introductory forensic anthropology courses. This

presentation will offer an example of an online forensic anthropology course that meets objectives as equivalently and effectively online as it does face-to-face.

This presentation will impact the forensic science community by increasing awareness of online learning and its application to introductory forensic anthropology courses. Online learning (for example, fully online courses, blended learning, game-based learning, and social networking) is one of the fastest growing trends in education. The advantages of online learning to students, instructors, and universities are well documented with the exception of certain disciplines like forensic anthropology. While there are many empirical studies of online learning, there is a paucity of research on best practices in anthropology, especially subdisciplines in bioanthropology, archaeology, and forensic anthropology. It would be useful to know how anthropologists are utilizing online learning tools and carefully consider the innovations that will increase the quality of online anthropology courses.

The concern that courses cannot be taught effectively online seems to be elevated in certain disciplines where the lack of hands-on laboratory demonstrations and exercises presents a major disadvantage. Forensic anthropology laboratory and field experiences are outstanding aids to learning but even traditional classroom environments may not have osteological collections or opportunities for conducting work in the field due to financial or logistical constraints. Indeed, online courses in forensic anthropology may require more creativity and effort than other anthropology courses but there are effective mechanisms to conduct virtual laboratory sessions without the tactile use of human remains.

The effectiveness of the online approach was tested by comparison of student learning outcomes and satisfaction between online and face-to-face forensic anthropology courses taught at Oregon State University and Western Oregon University. All sections of course material (readings, lectures, assignments, due dates, and other requirements) were similar in content but administered differently for each course. Four indicators of student success were examined using independent *t*-tests: cumulative lab scores, cumulative quiz scores, project scores, and total points earned. Two indicators of student satisfaction were examined, also using independent *t*-tests: satisfaction with the course as a whole and the instructor's contribution to the course. These two components of the evaluations were the same in content but administered differently between online and face-to-face courses.

Results demonstrate that course objectives are equally achieved and teaching is effective in both cases as student success is as high online as it is on campus. The results of the *t*-tests showed that of the four comparisons, none were significantly different (*p-value*>0.05). Additionally, student perceptions of the courses are above average for both methods of delivery. The results of the *t*-tests showed that there was no statistically significant difference in combined course and instructor satisfaction. Unedited student comments also tend to demonstrate fulfillment with the online course.

This study is likely the first to examine the efficacy of online instruction in forensic anthropology. The results provide a clear example of the design and delivery of online labs and experimental projects that may be useful for other anthropology and forensic science courses. Despite the challenges associated with using skeletal remains as teaching tools, it appears that students succeed in learning online and are satisfied with the results. Technology provides methods that meet today's student, instructor, and institutional needs but additional discussion is needed to improve online learning within forensic anthropology.

Forensic Anthropology, Pedagogy, Online Learning

H18 Positive Identification Using Chest Radiographs: Standards for Minimum Number of Concordant Points

Ann H. Ross, PhD, NC State Univ, Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107; and Sam Simmons, MD, NC OCME, Campus Box 7580, Chapel Hill, NC 27599-7580*

After attending this presentation, attendees will gain a better understanding of: (1) a method of decedent identification via comparison of vertebral column characteristics between antemortem and postmortem radiographs; (2) the associated statistical probabilities of a positive identification using this method; and, (3) the variance of those probabilities based on the quality and several other characteristics of the specimens and radiographs.

This presentation will impact the forensic science community by serving as a statistically valid and systematic means for positive identification of decedents when more traditional methods of identification are not available, or when those traditional methods need to be supplemented.

Positive identification is of primary importance for case resolution and bringing closure to the victims' families. Difficulties surrounding the identification process can result from taphonomic processes that result in incomplete recovery of skeletal materials and/or from inadequate antemortem records. Therefore, a variety of identification methods that utilize various anatomical structures is essential for timely and accurate identification. While there are a number of methods used to make positive identifications through radiographic comparison, many lack the scientific rigor necessary to make them admissible in court. The utility of radiographs for positive identification was examined in accordance with the United States Federal Court ruling (*Daubert vs. Merrell Dow Pharmaceuticals*, 509 US.579, 1993) and National Academy of Sciences (NAS) 2009 Report, *Strengthening Forensic Science in the United States: A Path Forward*, which calls for more testable and reliable scientific research. To date, there has been ample research exploring morphological variation in the frontal sinus, chest, and vertebrae for positive identifications; however, much of this research has focused on the investigator assessing morphological similarities or dissimilarities via side-by-side comparisons, which would not satisfy the *Daubert* criteria or NAS report. The utility of radiographs for medicolegal purposes is shown by the uniqueness of certain features of the skeleton in previous research; however, there is a need to quantify their uniqueness. Although vertebral radiographs are commonly used in the identification process, standards do not currently exist regarding a minimum number of concordant points that should be used. The case reports in the forensic literature show that one to four points with no discrepancies have been used to determine identity.

The purpose of this pilot study was to examine the vertebral column in a known sample of 60 antemortem and postmortem chest and abdominal radiographs from the North Carolina Office of the Chief Medical Examiner to: (1) evaluate the uniqueness of traits observed in the vertebrae; and, (2) explore the minimum number of corresponding traits necessary to make a positive identification in order to address the issue of probabilities, a growing concern in the court systems. Thirty comparisons were antemortem and postmortem radiographs from known individuals. To represent the unknown or no-match sample: either an antemortem or postmortem radiograph was compared to a randomly selected individual. The following eight traits were scored for each radiograph: cervical morphology (e.g., pedicle, spinous process shape, etc.), thoracic morphology, lumbar morphology, quality of antemortem X-ray (e.g., good, average, and poor), quality of postmortem radiograph, presence of congenital anomalies, elapsed time between antemortem and postmortem radiographs, and condition of remains (e.g., skeletonized, decomposed, etc.).

To explore patterns and relationships of the data, a robust data mining technique called a classification decision tree was applied. For categorical data, a G^2 or the likelihood-ratio chi-square for the variables is computed and used for multi-level split of the data. The advantages of decision trees are that they are easy to interpret, they are able to

handle both categorical and numerical data, and they are robust. Results show that the anatomical elements with the most predictive value were the lumbar vertebrae and indicate that if you have more than five concordant points, you have a 71% probability of correct classification (Fig. 1). If the postmortem X-rays are good or average quality, then the probability increases to 90% and if the antemortem radiographs are average quality, the probability of correctly matching the radiographs increases to 93%. Likewise, if there are less than five points of concordance, there is only a 33% probability of correct classification and if the antemortem radiographs are good or average quality, then the probability increases to 62%. Thus, these results show that a minimum of five points of concordance are needed with good or average quality postmortem radiographs in order to have a 90% probability of correctly classifying or making a positive identification based on the lumbar vertebrae. The cervical and thorathic vertebrae were not found to be unique enough to be used to make a positive identification on their own. However, the use of cervical and thorathic vertebrae in a larger sample is currently being examined.

This project was sponsored by the National Institute of Justice (2010-DN-BX-K214).

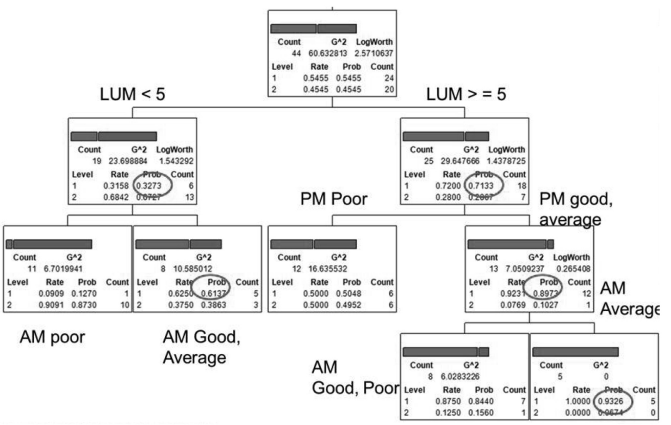

Fig. 1. Results showing the lumbar vertebrae as having the most predictive power and probabilities associated with corresponding traits.

Radiographs, Positive Identification, Number of Traits

H19 Adipose Distribution as a Predictive Model for Scavenging Sequencing and Intensity

Lisa N. Bright, MA, 1259 Hobart, Chico, CA 95926*

The goals of this presentation are to: (1) provide an assessment of current scavenging models; (2) provide an evaluation of actualistic experimental data; and, 3) provide a discussion of the role of adipose in scavenging sequencing and intensity. Attendees will be provided with examples of scavenging patterns from actualistic experiments using pig and deer carcasses and from forensic case report documentation of curated human remains housed at the California State University, Chico Human Identification Lab (CSUC-HIL).

This presentation will impact the forensic science community by providing a critical evaluation of current scavenging models and discussing the role of adipose in scavenging behavior.

Current anthropological scavenging theory states that elements disarticulated the earliest should show the greatest amount of damage. Much of the literature also states that the ventral thorax should be one of the first areas of the body to be scavenged. This study, however, shows that sometimes the internal organs are the last portions scavenged.

The actualistic study associated with this presentation was conducted in October 2009 and November through December of 2011 at the Big Chico Creek Ecological Reserve (BCCER) in Butte County, California. A single adult mule deer and five 100-pound pig carcasses were placed at six different locations within the BCCER. Digital game cameras were positioned at each of the sites in order to monitor scavenger activity. Two pictures were taken each time the motion-sensitive laser was triggered, with a delay of one minute between each image. Sites were monitored daily and the camera was repositioned if the carcass had been moved out of the camera's field of view. The carcasses were placed on the surface, and to prevent immediate removal from the site location, each carcass was tied down to rebar stakes with lengths of wire wrapped around the forelimbs and hind limbs. Documented scavengers included: black bear, gray fox, turkey vulture, red-tailed hawk, golden eagle, and the common raven. From the camera documentation, the sequence of tissue consumption and disarticulation were recorded and analyzed. The scavenging damage was then compared to 21 forensic cases curated at the CSUC-HIL. The deer, pig, and human skeleton element representation, and inter- and intra-element scavenging patterns, were documented in detail.

Results indicate that the carcasses were consumed in a predictable sequence from areas of high body-fat content to areas with low fat content. In the deer carcass, scavenging damage occurred first to the thorax and anal region, with all internal organs removed and consumed in the first 24 hours. The deer was completely skeletonized, disarticulated, and scattered by the second day. Total body fat of an adult female mule deer ranges from 3.7 to 10.9 percent (Torbit et al. 1988).[1] Conversely, in the case of the pigs, the skin and subcutaneous tissue were consumed first, followed by the forequarter, hindquarter, and lastly, the internal organs. In modern, commercially produced pigs, total carcass fat is kept at approximately 20 percent; this percentage is similar to the average American adult (Kouba and Sellier 2011, MedlinePlus 2011).[2,3]

The pattern documented in the pig carcasses, with regards to scavenging intensity and adipose amounts, was mirrored in the human skeletal sample. The most heavily scavenged portions of the human skeletons were the innominate, proximal ulna, proximal tibia, and proximal humerus; these areas are all surrounded by rich fat deposits. The higher rates of damage in high-adipose areas may occur because of the higher caloric, and thus energetic, return of fat-rich areas compared to protein- or carbohydrate-rich areas. Thus, areas that are richer in fat should have a higher degree of scavenging intensity than areas lower in fat.

Taphonomy, Scavenging, Adipose

H20 The Use of Joint Surface Pathology to Reassociate Commingled Human Remains in Forensic Anthropology

Colleen Cheverko, BS, 635 West 6th Ave, Apt 9, Chico, CA 95926*

After attending this presentation, attendees will have a better understanding of how joint surface pathology can be used to reassociate commingled human skeletal remains.

This presentation will impact the forensic science community by providing forensic anthropologists who are often confronted with the challenges of reassociating commingled skeletal remains an additional sorting tool.

Osteometric sorting, articulation, pair matching, taphonomic similarities, and DNA sequencing are among the established techniques used to reassociate commingled skeletal remains. The technique of articulation is based on the principle that two bones in articulation form a congruent joint; however, the effects of joint surface pathologies such

as osteoarthritis on articulation are unknown. These pathologies often exclude the use of traditional methods, warranting the development of new techniques to reassociate affected commingled remains.

The goal of the study was to evaluate the expression of osteoarthritis as a possible tool for sorting commingled remains. Medical literature indicates that the expression of osteoarthritis is consistent within an individual across joint surfaces in autopsy and surgical patients; however, bioarchaeological literature shows the variation in expression of the pathology is dependent on the method used to identify it.[1] To insure consistency in scoring osteoarthritis, the authors used the criteria published by Buikstra and Ubelaker to determine presence of osteoarthritis and the criteria established by Jurmain to determine the severity of the joint disorder.[2,3]

For this study, 258 discrete individuals from the Phoebe A. Hearst Museum of Anthropology were examined. The individuals included in the study were aged 30 years or older and had 50 percent of two or more surfaces from the same joint. The degree of lipping, eburnation, and porosity was examined in each synovial joint of the skeleton and a severity score was assigned that described the joint degeneration.

Overall, the majority of the osteoarthritis was expressed as marginal lipping and porosity; therefore, many of the joint surfaces were scored with a severity score of one. Chi-square tests were used to analyze the frequency of osteoarthritis in the hip, knee, elbow, and shoulder. The results showed that presence of osteoarthritis was consistent across surfaces of a joint. For example, the radial head was not marked with osteoarthritic changes if the capitulum of the humerus was not. Similarly, the medial condyle of the tibia was likely scored as one if the medial condyle of the femur was scored as one.

The study showed that osteoarthritis is a useful tool to reassociate commingled skeletal remains; although, it is most useful when used in conjunction with other techniques. While pathology of the joint surface may preclude the use of other methods such as the measurement of joint surfaces, joint pathology is a valid criterion to reassociate discrete individuals. This study only examined osteoarthritis; future studies should evaluate other pathological conditions.

Despite a great deal of past research, there is a need to develop additional tools to facilitate reassociation of discrete individuals. Future studies should investigate joint surface pathologies from modern and archaeological collections to increase our understanding of these pathologies and their value for reassociating commingled remains.

Commingling, Mass Burials, Joint Pathology

H21 The Power of Contextual Effects: A Study of Biasability in Visual Interpretations of Trauma Analysis on Skeletal Remains

Ian Hanson, MSc, ICMP, Sarajevo Headquarters, Alipašina 45a, Sarajevo, 71000, BOSNIA-HERZEGOVINA; Sherry Nakhaeizadeh, MSc*, Bournemouth Univ, Poole, Dorset BH12 5BB, UNITED KINGDOM; and Nathalie Dozzi, MSc, Bournemouth Univ, Poole, Dorset, UNITED KINGDOM*

After attending this presentation, attendees will understand how contextual information can bias assessment of trauma images.

This presentation will impact the forensic science community by demonstrating how bias can impact forensic anthropology and how contextual information can affect objective assessments by scientists with a range of experience and ability.

The potential for contextual information to bias assessments in the forensic sciences has been demonstrated, focusing on the DNA, ballistics, and friction ridge analysis disciplines. This has been discussed in the National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward.* However, in many forensic disciplines, such as anthropology, the presence of bias, its impact on objectivity, and how to mitigate its effects is still not fully assessed or appreciated. Effects that may impact the judgment and decision-making of forensic anthropologists need to be measured. No studies have been performed within the discipline assessing possible biasing effects within visual analysis.

Biasability potential within forensic anthropology was examined by constructing an experiment that analyzed the effects of external manipulations on judgment and decision-making in visual trauma assessment. Three separate websites were created containing 14 identical images of skeletal remains presenting a range of trauma. Each website presented participants with different contextual information. The three separate contexts described human rights mass grave excavations, a 19th-century archaeological excavation setting, and a control scenario with no specific contextual information provided. Ninety-nine participants were equally distributed and randomly assigned to one of the three scenarios. Participants completed a survey noting qualifications and experience, and were asked to assess the presence of trauma in the images and to describe their confidence in their interpretation by scoring for level of certainty. The interpretation of presence of trauma was assessed to determine if it would differ for the same images across the different scenarios.

The results indicated a bias correlation between the three scenarios, indicating a higher likelihood of identifying trauma within the mass grave excavation context. A significant biasing effect was associated with four of the images, notable for their ambiguous and distinct nature. Participants with less experience were more likely to interpret the presence of trauma. This research demonstrates that bias can be detected in the field of forensic anthropology, highlighting the importance of recognizing issues that may influence interpretation during investigation and analysis, as well as the need for further research on how to mitigate these effects.

Anthropology, Bias, Trauma Assessment

H22 Did I Teach Them That? Setting and Assessing Goals for Student Learning for an Introductory Forensic Anthropology Course

Phoebe R. Stubblefield, PhD, Univ of North Dakota, Dept of Anthropology, 236 Centennial Drive Stop 8374, Grand Forks, ND 58202*

After attending this presentation, attendees will be able to describe an appropriate goal for an introductory forensic anthropology course as well as the format of the assessment tool used in this presentation.

This presentation will impact the forensic science community by disseminating information regarding a technique for determining the effectiveness of forensic anthropology (or other science) courses.

In this presentation, a technique used for several years for assessing student learning in an introductory forensic anthropology course is described. This technique begins with a statement of the goals of the course, followed by design and implementation of a tool for determining if particular goals have been met. After viewing this presentation, observers should be able to describe an appropriate goal for an introductory forensic anthropology course and describe the format of the assessment tool used in this presentation. This presentation will have an impact on educators in the forensic science community by disseminating a technique for determining the effectiveness of forensic anthropology (or other science) courses.

Instruction of the course "Introduction to Forensic Anthropology" at the University of North Dakota is subject to learning goals occurring at the instructor, department, and university levels. Statement of the goals establishes the frame of reference for developing the assessment tool. Instructor level goals are public and private. Private goal setting is how instructors make clear to himself or herself the intent and significance of the course, and will affect the choice of course design (e.g., lecture, lecture with lab or hands-on activities, emphasis on videos, emphasis on small group activities), texts used, and frequency of offering. Institutionally based limits on course design should be reflected in departmental or institutional goals for the course. The instructor may set public goals, stated on the syllabus, based on criteria such as his or her own interest in what students should derive from the course, the content of the texts used in class, and/or requirements set by the department and institution. For example, a personal interest-derived goal for Introduction to Forensic Anthropology may be "Name and describe the contributions of famous forensic anthropologists." An institutional (department level) goal is "to demonstrate knowledge and understanding of the sources of biological and cultural variation and how these change over time." If a large number of public goals are applied, an overall assessment program may be needed to support inspection of different goals in different academic years, lest the assessment process become cumbersome.

The tool used to assess student learning is a test composed of Likert scale and short answer questions administered at the beginning and end of the course. The questions are designed to provide indirect (from the Likert questions) and direct (from the short answer questions) assessment data of the public goals for the course. For the tool to be relevant, the questions must be derived from the course goals and, as a consequence, may vary somewhat from year to year and are subject to revision. The Likert questions in this tool tend to demonstrate student confidence in knowledge. This is an indirect measure of student learning as it reflects only the student's opinion. The question, "I have a basic understanding of human skeletal anatomy, enough to name major bones," is answered with a spectrum of "describes me" responses. An appropriate short answer question provides data for the direct assessment, in this case being "Name all the long bones of your upper limb." Students may claim knowledge in the Likert, but then that knowledge must be demonstrated in the short answer. Here the instructor interprets the short answer response to determine if students can demonstrate the knowledge.

Once the tool is created, the greatest work in this process is in collating the data, but this is an appropriate project for a student worker sworn into Family Educational Rights and Privacy Act (FERPA) compliance. Likert questions can be collated in a spreadsheet program and meaningfully portrayed graphically. However, the short answer questions must be coded to allow the student worker to collate the data, which means the instructor must survey the responses and apply codes. Interpretation of the direct assessment data can be perfunctory to address student acquisition of knowledge (typically satisfying institutional goals) or rigorous (typically addressing private goals). In the long bone question, variation in the responses (such as inclusion of carpals and phalanges) may demonstrate that the test question should be reworded or vocabulary clarified in class. An assortment of course goal-Likert-short answer trios, and before-and-after results is presented in order to demonstrate the utility and format of the assessment tool.

Forensic Anthropology, Education, Assessment

H23 Analytical Test Method Selection and Validation of Laboratory-Based Methods

Paul D. Emanovsky, PhD, JPAC-CIL, 310 Worchester Ave, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will have a better understanding of the principles of selecting a method for inclusion in their laboratory's standard operating procedures (SOP) and the necessary steps to validate a laboratory-based method, which may include modifications of longstanding methods.

This presentation will impact the forensic science community by illustrating the principle, spirit, and intent of method validation through the use of a case study-validation of the Hefner Optimized Summed Scoring Attributes (OSSA) method for ancestry determination.

Forensic anthropology laboratories must weigh numerous factors when determining which analytical test methods to include in their SOPs. What is generally accepted as a valid method (*sensu Frye*) by the expert community influences the decision. Further, appropriate weight must be given to adherence to the principles set forth by the *Daubert*, and later, the *Kumo* rulings, which inform the forensic science community on what is admissible to the courts as expert witness testimony and within forensic reports. These rulings stipulate the need for an assessment of a method's relevance, reliability, and, in the case of *Daubert,* the "scientific knowledge" base from which it is developed. Legal requirements, as well as the sentiments developed out of these rulings, certainly have influenced how accrediting bodies recommend best practice and the perceived requirements for minimum standards of a test method. However, the expert community must still vet new and old methods alike to ensure they adhere to these guiding principles. Perhaps more importantly, these methods must also evolve alongside our understanding of the "scientific knowledge" base from which the tests derive *and* the policy-oriented realm in which they will be presented.

Under ISO 17025, the standard used by a testing laboratory to select an analytical method must include considerations of such issues as the needs of the customer, and whether the test is "appropriate." Preferred methods are those published in international, regional, or national standards. Since there are no national (or otherwise) standards in place for forensic anthropological tests, we must move to other tier-utilizing tests published by technical organizations. Also, analytical methods published in relevant scientific texts or journals, or those based on manufacturer's specifications (e.g., scanning electron microscope analysis) serve as *de facto* standards.

Forensic anthropology as a field has certainly taken up the call to ensure the methods used in day-to-day casework meet a *Daubert* challenge. A plethora of validation studies and subsequent modifications to longstanding methods have been presented. Still, not all methods that are published in scientific journals are created equal, and just because a method is published does not make it reliable, valid, or appropriate for the problem at hand. Thus, an additional source for methods which may be selected for inclusion in an SOP is laboratory-developed or adopted methods. This source is acceptable provided the method is appropriate and validated. The validation need only be as extensive as necessary to confirm the procedure fits its intended use; which is a point that could lead to rigorous debate. Confirmation comes from determining the performance characteristics of the intended method.

The Hefner OSSA method was initially developed as part of a doctoral dissertation born from the statistical quantification of the long-used morphoscopic gestalt. The method was then qualified as a laboratory-developed method. As such, it was subject to a planned validation study prior to being accepted into an SOP. Validation could have taken several forms, as will be discussed; however, ultimately the method was tested on an independent sample of American White (n=79) and American Black (n=49) individuals from the William M. Bass Donated Skeletal Collection. After applying the OSSA method, which requires scoring six cranial nonmetric traits according to published protocols, a systematic assessment of the uncertainty involved in the test results was undertaken. Based on the validation study results,

performance indicators point to the efficacy of the Hefner OSSA method (sensitivity=87.76%, specificity=89.87%, correct classification rate=89.06%, error rate=10.94%, positive predictive value=84.31%, and negative predictive value=92.26%; in this example, the positive predictive value (true positive/(true positive + false positive)) is the probability the individual is "Black" when OSSA indicates "Black"). The validation of OSSA is ideal to illuminate a discussion of the principle, spirit, and intent of method validation and selection.

Method Validation, Accreditation, Ancestry Determination

H24 Resolution of Cold Cases: A Multidisciplinary Approach to Identifying Remains Previously Interred as Unknown

Debra P. Zinni, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will gain strategies for using a multidisciplinary approach to resolve cold cases.

This presentation will impact the forensic science community by providing knowledge and methods for employing a multidisciplinary approach to resolve cold cases, particularly when DNA analysis is not available.

The Joint POW/MIA Accounting Command Central Identification Laboratory (JPAC-CIL) is charged with conducting global search, recovery, and laboratory operations to identify unaccounted-for Americans from past conflicts in order to support the Department of Defense's personnel accounting efforts. During the 1950s, the remains of deceased service members from the Korean War were processed through the Central Identification Unit (CIU), Kokura, Japan, in order to establish identity; however, 867 sets of remains were determined to be unidentifiable and were buried as "Unknown" with full military honors at the National Memorial Cemetery of the Pacific (NMCP) in Hawaii. In preparation for interment, the remains were subjected to postmortem chemical processing that, in turn, has affected DNA recovery. As part of the JPAC mission, CIL historians and analysts review case files (originally generated by the CIU) for each set of remains interred as "Unknown" to determine cases where new technology or information produces a high likelihood of identification. The CIL has yielded a high success rate in identifying unknown remains from the Korean War, despite problems with DNA analysis. This is accomplished by employing a multidisciplinary approach, utilizing military historians, anthropologists, and odontologists during the research and analytical phases. Analysts associate individuals with unknown remains through a combination of extensive archival research into loss locations and dates, recovery locations and dates, POW movements, and review and re-analysis of the anthropological and odontological information present in the files. Following exhumation of the remains, laboratory scientists conduct anthropological and odontological analyses. Since DNA analysis cannot currently be utilized for these cases, the CIL relies on comparison of the circumstantial information, biological profile, dental information, chest radiographs, and photographic superimposition to support a positive identification for these remains.

To date, 34 unknown graves from the Korean War have been exhumed from the NMCP and re-analyzed at the CIL by analysts "blind" to information on these cases. These analyses have resulted in the sorting of 37 individuals, of which 24 have been positively identified. Post-identification, the biological profile generated by the staff at the CIU in the 1950s, was compared to the biological profile produced by the CIL anthropologists (current analysis) in order to refine the methodology of associating individuals with unknown remains. In addition, both biological profiles were compared to the actual biological profile of the identified individual. From these analyses, several trends have appeared in the data: the CIU age ranges only captured the actual age of the individual 50% of the time. In regard to the ages that were not captured, 75% were overestimated in age. The CIL age ranges, in comparison, captured the actual age 96% of the time. The CIL age ranges were, on average, wider than the CIU age ranges, which may account for some of the error. Stature estimates produced at the CIU yielded a 26% accuracy, with an almost even distribution of cases being overestimated (47%) and underestimated (53%) in stature; whereas the CIL prediction interval for stature captured the actual stature in 96% of the cases. The low percentage generated by the CIU stems from narrow prediction intervals, which in some cases were point estimates. Race was correctly assessed in 87.5% of the CIU case notes and in 100% of the CIL forensic anthropology reports.

The data collected from the cases of unknown individuals who are now identified aids in the refinement of analyses, archival research program, and efforts of associating unaccounted-for individuals with remains that are buried as unknown. Continued development of background research and advances in forensic science increase the ability to identify remains previously interred as unknown.

Cold Case, Identification, JPAC-CIL

H25 Results Based Management and Forensic Anthropology: The Ontario Experience—Part 1: Human vs. Non-Human

Kathy L. Gruspier, PhD, JD, Ontario Forensic Pathology, Service, 26 Grenville Street, Toronto, ON M7A 2G9, CANADA*

After attending this presentation, attendees will understand how to apply Results Based Management (RBM) models to their own areas of practice, and how to assess the impact of a new input (in this case specifically, a full-time forensic anthropologist).

This presentation will impact the forensic science community and, specifically, jurisdictions utilizing forensic anthropology by providing assessment tools for their particular area of forensic science in order to demonstrate a measurable and positive impact of the use of the science in a language that governments understand (fiscal responsibility, accountability, stakeholder satisfaction, etc.)

Forensic anthropologists provide services to medicolegal death investigation systems. These systems are usually government-based, and are part of a broader legal system. Death investigations can also inform other government agencies, such as public policy and health departments/ministries among others. RBM strategies or approaches are those that focus on achieving outcomes and impact, rather than activities and input. RBM has been widely embraced by international development agencies as a way to assess the effectiveness of the billions of dollars of aid funneled through the United Nations. The end result of RBM is to improve the performance of an organization as well as its accountability. While all forensic anthropologists and the organizations which utilize their services or employ them understand why they are needed, the impact of the use of forensic anthropology is not often measured on a broader scale which may include such things as risk and economics.

This presentation introduces the first of a three-part analysis of the outcomes and impact of having a full-time forensic anthropologist in a government death investigation service. Here, the assessment of bones for their origin (human vs. non-human) over a two-year time period (July 2010 to July 2012) is presented. In Ontario, the forensic anthropologist works in a medical coroners' death investigation system, legislated by The Coroner's Act R.S.O. 1990. The Act outlines the duties of both coroners and forensic pathologists in the system. The responsibility of the coroners begins when they are informed about a body of a dead person in their jurisdiction. Although the remains of animals are not persons, historically, these have been assessed by coroners and/or pathologists. In the recent past, animal bones were also assessed by fee-for-service forensic anthropologists. It is known (anecdotally) but not documented that these remains are also assessed by police, academics, veterinarians, and local doctors. In July 2011, a salaried, full-time forensic anthropologist began working in Ontario.

In the period assessed, approximately 400 cases of non-human remains were reported on (ca. 200 per year). In the year following the hiring of a full-time forensic anthropologist, approximately half of these remains were assessed via digital images sent to the forensic

anthropologist from the scene where they were found (in a few cases, they had been moved to a police station). The other half were assessed either at a scene, a police station, or a forensic pathology unit by a coroner or forensic pathologist travelling to the scene to look at the bones. Utilizing the RBM model, the differences between the new approach (forensic anthropologist and digital images) and the historical approach were analyzed. The outcome effects were assessed by a number of factors including fiscal/economic (costs associated with paying fee for service coroners, police-person hours spent holding scenes or photographing remains, case management and reporting costs, etc.), stakeholder satisfaction, and risk, among others. A positive impact can already be demonstrated by the use of the forensic anthropologist and digital identifications at many levels; however, to date there is no widespread systemic change, and some reasons for this will be presented. RBM is a useful model which provides substantive data for other jurisdictions which may be considering the addition of a full-time specialist in a forensic field that may currently be serviced by fee-for-service specialists. Future analyses will look at the impact of full-time forensic anthropologists with other types of cases, including those that are not of recent forensic interest and those that are.

Forensic Anthropology, RBM, Impact

H26 The Pima County Office of the Medical Examiner Forensic Anthropology Postdoctoral Fellowship: An Advanced Training Model for Newly Emerging Forensic Anthropologists

Angela Soler, PhD, Pima County Medical Examiner's Office, 2825 E District St, Tucson, AZ 85714; and Bruce E. Anderson, PhD, 2825 E District St, Tucson, AZ 85714*

After attending this presentation, attendees will learn about the one-year forensic anthropology postdoctoral fellowship now being offered at the Pima County Office of the Medical Examiner (PCOME) in Tucson, Arizona.

This presentation will impact the forensic science community by providing an example of one of the two forensic anthropology fellowship training programs currently being administered by a Diplomate of the American Board of Forensic Anthropology (D-ABFA) and working within the medical examiner/coroner system in the United States.[1]

As a fast-paced medical examiner's office with an elevated number of unidentified human remains, the PCOME offers an exceptional training opportunity for forensic anthropology PhDs hoping to gain practical experience within the medical examiner system. With nearly 200 anthropology consults requested each year, the PCOME exposes the postdoctoral fellow to a substantial number of cases and a variety of anthropological case types. Moreover, desert conditions, the vast number of Southwest Hispanic undocumented migrants dying within PCOME jurisdiction, and the large number of unidentified human remains cases presents a rather unique caseload. Within an average year at the PCOME, skeletonized remains cases make up a considerable percentage of anthropological consults, and thus expose the postdoctoral fellow to one of the largest caseloads of skeletonized remains within the medicolegal system. In addition, a substantial diversity in anthropological consults are requested for non-human remains, as well as for fresh, decomposed, burned, and fragmentary human remains for local residents and undocumented migrants dying within PCOME's jurisdictions. Because the PCOME performs medicolegal investigations for 11 of the 15 counties in Arizona, diversity in geographical factors, such as climate and elevation, allows the postdoctoral fellow to appreciate differences between the Sonoran Desert and mountainous regions in estimating the postmortem interval. The PCOME also recognizes its role as a training institution because of the substantial casework and is in full agreement with the Scientific Working Group in Forensic Anthropology (SWGANTH) that this casework should be utilized to offer additional training to emerging forensic anthropologists.

At the PCOME, the forensic anthropology postdoctoral fellow functions as one of two fulltime forensic anthropologists and is responsible for a majority of the anthropological exams requested by one of the six forensic pathologists in the office. Anthropology cases at the PCOME cover a wide range of responsibilities and any consultation may include: scene recovery, determination of the biological profile and postmortem interval, dental examination, assessment of skeletal trauma, sampling of skeletal tissues for DNA analysis, and positive identification through comparative medical or dental radiography. The fellow is independently responsible for all processing and analysis of casework, authors his/her own case reports in accordance with SWGANTH and ABFA recommendations, and may be called to testify as an expert witness if any cases go to trial. The PCOME believes this level of autonomy is essential in rounding out the fellow's skill set. In addition to forensic examinations, anthropologists at PCOME are responsible for entering unidentified remains cases into the National Missing and Unidentified Persons System (NamUs); as well as comparing the biological profile and dental information of probable undocumented migrants with a list of missing persons reports compiled by foreign consulates and non-governmental organizations. Once an unidentified body is released, the anthropologists still maintain responsibility and continue to follow up on missing person's reports and NamUs comparisons. Aside from anthropological consultations, the postdoctoral fellow may also be involved in a number of other activities, including scientific research, presentations or training within the medicolegal or local university community, and the supervision and mentorship of both undergraduate and graduate student anthropology interns.

The PCOME forensic anthropology postdoctoral fellowship provides another potential model for an advanced training program that prepares the emerging forensic anthropologist for a promising future in the field. Through the fellowship, the postdoctoral fellow gains an immeasurable amount of forensic anthropological case experience and develops leadership skills and confidence in his/her ability to perform a wide range of anthropological consultations. Furthermore, the fellowship exposes the newly emerging scientist to the role of forensic anthropology within a large, high-functioning medical examiner's office and teaches how to directly cooperate with law enforcement, death investigators, and forensic pathologists. Most importantly, the PCOME postdoctoral fellowship allows the newly emerging scientist to work directly with a board-certified forensic anthropologist while attaining postdoctoral experience that will allow for further preparation for the job market and ABFA certification.

Forensic Anthropology, Postdoctoral Fellow, Medical Examiner

H27 The Contributions of Richard Jantz to the Development, Implementation, and Continuance of the Forensic Anthropology Data Bank

Kate Spradley, PhD, Texas State Univ, Dept of Anthropology, 601 University Dr, San Marcos, TX 78666; Joseph T. Hefner, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96583; and Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensic Sciences, Dept of Anthropology, 501 E 38th St, Erie, PA 16546*

After attending this presentation, attendees will have a better understanding of the historical development and current status of the Forensic Anthropology Data Bank (FDB).

This presentation will impact the forensic science community by detailing the significance of Richard Jantz's involvement in the implementation and continuation of the FDB.

The FDB was created in 1986 with a grant from the National Institute of Justice (NIJ). The concept of this NIJ-funded research initiative was sparked by the need to obtain modern skeletal reference collections: it was clear that the Terry and Hamann-Todd collections did not best represent variation in modern Americans.[1] In effect, Dr. Jantz recognized the issue of external validity that would be stressed decades later in the *Daubert* guidelines. Clyde Snow first commented on the need for modern skeletal reference data and suggested data bank curation as a solution.[2] In 1983, a committee appointed by then American Academy of Forensic Sciences (AAFS) Physical Anthropology Section President Michael Finnegan further developed the concept. The initial committee consisted of Clyde Snow, Larry Angel, Stanley Rhine, and Richard Jantz, with Douglas Ubelaker replacing Clyde Snow at a later date.[3] Ellis Kerley also played a critical role in the development of the FDB, providing external reviewer support.[4] While these historical aspects of the development of the FDB are well described in the literature and by the professionals that observed them directly or indirectly, Richard Jantz's impact on the implementation and continuation of the FDB is, to an extent, lesser known.

Originally designed to meet the need for archiving metric, non-metric, and demographic information from positively identified forensic anthropological cases that are returned to family, the FDB provided the first relational database of modern skeletal data made publicly available to further research in forensic anthropology. The FDB is unique as it is derived from modern forensic cases and provides up-to-date, timely reference data that meet the needs of the changing demographic structure of our society. The FDB was initially conceived as a tool for case submissions by practicing forensic anthropologists through standard data collection procedures, archiving this data to further the discipline. However, as pointed out by Jantz and Moore-Jansen, a perceived problem of the FDB was how much time forensic anthropologists can justifiably spend on data collection efforts, considering other job commitments, time spent processing the remains, and compiling information from the medical examiner, medical records, law enforcement, or family.[2]

To circumvent the time constraints faced by these practitioners, Jantz or his graduate students visited numerous collections, measuring and recording biological information on a large number of skeletons. To date, Richard Jantz is directly responsible for collecting over 70% of the data in the FDB. Dr. Jantz has also been instrumental in diversifying the FDB data. Through working with collaborators from outside institutions, a large number of otherwise under-represented groups, such as American Blacks, Hispanics, and Japanese, are now thoroughly represented, necessary for updating forensic anthropological methods and furthering relevant research. Funding for travel to various collections (following NIJ grant funding) has been supported through an FDB assistantship provided by the Department of Anthropology at the University of Tennessee and FORDISC sales. Numerous publications, theses, and dissertations have benefited from data obtained from the FDB. The majority of forensic reference samples in FORDISC come directly from the FDB. Without Dr. Jantz's dedication to keeping up-to-date samples in the FDB, there would not be the relevant resources needed to further methodological development within our discipline.

Although Richard Jantz has retired, he still continues work on upkeep and expansion of the FDB. The FDB will continue, and the types of data contained will also be expanded (including radiographs and CT scans). The value of the data bank concept was so well illustrated by Dr. Jantz's work and the *Daubert* ruling that it will continue to be an essential source on modern human variation. A detailed report of Dr. Jantz's specific contributions to the continuance of the FDB along with those that have supported his endeavors will be discussed.

H28 Introducing FOROST: An International Free-Access Visual Forensic Osteology and Osteopathology Metabase

William H. Gilbert, PhD, California State Univ, East Bay, 3095 Meiklejohn Hall, Hayward, CA ; Socorro Baez, MS, Univ of California, Berkeley, 3101 Valley Life Sciences Bldg, Berkeley, CA 94720; Raul Castillo, BS, Ciudad Universitaria, México, D.F. 04510, MEXICO; Carlos Serrano, PhD, Instituto de Investigaciones Antropológicas, Universidad Nacional Autónoma de México, Ciudad Universitaria, MEXICO; and Kate Spradley, PhD, Texas State Univ, Dept of Anthropology, 601 University Dr, San Marcos, TX 78666*

After attending this presentation, attendees will learn about a ***For***ensic ***Ost***eological (FOROST) (www.forost.org), image database of osseous trauma and pathologies.

This presentation will impact the forensic science community by presenting an educational tool that will assist forensic anthropologists with interpretations of trauma and pathologies.

DNA has revolutionized the way forensic scientists determine sex and identity, but detecting method, manner, and cause of death from bones remains a largely observational endeavor. Interpretation of bone modification and pathology is a visual and experiential skill, relying heavily on the background of the forensic osteologist. Each case is different, and more examples from which to draw comparisons mean better-equipped osteologists. Traditionally, such background is built first through books and "hands on" experience in a single collection, then gradually augmented through contact with multiple collections and cases. The FOROST initiative adds to this set of background material a large-scale comparative database of skeletal lesions that can be accessed from anywhere in the world.

The practice of electronically serving visual osteological information is nearly as old as the public Internet itself. Phil Walker and Ed Hagen developed the first professionally viable osteology web interface, a human dentition visualizer, at the University of California, Santa Barbara, in 1991 and 1992.[1] As digital cameras became viable in the late 1990s, the capacity for the Internet to open remote osteology collections to distant researchers was recognized, and a publication outlining the basic framework for a public visual osteology database was one of the outcomes of a 2001 collaboration between the Human Evolution Research Center, University of California, Berkeley (HERC-UCB) and Universidad Nacional Autonoma de México (UNAM).[2] HERC-UCB continued development of data systems for public databases of fossils and hominid casts.[3-7] Reinitiated collaboration between HERC-UCB, UNAM, and California State University, East Bay (CSUEB) in 2006 saw the application of the HERC-UCB-developed data architecture models to modern human collections housed in UNAM Faculty of Medicine. Each of the institutions (UCB & UNAM) house more than the one skeletal collection, and the idea for building a meta-database (metabase) to query multiple skeletal collections quickly emerged. The FOROST initiative is the realization of this idea, and a partnership quickly grew from the founding institutions to include 15 museums and universities from 6 countries. The FOROST metabase now serves multiple high-resolution images from 260 specimens with distinctive bony traumas and pathologies.

FOROST already has more images of skeletal trauma and pathology than any printed volume, in significantly higher resolution, and all images can be accessed freely. This has far-reaching implications, because along with making access to forensic osteology images easier

for professionals and students in the developed world, FOROST provides access to many that would otherwise have no connection to reference imagery. Many images of specimens on FOROST are of research quality and many are accompanied by known medical histories or the known mechanism of trauma. FOROST-linked specimens and their images thus have the potential to be utilized as the basis for illustration, description, or other published work. This means that specimens served on FOROST can be cited, and the partner institutions and individuals who curate, describe, and photograph the material served in the metabase retain citable credit and copyright for the information and images provided.

The FOROST initiative goal is to develop a globally accessible metabase serving records and images of forensic osteology specimens that can be used as a reference for forensics workers worldwide. This introduction will provide guidance in both use and individual or institutional participation in FOROST.

H29 Analysis of Experimental Wood Chipper Trauma on Bone

Kenneth Domenick, BS, 34 E 19th St, Front Royal, VA 22630-4133; and Angi M. Christensen, PhD, George Mason University, 4400 University Dr, Fairfax, VA 22030*

After attending this presentation, participants will understand the results of a study conducted to observe and analyze the skeletal trauma created by a home-model wood chipper.

This presentation will impact the forensic science community by providing information regarding trauma that may be suffered following dismemberment via wood chipper, thereby facilitating event reconstruction, victim identification, and conviction of perpetrators.

Since the highly publicized murder trial of Richard Crafts in 1989, there has been an explosion in pop culture media such as movies, television shows, and the internet postings involving body disposal using a wood chipper. It is repeatedly portrayed as a quick and effective method for disposing of a body and eliminating evidence while avoiding detection; however, in the scientific literature and research relating to human corpse dismemberment and mutilation, there are few studies focused on wood chipper trauma. This paper addresses these shortcomings through case reviews and a preliminary experimental study on wood chipper trauma to bone.

Five domestic pig (*Sus scrofa*) limbs were inserted into a light-capacity home model wood chipper, similar to models that are available for purchase at home improvement and hardware stores and most likely to be used in a criminal context. Following the insertion of each limb, the wood chipper receptacle was removed and the chipped materials were collected, weighed, photographed, and processed. After processing, chipped bone fragments of each limb were separated into five size categories using sieves with openings measuring 11.6mm, 5.85mm, 2.82mm, and 1.69mm respectively. Fragments from each category were weighed and examined for cut marks and other alterations.

Traumas observed had characteristics associated with sharp force trauma and blunt force trauma. Bone fragment sizes ranged from 45mm to less than 1mm. Only 13% of bone fragments by weight were collected in the largest sieve with 71% being collected in the second and third seized sieve. The chipping blade consistently cut the bone all the way through. A total of 239 bone fragments collected from the three larger sieves were observed to have at least one through-cut, and most had two such cuts, creating a roughly parallel-sided fragment. The average length between the two parallel cuts was 6.47mm. This characteristic is a product of the width and speed of the cutting blade as well as the speed and force with which the input chute or hopper brings the material in contact with the cutting blade. The consistent size and pattern of fragments produced are believed to be features that distinguish wood chipper trauma from other types of sharp force trauma.

The wood chipper used in this study produced square, V-shaped, and W-shaped alterations that were dissimilar to the cuts described above and most likely were not caused by the chipping blade. Possibly, these alterations were created when the bone came into contact with other metal components of the wood chipper, and may reflect components and defects specific to the wood chipper used. Other alterations observed included peeling, flaking, spurs, notches, and incomplete fractures. These and other non-cut alterations could potentially assist in associating fragments to a particular chipper model or perhaps to an individual chipper. Although not the primary focus of this study, several relevant soft tissue observations were also made. Of particular note was the fact that, while the bone material was consistently cut by the chipping blade, the skin remained largely intact.

This is a preliminary study, and additional tests such as using different models of chippers, different types of bones, different pre-chipping conditions (i.e., freezing or burning), and microscopic analysis of blade striations on the bone may be useful in further understanding wood chipper trauma patterns. Nonetheless, the study shows that wood chippers create a pattern of skeletal trauma that can be identified and associated to wood chippers in a forensic context. This pattern includes the production of bone fragments of a particular size, through-cuts resulting in roughly parallel-sided fragments, and other alterations that may be specific to the wood chipper used.

Skeletal Trauma, Sharp Force Trauma, Wood Chipper

H30 Patterns of Cranial Trauma in Korean War Remains at the Central Identification Laboratory (CIL)

Alexander F. Christensen, PhD, JPAC-CIL, 310 Worchester Ave, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will understand the variety of different peri-mortem cranial trauma observed in remains from the Korean War analyzed at the Joint POW/MIA Accounting Command-Central Identification Laboratory (JPAC-CIL).

This presentation will impact the forensic science community by describing peri-mortem cranial trauma that resulted from armed conflict and examining the correlation between different types of trauma and the circumstances of death.

The Central Identification Laboratory (CIL) and its predecessor organization, the Central Identification Laboratory-Hawaii, have identified a total of 209 Korean War casualties since 1982. In the

process, the CIL has generated a large corpus of Forensic Anthropology Reports on remains associated with the Korean War. In previous American Academy of Forensic Sciences (AAFS) presentations, the overall pattern of peri-mortem trauma in these remains was described and compared with wartime medical reports on trauma among United Nations casualties.[1,2] This presentation considers the cranial trauma observed in a sample of 56 individuals from both battlefield and Prisoner-Of-War (POW) recovery contexts. Peri-mortem fractures were recognized according to standard morphological and taphonomical criteria. When possible, ballistic trajectories were reconstructed from entrance and exit wounds. Blunt trauma was recognized by the lack of an entrance defect, as well as by plastic deformation. Unfortunately, the vagaries of taphonomy and recovery prevented an exact diagnosis of the form of trauma in every set of remains.

Eighteen of the 56 individuals exhibited non-specific peri-mortem fractures of the vault, face, or both; generally, the lack of a more specific interpretation is a result of incomplete preservation. One individual exhibited sharp-force trauma to the face. Six individuals, all from battlefield contexts, exhibited blunt trauma; one of these also exhibited ballistic trauma. Thirty-two individuals exhibited one or more ballistic defects or gunshot wounds. Of these 32, one was not well enough preserved to record directionality, while one was significantly fragmented by multiple projectiles and could not be reconstructed to determine their trajectories. Of the remaining 30, 14 exhibited a primary trajectory from an anterior origin, 12 from a posterior origin, and four laterally. Patterns of cranial trauma showed a clear correlation with postcranial trauma. The six individuals with cranial blunt trauma exhibited no postcranial trauma. Of the 14 individuals with anterior-origin ballistic trauma (one of whom also exhibited blunt trauma), only two exhibited postcranial fractures, and both were butterfly fractures of the distal right humerus that may have resulted from the individual's fall after being shot. Three of the four individuals with lateral ballistic entrances exhibited postcranial fractures to multiple elements which were consistent with either ballistic or blast trauma. Four of the 12 individuals with posterior ballistic entrances exhibited postcranial fractures consistent with either ballistic or blast trauma. Finally, of the 21 individuals that exhibited neither blunt nor directional ballistic trauma to the skull, 16 exhibited one or more postcranial fractures as well. It is possible that many of these individuals experienced blast trauma that fractured multiple elements with either no ballistic impacts or many small, irregular ones.

Previous studies have found the incidence of peri-mortem trauma in POWs to be significantly lower than in those killed in action. In this sample, only eight of the 56 individuals exhibiting cranial trauma were documented POWs. Two of these eight died soon after capture; one of the remaining five is known to have been killed by aerial strafing.

The views expressed herein are those of the author and not necessarily those of the Joint POW/MIA Accounting Command or the U.S. Department of Defense.

Peri-Mortem Trauma, Cranial Fractures, Military Medicine

H31 A Return to the Basic Principles of Biomechanics to Interpret Blunt Force Trauma in Long Bones

Steven A. Symes, PhD, Mercyhurst College, Mercyhurst Archaeological Institute, 501 E 38th, Erie, PA 16546; Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; Kyra E. Stull, MS, Univ of Pretoria, Dept of Anatomy, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; Ivana Wolff, MSc, Jose Federico Moreno 1213, Mendoza, ARGENTINA; and David Raymond, PhD, California State Univ, Los Angeles, Dept of Mechanical Engineering, 5151 State University Dr, Los Angeles, CA 90032*

After attending this presentation, attendees will gain knowledge on basic biomechanical theories necessary to interpret blunt force injury in long bones.

This presentation will impact the forensic science community in addressing two common problems associated with fracture interpretation of blunt force injuries in long bones. The recognition and examination of the failure mode of bone (compression/tension/shear) is often lacking in trauma analysis and is reflected in common errors made in the field. One misconception assumes the location and direction of bone failure is directly related to the point of impact. Another is that analyses often concentrate on a single broken bone as opposed to evaluating the complete trauma pattern on the body.

Five types of external loading conditions are commonly described with long bone fractures:—compression, tension, shear, bending, and torsion. These external loading conditions are typically associated with recognizable fracture patterns, namely transverse, oblique, oblique transverse, butterfly, and spiral fractures. Fenton et al., as a reaction to recent anthropology literature, examined the association between these external loading conditions and resulting fracture patterns and demonstrated that blunt fracture patterns, particularly butterfly fractures, can be used to determine the point of impact on experimentally broken bones.[1] They further suggested four common fracture patterns are recognized: incomplete butterfly fractures (tension wedges); transverse fractures (initiation); failure angle shifts of 45 degrees; and breakaway spurs. Fracture pattern "categories" linked to external loading conditions may lead an expert to a factual diagnosis regarding the point of impact, but the failure mode of the material (tension/compression/shear) is ignored and, as such, the forensic scientist may misinterpret the external loading conditions and/or the point-of-impact.

"Point-of-impact" is commonly used to describe and to interpret the wing of a butterfly fracture. Yet without soft tissue or a corresponding tool mark on bone, biomechanically, a butterfly fracture only indicates the direction of bending failure.[2] The area of failure in a bone shaft and the location and direction of impact are not one and the same concept. In any tubular bone, the failure mode only provides information as to the direction in which the bone bends (directionality) and to an anatomical weak point of the shaft. Furthermore, the failure modes involved in bending bone (tension, shear, and compression) are not mutually exclusive; thus, any failure mode can be used to establish bending direction and failure in long bones.[2] Therefore, a long bone fracture is attributed to the biomechanics of fracture production and not to a reconstructed fracture pattern or to a known impact site.[3] Despite the findings of three-point impacts in the laboratory, real-world scenarios such as automotive collisions, falls from heights, or beatings may result in long bone fractures via a variety of external loading conditions. Thus, a total body trauma pattern must be considered when examining and interpreting any fracture.

Complicated fracture patterns may be unraveled when a proper stress analysis of bone is conducted to determine stress/strain distributions as well as external loading and boundary conditions; all fractured surfaces are macro- and microscopically examined; and a complete analysis of body trauma is performed. For an accurate diagnosis, these steps need to supersede specific fracture interpretations. In this presentation, three cases of blunt traumatic injury to bone will be illustrated. While the reconstructed bone failure patterns are clear in each case, closer examination of biomechanics, along with

knowledge of the overall trauma pattern, reveals clues as to the mechanism of failure. With the use of these cases, the above-mentioned pitfalls of trauma analysis within tubular bone are addressed and clarified.

Forensic anthropologists and pathologists are encouraged to closely examine bone failure at the materials level; to observe stress risers and resistors involved in a bone injury; to consult biomechanical engineers to evaluate loading conditions and internal stress distribution in long bones; to correlate fracture morphology and failure mode evidence in the fracture pattern; and to avoid over-reaching assumptions and predictions regarding impact sites. The proposed approach is designed to reduce error in our contributions to cause and manner of death and to avoid the negative repercussions associated with an inaccurate trauma analysis.

Bone Trauma, Failure Mode, Point-of-Impact

H32 Skeletal Dismemberment Analysis Utilizing Surface Metrology

Sean Y. Greer, BA, 1414 Westminster St, St. Paul, MN 55130*

The goal of this presentation is to explain the potential applications of 3D computer modeling and surface metrology to saw-related dismemberment of skeletal remains. Specifically, the correlation of the surface variables Pv and Pp to saw tooth deviation will be demonstrated.

This presentation will impact the forensic science community by showing how it will increase the range of saw characteristics that can be gleaned from their resulting kerfs, and allow for more accurate and confident identifications of the tools used in a dismemberment.

Saw kerf examination is a vital part of any investigation of dismemberment as it provides many clues to the characteristics of the saw that was used. The accuracy and confidence of the methods used in this examination are vital, as they must now hold up to *Daubert* standards of scientific evidence in court. Symes was the first to create real standards for saw kerf analysis, and established many of the still-used characteristics of saw kerfs in bone that can be tied to their acting implement.[1]

Over the last two decades, other researchers including Bailey, Freas, and Saville have attempted to reduce the characteristics of saws that create changes in kerfs on bone to their most fundamental elements. These studies have confirmed the ability to tie kerf features to saw types within levels of statistical confidence. This research, however, has focused largely on increasing magnification of kerf walls, or ignoring the kerf wall all together, and examining so-called false starts or incomplete kerfs.[2-4] Very little research has been done on the potential discriminatory uses of peaks and valleys of the kerf wall itself.

The present study examined experimentally created kerf walls on twenty-five pig femora. Each kerf was created by one of a group of hacksaw blades meant to represent the variability seen in this type of sawing implement. Stereo images were taken of each of the kerf walls using a Leica MZ16 and combined to create a 3D computer model. These models were then examined using the programs StereoExplorer and SFRAX 1.0 where thirty different variables were collected that describe changes in the kerf wall surface.[5-6] These measures were then compared to quantifiable features on the saws for any correlations.

Of the measured saw characteristics, saw set was prioritized because of its presumed affect on the kerf wall striations. A strong correlation (R^2>0.70) was found between the amount of saw set deviation and the depth of the kerf wall striations. Previously, the saw set was inferred solely from the kerf width. The presented method provides a new avenue to evaluate this feature of the saw. This measurement is sensitive to variation between the right and left sides of the saw; therefore, it can be used to identify individual characteristics of the saw resulting from manufacturing deviations. This study shows the potential application of 3D computer modeling for saw kerf analysis as a method not only for gathering more quantifiable information from kerfs, but also for changing the traditional ways in which kerfs are viewed and analyzed.

Dismemberment, Surface Metrology, Kerf

H33 The Difficult Task of Assessing Peri-Mortem and Postmortem Fractures on the Skeleton: A Blind Test on 210 Fractures of Known Origin

Alberto Amadasi, MD, Viale Certosa 1, Milano, ITALY; Annalisa Cappella, BSc, Via Mangiagalli 37, Milano, ITALY; Debora Mazzarelli, BSc, LABANOF - Sezione di Medicina Legale, Dipartimento di Scienze Biomediche per la Salute, Via Mangiagalli 37, Milan, 20133, ITALY; and Daniel Gaudio, BSc, Elisa Castoldi, BSc, and Cristina Cattaneo, PhD, Via Mangiagalli 37, Milan, ITALY*

The goal of this presentation is to highlight the difficulties and pitfalls a forensic anthropologist has to face when diagnosing bone fractures as peri-mortem and postmortem.

This presentation will impact the forensic science community by showing how morphological and macroscopic evaluation on bone fractures has to be handled with care since the evaluation of a bone fracture as being peri or postmortem may be difficult, treacherous, and, at times, observer-dependent and thus influenced by knowledge, intuition, and training of the observer. If postmortem fractures can be detected more easily, on the other hand, peri-mortem fractures can be wrongly identified, especially when spongy bone is involved and when time has taken its toll on the remains.

In the field of forensic anthropology, differentiating between peri-mortem and postmortem fractures is one of the most difficult challenges. Indicators of peri-mortem injury have been identified (i.e., "green" characteristics of the fracture or fracture margin color), but most forensic anthropologists realize that determining between peri-mortem and postmortem fractures may be impossible. Few studies have focused on the error rate associated with classifying a fracture as peri- or postmortem. How many times will a postmortem or taphonomic fracture be mistaken for a peri-mortem fracture and vice versa? Which bones present the most difficulty?

The study goal was to evaluate the error rate associated with differentiation between peri-mortem and postmortem fractures. The study method was a blind test of two anthropologists with seven and three years of experience, respectively. Each anthropologist independently examined 210 fractures of known origin and classified the fracture as peri-mortem or postmortem.

Four skeletons were selected from a skeletal collection of 250 individuals who died in 1991 and whose skeletons were exhumed in 2001. These decedents were unclaimed and thus available for scientific research according to Italian Mortuary Police Regulations. Of these four skeletons, one had died of natural causes and three were pedestrians struck by motor vehicles: tram, car, and truck. All three motor vehicle accident victims had numerous blunt force, soft tissue, and skeletal injuries, that were documented during the autopsy.

For all cases, the number and sites of bone fractures documented during the 1991 autopsy were recorded as well as fractures observed on the exhumed remains. Fractures identified during the autopsy were designated as peri-mortem fractures. Fractures observed on the exhumed remains, but not documented during the autopsy were classified as postmortem fractures. The total number of fractures was 210. The two observers blindly scored all 210 fractures on the four skeletons as peri-mortem, postmortem, or uncertain. The results were analyzed by comparing the expected classifications with the observed classifications.

The results showed the observers were more accurate when classifying a postmortem fracture (75% accurate) compared to peri-mortem fractures (~45% accurate). Also, scoring postmortem fractures was easier than peri-mortem fractures; 16.5% of peri-mortem fractures and 7% of postmortem fractures were identified as uncertain. Bones with little cortical bone such as ribs and innominates were more difficult to score than long bones and skull bones.

Globally, this study illustrates the difficulty of differentiating peri-mortem from postmortem fractures in buried human remains. The correct identification of peri- and postmortem fractures is crucial to reconstructing the circumstances surrounding death, but macroscopic and morphological criteria are limited, and sometimes misleading. The study results serve as a cautionary note concerning interpretation of peri- and postmortem fractures as well as an invitation to search for novel methods of analysis (i.e., histology, immunochemistry, electronic microscopy) for differentiating peri- and postmortem fractures.

Blunt Force Trauma, Peri-Mortem, Postmortem

H34 Retrospective Study of Skull Fractures Observed Following Terminal Falls

Jennifer C. Love, PhD, Sharon M. Derrick, PhD, and Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Deborrah C. Pinto, PhD, 208 Hollyberry Trail, Toronto, ON M2H 2P4, CANADA*

The goals of this presentation are to review the current literature of skull fracture biomechanics and to evaluate the variation in skull fracture patterns observed in the medical examiner population.

This presentation will impact the forensic science community by increasing the general knowledge of skull fracture types associated with terminal falls.

Skull fractures are common in the medical examiner population. At times, the circumstances surrounding the death are unknown and skull fracture pattern interpretation plays a significant role in the manner of death classification. When faced with a complex skull fracture pattern, pathologists often look to forensic anthropologists for guidance in fracture pattern interpretation.

Recent research has focused on blunt force trauma to the head and associated fractures. For example, Hamel et al. developed a multibody study using finite elemental modeling to identify the parameters that influence the mechanism of skull fractures.[1] They concluded that two fall parameters, impact velocity and impact surface, and two biological parameters, cortical thickness and cortical rigidity, had the greatest influence on the mechanism of skull fractures. Additionally, Kremer and Sauvageau evaluated the relationship between three criteria Hat Brim Line (HBL) rule, side lateralization, and number of scalp lacerations) and the mechanism of injury.[2] Also, they evaluated the predictability of the mechanism of injury by combining the criteria. The authors conducted a six-year retrospective study of autopsy cases with skull fractures. They found that fractures resulting from falls tended to be within or below the HBL, on the right side, and have three or less scalp lacerations. Fractures resulting from homicidal blows tended to be above the HBL, on the left side, and have more than three scalp lacerations. When combining two criteria in favor of a fall, the predictive value of the mechanism was 65.9%. When combining two criteria in favor of a homicidal blow, the predictive value was 100%. The predictive value increased to 83.3% when three criteria in favor of a fall were combined.

Although the research has furthered the understanding of skull fracture dynamics, one feature of a skull fracture is being overlooked: fracture type. In children, fracture type has been used to differentiate between accidental and inflicted trauma.[3] Similar research investigating the correlation between fracture type and cause of injury needs to be performed in adults. As a result, the Harris County Institute of Forensic Sciences conducted a retrospective pilot study of skull fracture types observed in accidental deaths. The study included five years of records.

During the study period, 192 deaths were classified as accidental with fracture listed in the cause of death. Of these, 57 cases were autopsied and 46 cases had skull fractures documented during the autopsy. Thirty cases had skull fractures that resulted from terminal falls at or near a standing height. Reviewing autopsy photographs of these cases, the fracture types were coded as linear in 23 cases and as stellate or comminuted in seven cases. In comparison, 12 cases involved a fall from a significant height, such as a fall from a roof; again using autopsy photographs, ten of these fractures were coded as comminuted and two as linear. The occurrence of skull fracture types for the two groups, standing height falls and significant height falls, was shown to be significantly different using a Mann-Whitney test (p=.000). Although the sample size was small, the results indicate that fracture type may be an important variable in differentiating terminal falls from a standing height and other mechanisms of injury.

Skull Fractures, Fall, Fracture Types

H35 Craniometric Sex Determination in the Modern Thai Population

Laurel E. Freas, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853; Pasuk Mahakkanukrauh, MD, Chiang Mai Univ, Dept of Anatomy, Faculty of Medicine, Chiang Mai, 50200, THAILAND; Karnda Vichairat, MD, Chiang Mai Univ, Dept of Forensic Medicine, Faculty of Medicine, Chiang Mai, 50200, THAILAND; and Apichat Sinthubua, MS, Chiang Mai Univ, Dept of Anatomy, Faculty of Medicine, Chiang Mai, 50200, THAILAND*

The goal of this presentation is to introduce population-specific discriminant functions for sex determination in the modern Thai population and provide an understanding of patterns of sexual dimorphism within this population.

This presentation will impact the forensic science community by filling a gap in currently existing normative craniometric databases, and providing novel, statistically robust, population-specific discriminant functions for sex determination when analyzing unidentified individuals known or believed to be of Southeast Asian, specifically Thai, ancestry.

Metric approaches to the analysis of human variation are among the oldest scientific traditions in the field of physical anthropology.

Despite an ignoble intellectual adolescence, which saw craniometrics applied tacitly and overtly in support of racist sociopolitical and pseudoscientific agendas, these methods have matured into a robust and respected part of modern physical anthropology's analytical engine. Craniometric studies now find application throughout the whole of the discipline. Forensic anthropology is no exception, as craniometric analyses are essential tools for the determination of sex and ancestry in unidentified human skeletal remains. Yet the validity of such analyses depends upon having population-specific reference datasets of sufficient robusticity to adequately characterize the true range of morphological variation within a given population. This is especially true of craniometric discriminant function analyses (the preferred metric method for sex and ancestry determination), in which both the classification of an unknown individual and that classification's statistical certainty (in terms of posterior and typicality probabilities) is driven entirely by patterns of variation within and among the reference populations used to generate the discriminant functions. Reliable sex determination standards that are appropriate for the population(s) under consideration are of particular importance to forensic anthropology, as the determination of all other parameters of the biological profile is predicated on an accurate assessment of an unknown individual's sex. Similarly, reliable standards for ancestry determination are critical to identification efforts, as ancestry is arguably the second-most dominant criterion, after biological sex, by which individuals are classified and identified.

The 2004 Indian Ocean tsunami, which killed nearly 250,000 people in South and Southeast Asia, including approximately 8,200 in Thailand, is but one of a series of natural disasters and human rights violations that have laid bare the need for regionally-based, population-specific forensic anthropology standards and normative datasets. With regards to Southeast Asia, several studies have demonstrated significant patterns of craniometric variation among local populations within the region; however, to date, only a few scientific articles addressing the need for Thai-specific forensic standards have been published in the international forensic literature. Importantly, these studies clearly demonstrate that the available American standards are inaccurate when applied to Thai populations and, in such applications, lead to systematic misclassifications of Thai males as females, due to the relative gracility of the Thai population as compared to American populations. Nevertheless, these studies are an insufficient remedy to the lack of appropriate population-specific standards for the Thai, as they primarily address sex determination from postcranial skeletal elements, which are commonly regarded as less informative and reliable than the more robust craniometric analyses (but cf. Spradley and Jantz 2011).[1]

To address these issues, 20 standard cranial measurements were collected on a large sample (n=385; 262 males/123 females) of modern Thai skeletons from three medical school anatomical collections (Chiang Mai, Khon Kaen, and Naresuan Universities). These craniometric data were used to generate two separate linear discriminant function equations for sex determination: (1) using the full set of 20 craniometric variables; and, (2) using eight forward stepwise-selected variables to generate a function potentially applicable to incomplete crania. In both analyses, the discriminant functions were found to be most strongly driven by the larger, more generalized dimensions of the cranial vault and facial skeleton that contribute significantly to the overall size differences between males and females. This mirrors the patterns of variable selection observed in other craniometric studies, and indicates the broad pattern of craniometric sexual dimorphism within the Thai population does not differ significantly from other ancestry groups. Additionally, these functions have cross-validated correct classification rates of 82.6% and 82.9%, respectively. These results are similar to the performance of other population-specific sex determination standards, indicating the validity and broad utility of these functions to forensic anthropology, both in Thailand and the United States.

Craniometrics, Sex Determination, Southeast Asia

H36 Forensic Significance Beyond Taphonomic Characteristics: Using Archaeological Context, Craniometrics, and Radiocarbon Dating

Christopher W. Rainwater, MS, OCME, 520 1st Ave, New York, NY 10016; Scott C. Warnasch, MA, 520 First Ave, New York, NY 10016; and Gregory W. Hodgins, PhD, The Univ of Arizona, Dept of Physics, 1118 E Fourth St, Tucson, AZ 85721*

The goal of this presentation is to demonstrate archaeological, craniometric, and radiocarbon approaches to assessing forensic significance to supplement the standard taphonomic interpretation.

The presentation will impact the forensic science community by addressing the often difficult task of assessing the forensic significance of skeletal remains and by providing alternative approaches beyond simply interpreting taphonomic characteristics.

In the absence of primary contextual information, the assessment of forensic significance of remains found in a medicolegal context becomes difficult and often focuses on the taphonomic characteristics observed on the remains. This presentation follows a case study of remains removed from their primary context prior to medicolegal involvement and shows alternative approaches to assessing forensic significance that may be used to supplement the standard taphonomic interpretation.

In the summer of 2011, skeletal remains were discovered in the Greenpoint section of Brooklyn, New York. The remains consisted of a partial cranium, partial mandible, and two cervical vertebrae, which were discovered during outdoor construction in a residential backyard. The remains were removed by the property owner prior to the investigation; however, the general area remained undisturbed. The property owner was not able to provide additional details at the time of the investigation and the temporal provenience of the remains could not be assessed. In order to assess the forensic significance of the remains, the archaeological context of the immediate vicinity was documented and interpreted, craniometric data were assessed with respect to secular variation, and isotopic values were examined with respect to bomb-derived radiocarbon.

Archaeological excavation of the scene provided data used to reconstruct the context and determined that the remains, and associated artifacts, likely came from a secondary deposit within a shallow man-made depression. The associated diagnostic artifacts included: glass bottle fragments, a ceramic pipe stem fragment, a ceramic button, and a machine-cut copper nail. Although the pipe stem may date to the 18th or 19th-century, most of the artifacts were in use during the early 20th-century. The absence of modern debris within the discreet deposit suggests that the deposit was likely created more than 50 years ago.

Previous research has noted a secular trend toward higher, longer vaults and narrower vaults and faces in American crania and that cranial variables exhibit a high correlation with the birth year of the individual.[1,2] Accordingly, an analysis of the craniometric variables may assist in addressing the temporal origin of unknown skeletal remains. In this case, discriminant function analyses were performed using FORDISC 3.1 on the available measurements of the cranial vault using "19th-century" groups from the Terry and Todd Collections and "modern" groups from the Forensic Databank.[3] When tested against modern groups, the skull did not classify as being a typical member of any of the groups. When tested against White and Black groups of both sexes from the 19th-century and modern groups, the skull grouped most closely with Black females from the 19th-century.

Samples from the right parietal and left lower canine were extracted for radiocarbon analysis. Results indicated that the remains did not contain bomb-derived radiocarbon clearly indicating the individual lived and died before 1955. More precise radiocarbon dating in the five centuries before 1950 is hindered by natural fluctuations in environmental radiocarbon levels, but this case presented the possibility for refinement. The radiocarbon level in tooth dentin was found to be statistically different from that in enamel. Tooth dentin remodels throughout life but tooth enamel does not, so differences in radiocarbon

levels can appear as a person ages. Here, the osteological age estimate of the individual was coupled with the enamel and dentin measurements in order to derive an environmental radiocarbon level rate-of-change. The derived rate-of-change was then matched to the known environmental rates-of-change over the past five centuries and, thus, the remains were tentatively assigned to a more specific time frame than would otherwise be possible. In this case, two solutions were found; either the 17th-century or early 19th-century.

Significance, Taphonomy, Radiocarbon Dating

H37 Assessment of Presentation Methods for ReFace Computerized Facial Approximations

Adam H. Richard, MA, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135; Connie L. Parks, MA, 830 Belmont Bay Dr, #204, Woodbridge, VA 22191; and Keith L. Monson, PhD, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will understand that the way in which a facial approximation is presented to the public impacts the probability of achieving a successful identification of the unknown individual with certain presentation methods having a greater likelihood of eliciting identification success. Attendees will also be made aware of the possibility that traditional methods of evaluating facial approximation success may not be the most appropriate when considering the practical applications of these approximations.

This presentation will impact the forensic science community by recommending new methods of presenting facial approximations to the public in order to improve recognition potential. It will also provide new criteria for evaluating the performance of facial approximations in a way that is more representative of their practical application.

New computerized techniques have made it possible to present facial approximations in a variety of layouts, but there are currently no clear indicators as to what style of presentation is most effective at eliciting recognition. The primary purpose of this study is to determine which of the tested presentation methods produces the most favorable recognition results. A secondary goal of the research is to evaluate a new method for testing the accuracy of facial approximations. Previous studies have evaluated facial approximation effectiveness using standards similar to studies of eyewitness positive identification in which a single, definitive choice must be made by the research participant. These criteria seem inappropriate given the accepted understanding that facial approximations cannot produce positive identifications but are merely an investigative tool leading to positive identification.

Facial approximations were generated using CT scan data from living volunteers instead of scans from skulls of actual missing persons. Approximations were presented in one of five formats: Basic, Front and Profile, Weight Variation, Estimated Average Age, and Estimated Age Range. Participants were asked to compare one approximation at a time to one front and one profile photograph of the "missing person." If the participant felt the approximation looked enough like the missing person that they would contact authorities, the approximation would be placed in a folder marked "Yes." If they did not feel there was enough similarity to warrant contacting police, the approximation would be placed in a "No" folder. Once all ten approximations had been evaluated, the participant was asked to simultaneously compare all approximations in the "Yes" folder with each other and the missing person photos to determine which approximation looked most like the missing person.

Effectiveness of presentation methods was determined using three values: sensitivity (percent of true positive responses out of the total possible true positives), specificity (percent of true negative responses out of the total possible true negatives), and percent above chance for correct final selection (the criterion used by most other facial approximation studies). Functionally, a successful facial approximation is one that generates a short list of possible candidates, including the missing person in question. For this reason, and the fact that false positives can be ruled out with further investigation, sensitivity was chosen as the primary benchmark for success.

Weight Variation achieved the highest sensitivity, but this value was not significantly different from Front and Profile or Estimated Age Range. Interestingly, the two methods with the poorest performance each consisted of only a single picture, leading to the possibility that presenting more than one image of an approximation may improve recognition potential. When all criteria were considered, Front and Profile produced the best results. This is particularly encouraging because this presentation method can easily be achieved with traditional clay approximations as well. Also, it was found that percentage above chance for final selection failed to reflect the successfulness of particular presentation methods, and generally under-represented the successfulness of all methods, in terms of sensitivity. These results suggest that single-selection studies may not be the best method for determining the effectiveness of facial approximations.

Facial Approximation, ReFace, Method Performance

H38 Craniofacial Regional Variation in the United States: A Geometric Morphometric Study

Kenda Honeycutt, MA, 3532 Ivy Commons Dr, Apt 101, Raleigh, NC 27606; Amanda R. Hale, MA, 1326 Courtland Dr, Raleigh, NC 27604; and Ann H. Ross, PhD, North Carolina State Univ, Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107*

After attending this presentation, attendees will understand how environmental adaptation has impacted cranial variation in the United States within the last hundred years.

This presentation will impact the forensic science community by providing insight into craniometric variation as it applies to issues of cranial plasticity, migration, and genetic affinity. In addition, through the use of modern quantitative methods, this study will present a broader understanding of genetic versus environmental influences on cranial variation.

The main purpose of this study is to explore the effect of different environments within the United States on cranial variation. Two modern human samples were used in this analysis: 36 individuals from the donated New Mexico Unidentified and 31 individuals from the C.A. Pound Human Identification Laboratory (CAPHIL) at the University of Florida. The CAPHIL individuals represent populations residing along the eastern coast of the United States, while the New Mexico Unidentified represents populations in the west coast. Only European-American individuals were used in this analysis to establish a genetic baseline for cranial variation. Three-dimensional coordinate data for 21 landmarks were collected for individuals from these collections and a software program was used to run all multivariate statistical analyses. In order to reach a consensus least-square fit and acquire new shape coordinates for the entire dataset, Procrustes' superimposition was used to translate, scale, and rotate the landmark data. Principal Components Analysis (PCA) was performed to explore patterns of variation among the data in muliti-dimensional space, allowing the variables to be reduced to a few dimensions that represent the majority of cranial variation. The PCA identified seven principal components that represent 81% of the total variation. Typically, in closely related samples, the number of principal components representing total variation would be reduced; however, the larger number of principal components for this analysis is expected if environment can affect cranial shape.

To identify the landmarks responsible for the variation, Canonical Variate Analysis (CVA) was employed. The CVA produced two significant canonical variates with the first representing 91% of the

variation, which included landmarks in the posterior and base portions of the crania (e.g., opisthion and asterion). In addition, Multivariate Analysis of Variance (MANOVA) was used to measure the statistical significance of the variance between groups. The MANOVA found significant variation in both centroid size (p-value=*0.049)* and shape (p-value=*0.001*) for the three groups. This suggests significant regional variation. Discriminant function analysis was also performed to discern the approximate level of separation by measuring the degree to which individuals could be correctly allocated to their location. A correct classification rate of 74% was found from the cross-validation and suggests these individuals are easily classified due to variation in cranial shape. Lastly, Mahalanobis D^2 was calculated to measure the distance between populations. The Mahalanobis D^2 was found to be 1.969 between the east and west coast groups. The two east coast groups were found to have a distance of 0.826. The distances found suggest a larger degree of East-West separation in European-Americans.

The differences seen in this study may affect ancestry assessment in different parts of the country and warrant further study. However, most of the variation was observed in the cranial vault and base suggesting facial landmarks are less easily influenced by the environment.

This project was supported in part by a National Institute of Justice grant (2005-MU-BX-K078).

Geometric Morphometric, Ancestry, Regional Variation

H39 Sexual Dimorphism in Complete and Fragmentary Navicular Bones

Amber Schmuhl, BS, Middle Tennessee State Univ, 1301 E Main St, Murfreesboro, TN 37132; and Hugh E. Berryman, PhD, Middle Tennessee State Univ, Dept Sociology & Anthropology, Box 89, Murfreesboro, TN 37132*

After attending this presentation, attendees will understand how to use the navicular bone to aid in the estimation of sex in unknown individuals.

This presentation will impact the forensic science community by showing new measurements that will aid in the identification of sex in fragmented remains.

Accurate sex estimation is an essential step in the identification of unknown skeletal remains. Expanding sexing methods to include previously unused or underused bones adds to the battery of available techniques and can increase the accuracy of such assessments. Such novel techniques may also be invaluable when sexing incomplete remains. In 1976, Steele was one of the first researchers to examine sexual dimorphism of the talus and calcaneus, and since then other researchers have repeated the work and confirmed that the talus and calcaneus are useful in determining sex with accuracies as high as 96%.[1-10]

These researchers have not only shown that the accuracy rates of the talus and calcaneus are repeatable, but also that the techniques can be applied to different populations from the past and the present. Other than the talus and calcaneus, little research has been done on the remaining five tarsals. In 2009, Sheena Harris, using The William M. Bass Skeletal Collection and a mini-osteometric board, measured the maximum length and width of all seven tarsal bones.[11] However, her measurements required the bones to be complete and she did not look at the smaller dimensions on the bones. In 2011, it was demonstrated that the three cuneiforms, whether complete or fragmented, are useful for sex determination.[12] This finding has shown there is a need for investigating the other tarsal bones for this purpose.

The current study examines the navicular bone from 100 adult individuals (50 male and 50 female), both Blacks and Whites, from the William M. Bass Skeletal Collection for their possible use in sex determination. This study first examined the "maximum" measurements following Harris from complete navicular bones and then created additional original measurements (such as measurements involving specific articular surfaces and tubercles) that divide the bone into smaller segments.[11] Digital sliding calipers were used to take 11 measurements (three following Harris and eight new measurements) of the left navicular bone.[11]

FORDISC 3.0 was used to perform Discriminant Function Analysis (DFA) in order to test multiple measurements for their efficiency in sex determination.[13] The results of this study (78.8% accuracy for the maximum height, 78.6% for maximum width, and 86.6% for maximum length) show that while Harris' maximum measurements are fairly accurate, they may not be accurate enough to be used as the only deciding factor in sex determination, with the exception of the maximum length. Further, when a bone is incomplete, substitute measurements are also useful for sex determination. This study also demonstrates that if more than one measurement is present, all measurements should be included. Following the baseline suggested by Scheuer and Elkington, measurements (univariate) with an accuracy rate of 80.0% or greater were considered to be useful.[14] Four of the 11 variables used in this study meet or exceed that threshold. When multivariate approaches are taken into account, accuracies may be even higher. For instance, when all 11 measurements are used in a DFA, the overall accuracy rate is 87.4%. If the relative weight of these measurements are taken into account and the measurements with the lowest contributions to the model are systematically dropped, the accuracy then rises to 90.3%. While some of the individual variables have accuracy rates below 80%, the rate increased above 80.0% when combined with at least one other measurement. In conclusion, although the navicular is a small bone of the foot, it can be useful in sex determination whether the bone is complete or incomplete.

Navicular, Sexual Dimorphism, Bones

H40 Estimating Adult Stature From Metatarsal Length in a Galician Population (NW of Spain)

Xoán Miguéns, MD, Department of Physical Medicine and Rehabilitation, Monforte Hospital, Lugo, 27400, Lugo, SPAIN; Sonia Villar, BS, University Hospital Complex, Santiago de Compostela, SPAIN; Cristina Cordeiro, MD, Instituto Nacional de Medicina Legal, IP, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; María S. Rodríguez-Calvo, PhD, Institute of Forensic Science, Univ of Santiago de Compostela, Calle San Francisco, CP 15782, Santiago de Compostela,SPAIN; Manuel Febrero-Bande, PhD, University of Santiago de Compostela, Department of Statistics and Operations Research, Santiago de Compostela, SPAIN; and José I. Muñoz-Barús, PhD, Institute of Forensic Science, University of Santiago de Compostela, Calle San Francisco, CP 15782, Santiago de Compostela, SPAIN*

After attending this presentation, attendees will understand the potential contribution of new formulas to estimate adult stature from metatarsal length in a Galician population.

This presentation will impact the forensic science community by presenting new formulas and demonstrating how they can increase the accuracy of adult stature estimation, especially when long bones are not present or are fragmented.

While it is accepted that long bones provide a more accurate estimation of stature, in practice fragmentary remains make the task difficult. However, small bones, such as those of the hands or feet, are very often well preserved in a variety of contexts and, for this reason, it is necessary to develop methods for estimating stature from these elements. Although the formulas developed by Byers et al. have been used in the forensic arena for more than 20 years, it is clear that it is the reference population from which they were derived which limits their utility for use with other populations.[1] To verify the use of the dimensions of the metatarsals as estimators of adult height in our population, a method for estimating the stature of Spanish adults using radiologically determined metatarsal lengths has been developed.

Method: The present research is based on a study of 101 (36 males and 65 females) healthy Caucasoid volunteers, over the age of 25 years from Galicia (NW of Spain). All persons with skeletal deformities, pathologies, or fractures which could preclude accurate measurements were excluded from the study. Height was determined with a measuring rod, placing the volunteer barefoot, erect, and looking up, with the back against a graduated ruler. The first and second metatarsals of the left foot of the 101 volunteers were measured by a dorso-plantar X-ray using a digital medical image viewer with a Radiological Archive and Image Management (RAIM) application 1607 JAVA from UDIAT, commonly used in hospitals. Although digital measurement is calibrated by the system itself, in order to minimize errors, a metallic ruler was used to confirm precision. All measurements were obtained twice and registered in millimeters. Statistical analysis of the data was carried out using the R environment (www.r-project.org).

Description of the measurements:

- M1—Maximum length of 1st metatarsal—the distance between the tip of the tuberosity and the most distal point of the head.
- M2—Maximum length of 2nd metatarsal—the distance between the proximal tip and the most distal point of the head.

Results: The highest correlation obtained (R=0.755) was with the maximum length of the 1st metatarsal for males. The corresponding regression equation is as follows: S=756.336 + 13.686*M1. When the equation is applied to both the first and second measurements, no significant differences in the correlation coefficients were detected. Additional formulas and summary performance statistics will be presented. It is important to note that participants in the study were adults and, thus, these formulas should not be used for estimation of stature for individuals younger than 19 years old.

The addition of metatarsal data for the estimation of stature has proved to be a valuable contribution in assessing the biological profile of Spanish adults. Additionally, because the equations are based on radiographic measurements of the fleshed foot, they may be of use for mass disaster, dismemberment, or other non-skeletonized cases where the soft tissue of the foot is still present.

Estimating Adult Stature, Metatarsal Lengths, Dorso-Plantar X-Ray

H41 An Examination of Postmortem Interval Relative to Microbial Biomass of Soil at the MSU Forensic Science Research Facility Plot

Amber Plemons, BS, 107 Avondale St, Starkville, MS 39759; Nicholas P. Herrmann, PhD, Mississippi State Univ, Dept of Anthropology, 206 Cobb Institute, Starkville, MS 39762; Franklin E. Damann, PhD, National Museum of Health and Medicine, 2460 Linden Ln, Silver Spring, MD 20910; and Scott T. Willard, PHD, Mississippi State Univ, Dept of Biochemistry and Molecular Biology, Box A, Mississippi State, MS 39762*

After attending this presentation, attendees will be informed of the Mississippi State University (MSU) Forensic Science Research Plot and the interdisciplinary research taking place at the facility. The focus of this presentation will be on recent controlled decomposition studies examining the relationship of Postmortem Interval (PMI) to the microbial biomass of soil and bone.

This presentation will impact the forensic science community by contributing new data to the expanding knowledge base of microbial biomass in relation to PMI of various sample types (e.g., bone, tissue, and soil) and provide a new dataset to compare to recent studies at the Anthropological Research Facility in Tennessee as well as other research units across the United States.

The MSU Forensic Science Research Plot conducts interdisciplinary studies aimed at understanding PMI, decomposition, and taphonomic processes in Mississippi. Collaboration with the Mississippi Agricultural and Forestry Experiment Station (MAFES) allows access to non-euthanized porcine (*Sus scrofia*) samples and enables controlled research throughout the year.

To develop a baseline biomass reference sample, three porcine experiments were monitored throughout active decomposition to mummification/skeletonization. The pigs were enclosed in fencing to reduce scavenging which may alter soil composition. Basic observations and notes were maintained, as well as serial photography, and included into the Porcine Taphonomic Database. Two juvenile samples (approximately 25 – 30 pounds) were placed at the facility during the fall of 2011 and became mummified/skeletonized within two weeks due to high temperatures. The third sample (approximately 200 pounds) was placed in the winter of 2012 and became partially mummified and skeletonized throughout the spring. The high fat content, as well fluctuating temperatures, extended the decomposition interval. Prior to placing the pigs, control soil samples were collected. Daily soil samples were collected beneath the center of each specimen during active decomposition. As a final step, rib samples were collected and pulverized (200mg) for quantitative PCR analysis.

A quantitative real-time PCR for the evaluation of bacteria and fungi from each sample was performed. Standard quantification curves were created with universal primers targeting a 200-base pair fragment of the 16s rRNA gene from *E. coli* and a 300-bp fragment of the fungal ITS region from *Fusarium solani*. Five serial dilutions of known concentrations of PCR products were generated and run in triplicate for a single standard curve and used to estimate DNA concentration from the unknown samples.

With the same primers, test soils, bone specimens, and standard curve samples were analyzed. Asymmetrical cyanine dye was used for bacteria and a fluorescent DNA binding dye was used for fungi. Quantitative-PCR efficiencies of 94% and 77% were obtained for bacterial and fungal amplification, respectively.

Due to the climate in Mississippi, decomposition is generally accelerated and, therefore, bacterial growth is accelerated. Bacteria

naturally reproduce rapidly (every 15 to 20 min) in soil and can be greatly influenced by nutrient availability and physiochemical environment, such as temperature and moisture. The first two pigs displayed a dramatic increase in bacteria within the first week of decomposition and then declined. Pig 1 became mummified and experienced a gradual decrease in bacteria while Pig 2 became skeletonized with a rapid decline of bacteria. The differential results may be due to lingering nutrients provided by the mummified remains. Pig 3 is currently being analyzed and the results are expected to mirror the results from Pig 1 and 2.

Although quantitative PCR has been established as a useful tool for measuring microbial biomass as a means for determining PMI, more regional studies are needed to better understand the relationship between bacteria and decomposition in different ecological settings. Researchers with the MSU Forensic Science Research Plot have collaborated with the National Museum of Health and Medicine to develop a baseline reference sample for Mississippi. Ultimately, understanding the rates of change in bacteria throughout the decomposition process will aid in determining PMI in future forensic cases.

Forensic Taphonomy, Postmortem Interval, Microbial Biomass

H42 Assessing the Efficacy of Basicranial Angle to Determine Ancestry

Adam Kolatorowicz, MS, Ohio State Univ, 4034 Smith Laboratory, 174 W 18th Ave, Columbus, OH 43210; Kristine Mason, BS, 6772 Ohio Canal Ct, Canal Winchester, OH 43110; Veronica L. Brienzi, Ohio State Univ, 4034 Smith Laboratory, 174 W 18th Ave, Columbus, OH 43210; and Stephen P. Nawrocki, PhD, Univ of Indianapolis, Archeology & Forensics Lab, 1400 E Hanna Ave, Indianapolis, IN 46227-3697*

After attending this presentation, attendees will understand the potential application of using cranial base angle to determine ancestry of unknown human skeletal remains.

This presentation will impact the forensic science community by providing a new method to aid in the identification of fragmentary skeletal remains.

A primary task of the forensic anthropologist is to construct a biological profile of unknown human skeletal remains. The skull is recognized as providing the highest accuracy for determining ancestry. However, portions of the skull that are most diagnostic, such as the face, may be damaged or missing, particularly when a skeleton is discovered in an outdoor context. In such situations, data used to construct the biological profile may be limited. The cranial base is centrally located in the head and protected by soft tissue which may prevent bony destruction. While the basicranium is a popular region for evolutionary studies, it has not been used as frequently as an identifying feature in forensic contexts. Holland achieved 70% – 90% correct classification of White and Black males and females utilizing multiple linear regression models.[1,2]

Wescott and Moore-Jansen later found the measurements used in that study have high interobserver error rates.[3] McKeown and Wescott attained 85% correct classification using geometric morphometric methods for determining ancestry utilizing cranial base landmarks.[4] The current study examines basicranial flexion in modern human populations to determine if it is a useful indicator of ancestral group affiliation.

A total of 196 males and females of European American and African American ancestry from the Hamann-Todd Human Osteological Collection and the Robert J. Terry Anatomical Skeletal Collection were utilized in this study to test the null hypothesis that there is no difference in mean basicranial angle between ancestral groups. Nasion-sella length, basion-sella height, and basion-nasion length were measured and then used to calculate the cranial base angle at sella using the Law of Cosines. Interobserver and intraobserver error tests were conducted to determine if the measurements are repeatable. Intraobserver error is equal to or less than 1.20mm for each measurement and interobserver error averaged less than 1.83mm for each measurement.

There is a statistically significant difference in mean basicranial angle between European Americans and African Americans (t=2.49, p-$value$ <0.05). Analysis of covariance indicates that ancestry is the sole factor influencing basicranial angle while collection, sex, and age at death have no significant effect. Logistic regression analysis was employed to calculate the odds that an individual belongs to an ancestral group, producing the model *log(odds)=6.1233 + -0.0451*cranial base angle*. The probability that the angle is African American is given by the formula *P=1/(1 + e^log(odds))*. Individuals with a cranial base angle greater than 140.2° are more likely African American, whereas individuals with a cranial base angle less than 131.3° are more likely European American. Individuals with a cranial base angle between 131.4° and 140.1° cannot be classified with certainty greater than 0.55. A receiver operating characteristic curve analysis was performed to assess the sensitivity and specificity of the test at multiple levels. The probability that the ancestry classification for a randomly chosen positive case (African American) will exceed the result for a randomly chosen negative case (European American) is 0.617. Eighty-eight individuals could not be classified using the established cut-off rule. Of the remaining 108 individuals, 66% were correctly assigned to their ancestral category.

This study demonstrates that cranial base angle can be used to estimate ancestry of unknown skeletal remains. The current method only requires one to identify three cranial landmarks and record three measurements to calculate cranial base angle using sliding and spreading calipers. The calculated angle can be used to provide a probability that the specimen belongs to a particular ancestral group. The only difficulty in applying this method is accessing sella to measure anterior and posterior cranial base lengths. The vault must be absent if using sliding calipers or else a medical imaging modality must be used. Overall, this method is particularly useful for fragmentary remains to aid in the construction of the biological profile and should be used in conjunction with other metric and non-metric methods. It must be tested on an independent sample to further judge its classificatory power.

Cranial Base, Ancestry, Identification

H43 A Test of the Megyesi Equation on Scavenged Human Remains

Cheryl A. Johnston, PhD, Western Carolina Human ID Lab, Dept of Anthropology & Sociology, WCU, 101 McKee Bldg, Cullowhee, NC 28723; Paul S. Martin, BS, 305 Clement Rd, Rossville, TN 38066; and Neva H. Williamson, BS, Univ of Indianapolis, Dept of Biology, 1400 E Hanna Ave, Indianapolis, IN 46227*

After attending this presentation, attendees will be better able to conceptualize the importance of temperature in the decomposition process and to understand the limited role small scavengers may play.

This presentation will impact the forensic science community by contributing to an understanding of human decomposition so that the accuracy of postmortem interval estimates can be improved.

The purpose of this research is to address the contribution of small vertebrate scavengers to human decomposition and to discuss how such scavenging may affect estimates of postmortem interval calculated using the regression equation proposed by Megyesi *et al*.[1] Megyesi's equation uses a scoring scheme to produce a numerical representation of the state of decomposition and can be used to predict the number of accumulated degree days that have elapsed since death. Weather data

can then be used to relate accumulated degree days to chronological time since death. Postmortem interval estimates derived from Megyesi's equation assume that the cadaver is that of a complete adult human that has not suffered any trauma and has been allowed to decompose on the surface. Megyesi et al.call for future studies to address whether the equation accurately predicts postmortem interval in the event that the remains deviate from these specifications. Scavenging is one such deviation and is addressed in this project.

The scoring scheme described by Megyesi *et al*., the total body score, was used to document decomposition over a period of months for six donated human cadavers placed at an outdoor human decomposition research facility in western North Carolina. Motion sensitive cameras were used to gather evidence of scavenging. All six donated cadavers were scavenged by small mammalian and avian species.

Actual accumulated degree days were calculated for each donor and plotted against total body score as reported by observers. The resulting pattern for the entire data set was curvilinear, with an R-squared value of 0.395. Accumulated degree day values were transformed using a base-10 logarithm, and the resulting plot for the entire data set was more linear with an R-squared value of 0.75, suggesting that, when transformed, accumulated degree days are a strong predictor of variation in total body score.

When the regression equation of Megyesi et al. is applied to this data set, the equation worked reasonably well to predict the actual accumulated degree days when the suggested error range of +/-776.32 accumulated degree days was applied. However, a paired sample T-test of the actual accumulated degree days against the predicted accumulated degree days showed that the differences in the means were significant at $p<0.001$. Autocorrelation may be a factor because scores are from sequential observations of the same individuals. These results indicate that Megyesi's findings of the strong correlation between thermal energy, as measured by accumulated degree days, and level of decomposition hold true even in the presence of scavenging and in the western North Carolina region. However, future research in this biome may provide a refined regression equation for similar environments and may serve to quantify the contribution of scavenging to the percentage of total body score that is not explained by accumulated degree days.

Decomposition, Postmortem Interval, Scavenging

H44 Estimation Using Postcranial Measurements: A Validation Study of Spradley and Jantz on a White Population

Darryl R. Ricketts, BA, 20 Taft St, Apt 1, Boston, MA 02125; and Amelia M. Boaks, MSc, 107 Neville Pike Blvd, Toronto, ON M4E3P7, CANADA*

After attending this presentation, attendees will better understand the results and implications of a recent test of Spradley's and Jantz's postcranial classification rates for sex determination using two North American White collections.

This presentation will impact the forensic science community by demonstrating the accuracy of select univariate and multivariate postcranial measurements when determining sex on a large, known White sample.

A recent publication by Spradley and Jantz tested the accuracy of various discriminant functions using cranial and postcranial skeletal measurements from the Forensic Databank.[1] The purpose of the current study was to verify these univariate and multivariate postcranial formulas on individuals from two regionally diverse skeletal collections.

Thirty-five postcranial measurements were taken for 139 individuals from two documented skeletal collections in Canada and the U.S. Fifty-nine individuals (24 females and 35 males) were measured from the J.C.B. Grant Collection housed at the University of Toronto, and 80 individuals (35 female and 45 males) were measured from the collection housed at the Maxwell Museum in Albuquerque, New Mexico. Individuals in this study were between the ages of 18 and 101 years. As these collections are primarily composed of White adult individuals, only this ancestry group was tested in this study. Each collection was measured independently by the authors, and intra-observer tests were conducted on randomly selected sub-samples of the individuals used in this study.

Since most of the crania available were previously sectioned, only postcranial measurements could be tested. In total, 35 postcranial measurements which yielded accuracy rates of 80% or higher in the original study were used. Sectioning points were calculated in the same manner as that used by Spradley and Jantz. Once the sectioning points for each univariate and multivariate function were gathered, they were ranked in descending order and compared to the hierarchies published in the original study for the American White population.

The current study found that overall, the classification rates for both univariate and multivariate sex estimation functions are consistent with those reported by Spradley and Jantz. Of particular note are the accuracy rates achieved by the univariate humeral epicondylar breadth and the multivariate function for the scapula. Both of these functions yielded accuracy rates of 92% or above in both collections, suggesting these measurements are reliably applied to a wider sample of White individuals. Conversely, despite the fact that the univariate calcaneal accuracy rates are high between both studies' samples (Spradley and Jantz, 76% for calcaneal length and breadth; Maxwell sample, 82% and 74%, Grant sample, 60% and 71% for calcaneal length and breadth, respectively), the accuracy rate yielded by the original study for the multivariate calcaneal function (length and breadth) was nearly twice that of the validation sample's (Spradley and Jantz, 83%; Maxwell sample, 41%; and Grant sample, 44%); suggesting that an error may be associated with the original multivariate function.

The results of the current study strongly support and validate the claim set forth by the Spradley and Jantz equations, and shows that postcranial measurements can be reliably used to estimate the sex of unidentified individuals. Given these results, this paper hopes to justify a more widespread adoption of postcranial sectioning points for sex estimation within the forensic anthropology community.

Sex Estimation, Postcranial Elements, Sectioning Points

H45 Stature Estimation From Long Bone Lengths Among the Adult Colombian Population

Angelica Guzman, BA, National Institute of Legal Medicine & Forensic, Calle 7A No. 12A- 51, Bogota, DC , COLOMBIA; Megan K. Moore, PhD, Univ of Michigan-Dearborn, Dept of Behavioral Science, 4901 Evergreen Rd, Dearborn, MI 48128; Cesar Sanabria, PhD, Calle 7a #12-61, Segundo Piso, Bogota, COLOMBIA; and Juan M. Guerrero, BA, and Carlos A. Villalobos, BA, National Institute of Legal Medicine and Forensic, Cra. 7A Nº 12-61, Bogota, COLOMBIA*

After attending this presentation, attendees will be made aware of a new modern Colombian skeletal collection from which population-specific stature formulas for adult Colombian males and females are recently derived. The educational objectives are to present these new formulas and to compare the accuracy of these new formulas compared to previously published formulas.[1,2]

This presentation will impact the forensic science community by helping to develop population standards in Colombia that could potentially play a role in the identification of thousands of unidentified human remains from the ongoing conflicts in Colombia.

The aim of this study is to develop general formulas for stature estimation using inverse regression of long bone lengths (humerus,

radius, ulna, femur, tibia, and fibula) of Colombian adult males and females. Previous studies to estimate stature of individuals from the Colombian population made by Mantilla Hernández (2009) using tabias demonstrate that these population-specific formulas are more precise than those developed by Trotter and Gleser and Genovés.[1-3] This new collection will provide modern population-specific equations using a known modern skeletal collection to improve the accuracy of stature estimation. For this study, a new skeletal sample is used called the Human Skeleton Collection of Colombia, which is curated at the Institute of Legal Medicine and Forensic Sciences (INML y CF) and was developed under the supervision of Dr. César Sanabria. The Human Skeleton Collection of Colombia consists of individuals of known age, sex, and stature (stature from ID cards and/or cadaver stature) and offers a unique opportunity to develop and test stature formulas specific to the Colombian population. The individuals have dates of death from 2005. The study was conducted on 140 skeletons, 99 males and 41 females, aged 19 years and above, with an average age of 47 years. The collection and this research project have been part of a bigger collaboration to develop standards from this new sample with the help of the International Criminal Investigative Training and Assistance Program (ICITAP). By convention, the left bones in each skeleton were measured. Nine parameters (maximum lengths of humerus, radius, ulna, femur, tibia (without the intercondyloid eminence), and fibula)) were recorded. The current study uses measurement of the tibia that includes the malleolus, which has become standard for stature estimation. For the statistical analysis, linear and multivariate regression equations were generated for all bones for each sex separately. Only regressions with highly significant F values ($p<0.01$) were accepted. All of the long bones of the upper and lower limbs are included in univariate inverse regression formulas and the best multivariate regression equations are calculated using a stepwise procedure. All of the equations are significant for males and females ($p<0.01$). The equation from the femur for males (Stature=(Femur*2.46) + 5.9004 +/- 3.760) has a high correlation (r=0.857). The equation from the femur for females (Stature=(Femur*1.787) + 83.592 +/- 4.951) has a much lower correlation (r=0.692). The best multivariate equation for males was from the femur and tibia combined (Stature=(Tibia*1.592) + (Femur*0.967) +67.348 +/- 3.091; r = 0.891, adjusted R^2 =0.784). The best equation for the females was a univariate equation from the fibula (Stature=(Fibula*2.183) + 93.170 +/- 5.065; r=0.697; adjusted R^2=0.460). These results indicate that the sample size for the males is sufficiently large for reliable stature equations, but the sample size for the females should be larger to improve the correlations for reliability in forensic stature estimation. Since this study was first conducted, the Human Skeleton Collection of Colombia sample has since grown in size to be several hundred individuals, which will enable improved equations of females and the ability to test the validity of the male equations on an independent sample.

Stature Estimation, Femur, Tibia

H46 Asymmetry of the Humerus: The Influence of Handedness on the Deltoid Tuberosity and Possible Implications for Osteometric Sorting

Carrie B. LeGarde, MA, 974 Auloa Rd, Kailua, HI 96734; and John E. Byrd, PhD, 95-033 Hokuiwa St, #51, Mililani, HI 96853-5530*

After attending this presentation, attendees will have gained an understanding of how individual asymmetry may affect the sorting of humeri in a commingled assemblage and the possible correlation between this asymmetry and an individual's handedness.

This presentation will impact the forensic science community by illustrating which measurements may be most related to hand preference and whether this could adversely affect the osteometric sorting method for pair-matching.

The identification of individuals from commingled human remains can be a difficult task. Osteometric sorting is often utilized for these purposes since it sorts remains based on size. This research investigates whether asymmetry of the humerus is present, if it is due to an individual's hand preference, and if this asymmetry can cause incorrect sorting of elements when utilizing the osteometric sorting method for pair-matching.

The osteometric sorting formulas for pair-matching were used to classify individuals as asymmetric. This method utilizes a *p*-value to determine whether a significant difference in size between left and right elements exists. A *p*-value less than 0.10 indicated that two elements were significantly different, and therefore, deemed to be asymmetrical. Significant asymmetry was seen in multiple measurements and this asymmetry could be due to handedness. This relationship appeared more consistent with breadth measurements than length measurements, and the right side appeared to be larger more often. The epicondylar breadth of the humerus was the most asymmetric with 12.8% of individuals considered asymmetric. All breadth-only measurements of the humerus resulted in over 12% asymmetric. Asymmetry of the maximum length of the humerus occurred in only 7.3% of individuals. When breadth measurements were combined with the maximum length of the humerus, the number of the asymmetrical individuals was reduced to less than 9%. These results did not appear to correlate with the results seen on the radius. Maximum length of the radius was slightly more asymmetric than the maximum diameter of the radial tuberosity, 9.9% and 8.3%, respectively. Less than 20% were considered asymmetrical for both the radius and humerus. This indicates that asymmetry in the arm and forearm is not related.

The femur yielded results indicating asymmetry between left and right, but these results were not significant (only 6% of individuals). The mean difference of the maximum length of the femur between left and right elements was 1mm, which is incredibly small for a measurement that is generally at least 400mm.

When investigating male and female differences of the humerus, a notable difference was found. The range of the difference between left and right elements was greater for males than for females for both maximum length of the humerus (28.00mm and 11.50mm) and the maximum diameter at the deltoid tuberosity (7.6 mm and 2.67mm). The osteometric sorting method uses the variation in the data set to determine whether the difference between two paired elements is significant or not. When females are included in the data set with males, the difference between paired elements is not significant, but when analyzed alone, they are. This suggests that, in general, males have a greater difference between left and right humeri than females.

Asymmetry is present in the upper limbs. A significant difference in size between the left and right humeri and radii was seen. However, particular measurements were more asymmetrical than others. Breadth measurements were asymmetrical more often than length measurements. This asymmetry may be due to an individual's hand preference. Further investigation is necessary. No correlation was found between asymmetry of the humerus and asymmetry of the radius. This suggests that mechanical forces may act differently on the upper limb than the lower limb. These results indicate that anthropologists

utilizing the osteometric sorting method should be aware of measurements that tend to reflect asymmetry.

Asymmetry, Humerus, Osteometric Sorting

H47 The Potential for Sex Assessment From Dental Dimensions in Modern Forensic Cases

Nicolette Parr, MS, Univ of Florida, 1376 Mowry Rd, Rm G17, PO Box 103615, Gainesville, FL 32610; Sarah Kiley, MS, Univ of Florida, C.A. Pound Laboratory, 2033 Mowry Rd, Rm G-17, Gainesville, FL; Katherine Skorpinski, MA, 1626 SW 14th St, Apt 16, Gainesville, FL 32608; and Traci L. Van Deest, MA, Univ of Florida, Dept of Anthropology, Turlington Hall, Rm 1112, Gainesville, FL 32610*

The goal of this presentation is to examine the degree of sexual dimorphism in tooth dimensions and to explore the utility of these measurements in the assessment of sex.

This presentation will impact the forensic science community by investigating the potential of a method of sex assessment that could be used in cases where other indicators of sex are absent or ambiguous.

One of the most crucial steps in constructing the biological profile of an unknown individual is the assessment of biological sex from skeletal remains. Estimation of other aspects of the biological profile often relies on a prior knowledge of an individual's sex. However, in many forensic cases, the most diagnostic elements for sex estimation may not be present, have been damaged, or provide ambiguous results. Additionally, morphological and metric methods for sex assessment in subadult skeletal remains have not been reliably established; however, the permanent dentition has been used to accurately sex subadults with mixed dentition. Since 1972 at the C.A. Pound Human Identification Laboratory, approximately 20% of cases involved examination of either subadult remains or the skull/cranium or mandible as the only element available for sex assessment. In cases such as these, other means for assessment of sex from skeletal remains need to be investigated.

Human dentition is highly controlled by genetics and is the most durable portion of the human skeleton. Previous studies have shown that the adult dentition is sexually dimorphic, with sex prediction accuracies ranging from 62.3% to 85%. However, many of these studies are restricted primarily to archaeological populations or casts from living individuals. In forensic cases, odontometrics may prove a feasible option for sex assessment when remains are fragmentary, ambiguous, or a subadult with mixed dentition.

The current study examines the potential utility of odontometrics for sex assessment in a contemporary European American sample of forensic cases analyzed and curated at the C.A. Pound Human Identification Laboratory. Digital extended pointed jaw calipers were used to measure the mesiodistal and buccolingual diameters of the permanent dentition of 33 males and 20 females (total *n*=53). Measurements were not taken in dentition where attrition, carious lesions, restorations, or dental crowding prevented an accurate measurement. Due to these conditions, as well as antemortem and postmortem tooth loss, not all teeth are equally represented within the sample; however, this reflects actual conditions of remains in forensic casework. Student's *t*-tests were used to determine which dimensions were statistically different between the sexes, and sectioning points were calculated from these dimensions. Measurements higher than the sectioning point are classified as male, and those smaller than the sectioning point are classified as female.

Paired *t*-tests revealed statistically significant differences between the sexes (at a 0.05 alpha-level) in seven buccolingual dimensions: LI^2, LC′, LP^4, LI_2, LC′, LM_1, and RC_1 and four mesiodistal dimensions: LC^1, LP^4, RM^1, and LC_1. Sectioning points were established using a weighted mean for each of these teeth. Additionally, a discriminate function analysis was performed using those teeth that exhibited statistically significant differences in size between the sexes. Within this subset of the dentition, the combined buccolingual dimensions of LI^2 and LC^1 provide the highest accuracy levels at 77% for cross-validated correct classification of both males and females within the sample. Interestingly, the buccolingual dimensions are often easier to take than the mesiodistal measurements, particularly in modern populations, which exhibit significant dental crowding.

The correct classification of 77% falls within the range of accuracy levels of previous sexual dimorphism studies from the dentition. However, due to the established population specificity of sexual dimorphism in teeth, these results may not be applicable to non-European ancestral groups. Regardless, this study suggests that dental dimensions may provide additional information that should be considered in the assessment of sex, and may greatly aid in the analysis of fragmentary, incomplete, or subadult remains.

Sex Assessment, Odontometrics, Forensic Anthropology

H48 Pelvic Sexual Dimorphism in a Western Australian Population: Integration of Geometric and Traditional Morphometric Approaches

Daniel Franklin, PhD, Univ of Western Australia, Centre for Forensic Science, MBDP M420, 35 Stirling Hwy, Crawley, Western Australia 6009, AUSTRALIA; Ambika Flavel, MSc, Univ of Western Australia, M420, 35 Stirling Hwy, Crawley, Western Australia 6009, AUSTRALIA; Andrea Cardini, PhD, Univ of Modena, Dipartimento di Scienze Chimiche e Geologiche, Modena, ITALY; and Murray K. Marks, PhD, Univ of Tennessee, Dept of Pathology, 1924 Alcoa Hwy Box 108, Knoxville, TN 37920*

After attending this presentation, attendees will have an understanding of the utility of geometric and traditional morphometric approaches for the quantification of sexual dimorphism in the adult pelvis and how both approaches offer different (albeit complimentary) insights.

This presentation will impact the forensic science community by demonstrating the value of medical scans as alternate sources of contemporary population-specific skeletal data. The presentation also demonstrates that in the Western Australian population, it is possible to estimate sex with a high degree of expected accuracy using traditional pelvic measurements.

In the analysis of unidentified skeletal remains, it is crucial to formulate an accurate biological profile. The correct assignation of sex to skeletal remains not only contributes to establishing personal identity, but also provides an essential criterion for ensuring that the appropriate sex-specific age, ancestry, and stature standards are subsequently applied. It is widely accepted that the most accurate biological profile is achieved through the application of contemporary population-specific standards. The forensic anthropological community in Western Australia (WA) is currently working toward developing a suite of population-specific standards. Furthermore, in the absence of reference skeletal material (of a contemporary population and in appropriate numbers) a morphometric approach involving the analysis of Multi-Slice Computed Tomography (MSCT) scans has been adopted. This presentation demonstrates the sexual dimorphism of the pelvis in a contemporary WA population. This is achieved using both a 3D shape and traditional linear measurement approach. The study is part of ongoing research in population-specific standards from MSCT scans of living individuals.

The sample comprises pelvic MSCT scans with a mean slice thickness of 1.2 millimeters from 50 male and 50 female adults with a mean age of 46.94 years (range 22 – 63) for males and 45.76 years (range 21 – 62) for females. Following 3D volume rendering, the 3D coordinates of 41 landmarks were acquired using OsiriX® (v.4.1.1). A total of 30 linear measurements, suitable for a complete and/or a fragmented bone, were calculated using Morph Db (an in-house developed database application). Measurements were analyzed using basic descriptive statistics and discriminant function analyses; statistical analyses are performed using IBM® SPSS® Statistics 20.0. Shape analysis software morphologika (v.2.5) analyzed the 3D coordinates of the landmarks. Principal Components (PCA) and multivariate

regression analyses were used to explore relationships between the male and female samples. Shape differences were visualized and interpreted using 3D wireframe and rendered models. Significance of sexual dimorphism in pelvic shape was quantified using permutation tests for mean differences, whereby the true difference between means (Procrustes distance) is compared with the distribution of differences between means obtained by randomly permuting group membership 1,000 times.

Multivariate regression (PCs 1-5; 53.5% total variance) and permutation tests indicate significant pelvic sexual dimorphism in the WA population; males (relative to females) demonstrate an acute sub-pubic angle, narrow and short pelvic inlet/outlet, long and narrow ilium, and an anteriorly curved sacrum. A total of 24/30 linear interlandmark measurements are sexually dimorphic and sex differences explain 3.7% – 68% of sample variance. Cross-validated sex classification accuracy (stepwise and direct DFA of linear measurements) for the complete pelvis is 96%; measurements for a complete os coxa yielded accuracy rates above 90%. Other dimorphic regions in the pelvis, which may be useful for assessing fragmentary remains, include (but are not limited to) the ischium (ischial length: 88% accuracy) and the acetabulum (length and width: 84% accuracy). Only those discriminant functions with an accuracy ≥80% with a sex bias of ≤5% are deemed suitable for forensic application.

This preliminary study represents the initial forensic research into pelvic sexual dimorphism in a WA population. It was clearly established that this bone can be used to classify sex with a high degree of expected accuracy, irrespective of whether a complete or fragmented bone is examined. Future research will concentrate on expanding the pelvic database and further testing the derived standards using hold-out samples and resampling statistics, thereby improving the statistical robustness of the formulated standards and demonstrating their ability to meet the *Daubert* admissibility requirements.

Sex Estimation, Pelvis, MSCT

H49 Metric vs. Non-Metric: Accuracy in Sex Assessment Using the Greater Sciatic Notch

Erin B. Waxenbaum, PhD, 1810 Hinman Ave, Evanston, IL 60208; and Katya G. Siddall, Northwestern Univ, Dept of Anthropology, 1810 Hinman Ave, Evanston, IL 60208*

After attending this presentation, attendees will understand the effects of chosen methodology on sex assessment of the human pelvis. This presentation provides an analysis of whether metric or non-metric analysis of the Greater Sciatic Notch (GSN) provides greater accuracy in determining sex. Attendees will observe the results of comparisons between the predicted sex through non-metric assessment following Buikstra and Ubelaker and metric evaluation using the GSN index.[1]

This presentation will impact the forensic science community by explaining how, ideally, multiple morphological features are used in assessing sex in skeletonized remains. However, in forensic contexts this is not always possible. These results highlight that neither the traditional visual assessment of sex using the GSN nor the metric method employing the GSN ratio is perfect. Nonetheless, the combination of both methods generates the greatest accuracy in this sample. The importance of these results is in highlighting the accuracy of varying methods of assessing sex through the GSN of the os coxa. This area is robust and frequently survives both archaeological and forensic contexts. The results of this research provide an invaluable addition to physical anthropology with practical applications for archaeological analysis and forensic casework.

Human skeletal pelvic dimorphism, specifically the sciatic notch, has long been a topic of discussion in physical and forensic anthropology. Historically, the "tools of the trade" for assessing sex in the pelvis have focused on visual, nonmetric methods, which are often conducted without an ecogeographically specific standard for comparison. In addition, nonmetric methods make use of relatively ambiguous descriptors for assessment including "broad," "comparatively open," and "shallow" for females and "narrow," "deep," or "J-shaped" to indicate male. As for metric analysis, Walker notes that "although many attempts have been made to describe sex differences in the sciatic notch using measurements, these metrical sexing techniques have not been widely adopted."[2] Despite Walker's comments, many researchers have repeatedly found that metric analysis of the pelvis, specifically the sciatic notch, provides a greater and more accurate sex assessment. This investigation empirically tests these contrasting hypotheses.

The population examined included segments of the Terry Black (n=99) anatomical collection (all remains included in this analysis are housed at the National Museum of Natural History, Smithsonian Institution). Individuals were sampled from both sexes: 50 female, 49 male. All nonmetric and metric evaluations for the sex of each individual were completed by the first author. Metric assessment was made through measurement of the GSN index; the ratio of the posterior chord of the GSN divided by the maximum width of the GSN. Nonmetric assessment was evaluated following Buikstra's and Ubelaker's five-stage system generally employed in physical and forensic anthropology.[1] It was then determined whether metric and nonmetric assessments agreed or were in conflict. These results were compared to the known sex of the individual to determine whether there was agreement between the methods and if not, which method is more accurate.

The present research found that 77% of the sample was assigned the correct sex using the nonmetric method alone and 81% of the sample correctly sexed through the metric method employing the GSN ratio; however, when the two methods were combined, 92% of the total sample was sexed correctly.

Ideally, multiple morphological features are used in assessing sex in skeletonized remains; however, in forensic contexts this is not always possible. These results highlight that neither the traditional visual assessment of sex using the GSN nor the metric method employing the GSN ratio is perfect. Nonetheless, the combination of both methods generates the greatest accuracy in this sample. The importance of these results is in highlighting the accuracy of varying methods of assessing sex through the GSN of the os coxa. This area is robust and frequently survives both archaeological and forensic contexts. The results of this research provide an invaluable addition to physical anthropology with practical applications for archaeological analysis and forensic casework.

Sciatic Notch, Sex Assessment, Metric Analysis

H50 Chin Form as a Sex Trait: Not a Simple Gradient

Heather M. Garvin, MS, Johns Hopkins Univ, 1830 E Monument St, Rm 302, Baltimore, MD 21205*

After attending this presentation, attendees will have a better understanding of the morphological variation and sexual dimorphism in chin form present across diverse human populations, and the reliability of skeletal chin traits in adult sex determination methods.

This presentation will impact the forensic science community by providing sex classification rates for overall chin morphologies. In comparison to previous studies, which utilized subjective ordinal scaling methods, this study uses an objective morphometric method to quantitatively analyze sex differences in chin shape.

Chin form is a common non-metric cranial trait used by forensic anthropologists in adult sex determination methods. Traditional sex estimation methods present an ordinal scale of five line drawings, representing a gradient in chin form from more "feminine" to more

"masculine" morphologies.[1] Because these observed sex differences are in the form of localized shape changes and complex variations in bony relief, finding a method to quantify sex differences in external chin morphology has presented a great challenge to anthropologists. A recent study published a method to isolate the chin Region Of Interest (ROI) from 3D surface scans, and demonstrated how morphometric methods could then be used to quantify sexual dimorphism in chin morphology.[2]

This study employs their method of isolation and uses sliding semi-landmarks positioned across the surface of the chin ROI to quantify chin morphology in order to objectively test the reliability of external chin form in discriminating between sexes. The accuracy of using quantitative measurements of chin form to correctly sex individuals was evaluated on a pooled sample (n=666), as well as separately on each of the six population groups included in this study: U.S. Whites, U.S. Blacks, Arctic Native Americans, Plains Native Americans, Nubian, and Portuguese. Discriminant function analyses, using a leave-one-out cross-validation method, were performed on the principal components extracted from the morphometric analyses. Traditional ordinal scores were also collected on four of the population groups, and discriminant function analyses were performed on these ordinal scores for comparison to the morphometric results.

Overall, results suggest that external chin morphologies are not reliable indicators of sex and consequently, should be used with extreme caution in forensic anthropological contexts. Discriminant function analyses run on the first 30 principal components, reflecting overall chin morphology, resulted in a correct sex classification rate of 68.2% for the pooled sample. Within individual population groups, accuracy rates ranged from 49.4% for the Nubian population to 70.4% for the arctic Native American population. Only a 50.8% correct classification rate was obtained for the U.S. White population group, while U.S. Blacks displayed slightly higher accuracy rates (65.0%). These results were on par with the accuracy rates obtained from the traditional ordinal scores (65.0% correctly sexed in the pooled sample). Step-wise discriminant function analyses suggest that the shape component reflecting relative chin ROI height compared to breadth was the most sexually diagnostic feature, with males generally displaying relatively taller chin symphyseal heights than females. Principal component plots illustrate a high degree of variance and overlap between sexes and population groups in chin morphologies. In addition, individual chin features, such as degree of "squareness," symphyseal height, overall chin protrusion, midline eminences, and lateral tubercle formations, were observed in various combinations across the sample. These results suggest that specific chin traits may be expressed independently, and that chin form may not be easily categorized into a simple gradient from more "feminine" to more "masculine" forms. The existence of numerous distinct categories of chin morphologies was first presented in the 1930s, but has since been neglected in the anthropological literature.[3,4]

As demonstrated in this study, the external morphology of the chin is much more variable than traditional non-metric studies suggest. Oversimplified gradients may not accurately reflect complete variation in observed chin forms, and the independent expression of individual chin traits should be further investigated. Correct sex classification rates obtained from chin shape components did not exceed 70%, and in two population groups less than 51% of the individuals were correctly sexed from chin morphologies. These results indicate that chin form is not a reliable indicator of sex, and thus is not recommended for use in forensic sex determination methods.

H51 Sexual Dimorphism of Immature Pubis Bone: A Multislice Computed Tomography Study by Geometric Morphometrics

Marie Faruch Bilfeld, MS, and Fabrice F. Dedouit, Service de Médecine Légale, CHU Toulouse-Rangueil, 1 Avenue du Professeur Jean Poulhes, Toulouse Cedex 9, 31059, FRANCE; Nicolas Sans, PhD, Service de Radiologie, CHU Toulouse-Purpan, Place du Docteur Baylac, Toulouse, 31059, FRANCE; Hervé Rousseau, PhD, Service de Médecine Légale, CHU Toulouse-Rangueil, 1 Avenue du Professeur Jean Poulhes, Toulouse Cedex 9, 31059, FRANCE; Daniel Rouge, PhD, Service de Médecine Légale, CHU Toulouse-Rangueil, 1 Avenue du Professeur Jean Poulhes, Toulouse Cedex 9, 31059, FRANCE; and Norbert Telmon, MD, PhD, Service Medico-Judiciare, CHU Rangueil, 1 Avenue du Professeur Jean Poulhes, Toulouse Cedex 9, F-31054, FRANCE*

The goal of this presentation is to study pubis morphology during ontogeny, specifically examining size and shape dimorphism independently.

This presentation will impact the forensic science community by: (1) demonstrating pubis ontogeny in order to develop new methodology for sexing pubis bone in juveniles; (2) showing the potential of Three-Dimensional (3D) Multislice Computed Tomodensitometry (MSCT) reconstructions for future anthropological research; and, (3) showing the potential of using clinical MSCT investigations for anthropological purposes, rendering the concept of virtual anthropology more concrete.

Purpose: Recent developments in geometric morphometrics open new research avenues in biological anthropology. Difficulty in sex estimation of juveniles is frequently encountered in forensic medicine. Contrary to adult remains, few studies have been conducted to evaluate sex differences of immature coxal bone and, when studied, the results are often contradictory. The objectives of this study are to analyze the ontogeny of size and shape sexual dimorphism in the pubis.

Materials and Methods: A retrospective study to evaluate sexual dimorphism observed in the pubis was conducted. A combination of landmark-based geometric morphometric analyses using 3D reconstructions of MSCT were performed to evaluate the ontogeny of pelvic shape and size dimorphism. Specifically, the analyses were designed to examine differences between age groups and rates of change. Five osteometric landmarks were targeted. The study population consisted of 188 children (95 boys, 93 girls), ranging in age from 1 to 18 years. The subjects were of diverse ancestry and lived in the area of Toulouse, southern France. Data were collected by two observers following a data collection protocol. Briefly, PCA was used as an exploratory step. Two-way MANOVA and Goodall's F-test were used to test differences between the sexes and among age groups. Linear regression was used to compare rates of shape change. The authors analyzed sexual dimorphism in size (centroid size) and shape (Procrustes residuals) and patterns of shape change with age (development) and size change with age (growth). MorphoJ and R2.2.0 software was used to perform the statistical tests.

Results: The maximum intra- and inter-observer error was 3%. The results of the PCA analysis demonstrated that the ontogenetic trajectories of shape change were different for males and females. Two-way MANOVAs of shape variables, with sex and age as factors, revealed statistically significant differences ($p<0.001$) between the sexes and age groups. The pubis shape became significantly sexually dimorphic at 13-years-old, although visible shape differences were observed as early as 9-years-old. Also, the size was statistically significant between the sexes. Trajectories of shape (development) and size (growth) differed between sexes throughout ontogeny. Mean shape

superimpositions between sexes for each age group showed that shape differences between sexes occurred gradually with age.

Conclusion: Immature pubis bone sexual dimorphism is an age-dependent phenomenon, both manifesting by size and shape differences. The immature pubis presents sexual dimorphism in both size and shape. In ontogeny, pubis growth and pubis development are separate phenomena.

Geometric Morphometric, Ontogeny, Pubis

H52 Postcranial Osteometric Analysis of Korean Ancestry

Elizabeth C. Okrutny, MA, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96818; and John E. Byrd, PhD, 95-033 Hokuiwa St, #51, Mililani, HI 96853-5530*

After attending this presentation, attendees will have an understanding of a new method of ancestral classification that can be utilized when only postcranial remains are available as well as the regions of the skeleton yielding the greatest predictive ancestral accuracy when using osteometric sorting measurements and standard maximum length measurements.

This presentation will impact the forensic science community by providing information on a new postcranial method for the determination of ancestry and by providing forensic anthropologists an assessment which can be applied to incomplete or fragmentary remains, thereby increasing the possibility of identification.

Determination of ancestry is an important step in the development of the biological profile, which is made more challenging when the skull is not present for analysis. Previous postcranial research has focused heavily on differentiating Europeans and Africans from one another. When an Asian skeleton is present in ancestry analyses, the sample population is frequently limited to Native Americans. This research examines the potential to correctly predict ancestral classification of remains using an Asian sample from South Korea and African, and European samples from four collections in the United States.

Osteometric sorting measurements were originally developed to assist anthropologists in sorting commingled remains. Measurements focus on morphological landmarks, minimum and maximum diameters, and minimum and maximum breadths making it so complete bones are not necessary for assessment and increasing the possible information that can be utilized from fragmentary remains. ANOVA tests were used to select measurements displaying significant differences between the three ancestral populations, and these measurements were then grouped according to their corresponding skeletal region (upper limb, hand, pelvis, lower limb, and foot). Forward stepwise discriminant function analysis then minimized the number of measurements utilized in each of the resulting functions to only the most significant. To prevent inflated classification results discovered in preliminary testing, sample populations were assessed in a two-part analysis: Koreans from Africans/Europeans and Africans from Europeans. All functions contain between one and four measurements.

Of the 14 functions synthesized to differentiate Koreans from Africans/Europeans, most had cross-validated correct classification rates of 80% or greater for Koreans and 77% or greater for the pooled African/European sample. The highest classifying function for separating both groups consisted of upper limb measurements. Of the postcranial skeletal elements measured, the clavicle, ulna, and femur were most frequently selected in analyses to distinguish Koreans from Africans/Europeans. When separating Africans from Europeans, the lower limb measurements were found to be too similar for them to be differentiated using stepwise discriminant function analysis, so only 13 functions were produced. Most of the functions when cross-validated, correctly classified Africans with 70% or greater accuracy and Europeans with 72% or greater accuracy. The best discriminating function with the highest classification rates for both Africans and Europeans consists of a combination of pelvis, lower limb, and foot measurements. Elements included in the most functions for these two ancestral groups were the sacrum, cuboid, and radius.

Independent discriminant analyses also scrutinized differences in limb proportion between Koreans and Africans/Europeans as well as Africans from Europeans through standard maximum length measurements. Analysis of the humerus, radius, and ulna separated Koreans from Africans/Europeans with a cross-validated overall accuracy of 79.8%. Maximum length of the femur and tibia had a cross-validated correct classification rate of 81.9%, while the femur alone had a cross-validated correct classification rate of 82.1%. Comparison of maximum lengths of the humerus and femur differentiated with an overall cross-validated correct classification rate of 80.9%. Maximum lengths of the clavicle, humerus, radius, and ulna were able to differentiate Africans from Europeans with a cross-validated overall accuracy of 81%. Analyses of lower limb lengths were less discriminating, but when combined with those of the upper limb, overall classification accuracy (cross-validated) was 75.6%.

Ancestry can be determined with acceptable accuracy from complete and fragmentary remains using osteometric sorting measurements. Similarities in size of Africans and Europeans make it more advantageous to determine Asian from non-Asian ancestry first, instead of attempting to predict group membership against all three groups. The skeletal elements found to be the most conducive to each of the two analyses differ due to proportional as well as size differences. Further analyses are necessary to determine the potential influence sex may have on ancestral classification.

Postcranial, Osteometrics, Ancestry

H53 Application of Cranial Indices to Estimate Ancestry in Modern and Historic South Africans

Leandi Liebenberg, BSc, and Kyra E. Stull, MS, Univ of Pretoria, Dept of Anatomy, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; and Deona Botha, BSc, Univ of Pretoria, Dept of Anatomy, Private Bag x323, Arcadia, 0007, SOUTH AFRICA*

After attending this presentation, attendees will gain knowledge of the applicability and accuracy of using cranial indices to estimate ancestry in modern Black and White South Africans and the historic Khoisan.

This presentation will impact the forensic science community by contributing to the knowledge of human variation in South Africa through testing the validity of current methodology. The results are to be used to establish best practices for estimating ancestry among modern South Africans.

In a diverse country like South Africa, the estimation of ancestry is an essential component for both the biological profile and the identification process. De Villiers and Steyn employed five cranial indices to quantify morphological differences among Black and White South Africans and indigenous Khoisan groups.[1-2] Despite the absence of validity testing and the advent of robust statistical analyses, the mean values for these cranial indices continue to be used to separate these groups and to classify skeletal remains as either modern or archaeological.

The purpose of this study was to establish the accuracy of five standard cranial indices, namely the Cranial Index (CI), Upper facial Index (UI), Orbital Index (OI), Nasal Index (NI), and Gnathic Index (GI), in differentiating Black/White South Africans and Khoisan groups.

A total of 207 crania (110 females, 97 males) of Black South Africans, White South Africans, and Khoisan were used. White and Black groups were obtained from the Pretoria Bone Collection in South Africa, while skeletal remains of known Khoisan origin were obtained from the Rudolph Pöch Collection in Austria. Ten standard measurements were taken using a spreading caliper and a digital sliding caliper. Five indices were calculated and compared to specific

sectioning points that had been assigned to the above-mentioned groups in *Fisiese Antropologie*.[2] Statistical analyses included an ANOVA and Tukey's method to test mean comparisons and statistical significance and percent correct to test accuracy of the indices.

For all five indices, two or more of the three groups had similar mean values. All indices had similar means for Black and Khoisan groups and no statistically significant differences were noted between them. With UI, no statistically significant differences were found among the groups. White and non-White groups demonstrated statistically significant differences for CI, GI, and NI. With OI, Khoisan groups demonstrated statistically significant differences from Black and White groups, but the latter two groups demonstrated no statistically significant differences between each other for this index.

For the groups that demonstrated statistical significance, new sectioning points were both created manually and using the Fisher-Jenks test. When the new and original sectioning points were compared, accuracy rates were generally higher for the new sectioning points (CI=73.55%; OI=71.57%; NI=88.18%; GI=79.88%) than the original sectioning points (CI=34.9%; OI=78.85%; NI=90.63%; GI=48.09%). Due to similar means, the sectioning points are usually only distinguishing White from non-White groups.

With the current sectioning points and group separation, cranial indices are not useful for describing differences among these social labeled groups. While Khoisan is a strong historical term, the crania of this group are generally not morphologically distinct from Black South Africans. Thus, the social designation is neither useful to understand ancestry in the population nor to sort modern and archaeological remains. Similar to other studies, White South Africans are clearly distinct from their non-White counterparts.[3,4] Possible reasons include later emigration of White groups into South Africa (1652); past segregation laws; and social/cultural behavior.[4] While the average accuracy of cranial indices is not as high as other more statistical robust methods, a revision of cranial indices and of their correction points has made this a valid and more appropriate method for use in South Africa.

Human Variation, Sectioning Points, Best Practice

H54 Fluvial Transport Distances and Postmortem Interval in the Sacramento River, California

Susan S. DAlonzo, BA, and Eric J. Bartelink, PhD, California State Univ Chico, Dept of Anthropology, Butte #311, 400 W First Street, Chico, CA 95929-0400*

After attending this presentation, attendees will gain a better understanding of the relationship between fluvial transport distance and Postmortem Interval (PMI) for human remains recovered from the Sacramento River, California. The goal of this presentation is to evaluate the key variables that influence transport rates of human remains in fluvial systems.

This presentation will impact the forensic science community by promoting an understanding of how river systems transport human remains and how this information can be used to establish a predictive model for narrowing down search parameters for victims who entered the river on known dates.

The transport of human remains in riverine systems has received attention by forensic anthropologists and law enforcement over the past several decades, with effort directed at search areas for missing persons. Until recently, studies of fluvial transport of human remains have largely been limited to the eastern United States.[1-3] However, recent research conducted within the Sacramento River found that long-distance transport is correlated with high discharge rates at the time the victim entered the river.[4] This research hypothesized a correlation between discharge rates and transport distances over known PMIs. The present study examines this relationship using a large sample of river victim cases.

The Sacramento River comprises the largest fluvial system in California, flowing 335 miles north-to-south, and passing though eight counties in northern California. Discharge rates vary based on annual snowmelt and precipitation, with an average rate of 350m^3/sec. Modeled after previous research, this project involves two broad categories of variables: victim demographics and river dynamics.[3] Demographic variables include the biological profile of the victim; victim weight; PMI, or number of days in the river; date of river entry and exit; location and side of entry and exit; preservation state; manner and cause of death; and the number of river miles traveled. The study sample currently includes data on over 120 cases from sheriff's/coroner's offices in three northern California counties. These cases span the 1970s to present and include all cases where the PMI exceeded two hours. Variables related to river dynamics include: season; water and air temperature; water discharge rate; depth; and bed load. Transport rates of human remains were estimated using recorded average United States Geological Survey (USGS) water discharge rate records between the nearest river mile data collection station to each victim's point of entry and exit.

Together, variables from these two categories have demonstrated a relationship with transport rates of human remains within this fluvial system. Analysis of the current data indicates that the majority of victims are found within several hours to several days of entering the river, and they are usually found within two miles of the location of entry. Under these circumstances, water discharge rates do not factor significantly in the fluvial transport of human remains; however, for PMIs longer than several days, hydrological factors can significantly influence transport. In these cases, transport distances are associated with rapid increases in water volume, especially in cases in which dam regulation is used to offset heavy rainfall or snowmelt into the river.

While results indicate that the majority of individuals are more likely to be found in close proximity to where they entered the river, the addition of known death and recovery dates from case files from additional counties along the river, in conjunction with river discharge rates, will permit more precise estimations of transport rates for different sections of the river. This research will help to narrow down search parameters for locating victims.

Taphonomy, Fluvial Transport, Postmortem Interval

H55 Skeletal Trauma in the Tuskulenai Case: A Comparison of State-Sponsored Violence in the Former Soviet Union

Cate E. Bird, MA, 2740 Senate Dr, #3E, Lansing, MI 48912*

After attending this presentation, attendees will gain an understanding of how skeletal trauma varies between executioners in the Tuskulenai case and how state-sponsored violence in the former Soviet Union varied throughout the Stalin regime.

This presentation will impact the forensic science community by providing relative frequencies of skeletal trauma in the Tuskulenai case, which can be used to locate People's Commissariat for Internal Affairs (NKVD) violence within a global framework of state-sponsored violence. This project also demonstrates that state agents may not adhere to state guidelines as closely as historical data suggests.

Following the Second World War, the NKVD represented the Soviet security apparatus responsible for arresting and punishing "enemies of the state." From 1944 until 1947, the NKVD executed 767 prisoners in the Lithuanian Soviet Socialist Republic (L.S.S.R.) and buried their remains in mass graves at the Tuskulenai Estate. Guidelines for prisoner treatment and execution were established by Soviet authorities to be implemented at a local level by state agents, including in the L.S.S.R. In particular, the penal code of the Soviet Union mandated that the only legitimate means of performing executions was by fusillade, or firearms, to the back of the head. This study examined violence committed by state agents, investigating their actual adherence to state guidelines. Specifically, this project analyzes the sex, age, and frequency of skeletal trauma in a sample of prisoners in order to understand how patterns of violence differ between two primary execution squads in the Tuskulenai case. Execution squads include those led by NKVD agent Vasilij Dolgirev (operating from November 1944 until October 1946) and Boris Prikazchikov (operating from November 1946 until April 1947). Based on historical data, no difference in trauma patterns was expected between state agents who implemented violence. This project also attempts to shed light on how state-sponsored violence toward Soviet citizens changed during the 1930s and 1940s. Thus, skeletal trauma in the Tuskulenai case is compared to other instances of Soviet violence, including those at Vinnytsia (Ukraine), Katyn (Russia), and Rainiai (Lithuania). Data is collected with the intent to compare patterns of violence in the Soviet Union with other instances of state-sponsored violence during the twentieth century.

Preliminary analyses in the Tuskulenai case reveal that approximately 95% of prisoners are male, and consist mostly of young adults (45%) or middle adults (38%). Frequencies of skeletal trauma differ between the execution squads. The majority of prisoners executed by Dolgirev's squad exhibit gunshot wounds (91%), followed by blunt force trauma (16%), and undetermined trauma (42%). In contrast, prisoners executed by Prikazchikov's squad demonstrate a lower frequency of gunshot wounds (57%), but a higher frequency of sharp force trauma (1%), blunt force trauma (31%), square defects (31%), and undetermined trauma (60%). When the relative frequencies of trauma are combined for the Tuskulenai samples, preliminary analyses demonstrate that 80% of individuals exhibit gunshot wounds ranging from one to four shots, while blunt force (21%), square defects (11%), sharp force (1%), and undetermined traumata (47%) are also observed. The frequency of gunshot wounds in the Tuskulenai case is lower than that of Vinnytsia (100%) and Katyn (100%), but higher than that of Rainiai (14%).

Thus, while historical data characterize these execution squads as operating uniformly in accordance with state guidelines, skeletal data indicates that executioners may differ in their compliance with state guidelines. Furthermore, comparison of the Tuskulenai case with other instances of atrocity demonstrates the range of variability in state-sponsored violence in the Soviet Union.

State Violence, Executioners, Skeletal Trauma

H56 Our Place in the Sun—Investigations Into the Boot Hill Cemetery at the Florida School for Boys

Erin H. Kimmerle, PhD, Univ of South Florida, Dept of Anthropology, 4202 E Fowler, Soc 107, Tampa, FL 33820; and Richard Estabrook, PhD, E. Christian Wells, PhD, and Antoinette Jackson, PhD, Univ of South Florida, Dept of Anthropology, Tampa, FL 33620*

After attending this presentation, attendees will understand how to use multiple methods of remote sensing, archaeological field methods, archival research, and forensic interviews to locate clandestine burials. Attendees will also learn about methods for reconstructing a historical narrative for humanitarian missions.

This presentation will impact the forensic science community and others by offering research into the lives and deaths of more than 80 children, which have previously not been reported. This research was undertaken as a humanitarian initiative for families searching for missing relatives. The results of the initial phase of this effort are reported here and have the potential to impact future investigations into the school.

In 2011, the Arthur G. Dozier School for Boys (a.k.a., "Florida School for Boys"), located in Marianna, Florida, was closed after more than a 100-year history of controversy regarding abuse, financial scandals, and allegations of murder. The Florida State Reform School first opened in 1900 and is located on 1,400 acres of land. Children were committed to the school for minor offenses such as "incorrigibility" or "truancy" or for serious crimes such as "theft and murder." Originally, the school housed children as young as six years old, including both males and females. Beginning in 1901, reports surfaced of children chained to walls in irons, being brutally whipped, and hired out for labor. During the first thirteen years of operation, there were more than six state-led investigations. Allegations of beatings, rapes, and whippings by more than 300 men, called the "White House Boys," led to a more recent investigation in 2008 – 2009 by the Florida Department of Law Enforcement (FDLE). The FDLE report cites newspaper and archival resources and lists 81 deaths that occurred.

Ledgers found in storage, newspaper reports, and death certificates researched through this project show 86 deaths resulted from 1911 – 1973. Among these, records indicate that 21 individuals were buried in the cemetery (1914 – 1952) and nine entries indicate that the bodies were "shipped" away. Therefore, the final depositions of more than 50 children are still unknown. In 1996, 31 metal crosses were placed within the current boundaries of the Boot Hill Cemetery; however, their locations do not correspond to actual interments.

The purpose of this research was to conduct a pedestrian survey, map the Boot Hill Cemetery, and to research the history of the site to determine the number, location, and identity of graves. Specifically, the initial goals of this project were to: (1) document and map the cemetery; (2) identify graves through multiple forensic and archaeological methods, including remote sensing using ground-penetrating radar; (3) research the site's history, creation, and use based on anthropological methods of field investigation; and, (4) research the identity of those buried in the cemetery and the morbidity and mortality patterns of the decedents.

Through the course of this investigation, the number and location of graves present within the cemetery were determined and the potential presence of multiple burial areas was investigated. Clandestine graves in the wooded areas surrounding the current Boot Hill Cemetery were found as far as 20m from the current site. Moreover, the identity and circumstances surrounding the deaths, based on archival research and forensic interviews, establishes patterns among those who died at the school such as a higher number of African American juveniles, a high number of runaways, and the spread of several infectious disease outbreaks. This presentation will detail the multiple investigative methods used and will provide qualitative results. Further, results from remote sensing followed by archaeological trenching and soil chemical analysis, which clearly demonstrate the presence of burial shafts, will be discussed. Finally, the historical significance of human and civil rights violations in Florida in the area of juvenile justice and the rights of

families to have accountability and transparency are discussed.

Forensic Archaeology, Forensic Interview, Historic Cemetery

H57 The Use of an Alternate Light Source for Detecting Skeletal Material Under Water

Angi M. Christensen, PhD, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135; Kevin J. Horn, JD, FBI Laboratory, Evidence Response Team Unit, 2501 Investigation Pkwy, Quantico, VA; and Victoria A. Smith, MA, ORAU, FBI Lab TEU, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will understand how a submersible Alternate Light Source (ALS) can be used to locate skeletal material underwater.

This presentation will impact the forensic science community by improving the search methods used by forensic divers and increasing the quantity and efficiency of evidence recovered.

When searching underwater crime scenes or disaster scenes for human remains, it may be advantageous for forensic divers to be able to detect the presence of skeletal material among other non-skeletal marine materials (such as shells and rocks). In terrestrial environments, this can typically be accomplished by visual and instrumental methods, but underwater conditions make it difficult to employ segregation techniques in these environments. This study investigates fluorescence of skeletal and non-skeletal materials using a submersible ALS and concludes that an ALS can be a useful tool for detecting skeletal remains in underwater searches.

Tests were carried out using a hand-held, integrated-battery light source advertised as submersible to 100 meters and saltwater resistant. Skeletal material examined included human bones, burned human bone, non-human bones (pig, deer, turtle, and fish), and non-human teeth (pig and dog). Other non-skeletal marine material examined included gastropod shells, bivalve shells, echinoderm shells, coral, rocks, and beach glass. The first stage of testing involved an investigation of whether skeletal material (including both bones and teeth) could be differentiated from non-skeletal marine materials using the selected ALS in a terrestrial environment. This phase was performed using ultraviolet and 450nm wavelength settings and filters in red, orange, and yellow. The second testing stage involved deployment of the ALS underwater to examine the ability to differentiate skeletal material underwater, and also to evaluate the practicality of using an ALS system (including light source and filter) underwater. The ALS was deployed in a freshwater lake where the water depth was approximately 15ft, and the device was tested at a depth of approximately 4ft. Test specimens were placed in a mesh bag, and observations were made using a diving mask fitted with a yellow filter.

In terrestrial tests, skeletal material could be easily differentiated from the other materials using the 450nm setting and a yellow filter on the basis of the intensity of fluorescence. Under these conditions, skeletal samples fluoresce yellow to orange, while all other materials failed to fluoresce, appearing dark purple/blue or simply dark. In underwater tests, the device functioned well, proving to be water resistant and effectively projecting light at a distance of up to several feet. Because the test was conducted in the daytime in shallow water, the light was found to be difficult to detect in bright areas near the surface. When the device was used in a dark crevice, however, the skeletal material could be seen to fluoresce. These results suggest that the technique is likely to be most effective at greater depths or during nighttime investigations.

While this technique can distinguish skeletal material from other materials, it does not distinguish human skeletal material from that of other animals that may be encountered in an underwater environment. In cases where bones or teeth are identified by divers using the ALS, the specimens will still need to be brought to the surface to determine their ultimate forensic significance. Nonetheless, the technique may be useful in eliminating the unnecessary collection and transportation of non-skeletal material to the surface. Although examined for its utility underwater, the ability to distinguish skeletal from non-skeletal material in a laboratory environment may also be useful in forensic anthropological segregating exercises.

Further studies aimed at how long skeletal material underwater retains its fluorescent properties would be useful, as would additional tests of the depth and visibility limitations (if any) of the device. It is concluded that the use of ALS under the conditions described may be very useful in forensic diving for detecting the presence of skeletal material in underwater environments.

H58 The Use of Radiocarbon Analysis in a Chilean Human Rights Commingled Case

Claudia E. Garrido-Varas, MSc, 30 Rockliffe Rd, Middlesbrough, TS5 5DN, UNITED KINGDOM; Douglas H. Ubelaker, PhD, Smithsonian Institution, Dept of Anthropology, NMNH - MRC 112, Washington, DC 20560; and Marisol A. Intriago-Leiva, BA, Ave La Paz 1012, Independencia, Santiago, CHILE*

After attending this presentation, attendees will understand potential values of radiocarbon analysis in identifying recovered commingled remains, particularly those that date to within the radiocarbon bomb curve, such as those of human rights interests in Chile.

This presentation will impact the forensic science community by showing how radiocarbon analysis was used to determine the relationship of commingled remains to individuals missing during Chile's military dictatorship.

The period of military dictatorship in Chile between 1973 and 1990 produced 3,227 qualified fatal victims, of which 1,465 were detained and missing; from these, 364 correspond to executed without repatriation of the remains. Detention centers were distributed throughout the country. One of them, located in the north, named "Campamento de Prisioneros Pisagua" (Pisagua Prisoners Camp), was in use from September of 1973 to October of 1974, and it is estimated that it held more than 800 prisoners.

In 1990, as a result of an ongoing investigation, a mass grave situated in the vicinity of the cemetery of Pisagua was exhumed. This mass grave contained the remains of 19 individuals, who were all in a state of natural mummification due to the arid and hot conditions of the local climate. Apart from the 19 individuals, who were promptly identified, a commingled group of human remains were recovered and, at the time of the exhumation, named "Bolsa 20" (sack 20). The archaeologist in charge concluded in his report that these remains were not related to the event of the mass grave and the remains were kept in custody by the Forensic Service of Chile.

Although "Bolsa 20" was reported as being inconsistent with any human rights case being investigated, family members solicited a re-evaluation of the case. Particularly involved with the case was the family of Michel Nash Sáez. He was a 19-year-old conscript who was arrested on September 11,1973, transported to the Campamento de Prisioneros de Pisagua, and executed on the 29th of the same month along with five other persons who were under arrest at the same center. Since three of the six bodies were found in the mass grave exhumed in 1990, the family hoped that Michel Nash might be represented in the remains contained in Bolsa 20.

A historical review of the case, including videos, medicolegal reports, and documentation was performed. Following standard anthropological analysis of the remains, it was decided to use radiocarbon analysis as a first approach and, depending on the results, genetic analysis might be attempted.

Radiocarbon analysis, especially in relation to the modern bomb curve, is particularly useful in the Chilean human rights cases since the events of human rights interest date after 1973. The elevated levels of

^{14}C in the atmosphere produced by atmospheric testing of thermonuclear devices reached a peak in 1963 and then began a gradual decline due to the termination of such testing by the United States, Great Britain, and the former Soviet Union.

A minimal number of individuals of three was established, two of them adults and one subadult. The value of "percent Modern Carbon" (pMC) for individual 1, from soft tissues, was 97.7 ± 0.4; for individual 2, from soft tissues, 73.5 ± 0.3; for individual 2, from bone, 73.3 ± 0.3; and for individual 3, from bone, 64.4 ± 0.3. All of these values fall below those of the modern bomb curve and are inconsistent with those predicted if the individuals involved died in 1973.

The contents of "Bolsa 20" were excluded as belonging to any victim from the period 1973 to 1990. In fact, the remains could be dated using conventional radiocarbon dating as follows: individual 1 – 1840 to 1900 A.D.; individual 2 – 550 to 490 B.C. (from the soft tissue sample), 570 to 510 B.C. (from bone); individual 3 – 1900 to 1980 B.C.

This case constituted the first to use radiocarbon analysis in a human rights case in Chile. Subsequently, this methodology has been used in more than 50 cases.

Radiocarbon Analysis, Missing, Chile

H59 Computerized Reconstruction of Fragmentary Skeletal Remains

Mohamed Mahfouz, PhD, and Emam E. Abdel Fatah, BS, Univ of Tennessee, Dept of Mechanical, Aerospace, and Biomedical Engineering, 307 Perkins Hall, Knoxville, TN 37996; Natalie R. Shirley, PhD, Lincoln Memorial Univ, DeBusk College Osteopathic Medicine, 6965 Cumberland Gap Pkwy, Harrogate, TN 37752; Nicholas P. Herrmann, PhD, Mississippi State Univ, Dept of Anthropology, 206 Cobb Institute, Starkville, MS 39762; and Ali Mustafa, BS, Univ of Tennessee, 206 Perkins Hall, Knoxville, TN 37996*

After attending this presentation, attendees will gain an understanding of the process of fragmentary remains reconstruction using computerized methods and the use of Computed Tomography (CT) and 3D models to sort commingled fragmentary remains.

This presentation will impact the forensic science community by describing the development of a software program to facilitate the determination of the Minimum Number of Individuals (MNI) and make metric assessments of sex, ancestry, and stature from statistically sound bone reconstructions of fragmentary remains. Error rates in the form of a confidence score based on root mean square error will be established for the bone reconstructions, as well as for the computer-automated measurements generated by the software.

Within the medicolegal system, forensic anthropologists perform the essential task of creating a biological profile to aid law enforcement in identifying unknown human remains. The four primary components of the biological profile are age, sex, ancestry, and stature. The parameters of the biological profile are intricately interwoven in that, frequently, one component is necessary in order to make precise determinations about other components. In cases of mass disasters or commingled assemblages, the determination of individual biological profile parameters is complicated by the presence of multiple unassociated elements. The ability to make biological profile assessments using isolated bones or bone fragments is critical. Although developed independently, the 3D approach to the quantification of commingled remains is a logical extension of coding and two-dimensional methods developed in zooarchaeology and bioarchaeology.[1-3] Recent work quantified small fragmented remains into an Osteological Information System (OIS) using Geographic Information System (GIS) software to derive Minimum Number of Elements (MNE) values and MNI estimates.[3] These systems are time consuming and depend on the observer to manually digitize each fragment into the OIS application. The resulting image provides an MNE estimate for the element under investigation. The proposed application provides a system to perform such analyses and to manage complex mass disaster cases or commingled bone assemblages.

In order to enable the computerized reconstruction of fragmentary remains, a new method was developed to match fragmentary remains with 3D template bones for the pelvis, humerus, femur, and cranium. These template bones are average bones generated from a training set with homologous points on the 3D surfaces. In order to generate such homologous points, the 3D models had to be added to a statistical atlas[4] that redistributes the points on the bone surface to ensure correspondence among landmarks.[4] Fragmentary remains are then matched to each template bone using surface descriptors. Outputs of this process are fragmentary pieces that are registered together in space. The next step involves reconstruction of a full bone by interpolating missing data between registered pieces. This step is enabled by optimizing the principal components calculated from the training set. In order to develop and test the system, a highly fragmentary commingled sample was used as a proxy for a mass disaster: the Morton Shell Mound osteological collection. The Morton sample represents over 25,000 human bone fragments from approximately 125 individuals. At the time of submission, ninety catalog numbers containing 15,133 human bone fragments were sorted by element, of which 1,054 fragments have been CT scanned and isolated for analysis.

Upon completion of this study and finalization of the software, all scanned skeletal remains from each scene will be reviewable within the application. An estimate of MNE of the scanned material will be provided following osteological protocols developed in forensic anthropology and bioarchaeology.[3] MNE estimates will allow for the determination of MNI. Finally, the application calculates a combination of traditional anthropological measurements and frequently used biomedical measurements. The traditional measurements can be used in a program such as FORDISC 3.0 or manually entered into equations used for the metric assessment of the biological profile.

Fragmentary Remains, Commingled Remains, Computer Modeling

H60 Spatial Analysis and Modeling of Missing Persons Burial Locations in Multiple Armed Conflict Contexts

Derek Congram, PhD, JPAC-CIL, 310 Worchester Ave, Joint Base Pearl Harbor-Hickam, HI 96853-5530; Arthur G. Green, MA, Okanagan College, Geography and Earth & Environmental Science, 1000 KLO Rd, Kelowna, BC V1Y 4X8, CANADA; and Hugh H. Tuller, MA, JPAC-CIL, 310 Worchester Ave, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation attendees will be familiar with a new application of geographic analysis to search for missing persons who have been killed during armed conflict and are presumed to be buried in unmarked graves. Attendees will gain an understanding of the geographic trends of burial locations—despite varying contextual circumstances—that can assist the search for missing persons, which is often directed by forensic anthropologists. Attendees will also gain an appreciation for geographic information science tools, which have

seldom been exploited by forensic anthropologists. Such techniques are of increasing importance as the field of forensic anthropology becomes more standardized, particularly with respect to the use of archaeological methods.

This presentation will impact the forensic community by introducing innovative techniques available to those who are tasked with locating missing persons in armed conflict contexts. A thorough understanding of how to use geographic information science approaches and software packages for forensic research can provide interesting insights into the spatial behavior of killers, reduce field costs for contemporary operations, and help locate older burial sites in locations where witnesses are not forthcoming or several years have passed since burial. The location of remains is the first critical step in identifying remains for the purposes of death investigation and repatriation.

Only in recent years have forensic anthropologists adopted geographic methods to address problems often confronted in forensic anthropological research and casework, such as burial prospection or spatial distribution of surface remains.[1-3] This study builds upon and expands previous research on clandestine burial location analysis from the Spanish Civil War.[4] The study's hypothesis posits that limited resources in times of armed conflict and rational human behavior result in cross-context patterns of victim burial location. The material being presented is a subsample of a study of burials in seven countries/conflicts. This presentation includes analysis of burial site characteristics of three conflicts (Spanish Civil War 1936 – 1939; Bosnia-Herzegovina 1992 – 1995; and Korean War 1950 – 1953) and examines burial locations of both combatants and non-combatants. The study sample includes 155 burial site locations and uses geographic information software and methods including kriging, viewshed analysis, and Ripley's k-function cluster analysis. These methods are used to ascertain the geographic characteristics of burial locations (e.g., land use, distances from roads and populated areas, visibility of burial location, distances traveled between site of disappearance/death/burial), demonstrating the types of locations chosen for burial. In this study, preliminary results show strong inter- and intra-context consistency given certain contextual variables. This study also indicates that there is a general evolution of burial site selection from less clandestine (e.g., cemetery burials) to more clandestine (e.g., very rural or mountainous terrain) locations that is dependent upon prevailing socio-political factors, and the course of a particular armed conflict. Changing burial activities include the postmortem movement of bodies from primary to secondary locations. Secondary burial locations, however, are highly dependent upon motives for body relocation. Being able to ascertain such motives informs greatly upon geographic location characteristics that should be sought when searching for missing persons' remains.

Burial Prospection, Missing Persons, Spatial Analysis

H61 Sampling Procedure for the Histological Analysis of Pediatric Skeletal Trauma

Christian Crowder, PhD, OCME, 520 1st Ave, New York, NY 10016*

After attending this presentation, attendees will appreciate the use of hard tissue histology in evaluating pediatric trauma and be introduced to a skeletal sampling procedure that forensic anthropologists should consider when using bone histology to examine pediatric remains.

This presentation will impact the forensic science community by demonstrating the growing role of anthropology in the recognition and interpretation of pediatric fractures and the importance of skeletal sampling procedures to maximize evidence obtained during the skeletal survey.

The evaluation of fractures in children is vital for interpreting an injury as non-accidental and in determining if a history of injury exists. Thus, complete documentation of pediatric skeletal injury is paramount in diagnosing abuse.[1] The common anthropological approach to skeletal analysis is to remove the soft tissue and other organic components using a maceration procedure, leaving dry bone for analysis. Love and Sanchez discussed an approach to grossly examine the pediatric skeleton that requires the meticulous reflection of soft tissues at autopsy to expose the osseous and chondral tissues.[1] In addition to this approach, sampling fracture sites or potential fracture sites for histological analysis may identify fractures not seen during the gross examination or provide useful information as to the mechanism and/or timing of the injury that would be otherwise lost due to the maceration procedure. Furthermore, the typical anthropological assessment of fracture healing relies upon the observation of gross bony changes, which will appear secondary to histological changes.

Owing to the difficulty in evaluating pediatric skeletal trauma, a sampling technique was developed to remove specific fractures or segments of fractures for histological analysis as a part of the anthropological exam. The first step is performing a radiological and gross skeletal survey to determine if histological analysis would be beneficial and, if so, select the sampling area(s). The following criteria assist with the sample selection: Sampling is considered for (1) fractures with no gross evidence of healing; (2) fractures that demonstrate differential healing; (3) areas overlying hemorrhage with no apparent bone injury; and, (4) bones suspected of injury that contain chondro-osseous junctions.

Following the gross evaluation and documentation of a selected sampling site, the sample is removed for histological preparation. A small rotary tool with a cut-off wheel is used to remove a segment of the fractured bone. For example, a segment of a skull fracture is removed by cutting a window out of the fracture. An alternate method is to remove the bone in its entirety. Following specimen removal, the tissue is fixed in a 10% formalin solution for 24 hours and submitted to the Histology Laboratory within the Medical Examiner's Office for decalcification. Depending on the specimen, decalcification may take 1 – 3 days.

Once decalcified, the sample can be trimmed using a microtome blade or scalpel in order to fit the sample into a histological cassette for embedding. It is important to leave a portion of "normal" or non-traumatic bone on either side of the fracture so one can examine the lamellar bone leading to the fracture margins or callus, if present. The sample is then placed into the histological cassette and positioned for the desired histological section (e.g., cross section or longitudinal section). The samples are embedded into paraffin blocks and slides are prepared following standard histological procedures. A hematoxylin-eosin stain is applied to assist with the identification of histological features (i.e., new bone formation, mineralized callus, cartilaginous tissue, or fibrotic tissue). Finally, the anthropologist reviews the histological slides with the pathologist to evaluate any microscopic findings.

While this technique requires additional time to perform the analysis of pediatric skeletal trauma, it provides further opportunity to describe fractures that may be difficult to identify or fully characterize at the gross and radiological level. In addition, histological analysis may provide for a more accurate determination of the timing of an injury considering that

early reparative response to a bone fracture will not manifest at the gross level until osteoblasts and osteoclasts are given time to respond to the injured tissue. Therefore, the sampling technique described should be considered by anthropologists working with pediatric remains to ensure that skeletal injuries are fully characterized.

H63 Use of Silver Nitrate Stain to Visualize Microanatomical Features in Decalcified Bone Cross-Sections

Deborrah C. Pinto, PhD, 208 Hollyberry Trail, Toronto, ON M2H 2P4, CANADA; Stella Walters, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Eric D. Pace, 1140 Business Center Dr, Suite 370, Houston, TX 77043*

After attending the presentation, the attendees will learn about slide preparation modifications that can be used for visual microanatomical structures on decalcified bone cross-sections.

This presentation will impact the forensic science community by providing a technique for forensic anthropologists to continue their analyses using bone histology without the need for specialized equipment. Additionally, these slides can be prepared within the histology laboratories employed by medicolegal offices.

The use of histological techniques to assess bone is well established in anthropology. It is especially valuable in the applied field of forensic anthropology for the differentiation of human from non-human bone, age estimation, differential diagnosis of bone pathological conditions, and assessment of overall bone health. The standard petrographic technique for producing thin sections typically used by anthropologists involves undecalcified bone samples that are vacuum embedded in molds filled with epoxy resin and hardener. Once hardened, 1mm sections are cut from the embedded sample block using a diamond-blade saw and ground to a thickness of approximately 70µm. Due to the expense of specialized equipment and supplies, the petrographic technique is not generally available at medicolegal offices. The standard bone histological technique used in medicolegal offices to produce thin sections involves cutting decalcified bone into sections approximately 4µm thick using a microtome and staining with hematoxylin and eosin. Unlike petrographic sections, standard histological sections of decalcified bone are too thin for visualization of cement lines, a key feature used by forensic anthropologists to identify osteons and fragments. Previous studies have shown that silver nitrate stains can successfully be used to demarcate cement lines. Since silver nitrate adheres to calcium and darkly stains calcified tissue, the contrasting unmineralized cement lines remain unstained. This study explores the use of silver nitrate-stained decalcified sections in histomorphometric analyses of bone for the purposes of age estimation.

Samples from the anterior third of the sixth rib were collected from unidentified decedents who were exhumed as part of the Harris County Institute of Forensic Sciences Unidentified Decedent Review Project. Sections were prepared using the standard histological procedure where the samples were formalin-fixed and decalcified prior to embedding in paraffin wax. Once set, 8µm slices were sectioned from the paraffin block and placed on a slide. Eight micron sections were selected because they are thick enough to provide sufficient contrast between bone tissue and cement lines without causing the section to lift off the slide, as can happen with thicker decalcified bone sections. The sections were treated using a silver nitrate stain and cover-slipped. Once the slides were prepared, age was estimated for each sample following the Stout and Paine method as well as Cho et al. method using anterior cross-sections of the sixth rib.[1,2] These estimates were compared to the age estimated for the decedent using macroscopic techniques, in particular the sternal rib method and the pubic symphysis method.[3,4]

Histological age estimates derived from the decalcified sections, particularly using the Stout and Paine method, were within or close to the macroscopic age estimates for the decedents in the sample population.[1] The histological point estimate of age obtained for each rib was compared to the phase mean assessed for the pubic symphysis and/or sternal rib methods. Although there were differences in estimates between the microscopic and macroscopic groups, no consistent pattern was observed. The histological point estimate of age either fell within the 95% confidence interval for the macroscopic methods or exceeded the interval, therefore producing an overestimate. Since there is no clear understanding of how histological age estimates derived from petrographic slides compare to the macroscopic techniques, the efficacy of the decalcified method compared to the petrographic method could not be evaluated. However, because the age estimates are relatively close, these findings suggest that the decalcified silver-stained sections are appropriate for use in histological age estimation and the method should be explored further.

A limitation of the method is the use of extremely thin bone sections that have a tendency to fold when mounted on a slide, thus reducing the amount of bone that can be read. Tears and obliteration of the periosteal surface was also noted in some slides.

Bone Histology, Decalcified Bone, Stain

H64 Reconstructing Taphonomical History in Osseous Remains From the Korean War Using Histology

Miranda M. Jans, PhD, JPAC-CIL, and Jennie J. Jin, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will have knowledge of how different taphonomical processes affect the preservation of bone. Additionally, the aim of this presentation is to show how these processes can be identified using bone histology and how this can contribute to reconstruct taphonomic history of bone.

This presentation will impact the forensic science community by contributing to knowledge on taphonomic processes affecting bone microstructure preservation and how this can help reconstruct taphonomic histories of bone.

Taphonomic processes can alter or destroy information available from skeletal remains. Much research has been done to evaluate bone preservation, to identify diagenetic pathways as well as develop methods to screen for sample quality. One of the research methods that can be used to identify type and extent of bone degradation is thin

section histology. The different processes that influence bone preservation leave behind histological features that are preserved through time. This makes it possible to reconstruct taphonomical histories.[1,2] Factors that can be observed using histology are type and extent of microbial alteration, physical damage (cracking), and inclusion or infiltration of exogenous material. The latter can be very informative of the burial environment of the bone; for example, certain minerals only form under specific environmental conditions. Microbial alteration usually occurs relatively soon postmortem and is less dependent on environmental factors but seems to be influenced by deposition/burial methods. Certain types of microbial alteration are indicative for deposition in different (aquatic) environments or can indicate presence of oxygen in the environment (fungi). The presence or absence of bacterial degradation of bone has been linked in archaeological studies to differences in early postmortem treatment of remains.

As taphonomic signatures are preserved through time, information can be gained from their presence or absence. In this study, the taphonomy of remains from the Korean War, which come to the Joint POW/MIA Accounting Command-Central Identification Laboratory (JPAC-CIL) generally from three very different contexts, is characterized. Some of this material was recovered in the Democratic People's Republic of Korea (DPRK). Other samples come from a commingled assemblage of remains that were turned over by the DPRK to the United States government. A third category of samples comes from Korean War remains that have been buried shortly after the war as "unknowns" at the National Memorial Cemetery of the Pacific. Bone samples were examined from these three very different preservation scenarios using histology to identify diagenetic features. The main goal of the study is to characterize the effects of the different postmortem scenarios on bone preservation, and to elucidate the taphonomic history for these samples. Specifically, the effect of secondary burial on bone preservation will be discussed, and how this could be identified through patterns of taphonomic features.

H65 Validation Dental Cementum Increment Analysis for Determining Season at Death

Vicki Wedel, PhD, Western Univ of Health Science, Dept of Anatomy, 309 E 2nd St, Pomona, CA 91766; Shirley Hsieh, MS, College of Dental Medicine, 309 E 2nd, Pomona, CA 91766; and Kenneth P. Hermsen, DDS, Creighton Univ, School of Dentistry, 2500 California Plaza, Omaha, NE 68178*

After attending this presentation, attendees will understand the method of determining season at death using dental cementum increment analysis. Attendees will be able to explain how use of the method helped identify a cold case homicide victim.

This presentation will impact the forensic science community by providing criminalists, anthropologists, and odontologists with one more method to use in gathering evidence from unidentified human remains.

Dental cementum research was once exclusively the domain of zooarchaeologists who used the biology of cementum to determine the ages and seasons at death of mammals at archaeological sites.[1] Dental cementum forms the outermost layer of tooth roots and it binds to the periodontal ligament to hold teeth in their sockets. Cementum is not remodeled like bone, rather it is deposited and mineralized throughout adulthood. In humans, cementum is laid down in pairs of bands: one light or translucent band is laid down in the spring/summer and one dark band is laid down in the winter/fall. The layers of accumulated pairs of bands of cementum are used to determine age at death by adding the number of pairs of bands to the age at which the tooth erupts.

The applications and limitations for estimating age at death in humans using this method has been established previously; however, the use of dental cementum to estimate season of death was only recently evaluated.[2-6] Therefore, a pilot study was devised to test the applicability of using the color of the outermost band of cementum to determine season at death in humans by using 112 teeth donated by the patients of an oral surgeon.

Extracted teeth were embedded, sectioned, ground and polished, and examined under transmitted polarized light microscopy to great results: the color of the outermost cementum increment correlated with the season at death 99% of the time. Teeth extracted between October and April exhibited a dark outer band, thus, a fall/winter season. Teeth extracted between April and October exhibited a light outer band, therefore, a spring/summer season.

To confirm the results of the pilot study, 450 teeth were chosen at random from 1,300 teeth donated by patients of the Creighton University School of Dentistry. In addition to increasing the sample number, the geographic location from where the donated teeth originated differed, too. Creighton University is located in Nebraska, and Omaha has a very different climate than coastal Santa Cruz, California. Of particular curiosity was whether local weather differences would matter. Would the Nebraska teeth sort into the same broad seasons as had been identified in the Santa Cruz pilot study?

Analyses were performed in the blind, and it was not until the teeth had been embedded, sectioned, ground and polished, and data collection completed that the exact dates of extraction were made known to the investigators. Date of extraction was used as a proxy for date of death. Results of the study indicated that climate bore no effect on estimating season at death from dental cementum. The Nebraska sample sorted into the same two broad seasons as the Santa Cruz sample in 440 of the teeth, while 10 of the teeth yielded indeterminate results. Depicted in this paper are tables demonstrating the seasonal bands increasing in thickness from the beginning to the end of the season. Scatter plots form the basis of a discussion as to whether four seasons at death rather than just two are indicated.

Dental cementum increment analysis has now been used to determine season at death in a dozen forensic test cases in California. In one particular case, both age and season at death were determined for a 37-year-old cold case homicide. The remains of a young woman had been recovered in 1971 bearing evidence of sharp force trauma. Her remains went unidentified until 2008 when the remains were exhumed and reanalyzed for identification. Anthropological assessment indicated an age at death of 23 – 30 years based on medial clavicle and iliac crest epiphyseal fusion. Dental cementum increment analysis indicated an age at death of 23 – 25 years and a spring/summer season at death. The revised profile, along with a forensic facial reconstruction by Gloria Nusse, was posted to the Doe Network's web page, and a maternal relative came forward. The victim was 24 when she had gone missing in late August/early September.

Dental Cementum, Season at Death, Validation Study

H66 Does Cut Direction Affect Increment Viewing in Dental Cementum Increment Analysis for Age and Season at Death?

Shirley Hsieh, MS, College of Dental Medicine, 309 E 2nd, Pomona, CA 91766; Vicki Wedel, PhD*, Western Univ of Health Sciences, Dept of Anatomy, 309 E 2nd Street, Pomona, CA 91766; and Kenneth P. Hermsen, DDS*, Creighton Univ, School of Dentistry, 2500 California Plaza, Omaha, NE 68178*

The goal of this presentation is to compare two methodological preparations of dental cementum histological slides of the same specimen side by side to test whether cut direction affects cementum increment in determining season at death.

This presentation will impact the forensic science community by demonstrating how the validity of dental cementum incremental analysis on human teeth needs to be evaluated and expanded to answer which technique is most useful in determining season at death in humans. Of the same specimen, a transverse cut is found to yield readable seasonal information than its longitudinally cut counterpart.

Cementum is the tissue that binds the tooth to the periodontal ligament and is deposited throughout the course of life. Because cementum is variably mineralized, its fundamental structure of collagen fibrils yields a banded appearance to cross-sections of the outer edge of the tooth, analogous to tree rings. In mammals, one pair of cementum bands is laid down annually.[1-3] In the spring/summer, mammals lay down a translucent or clear band while in the fall/winter, they deposit an opaque or dark band. Counting the number of pairs of bands and adding that number to the age at which the tooth erupts yields an age at death estimate that is more accurate than age estimates achieved by most skeletal methods (e.g., epiphyseal union, sacroiliac joint surface appearance, rib end morphology, etc.).[4,5] Pilot work by Wedel demonstrated by observing the outermost increment, season at death could be determined with 99% accuracy.[6] She further demonstrated that the seasonal transition of the outermost cementum band in humans from translucent to opaque occurs in October and then transitions back to translucent in spring/summer, beginning in April.[6] All adult teeth that are erupted and in occlusion do exhibit increments.[6] Hsieh and colleagues demonstrated teeth of any type (cuspids, bicuspids, and molars) can be used in determining age or season at death without significant differences in the results.[7]

Hsieh et al.[7] focused on distinguishing the outermost increment in transverse thin sections of the middle third of the root by using transmitted polarized light microscopy; however, Stein reported a high accuracy (r=0.93) in age estimation using longitudinal cuts instead of transverse cuts.[7,8] Other recent researchers used longitudinal sections, while acknowledging a discrepancy in the sectioning method among cementum researchers.[5,9,10] Some authors prefer the section to be longitudinal, whereas a majority of authors prefer transverse cross sections. Unfortunately, no author explicitly explains his or her preference for transverse versus longitudinal sectioning. Further, none of the researchers compare these two techniques side by side, sectioning one tooth both transversely and longitudinally to see if the results differ.

Therefore, it becomes necessary to test the accuracy of determining season at death based on the color of the outermost cementum band using both transverse and longitudinal cuts from the same specimen in a fairly large sample of teeth of known season at death (or season at extraction, which is the proxy for season at death). It is hypothesized that transverse cuts yield more accurate and reliable results than longitudinal sections. This hypothesis will be rejected in either of two circumstances: (1) there is no statistical difference between the longitudinal versus transverse section results; or, (2) if either the season at death from each tooth does not match the season from when it was actually collected from the patient. In other words, the research will only be considered helpful if a fall/winter band is recorded from a tooth collected in the fall/winter.

Fifty-five transversely-sectioned single-rooted teeth were randomly selected and then sectioned longitudinally. Season at death was accurately determined in all of the transversely sectioned teeth, whereas season at death was only correctly determined in 56% of the longitudinally sectioned cases. Further, the sample of 55 longitudinal cuts contained six indeterminate samples (~10% of cases) in which the outermost increment could not be observed at all.

Of these 55 transversely and longitudinally cut teeth, the transverse cuts yielded a higher number of correctly classified samples and fewer indeterminate samples than the longitudinal sections. The longitudinal cuts yielded a significantly higher number of indeterminate samples and, thus, fewer samples were correctly identified as to season at death. Qualitatively, the transverse cuts were easier to read than the longitudinal cuts. In other words, a transverse cut is more likely to yield readable seasonal information than a longitudinal cut from the same specimen. Therefore, a transverse cut is preferred for its better preservation of information and a better chance to result in a valid sample for the use of anthropologists.

H67 Using Tooth Cementum Annulation for Age Estimation in Forensic Casework

Lauren Zephro, PhD, Santa Cruz Sheriff's Office, 701 Ocean St, Rm 340, Santa Cruz, CA 95060*

After attending this presentation, attendees will understand the basic premises behind age estimation using Tooth Cementum Annulations (TCA) and the current theoretical and methodological issues relevant to its application in forensic practice. The role of TCA, as an age estimator, in the analysis of two forensic skeletal cases will be discussed, including the methods used, documentation procedures, and analytical results.

This presentation will impact the forensic community by outlining the practical use of TCA in casework and make recommendations as to when it is appropriate to use as an age estimator. Further discussion as to how the results of TCA analysis should be conveyed to law enforcement is also suggested, using the case studies as examples.

Cementum is a dental hard tissue that anchors the teeth into their sockets via the periodontal ligament. Once a tooth has erupted, two bands of cementum are laid down per year of life, although the

phenomenon has been observed in unerupted teeth as well. Under magnification with transmitted light, the bands alternate light and dark in color, with each pair of bands representing one year.

The phenomenon of cementum increments is well documented in some non-human populations and does appear to show sensitivity to life history variables like birth, trauma, and nutrition. Although why cementum increments are initiated into production and their apparent circadian rhythm remains somewhat speculative, especially in humans, cementum annulation has been proposed as a forensic aging method. There are many fundamental questions that are as yet unanswered or theoretical in nature, but cementum annulation is observable and does correlate with age at least as well as other traditional aging methods, making it attractive as another tool in the forensic anthropologist's toolkit.

Case 1 represents a completely skeletonized cranium, mandible, atlas, axis, and hyoid (body only) discovered in a partially decomposed duffel bag with a closed zipper. Based on dental eruption, cranial sutures, and general condition of the limited bones recovered, age was estimated to be "adult," approximately 25 to 50 years old at the time of death. Case 2 represents a partially skeletonized female with extensive blunt force trauma to the cranium. The skeleton, originally discovered and analyzed in the early 1990s, was estimated to represent a female of European ancestry, aged 18 to 24 years. During re-evaluation of the case in 2009 for additional leads and the potential for new forensic techniques, it was discovered that the postcranial skeleton, including the mandible, had been cremated; however, the cranium was still in evidence. In each case, a tooth was analyzed for TCA.

The contribution of TCA to each of the cases was very different. In Case 1, TCA as a 'traditional' age indicator, was employed. Given the lack of other specific age indicators, TCA contributed to a narrowing of the original age estimate, from 25 to 50 years to 30 to 40 years old at the time of death.

Case 2 involved a much different role for TCA. Only 2.5 pairs of bands were observed on the tooth. When added to the average age of eruption for the tooth, a much younger age at death than was originally reported was indicated. Taking a holistic approach and integrating all age indicators available, a re-evaluation of the first skeletal analysis was prompted. Although the postcranial skeleton was cremated, excellent documentation and photographs were available so that the raw data on which the first biological profile was based was sufficient to use. During the second analysis, more inclusive, updated standards were employed, as well as a critical approach to the methods used in the first analysis. Ultimately, TCA contributed mostly to prompt an updated look at the case and appraisal of the skeletal indicators, which suggested an age between 14 and 18 years at death.

These cases illustrate the potential use of TCA; however, a realistic appraisal of TCA and the assumptions on which is it is based, both proven and unproven, need to be explicitly addressed before TCA is widely used in a forensic setting and to direct future research.

Cementum Annulation, Anthropology, Age-at-Death

H68 Femoral Midshaft Histomorphometric Patterning: Improving Microscopic Age-at-Death Estimates From Adult Human Skeletal Remains

Megan E. Ingvoldstad, MA, Ohio State Univ, 4034 Smith Laboratory, 174 W 18th Ave, Columbus, OH 43210*

After attending this presentation, attendees will understand how the use of microscopic techniques to estimate adult age at death is well established within physical anthropology's subfields of bioarchaeology and forensic anthropology, but diligent work is needed to overcome the long-standing problems of the Osteon Population Density (OPD) asymptote and relatively high Standard Error of the Estimate (SEE).

This presentation will impact the forensic science community by suggesting how the posterior Region Of Interest (ROI) can be utilized for production of the most accurate microscopic age-at-death estimates from adult human skeletal remains, and thus, for better understanding of the adaptive success of past populations by bioarchaeologists, and for more positive identifications by forensic anthropologists.

Review of the microscopic age-at-death estimation literature reveals that arbitrarily changing skeletal elements, histological variables, sample demographics, and sampling locations have not allowed for accurate age estimation of individuals over approximately 50 years or reduced the standard error of age estimates. This investigation, therefore, began with substantiated theory. All healthy, mobile femurs have in common: genetic programming to establish initial size and shape; the developmental processes of endochondral ossification, appositional growth, and modeling; biomechanical adaptation; periosteal adaptation; cortical thinning and shape change during aging; mechanosensation and mechanotransduction; and bone remodeling.

Building from this theoretical knowledge base, it was first hypothesized that topographical variation in remodeling exists around human femoral midshaft periosteal cortices that reflects the constraints of normal anatomical development, customary biomechanical usage, and standard mechanobiological functioning. Second, it was hypothesized ROIs associated with the I_{min} second moment of area biomechanical axis would exhibit the lowest remodeling as a result of minimal biomechanical loading. Third, it was hypothesized remodeling at biomechanical ROIs would be histomorphometrically more consistent than at anatomical ROIs due to unchanging functionality. These hypotheses were tested by counting remodeling events at eight standardized periosteal ROIs (four anatomical—A (anterior), P (posterior), M (medial), L (lateral) and four biomechanical—I_{maxAnt}, $I_{maxPost}$, I_{minMed}, and I_{minLat}) of 200 adult femoral midshaft cross-sections originally harvested by M.F. Ericksen from George Washington University dissecting room cadavers. The sample was specifically composed of 98 males and 102 females, largely of European descent, ranging in age from 30 to 97 years.

While no evidence was found for reduced remodeling at I_{min} ROIs or for more consistent remodeling at biomechanical ROIs, 14 statistically significant differences were found between ROI OPD medians indicating topographical variation in remodeling exists around the femoral midshaft. Specifically, the lowest OPD values were found to occur at the Anterior ROI, followed by the Posterior, I_{minMed}, $I_{maxPost}$, I_{maxAnt}, I_{minLat}, Medial, and Lateral ROIs. Additionally, although the anterior femoral cortex has traditionally been sampled for microscopic age at death estimation, here, the Anterior ROI was found to reach the OPD asymptote first and was associated with the highest SEE (± 11.542 years). Alternatively, the Posterior ROI was found to be associated with the lowest SEE (± 3.260 years) and second lowest median OPD value, but showed no signs of having reached the OPD asymptote. It therefore bears further investigation to see if this pattern can be replicated across multiple samples. If so, it is suggested the Posterior ROI be utilized for production of the most accurate microscopic age-at-death estimates from adult human skeletal remains, and thus, for better understanding of the adaptive success of past populations by bioarchaeologists, and for more identifications by forensic anthropologists.

Histomorphometrics, Age-at-Death, Regions of Interest

H69 Statistical Considerations of the Histomorphometric Test Protocol for Determination of Human Origin of Skeletal Remains

MariaTeresa A. Tersigni-Tarrant, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853-5530; and John E. Byrd, PhD, 95-033 Hokuiwa St, #51, Mililani, HI 96853-5530*

After attending this presentation, the attendees will have a better understanding of a test protocol using osteon area as the basis for recognizing remains as likely human in origin. They will also receive an exposition of the philosophy underlying the statistics used in the test, and how that philosophy underpins interpretation of test results.

This presentation will impact the forensic community by explaining a new test protocol that is widely applicable and by clarifying the appropriate use of statistics in a forensic test.

Tersigni-Tarrant et al. proposed the use of osteon area as an effective measure for recognizing human bone versus other species.[1,2] It is widely known that humans have exceptionally large osteons on average, and that most species that share similar histological structure have smaller osteons. However, it is also clear that there is variation in individual osteon size within species, within individuals, and even within the same histological section. Any test that will utilize osteon size must have a proper statistical foundation. A test protocol has been developed that provides a significance test as the basis for interpretation of the osteon size. The test protocol requires one to: (1) section the case specimen and prepare a digital image of the section with scale; (2) import the image into the program Image J; (3) randomly select 30 osteons to measure; (4) measure the osteon areas and calculate the arithmetic mean; (5) test the null hypothesis that the remains are human by formal comparison (t-test) of the case specimen mean with the mean and standard error (with N=30) from a reference database consisting of 1,204 osteons from multiple long bones of five known individuals; and, (6) assess the strength of the evidence using Deborah Mayo's concept of severity.[3] A critical component of this protocol is the use of the randomly selected osteons as the basis for the test.

Human reference data has been analyzed and statistically compared to a close living relative, the chimpanzee (*Pan troglodytes*). This comparison is arguably a rigorous way to evaluate the power of the test to exclude non-human bone specimens. This test has also been applied to 37 specimens from 35 different known human individuals. Collectively, these efforts serve as validation of the test protocol. From the reference data (N=1,204 osteons), the mean osteon area was calculated at 37,298.5μm^2, standard deviation at 14.623.7, and noted that the distribution was skewed to the left (non-normal). The chimpanzee data (N=794 osteons from 17 individuals) showed a mean osteon area at 25,324.8μm^2, a standard deviation of 14,346.5, and a distribution skewed to the left. Bootstrapping was used to derive estimates of the means and standard deviations. The original reference data for each species was sampled with replacement 1,000 times, with N=30 each iteration. The mean was calculated for each iteration, which facilitated estimation of the population mean and offered a standard deviation of the estimated means. These values were: human mean at 37,365.3, standard deviation (of means) at 2,727.7; chimpanzee mean at 25,377.6, standard deviation (of means) at 2,692.1. Both sets of means exhibit a normal distribution. The closeness of the bootstrap means to the original estimated means was noted, as was the closeness of the bootstrap standard deviations of the means to the standard errors of the original estimates when basing it on a sample size N=30 (human standard error at 2,669.9; chimpanzee standard error at 2,619.3). Subsequent analyses employ bootstrap estimates since they are slightly more conservative than the original estimated means. The power of the test with the human mean as the null hypothesis and the chimpanzee mean as the alternate is approximately 0.90. The high power suggests that the test will have utility. Severity estimates were utilized to evaluate individual test results. Severity of a test, as defined by Mayo, is based on the probability that the test would reject the null hypothesis if in fact an alternative is true.[3] The more severe the test, the more likely one will reject the null when it is false. High severity justifies greater confidence in the null hypothesis when it is accepted, supporting the interpretation as "human" in many instances.

Hypothesis Test, Statistical Power, Osteon Area

H70 The Use of Bone Histomorphology at the Central Identification Laboratory to Remove Nonhuman Remains From CIL Accessions

John E. Byrd, PhD, 95-033 Hokuiwa St, #51, Mililani, HI 96853-5530; and MariaTeresa A. Tersigni-Tarrant, PhD, JPAC-CIL, Central Identification Laboratory, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853-5530*

After attending this presentation, attendees will understand how histomorphology is used to identify non-human osseous fragments at the Central Identification Laboratory (CIL) at the Joint POW/ MIA Accounting Command (JPAC) and how the techniques used at the CIL could easily be employed into a variety of analytical laboratories that deal with fragmentary osseous material.

This presentation will impact the forensic science community by providing a methodology for the accurate and rapid identification of non-human osseous fragments within any size laboratory.

The CIL has consistently focused on the use of various types of validated methods for the assessment of osseous remains. This includes the use of techniques such as metric analysis, chest radiographic comparison, and various types of DNA testing for the purposes of aiding in identification. Since 2006, the CIL has also incorporated histological analysis for the assessment of possible osseous remains as part of its analytic toolkit.

The CIL has nearly 1,000 accessions that contain biological material housed in its laboratories at any particular time. While turnover is high, the speed at which fragmentary cases are resolved is a bit slower than that of the intact remains. Some of these accessions contain highly fragmentary remains that have been excavated from crash sites. There are many cases, however, that are small fragments of bone with little to no provenience and little to no other loss association information. Histological analysis has helped immensely to cull the non-human/non-osseous materials in these highly fragmentary or information-scarce samples.

The utilization of histological and histomorphometric techniques has significantly reduced the number of non-human osseous remains that are part of accessions at the JPAC-CIL. Since the inception of the Standard Operating Procedure (SOP) for histological analysis, the CIL has been able to efficiently remove non-human remains from an enormous forensic caseload by assessing the histomorphometric features of the often fragmentary remains.

For example, between 2007 and 2012, 112 of 269 samples tested (approximately 42%) were able to be removed from the CIL's active accession lists as they had the characteristic hallmarks of non-human bone. The removal of this large proportion of remains from active accessions using a relatively rapid type of assessment has made a significant impact on the overall number of cases that are able to be resolved as definitively non-human or non-osseous, as well as remove material that has no forensic value for the identification of the individuals the CIL is charged with identifying.

The methodology for standard histologic analysis at the CIL utilizes three steps: embedding, sectioning, and analysis. First, basic epoxy embedding techniques are used to stabilize the fragment for thin sectioning. Next, using a thin-sectioning saw capable of making bone sections approximately 0.8mm thick, the specimen is cut transverse to its longitudinal axis. Finally, the thin section is attached to a glass slide, viewed under a standard light microscope at 50x magnification, and compared to our SOP decision matrix.

The current histomorphology SOP provides analysts with an avenue to efficiently rule out remains as human with a simple histological

analysis. The analyst can nominate fragments of bone for histological analysis in much the same manner as they would nominate specimen for DNA analysis. The remains are then assessed by an analyst competency-certified in histological techniques. The current SOP allows for the following analytical conclusions: Match to Non-human, Inconclusive, or Non-Osseous Identification. A visual decision matrix is associated with each category and specific guidelines regarding what constitutes a match to any of the three categories is provided. The triad of categories ensures that only remains that are deemed to be conclusively non-human or non-osseous are removed from accessions. If any fragment cannot conclusively be deemed non-human or non-osseous, the remains are not removed from accession and are often sent for DNA analysis to include 12S species testing.

This method of identification of non-human and non-osseous remains can easily be incorporated into any size laboratory that deals with fragmentary osseous materials. The equipment necessary for this type of analysis is relatively inexpensive and the methodology for conducting this type of histological testing is not highly complicated.

Physical Anthropology, Histology, Human/Non-Human

H71 Present State and Future Prospects of Forensic Age Estimation in Living Adolescents and Young Adults: Recommendations of the Study Group on Forensic Age Diagnostics

Andreas Schmeling, PhD, Institute of Legal Medicine, Röntgenstr. 23, Münster, 48149, GERMANY; and Gunther Geserick, PhD, Zähringerstr. 34, Berlin, 10707, GERMANY*

After attending this presentation, the attendees will become acquainted with the spectrum of methods recommended by the Study Group on Forensic Age Diagnostics for age estimation in living adolescents and young adults. Moreover, attendees will understand the influence of the ethnicity and socioeconomic status of the individuals to be examined on the systems of characteristics studied, as well as that of diseases affecting growth and development.

This presentation will impact the forensic science community by demonstrating the complexity of forensic age estimations in living individuals. Age estimations performed *lege artis* are of great sociopolitical significance as they reinforce legal certainty.

As a result of increasing cross-border migration movements, recent years have seen a rise in numerous countries in the numbers of immigrants whose birth date is not unequivocally documented. Because of this development, forensic age estimations in living adolescents and young adults have become an integral part of forensic practice. The persons to be examined are foreigners without valid identification documents who appear to have misstated their age, which is of legal significance in criminal, civil, and asylum procedures.

The interdisciplinary Study Group on Forensic Age Diagnostics was founded in the year 2000 in Berlin, Germany. According to the recommendations of this study group, a physical examination, an X-ray examination of the hand, and a dental examination which records dentition status and evaluates an orthopantomogram should be carried out. In cases where skeletal development of the hand is complete, an additional radiological examination of the clavicles should be used.[1]

Besides anthropometric measurements such as height, weight, and constitutional type, the physical examination covers the externally recognizable signs of sexual maturity. The physical examination is of particular significance in excluding potential externally recognizable age-relevant diseases and checking whether the results of the skeletal and dental age determination are consistent with the development of the organism as a whole.

Criteria in evaluating the hand radiograph are the shape and size of the individual bone elements and the state of ossification of the epiphyseal plates.

Of particular relevance in the dental examination are the stages of eruption and mineralization of the third molars.

After skeletal development of the hand is complete, assessment of the state of ossification of the medial clavicular epiphysis plays a decisive role. Reference studies are available both for projection radiography and for computed tomography.

To increase reliability and improve the detection of age-relevant developmental disorders, all the above methods should be used. In this process, each part of the examination should be performed by a specialist with forensic experience.

As a rule, no forensically applicable reference studies are available for the regions of origin of the persons to be examined, giving rise to the question of whether serious developmental differences exist between the different ethnic groups which would preclude application of the relevant age standards to members of ethnic groups other than that of the reference population. Within the relevant age group, ethnicity has no appreciable influence on skeletal maturation. The rate of ossification is primarily dependent upon the socioeconomic status of a population. A comparatively lower socioeconomic status leads to a delay in development and, when standard reference studies are applied, to an underestimation of age. In the case of the eruption and mineralisation of the third molars, it has been determined that Black Africans manifest an accelerated development in comparison to Europeans. By contrast, in the case of Asians, a comparative retardation is to be reported. For this reason, population-specific reference studies must be used in assessing third molar development for the purposes of age estimation practice.

In the future, it is to be expected that radiation-free imaging techniques will increasingly be used for assessing skeletal maturation and tooth development. First ultrasound studies have been undertaken on ossification of the radius, pelvis, and clavicle. Furthermore, MRI studies on ossification of the radius, knee, and clavicle have been published. Most of these studies do not fulfill the requirements of forensically usable reference studies. There is a need for further research in this area.

Age Estimation, Living Individuals, Ethnicity

H72 A Bayesian Approach to Multifactorial Age-at-Death Estimation: A Validation Study

Natalie Uhl, MS, 308 N Orchard St, Apt 7, Urbana, IL 61801; and Christopher W. Rainwater, MS, OCME, 520 1st Ave, New York, NY 10016*

After attending this presentation, attendees will be able to assess the efficacy of a Bayesian multifactorial age-at-death estimation method. The goal of this presentation is to inform attendees about the performance of a Bayesian multifactorial approach to age-at-death estimation.

This presentation will impact the forensic science community by presenting a validation study of a statistically sound yet simple way to combine multiple estimates of age-at-death.

Accurate age-at-death estimation is often crucial to successful identification of unknown skeletal remains in a forensic setting. Garvin and Passalacqua showed that forensic anthropologists have a preference for age-at-death methods based on the pubic symphyses, sternal ends of the fourth ribs, and auricular surfaces, but that there is little consensus when combining estimates from multiple methods.[1] Practitioners often use their experience to combine methods and many previous techniques for multifactorial age estimation use linear combinations or simple averages of the separate age estimates and have little utility or statistical validity.

This research contributes to the validation of a Bayesian multifactorial approach first presented at the 2011 American Academy of Forensic Sciences Annual Scientific Meeting. Uhl *et al*. designed “look-

up tables" for easy use by forensic anthropologists for combining age-at-death estimates from different skeletal elements, including the pubic symphysis, auricular surface, and sternal rib ends.[2] This validation study tests the efficacy of this approach in identified cases analyzed by anthropologists at the New York City Office of Chief Medical Examiner Office. Review of case files provided data (Suchey-Brooks phases, İşcan sternal rib end phases, and Lovejoy auricular surface phases) to generate age estimates from the look-up tables. Those age estimates were compared with the actual age of the decedents for accuracy and precision.

Case files for 78 positively identified cases from the New York City Office of Chief Medical Examiner provided phase scores for pubic symphyses, sternal ends of the fourth ribs, and the auricular surfaces, as available. These scores were recorded upon initial anthropological assessment and only later were the individuals positively identified. Look-up tables first presented by Uhl *et al*. and published in Uhl provide mean log ages for each phase.[2,3] To combine the estimates, the precisions (the inverse of the mean age variance) for each indicator were summed. The inverse of the summed precisions is the within-indicator variance. The between-indicator variance is the variance of the mean log ages for the indicators, and the total variance is the sum of the within- and between-indicator variance. The standard deviation is the square root of the total variance; to obtain a 95% Confidence Interval (CI) for normally distributed data, multiply the standard deviation by 1.96 (a standard scaling variable for how wide a curve will be when normally distributed) and add and subtract that from the overall mean log age. Narrower confidence intervals were also constructed (90%, 75%, and 50%). The final step is to exponentiate (convert from log numbers to regular numbers) the endpoints of the interval and the mean log age to convert it from log years to actual years.

Overall accuracy of the point estimates is 6.45 years, while the overall precision is -4.62 years. Coverage (the percent of individuals falling within the confidence intervals) is very good. The 95% CI contained 77 of 78 individuals (99%), the 90% CI contained 75 of 78 individuals (96%), the 75% CI contained 71 of 78 individuals (91%), and the 50% CI contained 57 of 78 individuals (73%).

This Bayesian method of combining age estimates is advantageous for forensic anthropologists for many reasons. First, it is easy to use because the scoring methods are familiar. The look-up tables simplify the process of combining estimates from different age indicators, even if they are disparate. Second, it is a statistically sound means for combining separate age estimates—a method that could be demonstrated in case reports and testimony. Finally, the results of this validation indicate this method provides relatively accurate and precise age estimates. All analyses were done in R, a free statistical software program, so anthropologists can construct more population specific look-up tables for their own purposes.

H73 Testing the Accuracy of North American Growth Standards to Estimate Age-at-Death in Modern South African Subadults

Kyra E. Stull, MS, Private Bag x323, Pretoria, South Africa 0084, SOUTH AFRICA; Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; and Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensics, Anthropology, 501 East 38th St, Erie, PA 16546*

After attending this presentation, attendees will have knowledge of population variation in subadult growth. Long bone lengths of modern South African children are compared to North American children as a means to address validity and reliability of current methods.

This presentation will impact the forensic science community by demonstrating a need for population-specific age-at-death estimation methods from long bone lengths and the need for appropriate predictive statistical models.

The longitudinal growth study of Maresh has been adopted into anthropological literature and has been influential in estimating age-at-death from long bone lengths of modern subadults.[1] While this data has been reprinted in several research texts, the original purpose was to evaluate normal growth, not to estimate age. Though accuracy is low when used to evaluate age-at-death of modern North Americans, the accuracy of the data to estimate age-at-death is not known when applied to geographically distinct groups from North America.[2] The purpose of this study is to compare the maximum and relative diaphyseal lengths of Maresh charts to modern South African groups as a means to explore the applicability of the Maresh charts and to advocate for population-specific research.[1]

Maximum diaphyseal lengths of six long bones were recorded on 640 South African children (male and female) between birth and twelve years of age. A 21st-century sample was obtained from Lodox Statscan images from the Forensic Pathology Services in Salt River and the Red Cross War Memorial Children's Hospital in Cape Town, South Africa (n=600).[3] The 20th-century sample, which is temporally similar to Maresh, was acquired from the Raymond A. Dart Human Skeletal Collection (n=40).[1] A separate study validated the radiographic measurements were similar to dry bone measurements.[4]

Percent correct was done for both the 20th- and 21st-century South African data in order to gauge the accuracy of Maresh (1970). Results were higher for the Dart sample, with 41% correct while the 21st-century sample demonstrated 22% correct classification. The mean and relative long bone lengths of the Maresh (1970) and Lodox samples were sorted by age and bone and were compared using Student's t-tests. Using the mean values of each age group, statistically significant differences were demonstrated ($p < 0.05$) for most ages above seven years and for all long bones, except the radius. Mean differences between North Americans and South Africans revealed differences in growth. At birth, South Africans are larger than North Americans for all bones. A transition in size between groups was noted from three to seven years. At 12 years of age, South Africans were significantly smaller than North Americans for all bones. No statistically significant differences ($p>0.05$) were noted in relative long bone lengths. Similar results to mean maximum lengths were obtained when mean relative lengths were explored through graphical parameters. The mean relative lengths of all bones for the South African sample are larger than North Americans at birth, only to lag between four and nine years. By 10 years, the relative lengths begin to increase and by age 12 the proportions are similar to North Americans.

The South African and North American samples are of different socioeconomic status and genetic background, both of which contribute to differential growth. Mean adult stature in South Africans is smaller than the mean adult stature of North Americans in the 1970s. This difference in size mimics differences found in long bone lengths seen in the current study at age 12 years.

The problems with data used to estimate age-at-death are highlighted when applied to South African subadults. Due to a lack of modern skeletal material and a void of appropriate predictive methods,

validation of current subadult age-at-death techniques is difficult. Full-body Lodox Statscan images are an invaluable tool for addressing the dearth of subadult skeletal material. Data is continually being collected with the goal of developing population-specific age-at-death tables for South Africans.

Long Bone Lengths, Relative Lengths, Radiographs

H74 Error and Uncertainty of Adult Age Estimation of the Pubic Symphysis in an Australian Sub-Population Using Computed Tomography

Nicolene Lottering, BS, Queensland Univ of Technology, Lvl 5, Q Block, School of Biomedical Sciences, Faculty of Health, 2 George Street Gardens Point, Brisbane, Queensland 4001, AUSTRALIA; Donna M. MacGregor, MSc, Queesland Univ of Technology, School of Biomedical Sciences, Faculty of Health, Brisbane, Queensland 4001, AUSTRALIA; Matthew Meredith, BS, PO Box 594, Archerfield, Queensland 4108, AUSTRALIA; and Laura S. Gregory, PhD, Queensland Univ of Technology, School of Biomedical Sciences, Gardens Point Campus, Brisbane, Queensland 4001, AUSTRALIA*

After attending this presentation, attendees will gain awareness of: (1) the error and uncertainty associated with the application of the Suchey-Brooks (S-B) method of age estimation of the pubic symphysis to a contemporary Australian population; (2) the implications of sexual dimorphism and bilateral asymmetry of the pubic symphysis through preliminary geometric morphometric assessment; and, (3) the value of Three-Dimensional (3D) autopsy data acquisition for creating forensic anthropological standards.

This presentation will impact the forensic science community by demonstrating that, in the absence of demographically sound skeletal collections, postmortem autopsy data provides an exciting platform for the construction of large contemporary "virtual osteological libraries" for which forensic anthropological research can be conducted on Australian individuals. More specifically, this study assesses the applicability and accuracy of the S-B method to a contemporary adult population in Queensland, Australia, and, using a geometric morphometric approach, provides an insight to the age-related degeneration of the pubic symphysis.

Despite the prominent use of the S-B (1990) method of age estimation in forensic anthropological practice, it is subject to intrinsic limitations, with reports of differential inter-population error rates between geographical locations.[1-4] Australian forensic anthropology is constrained by a paucity of population specific standards due to a lack of repositories of documented skeletons. Consequently, in Australian casework proceedings, standards constructed from predominately American reference samples are applied to establish a biological profile. In the global era of terrorism and natural disasters, more specific population standards are required to improve the efficiency of medicolegal death investigation in Queensland.

The sample comprises Multi-Slice Computed Tomography (MSCT) scans of the pubic symphysis (slice thickness: 0.5mm, overlap: 0.1mm) on 195 individuals of Caucasian ethnicity aged 15 – 70 years. Volume rendering reconstruction of the symphyseal surface was conducted in Amira® (v.4.1) and quantitative analyses in Rapidform® XOS. The sample was divided into ten-year age subsets (e.g., 15 – 24) with a final subset of 65 – 70 years. Error with respect to the method's assigned means were analyzed on the basis of bias (directionality of error), inaccuracy (magnitude of error), and percentage correct classification of left and right symphyseal surfaces. Morphometric variables including surface area, circumference, maximum height and width of the symphyseal surface, and micro-architectural assessment of cortical and trabecular bone composition were quantified using novel automated engineering software capabilities.

The results of this study demonstrated correct age classification utilizing the mean and standard deviations of each phase of the S-B method of 80.02% and 86.18% in Australian males and females, respectively. Application of the S-B method resulted in positive biases and mean inaccuracies of 7.24 (±6.56) years for individuals less than 55 years of age, compared to negative biases and mean inaccuracies of 5.89 (±3.90) years for individuals greater than 55 years of age. Statistically significant differences between chronological and S-B mean age were demonstrated in 83.33% and 50% of the six age subsets in males and females, respectively. Asymmetry of the pubic symphysis was a frequent phenomenon with 53.33% of the Queensland population exhibiting statistically significant (χ^2-$p<0.01$) differential phase classification of left and right surfaces of the same individual. Directionality was found in bilateral asymmetry, with the right symphyseal faces being slightly older on average and providing more accurate estimates using the S-B method.[5] Morphometric analysis verified these findings, with the left surface exhibiting significantly greater circumference and surface area than the right ($p<0.05$). Morphometric analysis demonstrated an increase in maximum height and width of the surface with age, with most significant changes ($p<0.05$) occurring between the 25 – 34 and 55 – 64 year age subsets. These differences may be attributed to hormonal components linked to menopause in females and a reduction in testosterone in males. Micro-architectural analysis demonstrated degradation of cortical composition with age, with differential bone resorption between the medial, ventral, and dorsal surfaces of the pubic symphysis.

This study recommends that the S-B method be applied with caution in medicolegal death investigations of unknown skeletal remains in Queensland. Age estimation will always be accompanied by error; therefore, this study demonstrates the potential for quantitative morphometric modeling of age-related changes of the pubic symphysis as a tool for methodological refinement, providing a rigorous and robust assessment to remove the subjectivity associated with current pelvic aging methods.

Age Estimation, Pubic Symphysis, Australia

H75 Suchey-Brooks Method Applied to 3D Symphysis: A Comparative Study on a Sample of 193 Real Pubic Bones and Their Virtual Copies

Deshpriya N. Dhuny, MD, 35 Rue Sainte Catherine, Nancy, 54000, FRANCE*

After attending this presentation, attendees will learn how the Suchey-Brooks method of Age-At-Death (AAD) estimation can be applied to virtual bones and if virtual anthropology is reliable enough to replace traditional methods.

This presentation will impact the forensic science community by showing how classical anthropological AAD techniques can be used for analysis of virtual pubic symphysis, what are its scopes for the future, and how it can be improved to produce optimal results.

Virtual anthropology has been greatly developed by numerous teams in the past few years. Excellent agreement has been shown between the results of bone sample analysis and those of Three-Dimensional (3D) image analysis. The goal of this study was to show whether 3D reconstructions of pubic symphyses could render accurate AAD estimations by applying the Suchey-Brooks technique, in comparison to the original dry bones. A secondary objective was to test the inter-observer error between the results obtained by an experienced observer and a novice.

The study was carried out on a series of 193 dry pubic symphysis of known age and sex at death, obtained from the anthropological collection of Montpellier (Pr Baccino). Two observers, an experienced and a novice physician in forensic medicine, performed AAD estimation using the Suchey-Brooks method. The real ages of the bone samples were not known to either of the two observers prior to the test. Each observer first analyzed the series of real bones and their virtual copies afterward. The dry bones were each scanned separately on a large detector CT using high-resolution and standard mode. Helical acquisitions were obtained with 64 rows and the slice thickness was 0.5mm for acquisition and 1mm for reconstruction. Volume Rendering Technique (VRT) reconstructions were performed for each sample in order to obtain 3D images for every bone. For each observer, comparative tests were done between the AAD estimates of dry bones and the AAD estimates of 3D bones. Consecutively, inter-observer comparisons were performed. The Kappa reproducibility test was used for calculation of intra-observer and inter-observer agreement.

This study was performed on a population of 193 dry pubic symphysis (52 female and 141 male) from which 185 virtual bones (50 female and 135 male) were produced after CT. The loss of eight virtual bones was due to human error.

The study shows poor inter-observer reproducibility for the dry bones (Kappa=0.26) as well as for the scanned bones (Kappa=0.35). The intra-observer (dry bones versus scanned bones) Kappa coefficients are of 0.28 for the novice (poor reproducibility) and 0.44 for the experienced observer (moderate reproducibility). This suggests that the Suchey-Brooks method is better applied by a more experienced observer. The mean difference between real age and estimated age for each of the 193 dry bones varies between -0.4 years and +3.4 years, whereas for virtual bones, the mean difference on the 185 subjects was between +1.66 years and +2.76 years.

The poor inter-observer reproducibility could be explained by the different levels of experience of the two readers. Indeed, there is moderate intra-observer reproducibility with the more experienced physician, whereas, this value is poor with the novice. It is also observed that the mean difference between real bone ages and estimated bone ages is not greater than 3.4 years. This shows that the age estimations are highly reliable not only with dry bones, but also with virtual bones.

The application of CT to virtual anthropology is promising for the future. CT parameters need to be clearly defined and improved to obtain better reconstructions. In the study, the parameters were thoroughly tested so as to produce the most optimal visual results using VRT. The 3D reconstructions were of very high quality, but they can probably be refined. It should be kept in mind, however, that no matter how good the quality of a 3D image is, it remains virtual and, therefore, different from a real dry bone or a cast. It would be interesting to redefine the existing anthropological AAD techniques in order to make them applicable to virtual bones.

Suchey-Brooks, Virtual Anthropology, Pubic Symphysis

H76 Investigating Macroscopic Changes of the Pubic Symphysis at the Young End of the Age Spectrum

Natalie R. Shirley, PhD, Lincoln Memorial Univ, DeBusk College Osteopathic Medicine, 6965 Cumberland Gap Pkwy, Harrogate, TN 37752; and Beatrix Dudzik, MA, 3909 Briargate Ave, Knoxville, TN 37919*

After attending this presentation, attendees will have been provided with an introduction to an aging method using the pubic symphysis that provides more precise estimates than are currently assigned to individuals under the age of 40 years.

This presentation will impact the forensic science community by systematically documenting age-related changes that occur at the pubic symphysis within the first two decades after sexual maturity and by providing a method with more accurate and precise age estimates for individuals at the younger end of the age spectrum.

Among the standards employed for age estimation in forensic contexts, the Suchey-Brooks pubic symphysis method is a highly favored technique.[1,2] Difficulties arise, however, when researchers are forced to assign phase-based ages to complex patterns of growth and development *and* degenerative changes associated with biomechanical loading, both of which can be highly variable among individuals and across populations. In regard to the pubic symphysis, it has been documented that minute morphological transitions occur along the ventral and dorsal borders and at the superior and inferior aspects of the face and pubic tubercle.[1,3-7] Current pubic symphyseal aging methods combine the morphology associated with the developmental changes that occur into the mid-30s with the degenerative changes that span the latter portion of the age spectrum. The most popular methods are phase-based; however, the definitions currently used to assign age intervals may not be adequately defined and/or accurately understood by burgeoning researchers and seasoned practitioners alike. Furthermore, phase-based systems assume that these complex changes occur in lock-step, which may not accurately reflect biological reality.

This study investigated macroscopic changes in forensically relevant modern U.S. samples of known age, sex, and ancestry from the Maricopa County Forensic Science Center in Phoenix, Arizona, as well as donated individuals from the William M. Bass Forensic and Donated Collections at the University of Tennessee, Knoxville (n=210). As disparities have been noted in the Hispanic population with pubic symphyseal aging, the present sample is comprised of American Black and White individuals only.[8] Age-related traits at locations with ontogenetic and biomechanical relevance were broken into components and scored. The components included the pubic tubercle, the superior apex of the face, the ventral and dorsal demifaces, and the ventral and dorsal symphyseal margins. Males and females were scored and analyzed separately (n=141 and n=69, respectively). A range of two to three categorical values were assigned based on the changes observed within each component. Scores for each category ranged from presence/absence to a three-step categorical option, thus allowing for simplistic and unambiguous scoring. Transition analysis was applied to elucidate the transition ages between the morphological states of each component. The categorical scores and transition analysis ages were subjected to multinomial logistic regression to derive estimates with high classification accuracy. In addition, inter-observer error was assessed on 100 pubic symphyses using a kappa statistic.

The transition ages for the categorical states generally agree with the documented literature.[7] There were significant sex differences (α=.05) in the ages at transition for all categorical traits except the pubic tubercle, with males transitioning from one state to the next at earlier ages than females (1 – 5 years earlier). Interestingly, this is contrary to the expectation with regard to developmental traits, where females are usually precocious. The categorical output gave smaller age ranges for individuals aged 18 to 40 years, which translated to minimum ranges of three years. The logistic regression provided high classification rates for the age categories, with classification accuracy reaching 93%; the predictive model was significant (p<.001). Inter-rater agreement was high for the pubic tubercle, superior apex, ventral demiface, and ventral rampart (kappa≥0.8), but lower for the dorsal margin (0.6) and dorsal demiface (0.5). The latter will be addressed, with possible revision of the scoring categories and/or definitions.

Based on these preliminary results, it is proposed that an unambiguous scoring method for age-related changes of the pubic symphysis can provide precise age estimates for younger adults, and thus strengthen the quantification of the methods employed when building a biological profile for forensically relevant remains. This method can be combined with other methods for age estimation in young adults (i.e., sacrum and clavicle) or used as a stand-alone method to derive more precise and accurate estimates from the pubic symphysis than is possible with existing methods.

Age Estimation, Pubic Symphysis, Logistic Regression

H77 A Validation Study of Computed Tomography Extracted Cranial Landmarks

Kenda Honeycutt, MA, 3532 Ivy Commons Dr, Apt 101, Raleigh, NC 27606; Ann H. Ross, PhD, North Carolina State Univ, Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107; and Amanda R. Hale, MA, 1326 Courtland Dr, Raleigh, NC 27604*

After attending this presentation, attendees will understand the utility of Computed Tomography (CT) cranial scans for 3D geometric morphometric analysis, positive identifications, and ancestry estimation.

This presentation will impact the forensic science community by presenting the utility of using extracted cranial landmarks from CT scans that could be used in the estimation of ancestry.

The main research objective of this study was to investigate the variation between cranial landmarks extracted from CT scans and those collected from digitization. The sample consisted of 29 individuals from the Morton collection housed at the University of Pennsylvania's Museum of Archaeology and Anthropology. The dry skulls were digitized with a 3D digitizer and scanned with CT. The CT scans were made available by Janet Monge as part of the Open Research Scan Archive (ORSA) at the University of Pennsylvania. Thirteen traditional cranial landmarks were obtainable from each CT scan using the coordinate option of a software program. These coordinates were then compared to the digitized coordinates. A geometric morphometrics software program was used for multivariate statistical analysis. Procrustes' superimposition was used to translate, scale, and rotate the landmark data until a consensus configuration was identified with a least-square fit. New shape coordinates were derived for the entire dataset and for each digitized and scanned individual.

The digitized landmarks and CT-extracted coordinates were first treated as two separate groups to examine for overall differences. Principal Components Analysis (PCA) was performed to reduce dimensionality by decreasing the number of variables to the few that represented the majority of variation. Most of the variation (86%) was in the first four principal components with 57% of the variation found in the anterior portion of the cranium along the first principal component. Canonical Variant Analysis (CVA) was used to identify the landmarks responsible for the variation between the CT coordinates and the digitized coordinates. CVA provided one significant canonical variant, which accounted for 99.8% of the variation and included landmarks along the midline (e.g., nasion and opisthion). A Discriminant Function Analysis (DFA) was also performed to discern the approximate level of separation between the two groups with a correct classification rate of 64% using cross-validation. This was expected and illustrated the similarities between the two groups of coordinates. In addition, a Multivariate Analysis Of Variance (MANOVA) was performed to measure the variance between the two groups. A significant difference was found between the CT and the direct coordinates (*p-value=0.022)*.

To directly assess the difference between digitized and CT coordinates of each individual cranium a Procrustes' superimposition, PCA, and Procrustes' ANOVA were performed using a geometric morphometrics software program. Average Procrustes' ANOVA results of the Procrustes' coordinates suggested that the CT and digitized coordinates of each individual were not significantly different in terms of shape (*p-value=0.578)*. Also, bilateral variables were insignificant (*p-value=0.340*). The greatest PCA-derived one principal component variation was found in bilateral landmarks (e.g., zygomaxillare), which illustrated some distortion occurring in the CT coordinates for bilateral landmarks. Overall, these results validated the utility of CT coordinates.

The results of this study showed significant differences between CT and digitized coordinates when used in large datasets. Most of the variation observed included landmarks along the midline between the two groups. In contrast, the individual analyses exhibited the largest variation among bilateral landmarks. The significant differences found for the entire dataset suggested that the combination of CT and digitized coordinates may not be appropriate for population variation studies. However, the individual results of this study supported the utility of CT coordinates for putative identifications.

This project was supported in part by a National Institute of Justice grant (2005-MU-BX-K078).

Geometric Morphometrics, Computed Tomography, Crania

H78 Molar Size and Shape in the Estimation of Biological Affinity: A Comparison of Relative Cusp Location Using Geometric Morphometrics and Interlandmark Distances

Michael W. Kenyhercz, MS, PO Box 751845, Fairbanks, AK 99775; Alexandra R. Klales, MS, 1515 E Woodbank Way, West Chester, PA 19380; and William E. Kenyhercz, BS, The Ohio State Univ, 4034 Smith Laboratory, 174 W 18th Ave, Columbus, OH 43210*

After attending this presentation, attendees will have gained knowledge on the variation present in the size and shape of molars between ancestral groups. Furthermore, attendees will learn which cusp measurements can be used to accurately estimate ancestry.

This presentation will impact the forensic science community by contributing to the understanding of modern human variation in molar shape and size, which can, in turn, be used to aid in the estimation of ancestry in unidentified individuals encountered in forensic casework.

Dental morphology has long been utilized in anthropology as a means to examine biological affinity.[1-3] Dental variation has traditionally been recorded in accordance with the Arizona State University Dental Anthropology System (ASUDAS) scoring procedures in which morphological traits were scored either by presence or absence or by degree of expression on an ordinal scale.[4] Morris' work on occlusal polygons represented the first use of geometric techniques to analyze cusp location on molars for the estimation of biological affinity in modern human populations.[5] Occlusal polygons utilize the length, angles between cusp tips, and area of the molar crowns by using each cusp tip as a vertex. Occlusal polygons have continued to be utilized by Bailey and Bailey et al. as a means to investigate biological affinity, but occlusal polygons have also been analyzed using updated geometric morphometric approaches.[6-11] The purpose of this research was to analyze the variation present in the relative cusp location in two modern population groups and to assess whether this variation can be used to accurately discern ancestry.

Coordinate data were collected from the cusp tips of 216 adult upper and lower first and second molars. The sample consisted of 107 (F=52, M=55) American Blacks from the Hamann-Todd Osteological Collection at the Cleveland Museum of Natural History and of 109 dental casts from American Whites (F=60, M=49) housed at the University of Alaska Fairbanks, Department of Anthropology. Using a coordinate digitizer, the tip of the stylus was placed on the apex of each cusp tip. In the event of slight wearing, the stylus was placed at the center of the exposed dentine. Only the x and y coordinates were retained for the analyses because the differential degree of wear between specimens would introduce noise to the data along the z-axis. The coordinate data for each molar were analyzed individually through MorphoJ to perform a Generalized Procrustes Analysis (GPA) and calculate centroid size.[12] The GPA translated, scaled, and rotated each specimen to a common coordinate system so that each landmark's coordinates could be directly compared independent of size. The Procrustes coordinates were exported and analyzed using FORDISC 3.0 custom database feature to perform discriminant function analysis (DFA).[13] Lastly, interlandmark distances were calculated from the coordinate data and also analyzed through DFA. All DFA utilized leave-one-out cross-validation and forward stepwise selection of variables.

The results of the two-way DFA between Blacks and Whites using the Procrustes coordinates ranged from 70% – 85% total correct classification. Correct classification using Procrustes coordinates for Blacks ranged from 65% – 82% while correct classifications for Whites ranged from 74% – 87%. In each analysis, Whites classified correctly more frequently than Blacks. The analysis that yielded the highest classification accuracies was a combination of the first lower molar and the second upper molar (B=82%, W=87%; total correct=85%). The results of the DFA on the interlandmark distances ranged from 62% – 80% correct classification. The analysis that resulted in the highest correct classification of interlandmark distances utilized the upper first molar and both lower molars. Most of the interlandmark distances selected for discrimination between White and Black groups included the distal aspect of the tooth, frequently involving the hypocone, for the upper molars, and the hypoconulid for the lower molars.

The molars, especially when used in combination with one another, can accurately differentiate ancestral affiliation between American Whites and Blacks and can be used to estimate ancestry in unknown forensic cases with up to 80% correct classification. While the shape variables derived through the GPA yielded slightly higher correct classifications, interlandmark distances also showed promise as a means to determine biological affinity and can be more easily measured by using standard calipers.

H80 Received Wisdom vs. Reality: Utilizing Amelogenin Profiles to Evaluate the Accuracy of Skeletal Morphologic and Metric Sex Assessments in Adults

Bruce E. Anderson, PhD, Pima County Medical Examiner's Office, 2825 E District St, Tucson, AZ 85714*

After attending this presentation, attendees will gain a further appreciation of how genetic data can enrich the field of forensic anthropology by providing an independent line of evidence for the assessment of sex.

This presentation will impact the forensic science community by providing one method to evaluate the accuracy of morphologic and metric assessment of sex from skeletal remains.

Correct sex assessment is arguably the most important determination that is rendered upon unidentified human skeletal remains because most missing person databases are organized into males and females. Thus, to assess biologic sex incorrectly can drastically reduce the chance for identification. In addition, if sex is erroneously assessed, subsequent age and stature estimates will also likely be in error. Forensic anthropologists routinely utilize morphologic and metric analyses to assess sex from the skeleton, but exactly how accurate is any individual practitioner? The received wisdom is, in part, based upon forensic anthropology pioneers T.D. Stewart and W.M. Krogman stating they each could assess sex with 90% to 100% accuracy utilizing the entire skeleton and 80% to 92% utilizing the skull alone. Although these estimates are individual accuracy rates, the implication was that with enough practice, these percentages could be attained by other forensic anthropologists. Obviously, this is flawed logic and in these days of *Daubert* and error rate issues, individual forensic anthropologists should know their own error rate. Historically, the only way for the forensic anthropologist to learn the accuracy of a sex assessment was through identification. Thus, errors were likely under-reported. Today, we have another tool to reveal these errors: the Amelogenin locus that is a part of many DNA analyses.

The medical examiner's office has submitted more than 1,000 postmortem tissue samples for DNA analyses. Amelogenin profiles were derived for 862 cases and skeletal sex assessments were performed on 840 of these cases, with 350 of these being performed by the author. Thus, for each of these 350 sex assessments, there now exists a genetic line of evidence that can be used as a source of comparison and evaluation. While genetic data are not infallible, these Amelogenin profiles are a powerful tool for such an evaluation.

After controlling for variables that can influence a skeletal sex assessment, these 350 individual cases were subdivided by condition and completeness into categories ranging from a full body to a single osseous element. Because accuracy can be affected by incompleteness, different rates are expected and discussed. Additional sources of potential bias, such as the presence of soft tissue, personal effects, and name associations are also utilized to pare down the number of cases to minimize bias. A total of 203 cases involved skeletonized remains with no appreciable soft tissue or other associated factors. This present research will demonstrate that when all known biases are minimized, such as can be expected when only a cranium is present for assessment, a truer accuracy rate for skeletal assessment may be attained. However, if the error rate becomes unacceptably high, the recommendation is made to not render a sex assessment.

Of particular interest are sex assessments from the cranium alone. More errors were made when the cranium alone was relied upon than any other skeletal element or set of elements. Almost all of these errors were in the same direction: misclassifying small males as females. One explanation for this is that the majority of the skeletal analyses were performed upon foreign national migrants, most of whom are small males. Other errors were made on single elements, such as a femur, so one question to ask is, "Why render an assessment in all instances?" One reason, albeit poor, for stretching the limits of sex assessment methods is to choose one of two database categories: John Doe vs. Jane Doe.

Forensic anthropologists stand on the shoulders of giants. Today, the field is better for at least two reasons: anthropologists have learned from mentors and have developed methods that can test pronouncements. Observation and experience founded this field, and additional research and education are refining it. A part of this refinement is knowing one's own error rates for the different methods employed. After determining these rates, limitations can then be set on what skeletal elements should be used in sex assessments. Many forensic anthropologists chose this field because our assessments can be proven wrong or validated. DNA results enrich our field. Amelogenin profiles should be viewed as an independent line of evidence to evaluate skeletal sex assessments and should be welcomed. Other new tools, such as the National Missing and Unidentified Persons System (NamUs), now enable entry of the sex assessment of *Undetermined* because program algorithms will search all missing person lists, regardless of sex.

Forensic Anthropology, Sex Assessments, Amelogenin Locus

H81 Current Practices in Forensic Anthropology for Sex Estimation in Unidentified Adults

Alexandra R. Klales, MS, Univ of Manitoba, 1515 E Woodbank Way, West Chester, PA 19380*

After attending this presentation, attendees will be presented with an analysis of the methods currently employed by forensic anthropologists to estimate the sex of an unknown adult individual, and the current practices for reporting results when multiple methods are employed. This research is part of a larger study analyzing the same information within all of physical anthropology, including skeletal biology, and bioarchaeology, in addition to forensic anthropology.

This presentation will impact the forensic science community by reporting the variation within the field for sex estimation from the human skeleton. The goal of this research is to disseminate the results of a questionnaire among practitioners to promote discussion and standardization. Understanding the degree or variability, method preference, and modes of reporting is the first step toward standardization within the field of forensic anthropology for sex estimation practices.

Estimation of sex is generally the first step when constructing the biological profile of an unidentified individual, primarily because most of the methods currently used for ancestry, stature, and age estimation are sex-specific. Current methods used to estimate sex consist of either quantitative measures of skeletal elements or qualitative observations of gross morphology, primarily of the pelvis and skull. Historically, morphological assessments dominated forensic anthropology, especially for sex and ancestry estimation; however, there has been a shift in the past several decades toward the development of quantitative approaches.[1] Furthermore, attempts have been made to standardize the various methods used for biological profile estimation and the data collection process, including Buikstra's and Ubelaker's work *Standards for Data Collection from Human Remains*, best practice recommendations for sex assessment by the Scientific Working Group for Forensic Anthropology, and more recently with the Osteoware Standardized Skeletal Documentation Software.[2-4] Despite attempts for standardization, the methods employed and the way in which the results are reported for biological profile parameters varies considerably by practitioner. In many forensic cases, both metric and morphological methods are employed for sex estimation to generate the biological profile. Inconsistency within forensic anthropology for sex estimation method preferences, method applications, and subsequent result reporting is problematic in light of the *Daubert* decision and raises questions of methodological protocol for sex estimation and consistency within the field.[5]

An electronic questionnaire was created and participants were recruited via email through a bulk list server distribution from professional organizations that included forensic anthropologists or

through announcement of the research on these organizations' websites. The online questionnaire consisted of 32 questions concerning the participant's education, background, and their preferences and practices for sex estimation. Like Garvin's and Passalacqua's research on current age-at-death estimation practices, a multiple choice format was utilized when possible, and for the methodological questions, a rank system was used and included an area for additional written comments.[6] The survey software double-blinded all identification information, so that participation in the survey was anonymous on all accounts and participants were not compensated for taking part in this research.

Responses were received from 152 individuals; however, for this component of the research, only the individuals who self identified as forensic anthropologists were analyzed (n=92). The pelvis was overwhelmingly preferred as the best indicator of sex (94.3% selected as first choice), followed by use of the skull (64.8% selected as second choice), and then by the long bones as the third preferred area (65.1% selected as third choice). Using qualitative measures, traits listed in *Standards* were ranked highest for the skull and for the pelvis the three traits of Phenice ranked highest. For metric assessment, FORDISC was the preferred method for the skull and postcrania.[7-8] Most practitioners (63.6%) prefer to use both qualitative and quantitative methods; however, when both are not used, qualitative methods (23.9%) were preferred nearly twice as much as metric methods (12.5%). Finally, when results from the multiple methods employed disagreed, 41.2% of practitioners presented the results of all methods, 20.0% gave preference to one skeletal area over the results from others, and 15.3% decided which assessment to assign the individual based on experience and the overall impression. These findings highlight the high degree of variability in the methods used for sex estimation and the need for standardization within the field.

Sex Estimation, Biological Profile, Standardization

H82 The Problem of Estimating Sex From the Skull: A Comparison of Methods Applied to a Modern Colombian Sample

Jonathan D. Bethard, PhD, Boston Univ, School of Medicine, Boston, MA 02118; and Elizabeth A. DiGangi, PhD, Calle 125 #19-89, Ofc 401, Bogota, COLOMBIA*

The goal of this presentation is to demonstrate that metric methods of sex estimation from the skull do not yield classification accuracies of over 80% in a modern Colombian sample while visual methods applied to the same population perform slightly higher.

This presentation will impact the forensic science community by suggesting that forensic anthropologists utilize skeletal elements other than cranial remains for estimating sex. In cases when only cranial remains are present, caution should be exercised in arriving at sex estimates, particularly in cases where no population-specific standards are available.

In forensic anthropological contexts, estimating the biological profile from skeletal remains is of paramount importance. Researchers agree that elements of the bony pelvis provide the most reliable sex estimates, typically from visual assessment. Until recently, in cases where pelvic elements were absent or too damaged to be of use, protocols historically called for workers to preferentially choose the skull, as it was considered the second-best sex indicator. Recent publications in the literature have challenged this notion and have convincingly argued that post-cranial elements are much more sexually dimorphic than the skull. While this shift has been embraced in the United States, forensic anthropologists working in diverse international contexts often encounter solitary crania or work in locales where population-specific criteria for sexing post-cranial remains are non-existent. As a result, the skull is often still considered as a reliable indicator of sex despite evidence to the contrary. This is particularly true in Colombia where practitioners are currently in the process of identifying scores of unidentified skeletons while simultaneously developing population-specific standards for the Colombian population. Given this reality, there is a strong need for researchers to understand which methods for estimating sex from cranial remains are suitable and which might be appropriately abandoned in Colombia.

The influential work of Giles and Eliot ushered in an era of intense interest on quantifying sexual dimorphism from metric analyses of cranial remains.[1] Typical approaches utilized discriminant function analysis of interlandmark craniometric distances for sex estimates. Many of these studies used skeletal collections derived from the late 19th and early 20th-centuries to generate standards that were utilized by forensic anthropologists around the world. During this influential time period, the work of Acsadi and Nemeskeri also brought attention to five non-metric cranial characteristics that could be used to visually assess sex (i.e., nuchal crest, mastoid process, glabellar prominence, supraorbital margin, and mental eminence).[2] These morphoscopic traits are well known today and have been reproduced in numerous protocols which have been adopted by both forensic anthropologists and bioarchaeologists.

Though the work of Spradley and Jantz convincingly argued that practitioners should shift their attention to post-cranial sex estimation, more work remains to be done on modern samples drawn from populations outside of the United States.[3] The work presented in this study was based on an analysis of cranial remains from 198 individuals (m=133; f=65) drawn from two modern Colombian reference collections currently curated in Bogotá, Colombia, and Medellin, Colombia. The pooled samples' average age-at-death was 45.8 years for males and 56.79 for females. Each cranium was digitized with a Microscribe digitizer interfaced with the software program 3Skull. Sixteen interlandmark distances mined from 3Skull were then used to calculate univariate sectioning points in order to determine classification accuracies of each interlandmark distance. In addition, a subset of the Bogotá sample was visually assessed and five morphoscopic traits were recorded blind to real sex.

Classification accuracies of the 16 interlandmark distances ranged from 55% – 77%. Of all interlandmark distances, bizygomatic breadth (ZYB) achieved the highest classification rate, a result mirroring findings of Spradley and Jantz.[3] In the case of visual assessment, the observer estimated sex based on the *gestalt* of morphoscopic traits. Overall, 81.8% of the Bogotá subsample was sexed correctly. This result mirrors the work of others who have achieved classification accuracies of over 80% from visual assessment of cranial remains.[4] Ultimately, in both this study and that of Spradley and Jantz analyses of craniometric dimensions indicate that other areas of the skeleton should be preferentially chosen for sex estimation and that in cases of isolated crania, workers must qualify the limitations of currently available methods.[3]

Sex Estimation, Colombia, Skull

H83 A Test of Formulas Used to Estimate Stature in Modern Chileans

Elizabeth M. DeVisser, BSc, 200 S Regent St, Lansing, MI 48912*

After attending this presentation, attendees will understand some of the problems with previously reported stature equations developed to aid identification efforts for the "disappeared" from Pinochet-era and modern medicolegal cases in Chile.

This presentation will impact the forensic science community by providing new and more accurate equations for estimating the statures of modern Chileans.

Populations throughout history have differed in body dimensions. Modern populations are not exempt from normal variation in biological traits, both within and between various groups. Anthropologists have attempted to quantify this variability, and standards used to measure traits such as stature have been created for European and North American populations. Standards derived from European and American populations have produced mixed results when applied to Latin American skeletal samples, where there is a lack of local data that can be used to determine ancestry, sex, and stature. Creating new stature estimation equations has become increasingly important for countries such as Chile, where a legacy of human rights violations has resulted in unidentified remains.

In Chile, quantifying population variability has been difficult since living stature is not regularly recorded on official documents. To aid the Chilean government in this matter, Ross and Manneschi created equations using substituted population means from studies conducted in the 1970s and used long bone lengths from North American populations to calibrate these equations.[1] As long as these population means are similar to those of the Chilean target skeletal population, they should be effective substitutes. However, the obtained population parameters (means, variances, and shapes of the variance distributions) for these other reference groups do not match the values for local Chilean populations, introducing systematic errors when estimating stature.

This study tests Ross' and Manneschi's previously-published Chilean stature equations using a new sample of 34 males from the Cementario General Collection at the Universidad de Chile and modern forensic cases from the Servicio Medico Legal in Santiago, Chile. In lieu of recorded living statures, skeletal height was calculated for each specimen using Raxter's Revised Fully's Anatomical Method.[2] These data were substituted into Ross' and Manneschi's and Trotter's published equations for the femur and tibia, and success was evaluated using mean error statistics (inaccuracy and bias).[3] In addition, new equations were generated for comparison.

Mean stature for the Chilean test sample (161cm) is significantly different from the mean values used by Ross and Manneschi (170cm and 174cm). Mean femur length for the Chilean test sample (43.29cm) is also significantly different from the mean values used by Ross and Manneschi (46.91cm). Mean tibia length does not follow the same pattern and the values obtained for the current study (36.40cm) are not statistically different than those used by Ross and Manneschi (36.85cm). Trotter's equations for the femur and tibia perform reasonably well (inaccuracies=3.69cm and 8.59cm, respectively). However, Ross' and Manneschi's equation for the femur does not perform well, with the majority of specimens being severely underestimated (inaccuracy=20.28cm, bias=-20.78cm). Ross' equation for the tibia performs even worse, with some specimens falling well outside of Ross' published error intervals (inaccuracy=43.51cm, bias=-43.51cm). New stature equations generated from the current sample have inaccuracy values of 2.86cm (femur) and 2.31cm (tibia).

North American stature data does not appear to be an adequate proxy for modern Chileans. Researchers should avoid the temptation to substitute data from other populations when documentation of local skeletal samples is incomplete. Although limited data is available, this study emphasizes the importance of collecting all the data required to create accurate and reliable regression equations.

Stature, Regression, Chile

H84 Sexual Dimorphism in Thai Postcranial Measurements

Taylor S. Yuzwa, BSc, 922 E 31st St, Erie, PA 16504; Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensic Anthropology, 501 E 38th St, Erie, PA 16546; and Panya Tuamsuk, MD, Khon Kaen Univ, Dept of Anatomy, Faculty of Medicine, Khon Kaen, THAILAND*

After attending this presentation, attendees will understand the methods associated with sexing the skeleton, the different levels of sexual dimorphism in the skeleton and also in different populations around the world, and an example of the importance of selecting the most valid methods for the level of dimorphism.

This presentation will impact the forensic science community by raising awareness of the different levels of accuracy of sex estimation methods for different populations, and the importance of population-specific validation of metric and nonmetric methods in responsible biological profile assessment.

Sexual dimorphism has been observed and recorded in populations around the world for over a century, with recognition that different groups show different levels of sexual dimorphism. Nevertheless, forensic anthropologists universally apply nonmetric methods that focus on particular traits of the cranium and innominate for estimating sex of unknown individuals, regardless of suspected ancestry.[1,2] Furthermore, multiple methods are expected to yield equivalent levels of sexual dimorphism for a particular individual. Consequently, adherence to the *Daubert* standard of method validation is undermined by a lack of population-specific error rates in sex estimation methods.[3]

Recent published and unpublished results have indicated low degrees of sexual dimorphism in Thai crania, and moreover, typical sex markers of the postcranial skeleton, such as the pubis, appear to be less sexually dimorphic than contemporary American populations.[4] In contrast, high levels of sexual dimorphism have been observed in the postcranial skeleton of Thai in the examination of single bones (femur, tibia, and humerus), despite a generally smaller physique compared to other East Asian populations.[5] Therefore, it is necessary to compare the extent and location of dimorphism in the entire Thai postcranial skeleton as a potential alternative for biological profile assessment in which the traditional Walker and Phenice markers are less valid.

In this study, a modern sample of 122 males and 78 females from Khon Kaen University, Thailand, were compared to modern American Whites and Blacks in the Forensic Data Bank, with the objectives of testing the classification accuracy of postcranial metrics using Discriminant Function Analysis (DFA), as well as to identify the most dimorphic skeletal traits in each group. Each ancestral group was analyzed independently for seven robusticity indicators (breadth measurements) of the humerus, femur, and tibia, and for seven length measurements of the clavicle, humerus, radius, femur, and tibia, using discriminant function analysis in FORDISC 3.1 and R statistical software

programs. Forward stepwise selection was conducted to determine which measurements were most effective for differentiating sex in each ancestral group.[6,7] In all groups, robusticity indicators outperformed length measurements, achieving classification accuracies of 95.0% (White), 95.6% (Thai), and 97.8% (Black), compared with 92.6% (White), 93.0% (Thai), and 95.3% (Black). When all 14 measurements were combined, robusticity indicators continued to be more valuable characters for estimating sex.

When stepwise selection was used, classification accuracies were similar in all groups, exceeding 90%, but the Thai groups required five measurements for distinguishing males and females, in contrast to two measurements that were selected for each of American Blacks and Whites. Thus, Thai males and females can be classified with similarly high rates of accuracy, but sexual dimorphism is more pronounced in American Blacks and Whites.

Sexual dimorphism in the Thai illustrates the differential accuracy of sex estimation methods in different populations. Although the results indicate that dimorphism may be lower in Thais than in American Whites or Blacks, postcranial metrics can still be used to estimate sex accurately, in contrast to the typical nonmetric methods. In the wake of *Daubert*, the Thai sample emphasizes the importance of utilizing the most reliable and valid method in assessing parameters of biological profile.

Sex Estimation, Postcranial Metrics, Method Validation

H85 Sex Estimation in a Modern Thai Sample Using Non-Metric Traits of the Innominate

Ellen Powell, BA, Mercyhurst Univ, 502 E 38th St, Erie, PA 16504; Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensic Sciences, Dept of Anthropology, 501 E 38th St, Erie, PA 16546; and Panya Tuamsuk, MD, Khon Kaen Univ, Dept of Anatomy, Faculty of Medicine, Khon Kaen, Khon Kaen 40002, THAILAND*

After attending this presentation, attendees will understand that a popular non-metric method using traits from the innominate cannot be applied reliably to other ancestries.

This presentation will impact the forensic science community by demonstrating that any sex estimation techniques must be used with caution and that the source and nature of the samples must be taken into account.

Sex estimation is a vital part of constructing the biological profile of an unknown individual. Following the *Daubert* decision (*Daubert vs. Merrell Dow Pharmaceuticals, Inc.* 1993), in order to be considered admissible in court, scientific conclusions must be based on reliable and valid methods with estimated error rates.[1] Not all methods used to construct a biological profile that are derived from one group or population are necessarily applicable to another group, and should be tested for external validity, as has been repeatedly demonstrated in metric studies of the cranium and post-cranium. This study examines how well a recent method published by Klales *et al*. (2012), which used modified Phenice (1969) traits of the innominate, performs when applied to a sample of modern Thai individuals.[2,3] The three characteristics of the innominate (medial aspect, ventral arc, and subpubic concavity) were scored on 76 Thai individuals from Khon Kaen University Hospital and were compared to the scores of modern Americans in the UTK Forensic Anthropology Center. Because the observations were recorded as ordinal data, the American and Thai groups were compared using several non-parametric tests including the Shapiro-Wilkes test, Wilcoxon signed-rank test, and the Freeman-Halton test. The Thai individuals were classified using logistic regression and linear discriminant function analysis. Statistical analyses were conducted using R (R Development Core Team 2012) and FORDISC 3 (Jantz and Ousley 2010).[4,5] In group comparisons, the modern Thai sample was found to have significantly lower scores compared to the modern American sample in all three traits. Using the discriminant function analysis and logistic regression equations developed by Klales et al. (2012) based on a modern American sample, the modern Thai sample classified very poorly: the correct classification rates of the modern Thai males were as low as 27% using the logistic regression and only 43% using discriminant function analysis.[2] The Thai females were classified more accurately, indicating that the overall scores of both the males and females are lower (more feminine) than those of the modern Americans. However, sex estimation equations derived from the Thai sample itself also showed low accuracy rates, indicating they are simply less sexually dimorphic in these traits than the American groups. Thus, the Thai sample is both more feminine and less sexually dimorphic in these traits than either the Phenice (1969) or the Klales et al. (2012) samples.[2,3] Therefore, these traits must be thoroughly tested before being applied to any other group or population other than the American White and Black from which the equations were derived.

Non-Metric, Sex Estimation, Thai

H86 Date of Birth Estimation of Dead Bodies—A Compilation of C^{14} Reference Levels in Enamel to Assist in Identification Work

Kanar Alkass, BSc, Dept of Forensic Medicine, Retzius v 3, 171 77, Stockholm, AL SWEDEN; Hisako Saitoh, PhD, Dept of Legal Medicine, Chiba, JAPAN; Bruce A. Buchholz, PhD, Lawrence Livermore National Laboratory, Center for AMS, L-397, PO Box 808, Livermore, CA 94551; Gunilla Holmlund, PhD, Rättsmedicinalverket, Artillerigatan 12, 58758, Linköping, AL 58758, SWEDEN; David R. Senn, DDS, Univ of Texas Health Science Center at San Antonio, 7703 Floyd Curl Dr, Mail Code 7919, San Antonio, TX 78229-3900; Kirsty Spalding, PhD, Karolinska Institutet, Dept of Cell and Molecular Biology, Medical Nobel Institute, Stockholm, 17177, SWEDEN; and Henrik Druid, MD, PhD*, Dept of Forensic Medicine, Karolinska Institutet, Retzius v. 3, Stockholm, SE-171 77, SWEDEN*

After attending this presentation, attendees will understand how dental enamel formed after 1955 can be dated using the radiocarbon bomb-pulse. They will also learn how aggregated reference radiocarbon data can improve the precision of date-of-birth estimation. Further, the

attendees will learn that stable isotopes, aspartic acid racemization analysis, and DNA analysis of teeth can help to identify origin and sex.

This presentation will impact the forensic science community by showing how reported data are important to forensic investigators involved in identification work, since bomb-pulse ^{14}C dating can provide accurate information regarding the date of birth of unknown individuals.

For identification of unknown decedents, dental X-rays and DNA comparisons are the most important methods to determine identity, but each process requires an idea of who the deceased person is. In cases where there are no clues about the identity, then the sex, the date of birth, and age at death are decisive in the identification casework to limit and, hence, facilitate the search for possible matches. During the cold war, above-ground test detonations of nuclear weapons resulted in a substantial increase of ^{14}C in the atmosphere. By measuring such bomb-pulse-generated ^{14}C in modern biological material, a fingerprint of the time for its formation can be obtained. This method has been used in combination with aspartic acid racemization analysis (which gives an estimate of the age at death) to also estimate the year of death. Furthermore, stable isotope levels in teeth have been used to predict the origin of the person.

In this study, ^{14}C, ^{13}C, and ^{18}O concentrations in teeth from people in Mexico, the U.S., and Canada were analyzed. In order to isolate the enamel, the crown was treated with strong NaOH and sonicated. The teeth were then etched with HCl to limit external contamination. The concentration of ^{14}C in the samples was determined by accelerator mass spectrometry. DNA, ^{13}C, and ^{18}O levels in these teeth were analyzed using the Identifiler kit from Applied Biosystems, and isotope ratio mass spectrometry, respectively. Finally, all enamel ^{14}C results in this and previous studies were compiled to produce a tooth ^{14}C reference table.

Results-identified differences in ^{13}C concentrations in teeth over a limited geographical area such as North America are substantial. Teeth from Mexican subjects showed much higher ^{13}C levels than teeth from U.S. and Canadian subjects. The ^{18}O concentrations in tooth roots of U.S. subjects paralleled the levels in drinking water in the areas they were raised. Carbon-14 predicted birth year with an average absolute error of 1.8 ± 1.3 years. By using reference data on enamel ^{14}C levels, estimates of a person's date of birth, and thus age at death, can be provided with greater accuracy than that provided via radiographic analysis of enamel formation. By analysis of ^{14}C in both enamel and root of the same tooth, it could be determined whether the ^{14}C results corresponded to the rising or falling part of the bomb-pulse curve. DNA analysis of the tooth roots indicated the correct sex for all subjects tested.

In order to limit the search for possible matches, the year of birth, the year of death, sex, and geographic origin constitute important variables. Regarding age estimation, anthropological methods often show estimates of +/- 10 years, and such information will not reduce the number of possible matches significantly. In contrast, the bomb-pulse ^{14}C method provides a more accurate age by estimating the year of birth. Interestingly, substantial geographical differences of the stable isotopes ^{13}C and ^{18}O were observed, which can help indicate origin of subjects who are found dead far from their residential area. Both isotopes have also shown to display geographical variation in hair collected from only a few years back, which supports the notion that analysis of these stable isotopes in teeth are likely to be useful during many years to come. Bomb-pulse ^{14}C analysis is a robust method that can provide a very good estimate of year of birth. ^{13}C and ^{18}O analysis may give clues to geographical origin. DNA analysis can, in addition to providing an individual profile, determine the sex. All analyses described above can be performed on a single tooth.

H87 Decomposition in Central Texas and Utility of a Universal Postmortem Interval

Amy M. Sears, BA, and Kate Spradley, PhD, Texas State Univ, Dept of Anthropology, 601 University Dr, San Marcos, TX 78666*

After attending this presentation, attendees will understand the process of decomposition in Central Texas, the utility and accuracy of a universal Postmortem Interval (PMI) formula, and will be presented with a baseline postmortem interval for Central Texas.

This presentation will impact the forensic science community and medicolegal professionals by detailing the decomposition process that is unique to Central Texas with detailed explanations of each stage of decomposition, accompanied by photographic aids. This presentation will also impact the forensic science community by analyzing the pros and cons of using a universal PMI formula.[1]

Although decomposition has been studied by many over the past few decades, most notably Galloway *et al*. and Megyesi *et al*., the majority of research conducted regarding the decomposition sequence have used animals as human analogs.[2-5] These previous studies have provided a framework for further studies; however, animals are not always an appropriate proxy for human subjects.[6] Additionally, previous studies of decomposition in Central Texas had relatively small sample sizes, leaving room for potential error.[7-8] Unlike previous studies, this study includes over 60 individuals donated to the Forensic Anthropology Center at Texas State University-San Marcos. This study will provide individuals with access to a large-sample, region-specific collection of decomposition data.

Photos were collected daily for the first month after placement of each individual at the Forensic Anthropology Research Facility (FARF), and bi-weekly thereafter until decomposition was complete. Each donation was analyzed and the date of each stage of decomposition recorded. Stages of decomposition recorded at the facility were: fresh, early decomposition, late decomposition, mummification, and skeletonization.[2] In this study, fresh describes the conditions of the bodies at time of placement, prior to decomposition. Early decomposition at the facility is characterized by marbling, bloat, maggot activity, skin slippage, and increased odor. Donations at the FARF show that early decomposition occurs between 2 and 13 days after placement (34-302 ADD). Advanced decomposition is characterized by the loss of marbling, a sunken stomach due to the purge of fluid and gases from the body, and decreased insect activity. Advanced decomposition is initially shown to occur between 6 and 53 days after placement (212.5-784.4 ADD). Mummification occurs when all fluid has left the body and no soft tissue remains. Mummification at the FARF is characterized by a uniform beige or brown color, with a very thin, paper-like skin remaining over the skeleton. Complete mummification occurs between 11 and 106 days after placement (240.9-1697.7 ADD). Skeletonization, the last decomposition stage studied for this project, occurs when the complete skeleton is visible. Skeletonization presented in only 30% of the donations initially analyzed, and of those individuals, only half-skeletonization occurred. When data from the 2012 donations are applied to the Universal PMI formula introduced by Vass, a significant difference is found in the stages of early decomposition (x^2=251.49), late decomposition (x^2=291.85), and mummification (x^2=216.1) between the observed PMI and the PMI expected from Vass' formula.

When these data are used in collaboration with decomposition data acquired from different regions, a more accurate PMI can be established. Initial results vary greatly from other regions previously studied, and this shows the necessity of region-specific PMIs. This project builds upon previously collected data and adds new data that are part of an ongoing standardized decomposition database that includes photos and notes that will be beneficial for researchers interested in standardizing the visual assessment of decomposition.

Decomposition, Postmortem Interval (PMI), Forensic Anthropology Research Facility (FARF)

H88 Craniometric Assessment of Modern 20th-Century Black, White, and "Colored" South Africans

Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria, 0001, SOUTH AFRICA; Michael W. Kenyhercz, MS, PO Box 751845, Fairbanks, AK 99775; Kyra E. Stull, MS, Univ of Pretoria, Dept of Anatomy, Private Bag x323, Arcadia, 0007, SOUTH AFRICA; and Stephen D. Ousley, PhD, Mercyhurst College, Dept of Applied Forensic Sciences, Dept of Anthropology, 501 E 38th St, Erie, PA 16546*

After attending this presentation, attendees will obtain knowledge of human variation among modern Black, White, and "Colored" South Africans and will understand the statistical framework used to describe similarities and differences among these groups.

This presentation will impact the forensic science community in contributing to the knowledge of human variation in modern South Africans as well as the impact of forced segregation on cranial plasticity in different ancestral populations occupying the same geographic space.

While South Africa is not unique in its rate of violent crime or in its large number of unidentified persons, this poly-linguistic society with over 49 million people is an ideal country in which to evaluate human variation. Within the last 500 years, various population groups, such as Dutch, French, Malaysian, and Indian, have migrated to South Africa. Social behavior and 20th-century segregation laws affected gene flow among indigenous and migrated groups and contributed to distinct social/political designations which include Black, White, "Colored," and Indian South Africans. Approximately 80% of the population identifies themselves as Black, 9% "Colored," 8% White, and 3% Indian. "Colored" refers to a social group primarily from the Western Cape who are descendants of slaves brought from Indonesia, India, Malaysia, and Asia and who mixed with Europeans and the indigenous Khoi and San.[1]

The purpose of this study was to use craniometrics and Discriminant Function Analysis (DFA) to evaluate ancestral variation and sexual dimorphism among White, Black, and "Colored" groups as a means to explain current variation and to more accurately identify unidentified remains as to social group.

A total of 351 crania of Black (49 F, 110 M); White (45 F, 64 M); and "Colored" (29 F, 54 M) groups were used from the Pretoria Bone, Raymond A. Dart, and Kirsten skeletal collections. One-hundred and seven standard landmarks were digitized to generate various linear measures, fractures, angles, and subtenses.[2] Discriminant function analysis was employed and South African groups were tested against themselves to test classification accuracies. All accuracies were cross-validated.

In a three-way DFA for ancestry using 11 stepwise-selected variables, 82% classified correctly using cross-validation, indicating significant differences among all groups. Black South Africans classified 80% correctly, "Coloreds" classified 84% correctly, and Whites classified 83% correctly. In a six-way DFA for sex and ancestry using ten stepwise-selected variables, 63% classified correctly on the whole. Black females classified 76% correctly, Black males classified 74% correctly, "Colored" females classified 24% correctly, "Colored" males classified 41% correctly, White females classified 69% correctly, and White males classified 66% correctly.

Each ancestral group demonstrated comparable correct classification accuracies when tested for ancestry alone. Of the three groups, Black and White groups were least likely to misclassify as each other. For ancestry and sex, "Colored" groups demonstrate considerably lower classification accuracies than either Black or White groups. "Colored" males misclassify into Black or White groups, whereas "Colored" females misclassify more often as Black females than themselves and only twice as White females. The abovementioned results corroborate with nasal aperture research on South Africans which concluded that while Black and White groups were distinctly different, no clear discrimination could be made between Black and "Colored" groups.[3] Low classification accuracies for sex and ancestry were also observed and may be attributed to low sexual dimorphism among "Colored" and Black groups, despite strong separation of the groups in a three-way DFA.[3]

Diverse cultural/sociopolitical histories are reflected in variation among these modern social groups. Few studies have examined morphological variation within "Colored" groups in comparison to White and Black South Africans. While Black and White South Africans show roughly the same level of homogeneity, "Coloreds" are much more heterogeneous. Current variation in South Africa needs to be addressed to assist forensic anthropologists in accurately estimating ancestry from unknown remains.

Ancestry Estimation, DFA, Sexual Dimorphism

H89 The Chaotic Numerology of Anthropometry: A Proposal for a Univocal Numeric Codification of Bone Measurements

Matteo Borrini, PhD, Via del Mattone 17A, Cadimare, La Spezia, 19131, ITALY*

After attending this presentation, attendees will value the state-of-the-art anthropometrical measurement's classification and develop a better understanding of a new code that could be adopted by international scientists.

This presentation will impact the forensic science community by illustrating a new univocal and versatile three-number code for cranial and skeletal measurements.

Osteometrics have very important roles in forensic anthropology because they allow for the objective quantification of morphological characteristics when developing the biological profile of unknown skeletons, rather than relying purely on qualitative descriptions that are often subjective.

Various measurement coding systems have been developed in Europe and the United States; some of the most popular include those developed by Martin-Saller, Howells, and by Buikstra and Ubelaker.[1-3] As a scientific community that is becoming ever more global and

international, a nonshared language can create impasses and lead to miscommunications between scientists. Similar problems have been faced by odontologists that are involved in mass fatality and international scenarios. The odontological community has addressed this problem with the FDI World Dental Federation notation (i.e., the ISO 3950 notation), where quadrants are numbered from 1 to 4 for adult dentition and from 5 to 8 for deciduous dentition. The numbers proceed clockwise from the upper right quadrant to the lower right and teeth are numbered from the midline to the posterior.

In order to develop a new shared codification model, some imperfections in the main coding systems must be overcome. For instance, one issue with the Martin-Saller system is that all measurements are divided in chapters corresponding to single bones and are numbered with an arithmetic progression. This system can be ambiguous because the numbers are not univocal: for example the number "1" indicates the maximum length of the skull, of the femur, and of all the other long bones. The Howells coding system identifies measurements by an abbreviation of its description, which is problematic when a measurement has a very long or complex name, or if new measurements are acquired. The system developed by Buikstra and Ubelaker is problematic because codes are sequentially assigned from the skull to the calcaneus, so new measurements cannot be easily introduced into the sequence without creating confusion.

A coding system based on a three-number codification, where numbers are delineated by periods is proposes. The first number will indicate the anatomical area of which the measurement is referred:

- 1 – Cranium
- 2 – Upper Limb
- 3 – Lower Limb
- 4 – Spine
- 5 – Thoracic Girdle
- 6 – Pelvic Girdle

The second number will indicate the single bone or the topographic region in the cranium:

- Neurocranium, 1.2 Facial Skull, 1.3 Orbital Skeleton, 1.4 Nasal Region, 1.5 Maxillary Area, 1.6 Mandible
- Humerus, 2.2 Ulna, 2.3 Radius
- Femur, 3.2 Tibia, 3.3 Fibula, 3.4 Patella
- Vertebrae, 4.2 Atlantoaxial Joint, 4.3 Sacrum
- Scapula, 5.2 Clavicle, 5.3 Sternum
- Innominate, 6.2 Pelvis

The first two numbers in the code can be used to rapidly identify the anatomical area, where the bone is in the body, and in which bone the anthropometrical data is recorded; the third and last number is an arithmetic progression that allows operators to continually introduce new measurements without scrambling the entire series. A selection of the most representative measurements are selected and presented on the web site www.restiumani.it.

This presentation outlines a novel anthropometric coding system. The proposed coding system is an integral part of the "Forensic Protocol for Anthropometric Measurement of Human Skeletal Remains" developed at the University of Tor Vergata. The coding system and the protocol have been successfully utilized on a variety of historical and forensic Italian cases in a five-year research project at the University of Florence and are used by various Italian universities and by forensic investigators for the Italian State Prosecutor's Office.

Anthropometry, Standards, Codification

H90 Defining the Peri-Mortem to Postmortem Transition: Macroscopic and Microscopic Changes in Subadult Bone Undergoing Trauma

Donna C. Boyd, PhD, Radford Univ, Forensic Science Institute, PO Box 6939, Radford, VA 24142; and Charles C. Boyd, PhD, Radford Univ, Dept of Anthropological Science, Radford, VA 24142*

The goal of this presentation is to more clearly and accurately define the peri-mortem period in forensic anthropology by documenting changes in traumatized subadult bone across the peri-mortem to postmortem transition.

This presentation will impact the forensic science community by providing a better understanding of the peri-mortem /postmortem transition and enable practitioners to more clearly distinguish between peri-mortem versus postmortem pediatric trauma.

Scientific Working Group for Forensic Anthropology (SWGANTH) guidelines for trauma analysis[1] have called attention to the need for great caution when using the term "peri-mortem" due not only to different definitions of the term across soft and hard tissue, but to a paucity of understanding of the timing and process involved in fresh bone becoming "dry."[1] One approach has been to define this transition in terms of characteristic signatures related to biomechanical properties of "fresh" versus "dry" bone breakage. Using this approach, retention of classic macroscopic peri-mortem Blunt Force Trauma (BFT) signatures has been observed well into the postmortem period (five months); however, a discrete, standardized definition and timing of this transition has been elusive.[2]

The current study documents microscopic and macroscopic changes in subadult bone undergoing BFT across the peri-mortem to early postmortem transition (approximately seven weeks) (peri-mortem is defined in this study as at or very near the approximate time of death). Twenty (unprocessed) stillborn pigs (*Sus scrofa*), frozen at death, were used in the study. After thawing, two pigs underwent immediate trauma induction delivered by means of a standardized drop-force mechanism. Pigs were placed on a hard substrate and impacted by a 1,109g concrete cylinder on both their left and right sides. Right side impacts (three per pig—focused on the lateral cranium, lateral shoulder, and ribs) used the same standardized drop mechanism through a stabilized 50cm-long PVC pipe. Similarly, three impacts on the same areas (cranium, shoulder, ribs) on the left side were dropped through a 108cm-long PVC pipe. Pigs were radiographed after trauma induction, then underwent maceration. The remaining 18 pigs, immediately upon thawing 24 hours, were placed in outdoor and indoor surface environments in the summer season to decay. All were placed in cages lined with ¼ in, fine wire mesh to allow access to insects, but limit larger scavenging and allow natural decomposition to occur. At regular intervals over the seven-week period (Days 5, 10, 20, 35, and 50), three pigs from each environment (two outdoor, one indoor) underwent identical trauma induction, radiography, and processing. The final two pigs (one outdoor, one indoor) remained in their environment for the entire 50 days, undergoing no trauma.

Macroscopic and microscopic (using a Keyence VHX-1000 Digital Light Microscope with 5 – 50x and 20 – 200x lenses) comparisons were made across the Day 0 through Day 50 bone samples. Standardized variables examined included:

- Fracture (Fx) type (linear, hinge, diastatic, depressed, comminuted, stellate), frequency, completeness;
- Fx morphology (including fx outline, fx edge shape);
- Fx metrics (e.g., distance between incomplete fx edges; length of radiating fx lines);
- Presence/absence of hinging, radiating and/or concentric fx lines, inbending/outbending, displacement, curling/uplifting; degree of refit of fx edges.

Results indicate a change from many classic peri-mortem fracture signatures to postmortem ones early in the postmortem period (by Day 5). This includes an increase in overall fragmentation as indicated by fracture frequency (particularly those of ribs) between 0 and 5 days

postmortem, a pattern continuing until Day 50. Color differentiation between fractured and non-fractured surface edges is visible by Day 5. Decreases in sharp-edged denticulate fx edges and increases in jagged, irregular, and frayed fx edges are observed by Day 10. There is a concomitant decrease in the number of possible refits across this period. An illustrated timeline for microscopic and macroscopic bony changes across this peri-mortem/postmortem transition is provided. It is recommended that a standardized fracture terminology in the description of peri-mortem trauma and postmortem breakage be adopted, through quantifiable microscopic and macroscopic comparisons. These results will aid in the differentiation of peri-mortem versus postmortem pediatric fractures and further clarify both the nature and the timing of the peri-mortem period.

Peri-Mortem, Postmortem, Pediatric Trauma

H91 Quantification of Color Changes in Human Decomposition Using Image Processing Software

Darren Williams, PhD, Sam Houston State Univ, Chemistry Dept, Box 2117, Huntsville, TX 77341; Joan A. Bytheway, PhD, Sam Houston State Univ, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296; and Joe Trevino, BS, 2401 Montgomery Rd, Apt B109, Huntsville, TX 77340*

After attending this presentation, attendees will understand how image processing software can quantify color changes in human decomposition. This presentation will show how the software can be used to construct a chromaticity diagram based on the RGB and CIELAB values generated from a set of images taken for a study on postmortem interval estimation by a total body score and accumulated degree-days method.

This presentation will impact the forensic science community by exploring the relationship between temporal changes in human decomposition and changes in chromaticity diagrams. It will also explain how RGB and CIELAB values taken from digital images might be used to validate current postmortem interval estimation.

Scientists can use a spectrophotometer to measure quantitatively the transmission or reflection properties of a material as a function of wavelength.[1] The spectral wavelengths are converted into three values, known as CIELAB tristimulus values, which numerically represent the sensitivity curves of three linear light detectors. Then, the values are used to calculate the two parameters humans use to process color: chromaticity, a quantitative property that is a combination of luminance, hue, and saturation; and brightness, a purely qualitative property. The parameters are plotted as x and y coordinates on what is known as a CIE 1931 color space chromaticity diagram.

Dermatologists have used spectrophotometry to monitor skin lesions and color changes in patients' skin.[2] While spectrophotometry is an accurate method of quantifying color change, it requires direct contact with the material being analyzed. Not all lesions or conditions allow for direct contact with this instrument of analysis, nor is it suitable for all types of investigation. Ophthalmologists, for example, cannot use a spectrophotometer inside the eye to diagnose diseases such as macular degeneration.[3] They instead use a method known as digital colorimetry. Image processing software analyzes an image or any specific region of an image and generates a set of values known as RGB values. These RGB values are another set of color additive values and can be converted into the same tristimulus values that can be plotted on a chromaticity diagram.

The stages of human decomposition can be quantitatively classified using a system like the Total Body Score method.[4] While the scoring system is a quantitative measure, this system and others like it rely on color as a criterion for classification. Large changes in color are easy to detect, but reporting the overall color of a limb or torso at only one point in time might be difficult. Investigators need a quantitative way of evaluating color, or at least a quantitative method of validating their estimation.

Spectrophotometry would be an accurate technique in analyzing color in human decomposition, but it can be problematic. The area of analysis is restricted by the need for direct contact with the body. Forensic scientists might need to analyze the colors on a large part of the body or even on the body as a whole before they classify the stage of decomposition. Digital colorimetry is a comparable alternative. It uses the digital images of the bodies at the crime scene or recovery scene, and immage processingsoftware can analyze specific or larger regions of the images.

Six digital images representing all stages of human decomposition will be selected from a larger group of images taken for a previous study.[5] ImageJ software will be used to select a region in each photo and will generate the respective RGB values; the images analyzed will not be corrected or altered. The RGB values will be converted into chromaticity coordinates and will then be plotted on a CIE 1931 color space chromaticity diagram so that a trend in the values can be evaluated.[6] This process will be repeated on the images after correcting them for brightness and contrast.

Preliminary results show RGB values generated from both uncorrected and corrected images can be converted into CIELAB values, which can then be plotted on a chromaticity diagram. The red, green, and blue color channels will be plotted against the time progression to establish how strong a relationship exists. Differences in the sets of values will expose the necessity of image correction. Patterns in the plotted points will reveal how digital colorimetry tracks color changes, and if it can validate postmortem interval estimation.

Human Decomposition, Chromaticity Diagram, Digital Colorometry

H92 Wearing Down Old Perspectives: The Prevalence of Severe Dental Attrition in Modern Individuals

Katherine E. Skorpinski, MA, Univ of Florida, Cancer/Genetics Research Complex, 2033 Mowry Rd, Rm G17, Gainesville, FL 32610; and Alice E. Fazlollah, MS, Univ of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will have a better understanding of the frequency of severe dental attrition in modern individuals, as well of the possible causes of this condition.

This presentation will impact the forensic science community by highlighting the presence of severe tooth wear in forensic cases, which is typically observed only in archaeological contexts. Additionally, the

researchers explore how this degree of wear can affect the development of the biological profile and the process of identification.

In the analysis of skeletal remains in the United States, the presence of severe dental attrition is usually an indicator of ancestry (i.e., Native American) and can serve as a deciding factor in determining medicolegal significance. However, attrition occurs in all populations for a variety of reasons. For example, 121 contemporary individuals from the William M. Bass Donated Skeletal Collection were examined for severity of tooth wear in the posterior (premolar and molar) and anterior (incisor and canine) teeth. Large areas of exposed dentin, as indicated by a wear score of five or higher according to Smith, were observed in the posterior dentition of 14% of the sample, and in the anterior dentition of 12% of the sample.[1] While a relatively small percentage of the sample exhibited a severe wear score, none of the individuals fit the typical demographic or contextual profile for this degree of wear (e.g., prehistoric).

Possible causes for severe attrition in contemporary individuals were explored through the examination of the skull of a male in his early 40s exhibiting a degree of dental attrition akin to prehistoric populations. Although this condition typically rules out medicolegal significance in the United States, three key lines of evidence indicated that he was a modern individual. First, the remains were in an advanced state of decomposition upon discovery. Second, the individual displayed evidence of antemortem modern cranial surgery. Third, several modern dental restorations were present. Without these indicators, time since death for this individual may have been determined to be outside the realm of medicolegal significance; as such, these remains may never have been identified.

A number of hypotheses for the presence of this extreme attrition were examined through a review of the literature and a cross-disciplinary discussion with dental professionals. Hypotheses considered included wear resulting from this individual's particular occlusal alignment, wear related to subsistence strategies or other nonmasticatory use, and pathological bruxism secondary to neurotrauma. The investigation suggested that fewer and fewer researchers consider occlusal alignment to be a prominent factor in bruxism.[2] Although the individual exhibits edge-to-edge occlusion, the researchers surmised that this morphological factor did not play a significant role in the progression of attrition. Further review found that the individual exhibits a wear pattern unlike any previously documented population-specific wear.[3] Thus, cultural influence is an unlikely factor. Finally, literature describing similar wear in patients with neuromuscular disorders suggested that severe wear can occur over a relatively short time period due to constant diurnal and nocturnal bruxism.[4] Research also showed that disturbances in the central neurotransmitter system of the brain, specifically the basal ganglia, are directly linked to severe bruxism.[2] Therefore, the researchers conclude that this individual's advanced state of attrition was likely associated with the antemortem cranial trauma and resulting neuromuscular complications.

The frequency of tooth wear observed in the Bass Collection, as well as the presence of severe attrition in a fairly young individual, illustrated the necessity to consider the impact of severe attrition on the forensic identification process. Specifically, consideration of the full range of possible factors associated with tooth wear is essential in determining medicolegal significance. Additionally, the fact that this degree of wear occurs secondary to neurotrauma over a relatively short period of time is important in instances where tooth wear may be used for aging, as it would result in a significant overestimation of age. Forensic anthropologists should be aware that encountering similar modern cases of severe attrition may be more common than previously thought. Special attention to causal factors is required in these cases to determine the possible effects on the development of the biological profile.

Dental Attrition, Bruxism, Neurotrauma

H93 Biomechanical Evaluation of Frangible Skull Surrogates to Blunt Ballistic Temporo-Parietal Head Impact

David E. Raymond, PhD, California State Univ, Los Angeles, Dept of Mechanical Engineering, 5151 State University Dr, Los Angeles, CA 90032; Cynthia Bir, PhD, 818 W Hancock, Detroit, MI 48201; Gregory S. Crawford, MS, 818 W Hancock St, Detroit, MI 48201; and Chris Van Ee, PhD, 46475 DeSoto Ct, Novi, MI 48377*

After attending this presentation, attendees will obtain additional knowledge on the biomechanical testing of trauma-indicating skull surrogates for use in forensic investigation.

This presentation will impact the forensic science community and aid attendees by providing additional morphological fracture data from laboratory-based testing of Postmortem Human Subjects (PMHS) exposed to blunt impacts in additional to a biomechanical comparison between the PMHS and frangible skull surrogates.

Various breakable or frangible "trauma indicating" head models have been proposed over the years by the automotive safety community.[1,2] Effort was shifted to the improvement and development of nondestructible technologies with frangible models never making it to a production level. The need for a frangible head model has since resurfaced for forensic applications. Forensic applications of injury biomechanics is a unique and emerging field.

The "skin-skull-brain" model was developed by Thali et al. to reproduce fracture patterns seen in forensic cases due to blunt and ballistic traumata.[3,4] Known cases of blunt and ballistic traumata were used as validation of the model's fracture characteristics. While good agreement was found between fracture patterns, no biomechanical considerations such as biomechanical response (force and deformation characteristics) or fracture tolerance were addressed in the study.

The goal of the current research was to evaluate the biomechanical response and fracture tolerance of a frangible skull model to blunt and ballistic traumatic conditions. Biomechanical response, fracture tolerance, and resulting fracture patterns were compared to those produced in PMHS exposed to the same traumatic conditions. Two types of frangible surrogates were evaluated. Three material types (10% gelatin solution, lead shot surrounded by Styrofoam, and water) were used to represent intracranial contents to evaluate the effect of interior boundary condition. A leather chamois was used as a skin covering over the impact site. A 103 gram, 1.5 inch-diameter impactor was launched at 20 m/s from a custom air cannon at the surrogate/PMHS which was suspended via a lightweight cable. An accelerometer was embedded in the impactor to measure impact force via Newton's Second Law. High speed digital video was captured at 10,000 frames per second with two Kodak HG100k cameras mounted orthogonally to the specimen. PMHS specimens were tested with soft tissue intact for the first impact. Following the first impact, a second impact was performed following defleshing of the specimen to obtain forced-deformation response under both conditions for comparison. Force-deformation plots were generated from the PMHS tests for comparison to the frangible surrogate responses. Fractures in PMHS were photographed for morphological comparison to the surrogate tests.

The sphere designs investigated in the current study demonstrated an increased tolerance to fracture compared to PMHS. The fracture pattern created in the one fractured sphere did not compare well with the PMHS fracture patterns, but may be an artifact of the seam created by joining the two-piece skull model. The effect of internal boundary condition was evaluated by assessing three different brain substitutes. The 10% gelatin solution provided the maximum resistance to local deformation while the lead shot surrounded by Styrofoam provided the least resistance. The water-filled sphere resulted in the most biofidelic

force-deformation characteristics indicating it may be the more ideal internal boundary condition. Additional testing is necessary before statistical conclusions can be reached.

These results indicate material properties (polyester versus polyurethane) and structural composition are important factors that should be evaluated for the current frangible skull surrogate design. In addition to modifications to the structure of the model, consideration is needed for a biofidelic soft tissue covering.

H94 Interpreting the Injury Mechanisms of Blunt Force Trauma From Butterfly Fracture Patterns

Samantha L. Reber, BSc, 5 Webster St, Ashton Preston, Lancashire PR2 1BY, UNITED KINGDOM*

After attending this presentation, attendees will have a better understanding of: (1) which factors affect butterfly fracture formation; and, (2) how to interpret the direction of applied force from butterfly fracture patterns. The main goal of this research was to challenge previous assumptions made about the interpretation of blunt force injury mechanisms from butterfly fractures and to provide the forensic community with rigorously tested results on how and whether the direction of force can be accurately determined from butterfly fracture analysis.

This presentation will impact the forensic science community by demonstrating that the side and orientation of butterfly fracture fragments can be inconsistent and, therefore, inaccurate when used as the sole criterion for determining the direction of applied force; however, this study has also found that by analyzing the pattern of the fracture in its entirety for both complete and incomplete fractures, a specific blunt force fracture pattern can be observed and used to more accurately determine the direction of force.

The majority of current forensic literature suggests that the direction of applied force can be determined by analyzing the orientation of butterfly fracture patterns. More specifically, the side of the bone from which a butterfly-shaped fragment originates is thought to directly correspond to the direction of applied force.[1] The use of this method was recently cautioned by Thomas and Simmons after analyzing the controlled fractures of 94 sheep femora.[2] This study reported the formation of butterfly fractures to be highly inconsistent, observing butterfly fragment formation on both the impact and nonimpact side of bones. Another recent study by Fenton et al. analyzed the controlled fracturing of 15 dry human long bones.[3] This study reported that the direction of force could be determined in 14 out of 15 cases by analyzing the entire fracture pattern, including both gross and incomplete fracture lines, instead of focusing merely on the identification and orientation of butterfly fragments. These studies indicate that further controlled research is needed to corroborate, refute, or simply clarify the accurate interpretation of the direction of applied force from blunt force fracture pattern analysis.

In this study, 105 *Ovis aries* femora were broken using a customized pendulum impact apparatus made of a large wooden frame with a weighted base, a rigid metal pendulum, blunt anvil, and an adjustable bone stand with metal cup stabilizers. The bones were oriented in an upright position with the anterior mid-shaft surface facing the impact hammer. The bones were secured in place by adjustable metal cups that applied compressive forces in a fashion mimicking the intrinsic forces experienced by weight bearing.[4] The initiation and propagation of each fracture was captured with a high-speed camera at 1,000 frames per second.

According to the biomechanics of fracture production, the biomechanical response of a bone to applied extrinsic forces is highly dependent on its specific geometry; therefore, the following measurements and observations were recorded for statistical analysis: length; mid-shaft circumference; cortical thickness; moment of inertia; fracture classification; presence of butterfly fragment; fragment angle; fragment side; and overall fracture pattern and propagation.[4] In addition to this experiment's sample, the 94 sheep femora previously broken by Thomas and Simmons were re-analyzed with the intent of including both gross and incomplete fracture lines in the analysis of determining the direction of applied force.[2] Including this sample also allowed for a comparison between two different injury mechanisms; more specifically, between the fractures seen in bones held upright with compressive forces and bones held against a substrate.

Preliminary results suggest the wedge-shaped fragmentation traditionally described as a butterfly fracture pattern does, as reported by Thomas and Simmons, occur on both the impact and nonimpact side of the bone.[2] However, refocusing the analysis on the entire fracture pattern, as suggested by Fenton, reveals a specific pattern of gross and incomplete fractures in 76% of the sample.[3] Based on these observations, a new overall fracture pattern was defined. Subsequently, it was found that the direction of applied force could be determined accurately in 100% of specimens displaying a partial or complete variation of the identified pattern. At this time, no comparison has been made between the bones held upright with compression and the bones held against a substrate; however, this comparison will be addressed in the presentation.

In summary, this study demonstrates that the side and orientation of butterfly fracture fragments is indeed inconsistent and, therefore, inaccurate when used as the sole criterion for determining the direction of applied force. This study showed that through analyzing the pattern of the fracture in its entirety for both complete and incomplete fractures, a specific blunt force fracture pattern is observed and can be used to accurately determine the direction of force.

Butterfly Fracture, Blunt Force Trauma, Injury Mechanisms

H95 Reported and Observed Healed Fractures in a Modern Skeletal Collection

Heli M.K. Maijanen, MA, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will be informed about reported medical history data of a modern skeletal collection and the reliability of information regarding reported fractures.

This presentation will impact the forensic science community by increasing the knowledge of the reported data on the individuals in the W.M. Bass Donated Skeletal Collection, thus guiding future research

questions related to the medical history. It will also present healed fracture patterns observed in the collection and discuss how reliable the family-reported data is and whether it is applicable for identification purposes.

Forensic anthropology uses modern skeletal collections to create and test its methods. These collections usually have known demographic and other information for each individual. The information can be from different sources: self- or family-reported or measured. It is important to know the reliability of the reported information. For example, there are studies on the reliability of reported stature and weight information in the literature.

This presentation concentrates on the W.M. Bass Donated Skeletal Collection and the reported medical history of the individuals included in the collection, specifically healed fractures. This body donation program has a questionnaire for pre-donors and family members to complete. The questionnaire collects data on demographics, education, residence history, dental history, and medical history. The medical history section includes check boxes to document surgeries, fractures, amputations, prosthetics, diabetes, and cancer. Also, blank spaces are available for more detailed descriptions.

The focus of this study was to identify differences between the reported and observed fractures and to investigate possible sex dependence. The study population consisted of 160 White males and females. The age range of the population was 34 to 93 years, and females (average age 65 years) were slightly older than males (average age 62 years).

More self-donors reported fractures than family-donors. The number of individuals with reported fractures in males and females was nearly equal. Self-donors and family-donors had the same number of individuals with observed fractures. More females were observed to have at least one fracture than males.

An arm or spine fracture was the most common injury reported in females; an arm or leg fracture was the most common injury reported in males. Arm and leg fractures were reported more often by family-donors and arm and spine fractures more often by self-donors. Ribs and spine were fractured most frequently within both sexes.

Self-donor males reported the highest occurrence of fractures; 75% of the reported fractures were observed on the skeletal remains. In comparison, 77% of the fractures reported by self-donor females were observed; whereas, less than 60% of fractures reported by family donors (for both males and females) were observed. In general, the most under-reported fractures were rib fractures. Arm fractures were often reported and observed, while leg fractures were often reported but not observed.

The study of self- and family-reported fracture data has several limitations. Several individuals note a history of fracture(s), but do not provide specifics such as location. More often a leg, ankle, wrist, or arm is mentioned, not the specific bone or side. Other possible reasons for mismatch between the observed and reported fractures are missing or fragmentary elements, well-healed old fractures, fractures that occur after the self-donor questionnaire is completed, unawareness of the fracture, or forgotten fractures.

In conclusion, based on these data, the reliability of the reported information on fractures depends on the reporter (self-donor or family member) as well as the type of fracture. Other factors to be taken into consideration are how old the fracture is and how long ago the injury was reported.

Antemortem Fracture, Reported Data, Identification

H96 The Use of the Endocranial Base in the Estimation of Ancestry

Nicole D. Siegel, DVM, Mercyhurst Univ, Dept of Applied Forensic Sciences, 501 E 38th St, Erie, PA 16546*

The goal of this presentation is to inform attendees about an evaluation of selected internal (endocranial) base landmarks performed on crania from the Hamann-Todd Human Skeletal Collection, and to test the merits of inclusion of endocranial base landmarks in forensic analysis.

This presentation will impact the forensic science community by demonstrating the utility of endocranial base landmark analysis in estimation of ancestry on a large sample of known remains.

Ancestry assessment is an integral part of the analysis of human remains in forensic studies. The cranium is among the most useful parts of the skeleton for estimation of sex and ancestry. In metric analyses, ancestry assessment has traditionally relied on linear distances between landmarks on the external (ectocranial) surface of the cranium.[1-3] In particular, in forensic settings a current analytical tool is the multivariate group comparison of these interlandmark distances using the software FORDISC 3.[4]

The endocranium, in particular the endocranial base, is easily accessed after an autopsy cut routinely performed in forensic settings, and contains several consistent, easily identifiable anatomical landmarks. The endocranium is also very durable, and is often well preserved in fragmentary remains. Since similar developmental pressures affect both the internal and external surfaces of the cranium, it is likely that, like ectocranial landmarks, endocranial landmarks can be useful to discriminate different sex and ancestry groups.

Studies assessing the utility of endocranial landmarks are scarce in the literature. Cameron devised angles about the pituitary point on sagittal sections of crania from the Hamann-Todd Human Skeletal Collection to evaluate cranial flexion, which was revisited by May and Sheffer and Lieberman et al. in extant primates and modern humans.[5-7] Bruner and Ripani, in a forensic application of endocranial landmarks, evaluated the utility of 19 endocranial base points for sex estimation, finding that all detected sex differences were found to be primarily related to allometry, they did not evaluate differences in ancestry.[8]

In this study, the utility of a set of endocranial landmarks is assessed for ancestry determination using landmarks proposed by Bruner and Ripani, as well as an additional set of landmarks proposed by the author. A 3D digitizer was used to digitize landmarks on 200 crania from the Hamann-Todd Human Skeletal Collection. Both interlandmark distances and Procrustes coordinates were analyzed through discriminant function analysis using FORDISC 3 and a geometric morphometrics software. Sex differences were attributed to size, so they were detected in interlandmark distance measurements but not in Procrustes coordinates, which eliminate size differences, focusing solely on shape. When the sexes were pooled, shape differences between ancestral groups were found. Similar to traditional ectocranial landmarks, endocranial base landmarks showed significant differences between African American and European American crania, with African Americans displaying significantly longer and narrower cranial bases. Discriminant function analysis using FORDISC 3 classified ancestral groups with a cross-validated accuracy of 77.3%.

Endocranial, Base, Ancestry

H97 3D-CT Imaging and Global Crime Scene Reconstruction in Forensic Ballistics—Two Case Reports

Thomas Colard, DDS, PhD, and Yann Delannoy, MD, Institut de Médecine Légale, Place De Verdun, Lille, 59045, FRANCE; Francois Bresson, PhD, Insitut National Police Scientifique, Boulevard Vauban, Lille, 59000, FRANCE; Jean-Sébastien Raul, PhD, MD, 11 Rue Humann, Strasbourg, 67085, FRANCE; Didier Gosset, MD, PhD, Institut de Medecine Legale, Faculté de Medecine, Lille, 59045, FRANCE; and Valéry Hedouin, PhD, Iml de Lille, Lille, 59045, FRANCE*

After attending this presentation, attendees will have an enhanced understanding of 3D reconstruction of external and internal bullet tracks in case of gunshot wounds.

This presentation will impact the forensic science community by highlighting the value of virtual tridimensional reconstruction of both crime scene and Computed Tomography (CT) images to help in determining the course of events in forensic ballistics.

Postmortem investigations are increasingly assisted by Multislice Computed Tomography (MSCT). Over the past twenty years, these examinations, often termed *virtual autopsy* or *virtopsy*, have become more available to forensic pathologists. The aim of the presented study was to examine ballistic injuries using advanced radiological techniques and comparing the results with the autopsy findings. In cases of ballistic injuries, CT scanning and Three-Dimension (3D) reconstructions provide an accurate description of the bullet location, bone fractures, and, more interestingly, a clear visual of the intracorporeal trajectory (wound tracks). These forensic medical examinations are compared with tridimensional bullet trajectory reconstructions made by forensic ballistics experts.

The implementation of tridimensional methods and the results of the global crime scene reconstruction is shown through two case reports.

Case 1: A 33-year-old woman was shot in the shoulder by a twelve-gauge smooth-bore firearm with slug ammunition (Brenneke). The 3D-MSCT revealed the presence of numerous bullet and bone fragments and a trajectory of anterior-posterior, right-to-left. Two wound tracks were identified: the primary track that coursed from the entrance to the exit wounds; and a secondary track that terminated with small bullet fragments. The examination allowed the isolation of two possible scenarios for the external bullet trajectory. Both were modeled with the appropriate software. The confirmation of internal and external bullet trajectories confirmed the defendant version and showed the incompatibility of the victim's initial statements with the forensic findings.

Case 2: A 32-year-old man was found in a burned car with burn injuries corresponding to a Crow-Glassman level 3. A bullet (full metal jacket with lead core and brass jacket, .25 ACP) was found in the skull. The 3D-MSCT revealed a linear cranio-encephalic trajectory, strictly horizontal and right-to-left. The 3D crime scene reconstruction compared with forensic medical examination presented the best scenario, which was a shot from outside the car.

These case reports highlight the usefulness of CT imaging techniques for the reconstruction of ballistic trajectories. Virtual autopsy can be used to reliably reconstruct gunshot wound tracks, which are generally linear tissue defects associated with gas, bone, and metallic fragments. Postmortem CT imaging is, therefore, an important and useful complement to the forensic autopsy. Work collaborations between police forensic experts and forensic medicine institutes allow the incorporation of medical examination in a global crime scene reconstruction. CT imaging reconstruction is an interest in forensic science, and it's also a clear visual communication tool between experts and the court.

Forensic Ballistics, 3D MSCT Reconstruction, Bullet Trajectory

H98 The Analysis of Insect Succession Rate and Pattern of Decomposition in Charred, Clothed Remains

Gail E. Elliott, BSc, 109 Huntly Dr, Tanshall, KY6 2HT, UNITED KINGDOM; and Tal Simmons, PhD, Univ of Central Lancashire, School of Forensic & Investigative Sciences, Preston, Lancashire PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will gain an understanding of the effects of accelerants on the rate and pattern of decomposition.

This presentation will impact the forensic science community by providing important information regarding Postmortem Interval (PMI) estimations for forensic investigations and a broader understanding of factors that affect decomposition.

Clandestine fires are common in criminal settings where fire is used to destroy evidence which may link the perpetrator to the crime or to obscure the victim's identity.[1] The offender may cover the body in accelerant before ignition, while underestimating the amount of fuel and heat required, thus producing only partially charred remains.[2,3] Offenders use easily accessible accelerants, with petrol employed in most cases (50.4%) and paraffin in fewer (28%).[4] Due to the nature of clandestine fires, the victim's body is often not recovered immediately; therefore, the PMI estimation becomes forensically relevant because it allows an approximation of the date of the incident and may aid the identification process.

There is a paucity of literature regarding the decomposition of charred remains and techniques for the approximation of the PMI. Given the awareness that fire is employed in homicides to destroy human remains and the frequency of lengthy delay in discovery, the presence of this gap in the literature is surprising. Gruenthal *et al*. (2012) represent the single attempt in PMI approximations in remains charred to Crow-Glassman System (CGS) Levels 1 and 2.[5] This research provides an approach to the estimation of the PMI in accelerant-charred remains and aims to determine whether or not the use of these accelerants in burning the remains had a significant effect on insect succession (Coleoptera and Diptera), pattern, and rate of decomposition.

At the beginning of the experiment, 30 domestic pig carcasses (*Sus scrofa*) were transported to the Taphonomic Research in Anthropology Centre for Experimental Studies (TRACES), University of Central Lancashire. The pigs were separated into three groups and were washed and weighed, and thermocouples with data loggers were inserted rectally before dressing the pigs in T-shirts and shorts. The pigs were then placed in their field locations five meters apart, and treatment carcasses were covered with 2.5 liters of their respective accelerant before ignition, within minutes of application. The fires burned out naturally, and the extent of thermal destruction was scored using the Crow-Glassmann System (1996).[5] Each pig was covered in a wire mesh cage to prevent vertebrate scavengers from accessing the carcasses.

Data collection intervals were approximately every 30 – 40 Accumulated Degree Days (ADD). During each data collection, the treatment carcasses were scored using both the Gruenthal et al. (2012) and the Megyesi et al. (2005) scoring systems while the control carcasses were scored using only Megyesi et al. (2005)[6,7]. Data loggers were used to record ambient and internal temperatures (°C) at 6-hr intervals.

Data analyses were carried out using statistical software, R (V 2.9.3). A comparison of the two scoring systems for the accelerant-charred remains was carried out using a mixed effects model, and indicated both scoring systems can be applied with equal success for decomposition in accelerant-charred remains (r^2=0.89).[6,7] Rate of decomposition was analyzed using linear regression Analysis of Covariance (ANCOVA) with Total Body Score (TBS) as the response variable, and treatment and ADD as explanatory variables.

After 540 ADD, results showed the control group decomposed significantly faster than the burned groups ($p \leq 0.001$), while petrol decomposed significantly faster than the paraffin ($p \leq 0.001$).

Pattern of decomposition was scored separately for each of the three regions. The head and neck region was significantly different between the control and the two experimental groups ($p \leq 0.001$); there were no significant differences among any of the groups in the torso and limb regions.

The preliminary results suggest both scoring systems can be used for assessment of accelerant-charred carcasses. Accelerant-burned bodies decomposed significantly more slowly than unburned bodies. In particular, the head region of the treatment groups decomposed significantly more slowly than that of the controls. It is hypothesized that the presence of accelerants masks the volatile odors produced during early decomposition, thus delaying blowfly oviposition, and postponing the consumption of the carcass by maggots.

Burning, Accelerants, Decomposition

H99 Quantifying Heat Exposure of Osseous Material Utilizing Novel FTIR Peak Ratios

Sarah Ellingham, MSc, Thomas-Mann-Str. 39E, Schwarzenbek, 21493, GERMANY; and Tim Thompson, PhD, Meez Islam, PhD, and Gillian Taylor, PhD, Teesside Univ, School of Science and Engineering, Middlesbrough, TS1 3BA, UNITED KINGDOM*

After attending this presentation, attendees will have gained an understanding of how indices calculated from Fourier Transform Infrared Spectroscopy-Attenuated Total Reflectance (FTIR-ATR) absorption peaks can give vital information regarding the burn temperature and exposure time of bone that has been subjected to fire.

This presentation will impact the forensic science community by reforming traditional methods of predicting heat exposure of bone and significantly improving the rate of accurate temperature prediction in experimental burnings from 19% using the traditional method to 82% when incorporating the new ratios.

Bone can reveal insightful information about an individual's life and circumstances of death. Professionals of various disciplines have an interest in understanding the changes bone undergoes when subjected to fire, be they archaeologists investigating ancient burial practices or forensic personnel confronted with the reconstruction of a scene of accident or crime.

Traditionally, only the so-called Crystallinity Index (CI), which is defined by the splitting of the two absorption peaks at 605 and 565cm^{-1} when using spectroscopy as a mean of analysis, has been used to gain an understanding of the heat exposure bone has undergone. The higher the exposure temperatures, the more ordered the bone structure becomes, exhibiting larger hydroxyl apatite crystals; however, this trend is reversed at temperatures above 800°C, due to the complete loss of all organic components and a shift in the elemental ratios. The consideration of the entire FTIR spectrum, therefore, lends itself for a better understanding of heat-induced changes to the bone matrix.

The present study investigated the use of new absorption peaks for the determination of burning temperatures and duration. Research was carried out using defleshed rib bones of domestic sheep (*Ovis aries*) which were experimentally burned in a furnace for 45 min at temperatures between 50°C and 1100°C in 50°C increments. For each temperature, two bones were burned, each of which was sampled nine times, resulting in a total of 18 samples per temperature. These ground samples from the periosteal surface of the bones were then analyzed on a Nicolet 5700 FTIR-ATR at an optical range of 2000cm^{-1} to 400cm^{-1}. Principal Component Analysis (PCA) was performed on all possible absorption peak ratios of the normalized spectra and determined the following ratios to be the most powerful to discriminate between different burn temperatures: CI=(565cm^{-1}+605cm^{-1})/595cm^{-1}, CO/P=1650cm^{-1}/1035cm^{-1}, CO/CO_3=1650cm^{-1}/1415cm^{-1}, CO_3/P=900cm^{-1}/1035cm^{-1}, Phosphate High Temperature (PHT)=625cm^{-1}/610cm^{-1} as well as the Line Width, which is defined as the full width at half the maximum of the phosphate peak at 1035cm^{-1}.

PCA also determined that combinations of different ratios are appropriate for different temperature ranges; low temperature burnings (<400°C) are best identified using C/P, CO/CO_3, CO_3/P, CO/P, and the Line Width, temperatures in the middle ranges (400°C –700°C) by the CI and the Line Width and high temperature ranges (>700°C) by the PHT as well as the C/P ratio.

Subsequently, Linear Discriminant Analysis (LDA) was performed based on the calculated indices of each of the spectra. It was found that the rate of accurate temperature prediction within a range of +/- 50°C was 82% in experimental burnings, which is a significant improvement when compared to the 19% accuracy achieved when solely using the CI, as it has commonly been done in the past. These findings are very promising for the advancement of burned bone analysis.

Burnt Bone, FTIR, Crystallinity Index

H100 Patterns and Timing of Cervical Vertebral Ring Epiphyseal Union in Individuals Aged 10 – 30 Years at Death

A. Midori Albert, PhD, Univ of North Carolina, Wilmington, Dept of Anthropology, 601 S College Rd, Wilmington, NC 28403-5907*

After attending this presentation, attendees will have garnered new information concerning the timing and progress of union of the superior and inferior cervical vertebral centra or "ring" epiphyses as it relates to age at death, and as it varies by sex and population. The goals of this presentation are to: (1) provide an understanding of the progress of union of the superior and inferior epiphyses of the centra of cervical vertebrae; (2) explain the correlation between cervical vertebral ring epiphyseal union and age at death; and, (3) report and discuss findings from tests of sex and population differences in cervical vertebral ring epiphyseal union

This presentation will impact the forensic science community by providing an understanding of the timing and progress of cervical vertebral ring epiphyseal union as it relates to age and may aid in the estimation of skeletal age of unknown individuals, an important aspect of human identification.

For this study, data were collected from a sample of 100 individuals (34 African American females, 19 European American females, 21 African American males, 26 European males), aged 10 to 30 years at the time of death, from the Hamann-Todd Skeletal Collection. Eleven sites

of cervical vertebral ring union were observed: the inferior surface of the second cervical vertebra (C2) and the superior and inferior surfaces of C3 through C7. A modified five-stage scoring method was used: Stage 0, no union; Stage 1, beginning or progressing union; Stage 2, fully fused epiphyses but lacking in remodeling, thus revealing grooves throughout the centrum; Stage 3, full fusion with a groove in some areas and remodeling in other areas; and Stage 4, full fusion with complete remodeling throughout the centrum.

There was a strong correlation between mean values for vertebral ring union in the total sample (r=0.78). Females showed a higher correlation between vertebral ring union and age at death (r=0.83) compared to males (r=0.73). European females showed a slightly higher correlation between vertebral ring union and age at death (r=0.89) than African American females (r=0.83), while African American males showed a considerably higher correlation (r=0.76) compared to European American males (r=0.49). Student's t-test results indicated no statistically significant differences in mean epiphyseal union values between females and males with populations combined, or between African American and European American females; however, the difference between African American and European American males was significant ($p<0.05$).

Raw data observations showed that more cranially oriented epiphyses seemed more advanced in union than caudally oriented epiphyses. A student's t-test yielded a statistically significant difference between the inferior ring epiphysis of C2 and that of C7 ($p<0.01$), with C2 being more advanced than C7; yet, there was no statistically significant difference between C2 inferior and C7 superior. Epiphyses were divided by cervical vertebra type—mean epiphyseal union values for C2-C3 were compared to C4-C5 and C6-C7—and an Analysis of Covariance (ANOVA) test showed no statistically significant difference in the progress of union according to vertebra type. Further, age at death correlated similarly across vertebra types: the correlation between age and C2 – C3 epiphyeal union mean values was r=0.74, for age and C4 – C5 r=0.76, and for age and C6 – C7 r=0.78. Epiphyseal union mean values of the superior centra were compared to the inferior centra for each vertebra; results indicated no statistically significant differences.

Observational analyses of the raw data were as follows: in some females and males, aged 10 – 12 years, union had already begun (Stage 1). Stage 0, no union, was surpassed by 19 years in females and 21 years in males. Stage 1, union in progress, remained evident in some males at 23 years and 19 years in most females, except for one female aged 30 years, who was thought to be an outlier. Stage 2, complete union with grooves, was first evident at 13 – 14 years for females and 15 – 16 years for males. Stage 2 remained evident in males at 25 years and in what was believed to be an outlier female aged 30 years. Stage 3, complete union with both grooves and remodeling, was first seen at 15 – 16 for females and 17 – 18 for males. This stage remained evident in both females and males aged 30 years. Stage 4, complete union with complete remodeling (no grooves), was first seen in both females and males at ages 17 – 18 years.

No individuals in the sample displayed all Stage 4 union. This finding may reflect the difficulty in distinguishing a groove from a scar, a slight color demarcation not eradicated by remodeling. In conclusion, cervical vertebral ring epiphyseal union may serve as a useful guideline for age estimation in unknown skeletons.

H101 Detecting Submerged Remains: Controlled Research Using Side-Scan Sonar to Detect Proxy Cadavers

Carrie A. Healy, MA, 2324 W Skyler Dr, Fayetteville, AR 72703; John J. Schultz, PhD*, Univ of Central Florida, Dept of Anthropology, PO Box 25000, Orlando, FL 32816; and Kenneth G. Parker, and Bim Lowers, BS, Orange County Sheriff's Office, Marine Unit, 2500 W Colonial Dr, Orlando, FL 32804*

After attending this presentation, attendees should understand the application of side-scan sonar to forensic water searches, and specifically how this technology is used to detect submerged human remains. Controlled research will be presented that investigates the variables influencing side-scan sonar searches for submerged bodies.

This presentation will impact the forensic science community by explaining how this technology can be utilized in forensic water searches and the best parameters to employ when searching for a submerged body.

Searching for submerged bodies in water environments can be a challenging task for investigators. While traditional methods, such as cadaver dogs, dive teams, and underwater cameras are common methods for water searches, geophysical instruments and methods are being integrated into search protocols. The main advantages of incorporating geophysical methods for submerged body searches include: a more thorough search, a considerable decrease in search time, and a reduction in the personnel required to perform a detailed search. As a result, numerous law enforcement agencies have now incorporated side-scan sonar as the initial method for their search protocol. When water conditions are appropriate, this technology is used to locate submerged bodies that are usually then retrieved by divers. While side-scan sonar has become a valuable geophysical tool for forensic water searches, controlled research is paramount to determine the best practices for searches in various aquatic environments. Controlled research provides a structured environment in which to investigate variables that influence the effectiveness of the technology and to provide valuable experience for sonar operators. The purpose of this study was to conduct controlled research, using proxy cadavers, in order to evaluate the applicability of side-scan sonar technology and search methods. In addition, the best practices for employing this technology in forensic searches in freshwater ponds and lakes, in a humid, subtropical environment in Central Florida, were developed. Three pig carcasses (*Sus scrofa*), utilized as proxies for human bodies, were staked to the bottom of a large borrow pond, on a flat, sandy bottom. This set of pig carcasses represented medium-sized adult bodies (51 – 54kg). The specimens were monitored for a period of 81 days, which resulted in nearly skeletonized and disarticulated bodies. A dual frequency (900/1800kHz) side-scan sonar unit (deployed from a pontoon boat) was utilized to monitor the pig carcasses, and divers photographed the carcasses during each data collection event when water visibility was appropriate. Transects were conducted with a 20m swath width using both the 900kHz and 1800kHz frequencies. Results show that this technology successfully located medium-sized proxy carcasses on a flat, sandy lake bottom when experienced operators were conducting the search. In the initial stages of decomposition, the carcass (i.e., the acoustic shadow of the carcass) maintained the morphology of a pig that could be easily discerned. However, in later stages, the decomposing carcass was still detected with an accompanying shadow, but did not maintain the morphology of a pig. As decomposition advanced to disarticulation, the carcass progressed to a cluster of distinct features with little to no accompanying shadow. Also, the optimal towfish frequency was 900kHz because this frequency depicted a more discernible and consolidated carcass when compared to the higher resolution of the 1800kHz frequency. Therefore, in the appropriate conditions, side-scan sonar is an effective tool for locating submerged bodies in freshwater lakes and ponds, in a humid, subtropical environment. However, during the later stages of decomposition and disarticulation, it may be more difficult to locate a body since the disarticulated remains will no longer appear as a

clustered group of features and may be devoid of a discernible acoustic shadow.

Submerged Bodies, Geophysical Searches, Side-Scan Sonar

H102 Preliminary Validation of Handheld X-Ray Fluorescence (HHXRF) Spectrometry for Distinguishing Osseous and Dental Tissue From Non-Bone Material of Similar Chemical Composition

Heather A. Zimmerman, BS, 17413 Meadow Lake Cir, Fort Myers, FL 33967; John J. Schultz, PhD, Univ of Central Florida, Dept of Anthropology, PO Box 25000, Orlando, FL 32816; Caitlin Rinke, BS, PO Box 162367, Orlando, FL; and Michael E. Sigman, PhD, Univ of Central Florida, NCFS, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will have a better understanding of the benefits of utilizing Handheld X-ray Fluorescence (HHXRF) spectrometry and statistical analysis to distinguish fragmentary osseous and dental material from non-bone material of similar chemical composition.

This presentation will impact the forensic science community by demonstrating that the HHXRF is a valid method for distinguishing between fragmentary osseous or dental material and non-bone material of similar chemical composition in a laboratory setting.

Identifying bone and osseous material that is highly fragmented, burned/charred, and subjected to extensive taphonomic processes can be difficult based on the poor quality of the bone. In most cases, bone and non-bone fragmentary materials are sorted in the field using gross methods; however, in cases involving indeterminate fragments, other methods may be used to sort the material in a laboratory setting. Current laboratory methods include histological analysis and chemical methods determining elemental composition. A recent chemical method proposed by Ubelaker et al. (2002) involves the use of Scanning Electron Microscopy and Energy-Dispersive X-ray Spectroscopy (SEM/EDS).[1] This method provides the Ca/P ratios of analyzed materials, and allows for the formation of a spectral library. More recently, X-ray Fluorescence (XRF) spectrometry, which analyzes the chemical composition of small, fragmentary specimens, and then allows for the specimens to be sorted based on Ca/P ratios, was proposed as a viable method.[2] HHXRF instruments have recently come into use in areas of criminal justice and physical anthropology.

The purpose of this research was to determine the applicability of using an HHXRF for discriminating non-bone material (including material with a similar composition to bone) from osseous and dental material using statistical methods for discrimination purposes.

A total of 28 samples were analyzed, with three spectra taken from different locations on each sample. Samples consisted of human and non-human bones (archaeological, anatomical), non-biological specimens (rock phosphate, rock apatite, synthetic hydroxyapatite, plastic, glass), and other biological specimens (sand dollar, three shell species, two coral species, turkey spurs, bark). A Bruker Elemental S1 Turbo-SDR HHXRF unit was used with upgraded analytical software, S1PXRF (provided by the manufacturer), which allowed for the detection of low-mass elements. The HHXRF was mounted on a vertical stand for stationary analysis and samples were placed directly onto the examination window for analysis using a 15 kV/Filter 2. Post-processing of the data involved removing calcium from the spectrum and normalizing the integrated area of the remaining trace elements, Principle Component Analysis (PCA) using MatLab version 2011b by Mathworks, and Linear Discriminant Analysis (LDA) based on principle components representing 95% of the variance in the data using SYStat version 13 by Cranes Software International.

Initial analyses indicated that cleaning may be required when soil staining is involved, as a number of dental specimens were discriminated from non-bone samples only after minimal processing with a Dremel tool. Results of the LDA showed 97% average discrimination between bone and non-bone samples (with 2% of bone samples misclassifying as non-bone and 5% of non-bone misclassifying as bone). The samples that misclassified were rock apatite, synthetic hydroxyapatite, and an alligator rib bone. The misclassification was a result of only one out of the three collected spectra per sample, as the other two spectra were correctly classified for these specimens. Statistical methods are being examined to remove possible outliers in the data.

The combination of an HHXRF with statistical analysis shows promise for discriminating fragmentary osseous and dental tissue from other types of material, due to the analysis of all detected elements after removal of calcium from the spectrum and normalization of the integrated area of the remaining trace elements. Further research will explore the application of this method by expanding the sample size and determining which location on the bone offers the most accurate discrimination, as well as the applicability of this method to the field in the form of the establishment of a bone library on the HHXRF.

Forensic Science, X-Ray Fluorescence, Elemental Analysis

H103 Evaluation of the Oettlé and Steyn Sternal Rib End Aging Method on an American Sample

Nicole L. Geske, BA, Michigan State Univ, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will have an understanding of the overall accuracy of the Oettlé and Steyn sternal rib end aging technique on an American sample, as well as possible ancestral differences for the method.

This presentation will impact the forensic science community by evaluating if the Oettlé and Steyn technique is applicable to an American Black sample.[1]

Sternal rib end aging was originally developed by İşcan, Loth, and Wright.[2,3] Although their method was developed specifically on White individuals, it was later tested on American Blacks (İşcan *et al.*), in which differences in morphological age-related changes between Blacks and Whites were found, with a general tendency to overage older Black individuals.[4] Additional key features associated with Black individuals were also identified, such as a difference in the scalloping pattern, an earlier development of bony projections, and overall good bone quality, even through old age.

Due to these known ancestral differences, Oettlé and Steyn tested and applied the İşcan *et al*. methods on a South African Black sample.[1-3] Low accuracy rates of the method and a tendency for delayed maturation of South African Blacks were found; therefore, the method was revised to reflect the population. Similar morphological differences observed in the İşcan *et al*. study, as well as plaque-like deposits that formed on the interior pit, were also seen in the South African Black sample.[4]

Ancestral and population-based differences have previously required the use of separate standards in other aging techniques, such as with cranial suture closure; therefore, other aging methods also need to be examined for these possible variations. Due to the presence of known ancestral differences in the aging process of the sternal rib end, the purpose of this research was to determine the accuracy of the Oettlé and Steyn sternal rib end aging method on an American sample, consisting of both White and Black individuals.[1]

In order to evaluate this method, data was collected from the Hamann-Todd collection. The sample consisted of 333 individuals and included male and female right fourth sternal rib ends from both White

and Black individuals, ranging in age from 14 to 80 years. The method was tested on all individuals using both photographs and phase descriptions from the original article.

Accuracy was evaluated through the use of cross tabulation tables, with 34% of the sample correctly assigned to the actual age phase. Additionally, 79% were correctly assigned within one phase, and 94% were within two phases. Spearman's coefficient of rank correlation was also used to examine the relationship between the estimated and actual ages, as well as any differences in accuracy based on ancestry or sex. The overall correlation coefficient for the sample was 0.690, with the highest coefficient of 0.714 for Black males.

Results indicate the Oettlé and Steyn method performs somewhat poorly overall on an American sample, although it is slightly more accurate for American Blacks compared to Whites.[1] Even though accuracy rates were relatively low, results do reflect the need for ancestral and population-based standards. Further research is needed to determine if this method is more accurate than that of other sternal rib end aging techniques, and additional data will be collected from the WM Bass collection to include a more modern sample, as well as to test for possible secular differences.

H104 3D Methodology Used for Exclusionary Identification at Crime Scenes—Who Was and Who Wasn't Here?

John A. Anderson, PhD, Univ of New Mexico, Valencia, Social and Cultural Studies, 280 La Entrada Rd, Los Lunas, NM 87031; Vincent H. Stefan, PhD, Lehman College, CUNY, Dept of Anthropology, 250 Bedford Park Blvd, W, Bronx, NY 10468; and Lisa A. Hogan, MA, Univ of New Mexico, Dept of Anthropology, Albuquerque, NM 87131*

After attending this presentation, attendees will learn about a morphometric technique for collecting a simple series of intra-hand measurements from photographic evidence and for analyzing these measurements in three dimensions for the purpose of establishing exclusionary identification.

This presentation will impact the forensic science community by showing results from a study to determine inter-observer error for this morphometric technique, expand the scope to include population variability, and examine the comparison of mono- and dizygotic twins to the robustness of this exclusionary technique.

The results of the study presented represent a step toward peer review for the described morphometric technique to broaden its utility in court. This technique was developed for a case in which the defendant claimed his older brother, a convicted child abuser, was the perpetrator of rapes against their 2-year-old niece. The rapes were recorded in a series of photographs that the Federal Bureau of Investigation determined to have been taken on two separate dates and in a videotape that occurred on the same date as one of the sets of photos; there was no DNA or dermatoglyphic evidence collected in this case. The prosecutor sought to add to the list of charges against the defendant by identifying whose hands were depicted in the photos, which for the most part showed an adult's fingertips and the victim's anatomy. The judge allowed the analysis to continue and ruled that the results were scientific in nature; however, he eventually did not admit the results into evidence at trial because the technique had not been peer-reviewed, which could have been a basis for appeal by the defendant.

When photographic imagery is introduced into evidence, one of the difficulties encountered can be the identification of subjects present or absent at the crime scene, absent the gold standard of results from DNA. The measurements of intra-hand landmarks described in this presentation are valuable in that they: (1) are conserved against weight gain and weight loss; (2) become fixed at maturity; and, (3) are easy to take. Such information is currently gathered in hand scanners and analyzed in two dimensions to establish identification for access to secure facilities. These landmarks represent conserved proportional relationships in adults; at maturity (~ 18 years), the growth of the digits, palm width, and other key aspects are established for life. For example, there are now several hundred articles addressing one feature used in our analysis: the relationship of 2nd to 4th digit length, a marker of intrauterine testosterone. Preliminary results from the above-referenced court case suggest that a 3D analysis enables unique identification of individuals. How unique? This presentation seeks to establish that.

The described procedure involves taking standard measurements of the hands in the photographic evidence, scaling them, and then statistically comparing them. This shape analysis relies on proportional relationships which also overcomes problems of scale and parallax. The scaled images are measured and then a Generalized Linear Model (Principal Component Analysis (PCA)) is used. When data are sufficient, the analysis allows differentiation of persons of interest based on the pattern unique to the individuals. In the proprietary report compiled for the prosecution in the child abuse case described, this pattern does not approximate the certainty level commonly derived from identifications derived from DNA or dermatoglyphs; however, the results showed the individual least likely present at the scene was the brother whom the defendant accused ($p<.031$). It is suggested that application of this technique will have broad-reaching implications in both the conviction of the guilty and exculpatory evidence for those not involved.

3D Morphometrics, Exclusionary, Identification

H105 Developing Frameworks for Regional Forensic Taphonomy Research and Practice: A Multi-Regional Symposium

Marcella H. Sorg, PhD, Univ of Maine, Margaret Chase Smith Center, Orono, ME 04469; William D. Haglund, PhD, 20410 25th Ave, NW, Shoreline, WA 98177; and Kerriann Marden, PhD, Univ of West Georgia, Dept of Anthropology, 1601 Maple St, Carrollton, GA 30118*

After attending this presentation, attendees will appreciate the importance of understanding regional taphonomic variation for forensic anthropology research and practice.

This presentation will impact the forensic science community by stimulating research and collaboration to establish, utilize, and refine methods and guidelines for interpreting regional taphonomy patterns, particularly decomposition.

From both a theoretical and practical point of view, forensic anthropologists need to improve their knowledge of regional and microenvironmental taphonomic variation, particularly related to the estimation of postmortem intervals. During the past 25 years, there has been an increase in attention to forensic taphonomy, but the focus has been largely on taphonomic "universals." Because there is a lack of adequate local datasets, researchers in taphonomy have tended to look where the light was best, and borrow guidelines developed in other regions.

With the expansion of forensic anthropology programs, and the proliferation of associated "body farms," there are now opportunities to rectify this research gap. But it should be done systematically and in a coordinated manner; this symposium is organized as a first step in that direction.

Attention needs to be focused on a conformation of methods and nomenclature to describe variation along a set of common taphonomic

parameters, so that a more complete, multivariate taphonomic data field, based on ecological variables, can be stitched together. This includes the following examples: common ways to express access to heat, such as Accumulated Degree Days (ADD); humidity, such as Accumulated relative Humidity Days (AHD); and decomposition progress, such as Total Body Score (TBS). It also includes standardizing methods for scene investigation and data collection, particularly: (1) logging heat at the scene; (2) calibration with weather station data; (3) collecting data about solar access (e.g., percent of tree canopy and evergreen versus deciduous vegetation shading the body); (4) noting scavenger access (e.g., identifying the local scavenger guild and signatures of their presence); (5) describing seasonal and sub-seasonal patterns; (6) noting variation in the timing of metamorphosis of local sarcosaprophagous insects in terrestrial cases and in the biology of amphipods in marine cases; and, (7) noting variation in local plant distribution and biology.

In the following symposium, Nawrocki and Latham offer a re-framing of the problem of interpreting decomposition within ecozones, rather than "regions" *per se*, differentiating between "core" processes that are more predictable and "peripheral" processes that are more stochastic and disruptive of core process predictability. Simmons and Moffat review non-human animal experiments done in the United Kingdom (U.K.) over five years to validate the relationship between TBS and ADD across variation in climatic conditions and observers. Carter et al. present an effort to validate a universal formula for estimating postmortem interval across regional variation. Dirkmaat and Cabo emphasize the criticality of taphonomy as an integrating principle within forensic anthropology. Milligan et al. provide an overview of issues and patterns related to northern California; Galloway to the California mid-coast; Connor and France to the Colorado Plateau; Bytheway to an arid Texas environment; Dabbs and Martin to southern Illinois; Woods and Pokines to terrestrial and coastal Massachusetts; Anderson and Bell to western Canadian coastal waters; and Sorg and Wren to northern New England.

The papers in this symposium are offered as still-isolated examples of work being done in the U.S., Canada, and the U.K. Work needs to be done via publications and professional conferences, and funded research, in order to cultivate this growing edge of the field. It is interdisciplinary and will require cooperation among disciplines and regions. A proposal is made in this symposium for creating a Regional Forensic Taphonomy Network (regionaltaphonomy.net) as a framework for taphonomy research.

The symposium represents early steps rather than conclusions. There are programs that are not represented, but which are hereby invited to participate in the Network as it progresses forward.

Taphonomy, Regional Variation, Decomposition

H106 Modeling Core and Peripheral Processes in Human Decomposition: A Conceptual Framework

Stephen P. Nawrocki, PhD, Univ of Indianapolis, Archeology & Forensics Lab, 1400 E Hanna Ave, Indianapolis, IN 46227-3697; and Krista E. Latham, PhD, Univ of Indianapolis, Biology Dept, 1400 E Hanna Ave, Indianapolis, IN 46227*

After attending this presentation, attendees will understand the difference between: (1) systemic "core" ecological processes that drive soft tissue decomposition and on which the prediction of the postmortem interval is based; and, (2) more stochastic "peripheral" phenomena that can significantly deflect the modal decomposition process and thus introduce error into the prediction process.

This presentation will impact the forensic science community by encouraging forensic taphonomists to replace their regionally specific decay models with a more systemic perspective that emphasizes the underlying continuity of decay across different ecozones.

The decomposing corpse is a complex mini-ecosystem. Nutrients and raw materials that once sustained the living body become available to a host of micro- and macro-organisms, including bacteria, fungi, molds, and invertebrates. The chemical and biological processes that drive this biomass conversion (autolysis, enzyme activity, bacterial replication, and insect growth) all depend, in part, on temperature. As ambient temperature increases, chemical and biological reactions occur more rapidly. As a result, the corpse releases energy and molecules into the surrounding environment, to be exploited by other organisms. The result of this process is soft tissue decay.

The relationship between temperature and insect growth was well understood by at least the 1940s. Although anthropologists recognized that human decomposition occurs more rapidly in hot environments, historical research focused on defining qualitative "stages" of human decomposition that could be tied only loosely to postmortem intervals. Over a decade ago, the University of Indianapolis began to explore the relationship between accumulated temperature and soft tissue decomposition. In three major studies, accumulated temperature explained 73% to 87% of the observed decomposition.[1-3] Time since death fared worse, explaining only 45% to 65% of the observed variation. Despite being drawn from different regions of the U.S., the three samples display remarkably similar decomposition curves. Each curve has a steep initial portion representing wet decay driven by active insect and bacterial breakdown, followed by a plateau where decay slows considerably and the tissues dehydrate. The curves are so alike that the initial equation describing the cross-sectional human sample requires no further modification when subsequent longitudinal pig and human datasets are applied.[1-3] Seasonal variation slightly alters the slopes of these curves and their plateau points, with cool-weather curves being flatter and hot-weather curves being steeper, but seasonality itself does not seem to change the essential form of the curves.

In these studies, accumulated temperature and the dependent biochemical and metabolic processes emerge as the primary determinants of systematic soft tissue decay. When one accounts for temperature, most if not all of the differences observed in the rate of decomposition in different latitudes and regions disappear. It is useful, then, to treat temperature-dependent organismal and biochemical processes as "core" processes that drive decomposition. Because there is a systematic, mathematical relationship between accumulated temperature and decay, methods for predicting the postmortem interval must rely primarily on these core processes. Tables that attempt to relate observed decay status directly to time intervals without incorporating temperature should be abandoned, and studies purported to display regional differences in decay rates should be re-evaluated if they did not explicitly control for differences in temperature.

Clearly, factors other than temperature and invertebrate necrophagy, such as an abundance or absence of water and vertebrate scavenging, can significantly affect decomposition in specific cases. These factors, however, are qualitatively different from core metabolic processes that vary systematically with temperature. It should be difficult, if not impossible, to quantify the effects of these more stochastic variables in most environments, and it is likely that they vary much more randomly across short distances within ecological zones or geographical regions. At best, postmortem interval predictions can be informed by, but not based on, these "peripheral" processes.

Decomposition, Temperature, Taphonomy

H107 The Taphonomic Revolution: Taphonomy as an Integrating Principle in Forensic Anthropology

Dennis C. Dirkmaat, PhD, and Luis L. Cabo, MS, Mercyhurst College, Dept Applied Forensic Sciences, 501 E 38th St, Erie, PA 16546*

After attending this presentation, attendees will have a better understanding of the significant role forensic taphonomy plays in redefining the field of forensic anthropology as a scientific discipline.

This presentation will impact the forensic science community by outlining the components of forensic taphonomy and how they provide a strong conceptual framework and new lines of research for forensic anthropology.

As originally conceived, and perpetuated for several decades, forensic anthropology was focused almost exclusively on the practical task of victim identification. This perspective provided the driving force behind the development of the field and its professional practice as it is understood today. However, this myopic focus on only the applied nature of the proposed task also imposed severe restrictions on the scope of forensic anthropology and its growth as a scientific discipline. In particular, the paradigm sprung from the classic definition largely failed to produce a cohesive, distinctive conceptual framework capable of supporting strong theoretical foundations or promoting clearly defined lines for basic research.

This presentation discusses how the emergence of forensic taphonomy in the last two decades has come to provide a much-needed theoretical framework, representing not merely a subfield within forensic anthropology, but the conceptual scaffold supporting the discipline and directing the development of the field, especially, the progress of the rapidly evolving subfields of forensic archaeology and skeletal trauma analysis.

The classic laboratory-based, osteological paradigm has focused narrowly on the diagenetic and bone-modification aspects of forensic taphonomy (mostly to assess bone trauma or diagenetic alteration); however, modern forensic applications are increasingly related to other classic taphonomic issues, such as site formation processes or quantitative taphonomy estimates. In turn, these issues serve to outline clear basic research subjects, such as bone transport and transport potentials, bone alteration by a wide variety of agents and natural factors, or anatomical part representation biases.

Moreover, forensic contexts actually offer a unique crow's nest for the observation of early taphonomic processes in real settings, allowing for powerful actualistic studies (this is currently one of the main Achilles' heels of taphonomic research at paleontological settings).

It is concluded that forensic anthropology would benefit from a stronger integration of forensic analysis (and not only taphonomic analysis, but also taphonomic theory), both in professional practice and when designing research. A forensic investigation is better understood and more meaningfully implemented, and communicated, when it is viewed as a taphonomic analysis, thus integrating scene and osteological information within a meaningful conceptual and methodological framework. This also has implications for the training of future generations of forensic anthropologists, who will need to be well-versed and experienced in field recovery techniques and paleontological theory.

Forensic Taphonomy, Forensic Archaeology, Forensic Anthropology

H108 Microbial Community Change Associated With Decomposing Corpses

Jessica L. Metcalf, PhD, Univ of Colorado, Dept of Chemistry and Biochemistry, Jennie Smoly Caruthers Biotechnology Building, Boulder, CO 80309; Laura Wegener Parfrey, PhD, Univ of Colorado, UCB 215 Dept of Chemistry and Biochemistry, Boulder, CO 80309; Antonoi Gonzalez, PhD, Univ of Colorado, Dept of Computer Science, Boulder, CO 80309; Christian Lauber, PhD, Univ of Colorado, Dept of Chemistry and Biochemistry, Boulder, CO 80309; Dan Knights, PhD, Univ of Colorado, Dept of Computer Science, Boulder, CO 80309; David O. Carter, PhD, Chaminade Univ of Honolulu, Division of Natural Sciences and Mathematics, 3140 Waialae Ave, Honolulu, HI 96816; Noah Fierer, PhD, Univ of Colorado, 596, Boulder, CO 80309-596; and Rob Knight, PhD, Univ of Colorado, Dept of Chemistry and Biochemistry, Boulder, CO 80309*

After attending this presentation, attendees will understand the basics about microbiome research (study of the genes of microbes) and how recent advances in sequence technology have allowed microbial ecologists to characterize the vast, but measurable, microbial diversity present in animal hosts (e.g., humans) and environmental habitats (e.g., soil). Attendees will be presented with results from recent experiments in which microbial community change was assessed in and on corpses and in their associated gravesoil over the time course of decomposition.

This presentation will impact the forensic science community by revealing the potential of microbial succession during the decomposition process to help: (1) determine the time since death; and, (2) locate clandestine graves.

Biotic signatures of corpse decomposition, such as chemicals or the succession of insects, are commonly used to determine the postmortem interval and to detect gravesoil, but no method is successful in every scenario. Therefore, the development of new forensic tools is important. Microbes are ubiquitous in the environment and they play a key role in regulating the speed of decomposition. However, microbial communities are not currently utilized to their full potential as a forensic tool. Testing whether changes in microbial communities are predictable over the timeline of decomposition is crucial for assessing whether microbes can be used as a "clock" to assess time since death.

Powered by advances in culture-independent microbial community analysis methods and sequencing technologies, recent research has revealed that microbial communities are quantifiable and predictable across habitats such as human skin and soil. In the research presented here, a laboratory experiment was conducted to characterize temporal changes in the microbial communities associated with mouse corpses as they decomposed on soil at ambient temperature for more than a month. Samples from the abdominal cavity, skin, and gravesoil were collected at regular intervals from five corpses. Partial 16S and 18S ribosomal RNA genes were sequenced using Illumina HiSeq deep sequencing technology. Computational pipelines were used to characterize the succession of bacterial and eukaryotic communities during the decomposition process.

Microbial community change was significant and fairly consistent across replicates within each sample site (skin, abdominal, or soil) through the decomposition process. For each corpse-associated site, Proteobacteria increased over time, but most notably in the abdominal cavity—a site in which bacteria of the family Enterobacteriaceae dominated at late stages of decomposition. Furthermore, the decrease in abundance of genera such as Bacteroides and Lactobacillus in the abdominal cavity over time lends support to the long-held hypothesis that decomposition in the abdomen shifts from anaerobes to aerobes or facultative anaerobes after corpse rupture occurs. Importantly, the microbial diversity of gravesoil was significantly modified by corpse decomposition. Several genera from the families Enterobacteriaceae and Rhizobiaceae may be important indicators of gravesoil. Eukaryotic sequence data revealed that nematodes of the family Rhabditidae dominate the meiofauna of both the corpse and soil during late stages of decomposition. Nematodes of the family Rhabditidae may also serve as an indicator of gravesoil. Results demonstrate that microbial

communities hold great promise as a forensic tool as there is a predictable succession over time and taxa are detected.

Microbiology, Decomposition, Ribosomal RNA Genes

H109 An Investigation Into the Relationship of Postmortem Interval and Bacterial Metagenomics of Bone

Franklin E. Damann, PhD, National Museum of Health and Medicine, 2500 Linden Ln, Silver Spring, MD 20910; and Alice C. Layton, PhD, Univ of Tennessee, Center for Environmental Biotechnology, 1416 Circle Dr, 676 Dabney Hall, Knoxville, TN 37996*

After attending this presentation, attendees will gain an understanding of the relationship between Postmortem Interval (PMI) and bacterial metagenomic profiles recovered from human skeletal remains.

This presentation will impact the forensic science community by providing baseline data for exploring the relationships among bacteria, cadaver decomposition, and estimating PMI.

Microbially mediated decomposition of a corpse leaves signatures in bone and their deleterious effects on structural integrity of bone have been defined previously.[1] The amount of bone destruction due to microbial activity has been loosely correlated with PMI, which has been observed occurring later than five years after death.[2] Yet bacteria are involved in postmortem processes immediately following death.[3] Thus, the goal of this research is to produce a community survey of bacterial phyla present in bone of varying PMIs.

Previous analyses of microbial concentration in bone from the University of Tennessee Anthropology Research Facility (UTARF) demonstrated an inverse relationship between total bacterial load and PMI.[4] This study used the same skeletal tissue to determine the bacterial composition of those samples. In doing so, the relative contribution of specific bacterial phyla was expected to change with advancing decomposition, as the sampled bodies transitioned from a high-quality to a low-quality resource.

Eleven human ribs sampled from as many actively decomposing corpses were analyzed. The corpses spanned a PMI of 1 – 48 months. Three soil samples with no known history of human decomposition were also analyzed in order to compare bacterial communities between decomposing bone and "normal" soil. Total DNA was extracted and next-generation sequencing was used to amplify and sequence a 200-base-pair product of the universal eubacterial 16S rRNA gene.[5,6] Recovered sequences were trimmed, aligned, and classified using the Ribosomal Database Project (RDP) pipeline and classifier.[7,8] Identified phyla were analyzed using cluster analysis on standardized abundance data.

Sequences from all rib samples provided 124,164 classified sequences. Results indicated consistency in the presence of specific bacterial phyla. The six most abundant phyla across all bone samples accounted for 94.37% of all classified bacterial phyla. The six most abundant phyla were: Protebacteria (64%), Firmicutes (12%), Bacteroidetes (10%), Actinobacteria (7%), Acidobacteria (1%), and Gemmatimonadetes (0.26%). Nearly 6% (5.62%; n=6,976) of the trimmed and aligned sequences remained unclassified at the bacterial phylum level. Chloroflexi, TM7, and Deferribacteres were consolidated into a single group "other" due to low representation (0.008%). Cluster analysis and MDS mapping on bacterial abundance data identified three significantly different clusters ($p<0.05$). One cluster was characterized by samples 1.2, 2, and 12.3 months. The second group consisted of samples with PMI of 7 – 20 months. The third cluster was composed of the non-UTARF soil samples and the 24- and 48-month PMI bone samples.

In all samples, Proteobacteria were the most abundant and were therefore determined to be of little value as a marker for evaluating temporal trends in phylum-level bacterial community structure. The greatest change in relative abundance occurred among the Firmicutes, Bacteroidetes, and Actinobacteria. The early PMI samples were dominated by Firmicutes. Bacteroidetes dominated the second phase of samples from 9 to 20 months, with the exception of one 12-month sample. The 24- and 48- month samples were dominated by Actinobacteria, and the level of Acidobacteria increased between these two samples, which was consistent with the non-UTARF soil samples.

These results provide baseline data for further exploration regarding the relationships among bacteria, cadaver decomposition, and PMI. Within these data, a succession in the relative abundance of three bacterial phyla was observed, demonstrating the potential for using bacterial metagenomics as a method for estimating PMI of decomposed skeletal remains.

This project was supported by Award No. 2008-DN-BX-K165 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice.

Taphonomy, Postmortem Interval, Bacterial Metagenome

H110 The Consistency of ADD, TBS, and Decomposition Rate: A Validation Study Spanning Five Years

Tal Simmons, PhD, and Colin Moffatt, PhD, Univ of Central Lancashire, School of Forensic & Investigative Sciences, Preston, Lancashire PR1 2HE, UNITED KINGDOM*

After attending this presentation, attendees will understand that experimental studies using Total Body Score (TBS) to predict Accumulated Degree Days (ADD) and decomposition rate have produced consistently accurate results over time.

This presentation will impact the forensic science community by presenting a validation of using the TBS methodology to provide an estimate of the Postmortem Interval (PMI). This method will be shown to produce consistent and accurate results over a lengthy period of time, using different carcasses and different observers; this validation study provides confirmation that this methodology produces robust and reliable results.

When Megyesi *et al*. introduced the TBS system as a means of quantifying the decomposition sequence, and derived an equation based on observed TBS to predict ADD, this provided forensic anthropology practitioners with a standardized method to estimate PMI.[1] Further research has since demonstrated the utility of TBS in predicting ADD and producing PMI estimates under a variety of scenarios relating to both intrinsic and extrinsic aspects of decomposition, including: the

size of the body; the condition of the body; the deposition of the body (e.g., surface, water, buried); and what is often loosely termed the "environmental conditions."[2-6]

This study reports on the consistency of results from research performed at the Taphonomic Research in Anthropology: Centre for Experimental Studies (TRACES) facility in the northwest of England from May to August during the years 2007 to 2012. Data collection protocols at TRACES have remained consistent throughout this period of time; visual observation, body scoring, and photography were undertaken every 50 ADD (as recorded by both the on-site weather station and self-contained thermocouple/data loggers with each pig). Approximately 100 domestic pigs (*Sus scrofa*) were used as controls over five years of experiments, under variable climatic conditions, and using different observers. Decomposition rates were not significantly different and graphs of TBS against ADD produced slopes that were nearly identical. Not only TBS, but individual body region scores (e.g., head/neck, trunk, and limbs) were significantly consistent at comparable ADD intervals regardless of observer, body, or year and prevailing climatic conditions.

To cite just one example where decomposition rate was not significantly different ($t=0.50$, $df=372$, $p=0.616$), the scores for the head/neck region in 24 control pigs from 2009 were virtually identical to those of 10 control pigs from a 2011 study at comparable ADD intervals:

TBS (2009) = -0.799 + 0.458 x √ (ADD)

TBS (2011) = -0.759 + 0.452 x √ (ADD)

The results of this study provide strong evidence that using TBS to predict ADD is consistent with regard to observers, time, and both intrinsic and extrinsic factors affecting a body—and, hence, a relevant, reliable, and valid methodology in the estimation of the PMI.

Validation Study, TBS and ADD, Decomposition Rate

H111 The Effect of Outdoor Microclimate on Time to Skeletonization in Clothed and Unclothed Remains in an Arid Southwest U.S. Environment

Allison M. Sharplin, MA, 1812 Sunset Dr, Vista, CA 92081-6315*

The goal of this presentation is to explore the forensic taphonomic effects of clothing and exposure to sunlight, with previous research indicating that varying amounts of sunlight have caused differential rates of decomposition due to preferences in feeding behavior of insects and desiccation of tissue. Effects of these conditions were compared based on the Accumulated Degree Days (ADD) to produce a skeleton among domestic pig (*Sus scrofa domesticus*) subjects in an arid environment.

This presentation will impact the forensic science community by demonstrating decomposition patterns in an arid environment as well as the effect of variation caused by cover on decomposing remains from amounts of shade or clothing. Additionally, this study examines the method of estimating PMI developed by Megyesi *et al*.[1]

Six subjects were placed at a site in Warner Springs, CA, located approximately 1341.12m above sea level, in June 2009, in pairs of one clothed and one unclothed pig inside wire enclosures in three outdoor microclimates: full shade; partial shade; and sun. Observations of the subjects' environment, decomposition progress, and associated arthropod activity were made regularly for 40 days, at which point changes ceased to occur hourly. Subjects were then observed every third day for 14 days, and then once per week for 28 days. Decomposition events were noted, including observations of carcass skin color, bloat circumference, lividity, skin slippage, odor, kill-wound discharge, fluid discharge, skeletal disarticulation, and tooth loss. Site observations included ambient temperature, relative humidity, soil temperature, and atmospheric conditions (e.g., sky appearance). Weather data from microenvironment sites and from the National Weather Service/National Oceanic and Atmospheric Administration weather station in Anza, CA, (19.29km from the study site), were used to Calculate ADD (CADD). The ADD were also Estimated (EADD) according to the Megyesi *et al*. (2005) regression equation. The CADD and EADD were compared by Student's t-test in order to examine the effectiveness of the Megyesi *et al*. (2005) method of estimating ADD by calculating a Total Body Score (TBS). The time to each decomposition event between subjects in each microclimate site, and between microclimate sites, was compared by using a two-tailed Student's t-test and/or two-factor ANOVA without replication.

Results from this experiment indicate that microclimate had a greater overall effect on decomposition rate than clothing. However, clothing did play an important role in shielding from necrophagous insects while they consumed decomposing remains. Subjects in shade and partial shade locations reached the skeletal stage prior to the subjects located in the sun, with the clothed subject located in full shade reaching skeletonization first. Statistical comparisons indicate that time to decomposition events were more greatly affected by microclimate than clothing condition. Weather data from a weather station located in Anza, CA, which is at a similar elevation to the study site, was found to be statistically similar to the data from the microclimate locations. There was no statistical difference between EADD and CADD. In a comparison of EADD and CADD to decomposition events by Student's t-test for unequal variance, there was no statistical difference. Calculations based on this experiment indicate that the regression equations developed by Megyesi *et al*. (2005) are a good estimate of ADD in a more arid environment than the environment for which they were formulated. The regression equations will require further testing in other seasons and climates.

The results of this experiment demonstrate that advances have been made in quantitatively estimating PMI. However, repeated testing and longitudinal studies must be undertaken to increase accuracy in future investigations. It is advisable that investigators use caution in outright estimating the PMI of remains found in direct sunlight in arid environments because of the stark lack of change that occurs following desiccation.

Decomposition, Microclimate, Clothing

H112 The Contribution of Nuclear Magnetic Resonance to the Study of Bone

Vanessa Urzel, DDS, UMR 5199 PACEA, Bat B8, Avenue des Faculté, Talence, FRANCE; Yves Schuliar, MD, PhD, IRCGN, 1 Blvd, Theophile Sueur, Rosny Sous Bois, 93 110, FRANCE; Axelle Grélard, MSc, UMR 5248 CBMN, All. Geoffroy Saint-Hilaire, B14, Pessac, FRANCE; Cécile Courrèges, PhD, UMS 3033 IECB, 2 rue Robert Escarpit, Pessac, FRANCE; Erick J. Dufourc, PhD, DSc, Univ Bordeaux, CNRS, All. Geoffroy Saint-Hilaire, UMR 5248 CBMN, Pessac, 33600, FRANCE; and Henri Duday, MD, PhD, UMR 5199 PACEA, B8, Avenue des Facultés, Talence, FRANCE*

After attending this presentation, attendees will have a better understanding of the use of Nuclear Magnetic Resonance (NMR) spectroscopy in forensic science contexts and particularly forensic anthropology and archaeology. The application of NMR is original for these purposes and gives new information about bone composition and its changes during postmortem decomposition.

This presentation will impact the forensic science community by introducing a novel methodology to human bone study by the analysis of carbon ^{13}C and hydrogen ^{1}H atoms contained in bone, and by the observation of differential modifications in bone chemical components over time.

NMR, well known in medicine thanks to Magnetic Resonance Imaging (MRI), can also make possible quantitative studies of different materials from atomic or molecular viewpoints. NMR has been widely used for *in vitro* biological tissues analysis and provides access to fats, molecular conformation, membranes lipid metabolism, and metabolomic analysis as a diagnostic technique to assess the severity of coronary heart disease by the analysis of human serum. However, NMR spectroscopy has been weakly used for bone analysis. It can indeed provide quantitative information on bones, such as composition of the mineral or organic part, hydroxyapatite characterization, identification of amino acids in collagen, presence of citrate, presence of lipids, etc. For this technique, only 80 – 150mg of bone are required for non-invasive analysis, and no chemical treatment is required. With all these advantages, NMR is a tool that should be investigated in physical anthropology and forensic sciences.

Experimental optimization is accomplished on a Bruker Avance 500 spectrometer (protons and hydrogen isotopes are detected at 500MHz, whereas ^{13}C, one of the observable carbon isotopes, is detected at 125.75MHz) under Magic Angle Sample Spinning at 10kHz. Cross polarization with protons is performed to enhance ^{13}C detectivity. Different samples were used in order to choose the better technical parameters according to each sample: fresh human bone (n=4); pig bone with a Postmortem Interval (PMI) of one year (n=4); forensic human bone (PMI=15 years; PMI=30 years; and PMI=60 years).

Using the optimized conditions, NMR bone spectra provided comparative information among samples, such as the presence of citrate or lipids in modern bones, the differential preservation of citrate and lipids in dry bone according to PMI, the presence of exogenous calcite in archaeological bones, the degradation of collagen and its amino acids as a function of time since death, etc. Collagen was found in all samples whatever the PMI. Bio-hydroxyapatite, the main component of the mineral fraction of bone, evolved with time since death toward the chemical structure of pure hydroxyapatite. Similarly, the fats and lipids component of bone are rapidly lost. Such information could lead to use NMR as an alternative method for bone aging, or at least to discriminate between archaeological samples and forensic samples.

More generally, the use of NMR as a complementary tool in forensic anthropology and archaeology opens up new prospects for the study of bone composition and its implications.

Forensic Anthropology, NMR Spectroscopy, Time-Since-Death

H113 Slow and Steady Wins the Race: The Rate and Pattern of Soft Tissue Decomposition in Southern Illinois

Gretchen R. Dabbs, PhD, Southern Illinois Univ, Dept of Anthropology, 1000 Faner Dr, MC 4502, Carbondale, IL 62901; and D.C. Martin, MA, Southern Illinois Univ, Dept of Anthropology, 1000 Faner Dr, Rm 3525, Carbondale, IL 62901*

After attending this presentation, attendees will gain knowledge of the decomposition rate, pattern, and sequence of surface remains over two years in southern Illinois. Scientists and law enforcement officials involved in human remains investigation will benefit greatly from the data and visuals presented, gaining understanding that the currently published decomposition standards are not directly applicable to the regional environment of southern Illinois.

This presentation will impact the forensic science community by instituting a baseline of information for the decomposition of soft tissue in the southern Illinois region. The findings of studies at the Complex for Forensic Anthropology Research (CFAR) will prove more applicable to forensic cases in climatologically and environmentally similar regions than those from any other comparable facility. This location represents a geographic area that is farther north and has a lower temperature than the locations used to create current methods for estimating Postmortem Interval (PMI). Additionally, the soil is extremely poorly drained and acidic which may have some yet-to-be identified impact on the surface decomposition of research subjects.

Twenty pigs (*Sus scrofa*) are being assessed to establish baseline rates and patterns of decomposition at the CFAR. The research subjects were placed on the surface in both sun and shade areas. Three subjects were covered with 18-gauge wire fencing to prevent scavengers from removing them; two were placed inside a chain-link dog kennel; and the remaining subjects were left unprotected. Research subjects were deposited in all four seasons and have been in place for a minimum of nine months. Several have been exposed for two years. Thermochrons were placed at the CFAR to monitor the exact temperature in the specific microclimate at the site for use of accumulated degree days as the method of quantifying the decomposition rate. Observations of the decomposition stage for each subject were collected daily according to the method set forth by Megyesi *et al*. (2005) using the Total Body Score (TBS) for each subject.[1] Motion-activated cameras were used to record still photographs and video of research subjects. The cameras proved extremely useful in identifying the types and activities of avian and mammalian scavengers in the region.

The recorded data show significant differences in both the rate and pattern of decomposition when the CFAR is compared to other facilities. The CFAR has exhibited a range of scavengers, such as the possum and North American Black vulture, which have fed on the subjects throughout the research period. Furthermore, the CFAR has exhibited a slower progression in time between decomposition stages. Compared to previously published standards from east Tennessee, the Sonora desert, and Texas, decomposition in southern Illinois progresses from the “fresh” to “early” decomposition stage at approximately the same time, but then slows drastically. The research subjects at the CFAR stay in the “early” decomposition phase up to 33 days longer (days used to compare to results published before the use of ADD became standard) than in other climates. Additionally, the length of time spent in the “advanced” decomposition stage is longer than previously reported from other regions of the United States. Currently, the fastest time to skeletonization at the CFAR is approximately 20 days. Much of this variation likely results from the lower temperatures observed in southern Illinois compared to those locations from which previous reports have been published. Further research is necessary and ongoing.

Taphonomy, Decomposition, Forensic Anthropology

H114 California Central Coastal Morphology, Microenvironments, and Human Decomposition

Alison Galloway, PhD, Univ of California, Chancellor's Office, Santa Cruz, CA 95064; and Lauren Zephro, PhD, Santa Cruz Sheriff's Office, 701 Ocean St, Rm 340, Santa Cruz, CA 95060*

The goal of this presentation is to assess the applicability of available temperature data to microenvironment and human decomposition rates.

This presentation will impact the forensic science community by providing guidance as to the methods to interpolate temperature data and uses case studies to show variation in microenvironments.

Accumulated degree days, and consequently decomposition, vary widely within seemingly homogenous environments as seen in case studies and associated temperature data.

The coast of California encapsulates a series of microenvironments in which the average temperatures vary considerably throughout the day and by season. Along the Central Coast, approximately from San Francisco in the north to Santa Barbara in the south, the Santa Cruz and Santa Lucia Mountain Ranges form a coastal barrier with only intermittent gaps. These ranges also block much of the action of the cooling sea breezes, confining much of their action to the narrow bands along the coasts.

In addition to the complication of the mountain barrier, summer months are accompanied by dense coastal fogs which keep the average daily temperatures lower. These thick marine layers form in the late afternoon, remain inland throughout the night, and often only burn off in the late morning of the next day. This fog is a vital ingredient for the thick redwood forests that characterize the coastal regions, providing shade in much of the area.

Inland, including in the valleys between the ridgelines of the mountains, temperatures rise dramatically during the summer, but are also subject to lower temperatures and heavy frosts in the winter months. The summer fogs penetrate less deeply and the redwoods are gradually replaced by larger numbers of scrub oaks. Seasonal variation in average daily temperatures is more extreme in these areas than along the coast.

Analysis of human decomposition in this area has depended primarily on extrapolating from studies elsewhere, the experience of the anthropologists, and on some retrospective studies. The latter have largely been confined to the marine environments. Suggested postmortem intervals are often long, reflecting the lack of comparative information. While additional experimental studies may be helpful in providing guidance, the variation in microenvironments presents an extremely difficult set of parameters.

Using case studies of remains found within various microenvironments in coastal California, the accumulated degree days are shown, along with the total body score, to highlight the importance of localized data on decomposition. Proximity to the coast, position with regard to mountain ridges, local vegetation, and season all present complications. This variation holds even when the interference of local scavengers is excluded. Animals known to consume human remains in these areas include coyotes, raccoon, opossum, wild boar, and rodents.

To utilize accumulated degree days and total body score, relevant data from the recovery area is needed. Weather station data, while distributed throughout California, is rarely adequate for the types of forensic reconstructions needed for presentation in court. Interpolation from known sources can be accomplished and it provides one line of evidence to assist the anthropologist. Recording data from the recovery site in order to compare to the known historical data from a weather collection site is also possible, but here seasonal variation requires long-term comparisons.

Taphonomy, Degree Days, Decomposition

H115 Regional Factors in Central Texas Affecting Postmortem Decomposition in Human Remains

Daniel J. Wescott, PhD, Michelle D. Hamilton, PhD, and Kate Spradley, PhD, Texas State Univ, Dept of Anthropology, 601 University Dr, San Marcos, TX 78666; Sophia R. Mavroudas, MA, Texas State Univ, 601 University Dr, ELA 232, San Marcos, TX 78666; Amy M. Sears, BA, Texas State Univ, Dept of Anthropology, 601 University Dr, San Marcos, TX 78666; Jeffery K. Tomberlin, PhD, Texas A&M Univ, Dept of Entomology 2475, College Station, TX 77843-2475; and Lauren R. Pharr, MA, Louisiana State Univ, Dept Geography & Anthropology, 227 Howe-Russell Geoscience Complex, Baton Rouge, LA 70803*

After attending this presentation, attendees will understand how regional ecological factors of central Texas, including climate and local scavenger populations, affect human decomposition stages and rates and complicate estimates of time-since-death.

This presentation will impact the forensic science community by demonstrating the regional variation in decomposition processes and rates in central Texas, the need for collaborative, multidisciplinary research between regions, and the need for regional models for estimating time-since-death.

Forensic anthropologists and entomologists are often asked to predict the time-since-death for a decedent in medicolegal death investigations. Over the past decades, researchers have worked to develop stages and rates of decomposition that can be used to estimate the time-since-death. However, the process of decomposition is highly dependent on microenvironmental and regional-ecological conditions, making it difficult to apply time-since-death estimations across regions.

Located in the Hill Country of central Texas, the Forensic Anthropology Research Facility (FARF) at Texas State University serves as a natural laboratory for examining decomposition in an ecological zone that is transitional between eastern and western climates. The mean annual temperature is 20.3°C, and the mean annual rainfall is 83.1cm. However, central Texas is known for extreme droughts, extraordinary rainfall events, intense sunlight, and strong winds.

A longitudinal study of human decomposition (N=68 as of July 2012) has been in process at the FARF since 2008. Human bodies donated to the Forensic Anthropology Center at Texas State are placed at the FARF on the ground surface in a supine position, usually under a wire cage that prevents scavenging by medium and large mammals and birds. In many ways, bodies placed at the FARF undergo similar decomposition processes that have been recorded in other geographical regions, but there are several ecological factors unique to central Texas that greatly alter the decomposition rate.

Mummification of soft tissue is one factor commonly observed in central Texas that greatly affects the rate of decomposition. Preliminary results of the study indicate that desiccation of the body by the sun, wind, and soil reduces or prevents putrefaction by microorganisms, which leads to natural mummification. Rapid mummification can reduce the duration of other decomposition stages, such as bloat, and increase the time required for skeletonization. By preventing additional visible changes to the remains, mummification can make estimating the time-since-death difficult. At the FARF, skeletonization can take as little as two months to more than two years depending on the degree of mummification that occurs. Accumulated degree days so far for mummification range from 241 to 1,698.

Scavenging by vultures and other animals is another factor that can greatly affect decomposition rates in central Texas, thus complicating the estimate of time-since-death for forensic scientists working in the region. While vultures are found throughout the United States, the greater population sizes of these birds, and the reduced tree cover of central Texas, makes them extremely important in determining time-since-death. Observations of uncaged individuals at the FARF indicate that it can take between three days to approximately one month for the vultures to begin scavenging the human remains. However, once

scavenging is initiated, an individual in pre-bloat stage of decomposition can be skeletonized in less than 24 hours.

In addition to climate and scavenging, microbial population densities in central Texas may have an effect on decomposition rates. Postmortem interval studies of microbial populations at the FARF have demonstrated there is likely regional variation in the species, or at least population densities, of microbes present on the body after death due to temperature, humidity, and other environmental factors. Preliminary results show that variation in microbial populations can directly affect insect colonization, thus complicating time-since-death estimations.

Ideally, forensic scientists would like to develop a universal model of human decomposition that can be used to estimate time-since-death. However, regional ecological conditions that affect the rate (and possibly stages) of decomposition appear to make this an unrealistic goal. Until forensic scientists truly understand the rates and stages of decomposition, and how they vary from region to region, it is unlikely that they will develop accurate universal or even regional models for estimating the time-since-death. Answering questions about regional variation in decomposition is going to require collaborative research across regions and disciplines with standardized data and collection protocols.

Taphonomy, Decomposition, Time-Since-Death

H116 Regional Taphonomy and Estimations of the Postmortem Interval From Northern California

Colleen F. Milligan, PhD, P. Willey, PhD, and Eric J. Bartelink, PhD, California State Univ, Chico, Dept of Anthropology, Butte #311, 400 W First St, Chico, CA 95929-0400*

The goal of this presentation is to examine the complexity of estimating the postmortem interval in the context of Northern California's varied environments. After attending this presentation, attendees will gain an understanding of the challenges of assessing regional taphonomic processes and the impact of various environments on the active decomposition of human remains.

The presentation will impact the forensic community by highlighting the role of various factors on the distribution of human remains, the rate of decomposition, and the variation seen both between and within regions. These factors contribute to a complex and varied estimation of time-since-death.

In the context of varied microenvironments, estimations of postmortem intervals must consider factors beyond those often considered in controlled studies of decomposition. This presentation will highlight several of the most prominent factors affecting postmortem interval estimations in Northern California. The factors considered include the following: scavenging; fluvial transport; high altitude environments; and, the influence of vegetation growth.

Northern California is both climatically and geographically diverse. The region encompasses the San Francisco Bay Area; the Sacramento Valley and part of the San Joaquin Valley; various mountain ranges, including the Sierra Nevada and the Cascade ranges; large national forests; and, massive waterways, such as the Sacramento and the Klamath Rivers. The climatic zones include coastal environments, Mediterranean zones with dry, hot summers and mild, wet winters, and mountainous environments with substantial snowfall. The varied environments encountered in Northern California provide a unique range of conditions for the recovery and analysis of human remains.

The California State University, Chico-Human Identification Lab (CSUC-HIL) provides search and recovery and forensic anthropology services to most counties in Northern California. On average, the CSUC-HIL is contacted for 10 – 15 searches annually, ranging from clandestine burials to surface-scatter sites. In the last year, these searches have been conducted along several major rivers in Northern California, at altitudes above 7,000 feet, in national forests, in the agricultural areas of the Sacramento Valley, and in coastal areas. Most often, recovered human remains exhibit various taphonomic changes, including exposure to natural elements and scavenging from both small and large scavengers.

Given the diversity of possible environments, the study of taphonomic changes to human remains encompasses a multi-disciplinary approach. The CSUC-HIL incorporates entomologists, pathologists, archaeologists, botanists, and other forensic scientists in scene assessments during recovery efforts. In particular, many of the searches conducted by the CSUC-HIL are complemented by the assessment of vegetation growth rates for the various flora found in Northern California. The use of a forensic botanist in these contexts greatly enhances the ability to narrow the time frame considered for the deposition of recovered remains, as well as the changes to the site of recovery over time. In addition, the CSUC-HIL recovery team often includes a forensic archaeologist when the context of the search is buried remains. The partnership between physical anthropology and archaeology increases the understanding of soil formation and disruption patterns.

This presentation will discuss current and future directions of research related to taphonomic patterns. The prevailing trend has been a steadily increasing case volume for the CSUC-HIL. In light of an increased presence in the search and recovery of human remains in Northern California, research objectives focus on those areas that most affect regional taphonomic patterns. Specifically, studies are focused on examining similar taphonomic factors across multiple microenvironments. These factors include the patterns of fluvial transport, varied access of scavengers in remote sites with dense vegetation or extreme climatic conditions, and the patterns of distribution related to various scavengers native to the region.

Forensic Anthropology, Taphonomy, Postmortem Interval

H117 A Two-Pronged Model for Regional Taphonomic Research: A Case Example From Mesa County, Colorado

Melissa A. Connor, PhD, Colorado Mesa Univ, 406 Lowell Heiny Hall, 1100 North Ave, Grand Junction, CO 81501-3122; and Diane L. France, PhD, Human Identification Laboratory of Colorado, 1713 Willox Court, Ste A, Fort Collins, CO 80524*

The goals of this presentation are to: (1) characterize expected and observed taphonomic variation in an arid, high-altitude biome; and, (2) exemplify a taphonomic research model using both experimental and historic research paradigms.

This presentation will impact the forensic science community by providing better appreciation for the high-altitude desert as a unique taphonomic environment.

Experimental taphonomic studies isolate and examine variables responsible for differences in the decomposition process. Taphonomic research may also be historic, using past cases and the known taphonomic influences in those cases to better understand the decomposition process. This study is an example of combining the two paradigms.

This study uses both approaches to assess the variability in taphonomic variation in west-central Colorado, including Mesa County, the site of Colorado Mesa University's Forensic Investigation Research Station. Mesa County is on the Colorado Plateau, on the western slope of the Rocky Mountains, and east of the Great Basin. The county includes the largest city on the Rocky Mountain's western slope, Grand Junction.

The Forensic Investigation Research Station was established in 2012 as a taphonomic facility to examine decomposition in an arid, high-altitude desert. The area is at an altitude of approximately 4,600 feet above sea level and receives an average of about 9in of precipitation per year, with very low humidity. Vegetation is xeric, consisting mainly of scattered sage and rabbit brush.

While the Station is initializing a human donation program, domestic pigs are currently being used for research. For this study, beginning in the fall of 2012, a freshly-killed pig is placed outside in the

Station at the first of each month and left outside for one year. This will continue for one year so that a total of 12 pigs are used. The goal is to create a decomposition baseline for the region. Data collected will include temperature, lumens, humidity, entomological data, and a total body score.

The historic approach consists of a review of Mesa County area forensic cases with an assessment of the taphonomy of the remains in each case. The rate and pattern of decomposition in the cases are compared to the baseline data from the facility. Discrepancies between the two will identify variables affecting decomposition that will be added to the baseline study.

The research at Mesa County, Colorado, adds to the growing taphonomic database with information on the arid, high-altitude desert environment. It also adds to extant examples of combining experimental and historical research paradigms in taphonomic research.

Taphonomy, High Altitude, Desiccation

H118 Comparison of Faunal Colonization: Taphonomic Macro- and Micro-Skeletal Changes in Pig Carcasses Submerged in a Deep Coastal Marine Environment During Spring and Fall

Gail S. Anderson, PhD, and Lynne S. Bell, PhD*, Simon Fraser Univ, School of Criminology, 8888 University Dr, Burnaby, BC V5A 1S6, CANADA*

After attending this presentation, attendees will have a greater understanding of the impacts of marine submergence on animal carcasses used as human proxies and on the tremendous potential offered to forensic science by the use of underwater cabled laboratories.

This presentation will impact the forensic community by: (1) illustrating, through photos, video, and micrographs, the effects of deep coastal marine submergence on pig carcasses; and, (2) showing the taphonomic changes found in two different seasons, spring and fall.

The studies presented here are part of an ongoing marine-based, high-resolution, data-rich study of the effects of submergence on faunal colonization, decomposition, skeletal dispersal, and survival, in a variety of habitats, seasons, and depths in the coastal waters of Western Canada. The studies utilize the Victoria Experimental Network Under the Sea (VENUS) underwater observatory which allows for real-time observation using a number of remotely controlled cameras and sensors.

Methods: Two sets of two fresh pig carcasses (*Sus scrofa domesticus*) were placed on the seabed in 2012; the first set was placed in February and the second in August. In both cases, the carcasses were observed using a remote connection to the camera. The carcasses were placed on a custom-built platform directly beneath a video camera mounted on a tripod. One carcass was caged, while the other was fully exposed. The cage bars were spaced to allow sufficient access to large crabs and fish, but small enough to prevent shark access. The platform supporting both carcasses, and the tripod and camera, were lowered onto the sea bed in the Strait of Georgia at a depth of 300m. The video camera was programmed to turn on, with lights, every 15 min and scan both pigs for a total of three minutes. An array of sensors recorded physical and chemical water conditions every minute. These included an oxygen optode recording dissolved oxygen and temperature, a vector current meter, and a CTD measuring conductivity, density, pressure, salinity, Sigma T, and sound velocity. Recording continued for six months. At the end of this time (six months of submersion), the skeletal remains were recovered in order to investigate any surface and microstructural changes using Environmental Scanning Electron Microscopy (ESEM) and sectioned material using Backscattered Electron (BSE) imaging. Sections from several different skeletal elements were embedded in plastic and polished in transverse section for assessment.

Results: In the spring study, the carcasses immediately attracted sixgill sharks (*Hexanchus griseus Bonneterre*) to the area. The cage bars successfully protected the caged carcass and, although the exposed carcass was frequently attacked during the first 24 hours after placement, only a few pieces of tissue were removed. Small (<1mm) amphipods were attracted to both sets of remains within a few hours, although shark disturbance of the exposed carcass prevented settling for 24 hours. After this time, thick layers of amphipods settled on both carcasses to a depth of 2 – 3cm, as well as spreading onto the sediment and cage bars. By the end of Day four, both carcasses were skeletonized and the amphipods had displaced skeletal elements. Other arthropods, such as the three spot shrimp (*Pandalus platyceros Brandt*), were originally attracted to the remains but were competitively excluded by the amphipods. Once the remains were skeletonized, the shrimp returned, as did a variety of crab species. Despite the early shark damage, skeletonization and colonization were very similar in both carcasses. Faunal attraction was greatly reduced by Day 12. A biofilm began to develop on the skeletal elements from Day 28 and extended over the sediment by Day 36. The skeletal elements appeared to degrade, and only the crania were visible by Day 117. The study was repeated in the late summer/early fall. The histotaphonomy from the two pigs will be presented and cross-referenced to the events seen during the exposure experiment, particularly the presence of the biofilm.

Taphonomy, Marine Submersion, Microstructural Change

H119 Underwater Decomposition: An Examination of Factors Surrounding Freshwater Decomposition in Eastern Massachusetts

Lauren K. Westling, BA, 1245 Apache Ave, Green River, WY 82935; and Donald F. Siwek, PhD, and James Pokines, PhD, Boston Univ School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord St L1004, Boston, MA 02118*

After attending this presentation, attendees will have a better understanding of the factors surrounding freshwater decomposition in eastern Massachusetts during the summer.

This presentation will impact the forensic science community by establishing a base set of data for freshwater decomposition in a deciduous forest of eastern Massachusetts. Data collected included the water temperature, ambient temperature, stages of body decomposition, rate of decomposition, invertebrate activity, and scavenger activity.

This study investigated the decomposition of three porcine (*Sus scrofa*) carcasses in the same body of water, under lentic and lotic conditions, and at variable depths. The study was performed in a temperate, mixed forest at the Boston University Outdoor Research Facility in Holliston, Massachusetts, during June and July. The remains were placed in wire dog kennels and positioned at the waterline so they could float or sink and be protected from large scavengers. Two controls were placed in dog kennels and placed in terrestrial environments near the aquatic sites. Data were collected on the invertebrate activity, scavenger activity, water and ambient temperature, stages of body decomposition, and the rate of decomposition for each set of remains. Accumulated Degree Days (ADD) and Total Body Scores (TBS) were used to determine two equations (differentiated by their microhabitat) for potential use in estimating the Postmortem Submergence Interval (PMSI) in death investigations involving similar conditions.

The three aquatic remains floated at the waterline throughout the project until they reached skeletonization on days 16 to 45. The terrestrial controls, in contrast, took 13 to 14 days to reach skeletonization. This slowed rate of decomposition at two of the three aquatic sites was due to adipocere formation, cooler water temperatures, limited access by terrestrial invertebrate activity, fluctuations in water levels, and limited scavenger activity. The third aquatic site, located in the shallow lentic water, underwent

decomposition faster than the other two aquatic sites because it received direct sunlight and underwent extreme fluctuations in the amount of water present around it. These variations had a significant effect on its rate of decomposition, as ambient temperature around the remains was significantly higher than all of the other sites, and mummification occurred rather than adipocere formation.

The terrestrial and aquatic invertebrate activity was extensive both above and below the waterline with 42 families from 17 orders collected and identified. All three sites had similar terrestrial invertebrates including: water striders, blow flies and their respective maggots, and spiders. Dragonflies were prevalent around the lentic sites and damselflies around the lotic site. Aquatic invertebrate taxa that were present below the waterline at all of the aquatic sites prior to and during the decomposition phase included: predaceous diving beetles, aquatic sowbugs, giant water bugs, midge larvae, scuds, dragonfly and damselfly larvae, snails, and leeches.

Through the use of motion detector cameras, the researcher was able to view the activities performed around the remains by vertebrates including: a blue heron, a coyote, a raccoon, multiple black vultures, multiple turkey vultures, multiple squirrels, and multiple adult American bullfrogs. Snapping turtles were present in the lentic environment, but their activity around the remains was unclear.

The information presented in this presentation will be valuable to researchers studying the taphonomic processes that occur in aquatic environments similar to these in the Northeastern United States. An understanding of the invertebrate and vertebrate activity will assist in identifying the cause of postmortem artifacts. The climate, ADD, and TBS data can be combined with existing data to establish a more accurate method for estimating the PMSI.

Taphonomy, Freshwater Variables, Decomposition

H120 Regional and Micro-Environmental Taphonomic Variation and Decomposition in Northern New England

Marcella H. Sorg, PhD, Univ of Maine, Margaret Chase Smith Center, Orono, ME 04469; Jamie A. Wren, BA, Univ of Maine, Dept of Anthropology, 5773 S Stevens Hall, Orono, ME 04469; and William D. Parker, BA, Univ of Maine, Margaret Chase Smith Center, Orono, ME 04469-5784*

After attending this presentation, attendees will better understand the potential impact that regional and site-specific microenvironmental factors, particularly temperature, can have on the timing of postmortem processes, and the estimation of the Postmortem Interval (PMI).

This presentation will impact the forensic science community by demonstrating the importance of addressing regional and microenvironmental variation in outdoor forensic cases that do not involve animal scavenging.

Published models for the estimation of PMI generally present a sequential decomposition process that includes insect involvement and no scavenger modification. These models are all based on regionally-specific datasets, which may not be applicable to other geographic locations, or even to different microenvironments within that region.

Important regional taphonomic factors for Northern New England include a colder, seasonal climate, a densely forested landscape, and a high level of scavenger access. Using an experimental pig cadaver outdoor case series that excludes mammalian and avian scavengers, the authors have found that both regional factors (such as seasonal temperature fluctuation) and microenvironmental site differences (such as the amount of a forest canopy and the level of moisture retention) impact the rate and character of decomposition. This research utilizes decomposition phase, Accumulated Degree Days (ADD), Accumulated Humidity days (AH), Total Body Scores (TBS), and percent decomposition to track postmortem change including contextual information about forest canopy and ground vegetation.[1]

Two pig cadavers were placed in cages measuring 1.8x2.4m, which allowed insect access, but excluded most mammalian or avian scavengers. The pig cadavers were placed on the same day in late fall, on the day of death. Wildlife cameras were set up within the cages to capture photographs of the cadavers in 15 min intervals. A weather station recording hourly temperature and humidity data was also placed next to the cages. The cages were placed approximately 30m apart. Each pig was placed in a unique microenvironment, one in an open, grassy meadow (designated “Field Pig”), and the other under an evergreen canopy with a pine-needle forest floor (designated “Woods Pig”). These are typical sites for forensic cases in northern New England. This paper focuses on the time period from placement on November 3, with a subsequent snowy winter, extending to June 30. Complete skeletonization occurred during this time frame.

Observations of these two microenvironments showed that year-round forest canopy significantly impacted the rate of decomposition. The Woods Pig progressed through stages of decomposition at a faster rate than the Field Pig, particularly bloat and the early decomposition phases. The Woods Pig had a higher TBS at all 100-ADD benchmarks, despite lower temperatures and a slower build-up of ADD in the woods. The Woods Pig reached full skeletonization earlier, on June 24 (TBS 29), at 1,151 ADD, and an AH of 18,919. By this date, the Field Pig was not completely skeletal (ADD 1,365 and AH 18,827). The Field Pig reached full skeletonization (TBS 29) four days later, on June 28, at 1,440 ADD and 19,145 AH.

Analysis of ADD and AH showed that the insulating effect of the evergreen canopy not only slowed the progression of ADD, but allowed for greater retention of moisture at ADD benchmarks and sped decomposition. By comparing the trends of ADD and AH for each pig, we found that the Woods Pig had similar AH on the same dates, but consistently higher AH than the Field Pig at the same ADD. Vass presents a formula for an aboveground, universal estimation of PMI that includes percent humidity.[2] The documented results during this study also suggest that factoring in humidity during the estimation of PMI can be helpful in explaining microenvironmental differences seen within various geographic regions.

This project is supported by Award No. 2008-DN-BX-K177 through the National Institute of Justice, Office of Justice Programs, and the U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Taphonomy, Decomposition, Regional Variation

H121 On Repeatability in Nature and Human Identification

Jane C. Wankmiller, MS, and Norman J. Sauer, PhD, Michigan State Univ, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824*

The goal of this presentation is to ask the scientific audience to re-evaluate the framework that has traditionally been the basis for human identification studies. A bottom-up rather than a top-down approach to studies involving human variation as it relates to identification is suggested.

This presentation will impact the forensic science community by demonstrating the utility of the human ear in image comparison cases and by offering an alternate conceptual framework for human identification.

The impetus for this presentation is a series of questions that arose during the trial of a 2008 robbery/homicide suspect from Michigan. The criminal act was captured on surveillance video and multiple images of the perpetrator’s left ear were clearly visible. Forensic anthropologists at Michigan State University used a dynamic orientation protocol to

capture comparable images of the suspect, morphological analysis, and superimposition to present compelling evidence that linked the offender's ear with the primary suspect in the case.

A question that is typically raised during cross-examination in such cases is, "Are all ears (fill in the structure) different?" One way to answer that question (the empirical, top-down approach) would be to say that no two ears have ever been shown to be exactly alike, based on the samples that have been analyzed. An expert witness could cite Iannarelli who famously is said to have compared some 10,000 ears and found all to be detectably different.[1-4] Then the question becomes, "Just because there were no two identical ears in a sample of 10,000, how do you know there won't be a pair of identical ears in a sample of 20,000 or 100,000?" It is impossible to answer such questions because that would require direct observation of all human ears.

Rather than the traditional empirical (top-down) approach, the question is posed; "Are all ears different?" is better answered with a bottom-up approach, based on the simple and long-accepted principle that nature never repeats itself. No two oak trees, snowflakes, zebra stripe patterns, fingerprint patterns, sets of teeth, irises, or ears are completely identical. Each organism and each component of an organism is produced by interactions among genetics, embryology, fetal development, and post-natal environmental influences. There is a DNA component (certain characteristics run in families); the embryology of any structure is complicated and related to a host of intrauterine variables including the endocrine environment and maternal nutrition; and then, not unlike shoe and tire prints, the anatomical feature will be altered by its continued exposure to an environment.

Of course, the challenge to the forensic community is to detect the anatomical variation that makes all structures unique and present it in such a way that it can be applied to human identification cases. While one scientist may be able to detect differences in some structure, it will be of no value unless the forensic community (and ultimately a lay audience) accepts the conclusion that the variation is individualizing.

There may be no doubt in anyone's mind that the two sets of ear images in the case presented represent the same individual. But can it be proven empirically? In reality, no. Theoretically? Only if nature repeats itself.

Human Identification, Image Comparison, Ears

H122 Testing a New Computer-Assisted Forensic Identification Method Developed Through Interdisciplinary Collaboration

Sharon M. Derrick, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; John A. Hipp, PhD, Medical Metrics, Inc, 2121 Sage Rd #300, Houston, TX 77056; Michelle H. Raxter, PhD, Jennifer C. Love, PhD, and Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; N. Shastry Akella, PhD, 2121 Sage Rd, Houston, TX 77056; Priya Goel, MS, Medical Metrics, Inc, 2121 Sage Rd #300, Houston, TX 77056; and Luis A. Sanchez, MD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to provide attendees with an example of successful interdisciplinary collaboration to develop a new method of decedent identification for routine use in the medicolegal setting. The attendees will receive a detailed account of method testing and results.

The presentation will impact the forensic science community by describing a practical, time-sensitive identification method for decedents associated with a tentative name on arrival to the medical examiner's/coroner's office. The method is responsive to the National Academy of Sciences. Report recommendations and post-*Daubert* evidence admissibility standards because it is replicable and incorporates a quantified error rate.

Decedent identification obtained by a forensic anthropologist through comparison of postmortem and antemortem radiographs is a relatively routine procedure in the medicolegal setting. The determination of consistency in skeletal features is made by comparison of the radiographs based on the expertise of the anthropologist. Computer-assisted radiograph comparison methods have been explored with some success.[1-3] Computer-assisted methods typically work by first determining a score that quantifies how well the shapes represented in two different radiographs match. There are multiple paradigms for using these raw match scores to determine if a correct match has been found.

A computer-assisted radiograph comparison method has been developed for medicolegal decedent identification through interdisciplinary collaboration between forensic anthropologists, biomedical engineers, and software engineers and designers. The paradigm for this method is calculation of the match score for postmortem and antemortem radiographs of the index individual and also for a postmortem radiograph within an array of similar radiographs from random persons of the same age cohort. Early theoretical efforts, pilot study results, and method development were reported at the 63rd and 64th Annual Scientific Meetings of the American Academy of Forensic Sciences.[4,5]

Preliminary testing of the method produced a 0% error rate for comparison of single lateral cervical vertebrae (5 tests of 55 images=100% correct). The error rate for single lateral lumbar vertebrae was inflated by an index image with substantial out-of-plane artifact (15 tests of 30 images=80% correct). When the out-of-plane image was removed, the error rate fell to 0%. For this study, 36 pairs of anonymized lateral cervical radiographs (n=72 radiographs) were collected from a historical archive. Each pair consisted of radiographs of a specific person taken three years apart. All patients had undergone a cervical fusion procedure between the time-points, but only the vertebrae adjacent to the fusions were used. Match scores were calculated for a cervical vertebra (C3, C4, C5, C6 or C7), using the latest time-point to represent the "postmortem" radiograph. The radiograph taken three years earlier represented the antemortem radiograph. In some cases, match scores were calculated for two vertebrae from one person. Prior to calculating match scores, all images were reoriented and magnification adjusted using the QMA® computer software interface (Medical Metrics, Inc.). Match scores were calculated by QMA® for the correct match and also for matches of the "postmortem" radiograph compared to five radiographs from other persons. Different combinations (100) of Region-Of-Interest (ROI) definition, pre-processing filters, and match score algorithms were tested on this data set, resulting in 54,000 match scores to use in optimizing the algorithms. Data were analyzed using effect sizes and Receiver-Operator-Curve (ROC) analysis.

The study resulted in several key findings. Radiograph pairs could be classified as a correct versus an incorrect match in greater than 95% of matches (5% error rate), using the optimized protocol and algorithms in the larger sample. The fine details of higher resolution radiographs can reduce the percent of correctly matched radiographs since the fine details are harder to reproduce from one time-point to another. Improved results were obtained after reducing the resolution of the radiographs to approximately 0.2mm per pixel. A geometrically simple ROI (rectangular) worked well, thus avoiding the need to define a complex ROI (polygon). The reliability of the match algorithms is reduced if significant osteophytes form between the time-points. Using the maximum match score when more than one vertebra is compared between postmortem and antemortem radiographs improves the reliability of the computer-assisted match, an important finding for future systematic testing of skull and chest films. Refinement of the method is

ongoing with further algorithmic optimization testing and inclusion of real postmortem radiographs that may be of different quality than clinical radiographs.

Identification, Anthropology, QMA®

H123 The Utility of Postero-Anterior Chest Radiographs and the Cervico-Thoracic Junction for Human Identification

Carl N. Stephan, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853; Pierre Guyomarc'h, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853; and John E. Byrd, PhD, 95-033 Hokuiwa St, #51, Mililani, HI 96853-5530*

After attending this presentation, attendees will have an appreciation for the accuracy, sensitivity, specificity, and predictive values that postero-anterior chest radiographs offer for identification using osteology of the cervico-thoracic junction (clavicles and the C3 – T3 vertebrae).

This presentation will impact the forensic science community by providing key validation data for the aforementioned methods in respect to a large radiographic sample (1,178 antemortem chest radiographs) and 10 analysts (five trained and five untrained).

Comparisons of Antemortem (AM) and Postmortem (PM) chest radiographs have long been undertaken for human identification purposes. The number of radiographs used in past validation tests has often been small (n<100) and the opportunities for true positive matches limited (i.e., small samples of known individuals with correctly matching radiographs have been used (n<50)). This also applies to recently proposed and standardized methods that employ the clavicles and the C3 – T3 vertebrae. This study aims to redress this situation with a blind test that employs 589 pairs of postero-anterior AM chest radiographs (299 pairs representing the same individual or correct matches) and ten individuals who served as analysts. Five of the analysts were trained in the chest radiograph comparison methods (Joint POW/MIA Accounting Command Central-Identification Laboratory (JPAC-CIL) competency certified), and five analysts had not successfully completed the training and/or were yet to undertake it (untrained). The pairs of radiographs, which were 1940s photoflurographs of military inductees, were sequentially presented on a computer to each analyst, one at a time, with the question: do these radiographs represent the same or different individuals? None of the 1,178 radiographs represented duplicates; that is, radiographs of the same individual were taken by different radiographers on different days. A mask was applied to each chest radiograph to limit the analyst's view of the radiographs to the clavicles and the C3 – T3 vertebrae. Analysts conducted their examinations of the pairs back-to-back wherever possible and a 10 min break every hour was awarded.

Trained analysts completed the radiograph array in a mean time of 206 min (breaks not included; sd=24 min). Untrained analysts completed the array in a mean time of 256 min (breaks not included; sd=97 min). Untrained analysts, therefore, held the fastest and the slowest times. Trained analysts possessed: a mean efficiency (correct classification rate)=0.89; sensitivity=0.93; specificity=0.85; positive predictive value=0.89; negative predictive value=0.92. The total number of correct and incorrect responses for the trained group differed to chance at statistically significant levels (c^2 1074, df=1, p<0.01). The untrained analysts performed slightly worse, mostly due to a higher rate of false positive calls: mean efficiency=0.85; sensitivity=0.86; specificity=0.83; positive predictive value=0.87; negative predictive value=0.88. This result was also different to chance (c^2 =1074, df=1, p<0.01) and different to the results of the trained analysts (c^2 =24, df=1, p<0.01) at statistically significant levels. Two of the untrained individuals who could spare the time to be trained increased their performances on the test two-weeks later by significantly reducing their false positive rate, to call true negatives: mean efficiency=+0.11; sensitivity=-0.04; specificity=+0.27; positive predictive value=+0.19; negative predictive value=-0.02. This degree of improvement was not observed by the four trained analysts who repeated the trial after a two-week period: mean efficiency=-0.03; sensitivity=+0.03; specificity=-0.10; positive predictive value=-0.06; negative predictive value=+0.02.

These results indicate that clavicles and the C3 – T3 vertebrae, visible on AM postero-anterior chest radiographs, can be used as accurate markers of an individual's identity. Untrained individuals can undertake the methods with a high degree of certainty for correct answers; however, trained analysts perform better with fewer false positive responses overall. With training, untrained analysts are observed to improve in the same direction as trained analysts. These results hold significant ramifications for the identification of unaccounted-for individuals from the Korean War, 72% of whom are represented by chest radiographs, buried as unknowns at the National Memorial Cemetery of the Pacific.

Validation Test, Chest Radiographs, Human Identification

H124 Morphometric Comparison of Clavicle Outlines From 3D Bone Scans and 2D Chest Radiographs Using Elliptic Fourier Analysis: A Short-Listing Tool for the Radiographic Identification of Human Skeletons

Carl N. Stephan, PhD, and Pierre Guyomarc'h, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853; Brett G. Amidan, MSc, James Chung, MSc, and Harold E. Trease, MSc, Pacific Northwest National Laboratory, 902 Battelle Blvd, Richland, WA 99352; and John E. Byrd, PhD, 95-033 Hokuiwa St, #51, Mililani, HI 96853-5530*

The goal of this presentation is to report the performance of a semi-automated computer capability that enables fast large-scale searches of 2D antemortem chest radiograph libraries for potential matches to 3D bone scans. The radiographs of the short-listed candidates can then be compared against postmortem radiographs of the skeleton to confirm, or deny, their "match" status.

This presentation will impact the forensic science community by delivering a method that enables large databanks of 2D antemortem chest radiographs to be quickly searched in reference to 3D bone scans. This holds vital importance for the identification of individuals represented in large assemblages of antemortem chest radiographs, e.g., c.8,100 unaccounted-for U.S. soldiers from the Korean War who were subject to chest radiography at induction into the military.

The visual comparison of postmortem radiographs to thousands of images/individuals in large antemortem chest radiograph libraries, for identification, is impractical in terms of time and cost. Instead, these circumstances demand a computer-automated short-listing tool,

whereby individuals of high match potential can be quickly and reliably isolated for finer and more time-intensive analysis using manual methods. This presentation describes such a method, which uses quantified clavicle shape as the filtering mechanism. The clavicles are useful in this regard because: they are morphologically variable between individuals; are visible on the chest radiographs; and possess high field-survivability in comparison to other osseous elements of the thorax (such as ribs). This study uses 414 postero-anterior chest radiographs (many of which are 1940s 4"x5" photoflurographs) as its antemortem reference sample (note: the clavicle outlines were manually traced on Wacom touch-screens), and uses clavicles from 17 field-recovered skeletons as its test group.

The first procedure necessary for the above-outlined computer-automated comparison is 3D scanning of the clavicles and generation of a surface mesh of the bones (.stl file). The computer then rotates the 3D model and captures regularly spaced 2D images at different orientations. This serves two purposes. First, precise position of the clavicle on any antemortem radiograph cannot be reliably predicted *a priori* so a range of positions is examined; and second, it produces 2D images of the 3D model comparable to the 2D radiographs. From the array of snapshot images, four that cover common antemortem clavicle positions are selected to provide good coverage (the small number reduces the chance for false positive matching). The medial and lateral ends of the clavicles on these four 2D snapshots are then trimmed off as they cannot often be seen on the antemortem radiographs (e.g., shoulders fall beyond the image receptor of the X-ray machine). Both the 2D tracings of the clavicles on the antemortem radiographs and the trimmed 2D outlines of the scanned osseous elements are then subject to elliptical Fourier analysis using 40 harmonics (=160 Fourier descriptors for each clavicle). The shape distance between each of the trimmed 2D outlines and the tracings of the antemortem radiographs is computed by the sum of the squared differences across the 320 Fourier descriptors (left and right clavicle sides combined). The computer then ranks the individuals represented by the antemortem radiographs in order of their shape distances.

Using 17 skeletons of known identity, and tracings of 414 antemortem radiographs, short-lists of the top 5% of the antemortem sample (20 individuals) to include the correct match to the skeleton 74% of the time were found. Short-lists of 104 individuals (25% of the antemortem sample) included the correct match 91% of the time. It took less than 1.5 seconds for each search against the 414 person database. It is concluded that elliptical Fourier analysis of clavicle outline shape provides fast and efficient short-listing of potentially matching candidates from postero-anterior chest radiograph libraries. These short-lists can then be subject to closer inspection using more detailed visual inspection methods, sparing their blanket and time-intensive application to all individuals in the reference library. In the future, this computer search capability will likely facilitate identification of several hundred unaccounted-for U.S. soldiers from the Korean War buried at the National Memorial Cemetery of the Pacific.

Radiography, Morphometrics, Fourier Analysis

H125 Down to the Wire: Radiographic Positive Identification Using Midline Sternotomy Wires

Julie M. Fleischman, MS, and Todd W. Fenton, PhD, Michigan State Univ, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824*

The goal of this presentation is to report the findings of research investigating the use of midline medical sternotomy wires as a means for positive radiographic identification of unknown human remains.

This presentation will impact the forensic science community by addressing the feasibility of making a positive identification using medical chest radiographs when sternotomy wires are present.

Forensic anthropologists are regularly called upon to positively identify hitherto unknown individuals using comparative medical radiography. Given the *Daubert* criteria for evidence admissibility, and the need for validated forensic methods, this study was conducted to document the statistical validity of employing sternotomy wires as a method of positive identification. This research follows numerous other radiographic studies which have focused on the hyoid, hand, frontal sinuses, vertebrae, clavicle, maxillary sinuses, ankle, and orthopedic surgical devices to identify human remains. While previous studies have tested the reliability of surgically implanted devices, these findings have focused on the type of device, such as hip implants and plates/screws related to fracture repair, or the manufacturer and lot number and serial number of the device. These devices can be useful for refining potential matches, but they are not unique discriminating elements since many individuals have their hip or knee replaced and fractures surgically repaired.

This study is unique in that it evaluates surgically implanted metal sutures for their distinct and individualizing characteristics. To the knowledge of the authors, this is the first radiographic positive identification study in which sternotomy wires have been analyzed. Additionally, this study has the largest participant sample size (46 professionals and students) of any medical radiography comparison study to date.

Sternotomy wires, or sternal wires, are metal sutures used to secure the sternum after open heart surgery or any other surgical procedure in which the sternum is bisected. Sternotomy wires are typically midline along the sternum and can vary in size, shape, and number since they are hand-tied by surgeons. The foundation of this study was the comparison of antemortem and postmortem radiographs with sternotomy wires. The 46 participants were forensic anthropologists and graduate students trained in this identification technique. Participants were asked to match five antemortem radiographs to 20 postmortem radiographs and complete an anonymous survey detailing their education level, degree held, experience making radiographic comparisons, the number of cases they have completed involving radiographic comparisons, and whether they had ever made an identification using sternotomy wires. Additionally, they were asked which aspect of the wires they found most useful in making a match. The chest radiographs with sternotomy wires were obtained from the Michigan State University Forensic Anthropology Laboratory (MSUFAL), the Michigan State University Anatomy Laboratory, the Office of the Chief Medical Examiner in Genesee County, Michigan, and Sparrow Forensic Pathology Services in Lansing, Michigan.

The anonymous survey responses were used to assess accuracy, sensitivity, and specificity. Collectively, participants were 99.5% accurate in correctly matching the antemortem radiographs to the postmortem radiographs. When separated by highest degree held, those with a PhD were 99.7% accurate, those with a Master's were 99% accurate, and those with a Bachelor's were 99.5% accurate. The sensitivity of the 46 examiners was 98.7% and the specificity was 99.7%, indicating very few false positives and false negatives (only two false positives and three false negatives). The majority of participants (65%) found the shape of the sternotomy wire loops the most useful characteristic in determining a match. This was followed by the shape or location of the sternotomy wire ties (26%).

The results of this study demonstrate that sternotomy wires can be used as a reliable method for making radiographic positive identifications. Regardless of a participant's education level or case experience, the presence of sternotomy wires in antemortem and postmortem radiographs yielded high sensitivity and specificity. As the high accuracy rates indicate, sternotomy wires are unique; therefore, the shape, size, and various characteristics of the wires are individualizing and can be used to confidently make positive identifications. This research has contributed a new, statistically acceptable method of positive identification to the forensic anthropology community, and satisfies the *Daubert* standards.

Sternotomy Wires, Positive Identification, Comparative Radiography

H126 Positive Identification Through Comparison of Lateral Patella Radiographs and 3D Scans: A Validation Study

Emily R. Niespodziewanski, BA, 354 Baker Hall, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State Univ, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; and Carl N. Stephan, PhD, and Pierre Guyomarc'h, PhD, JPAC-CIL, 310 Worchester Ave, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853*

The goals of this presentation are to: (1) report the findings of research investigating the use of lateral patella radiographs as a means of positive radiographic identification of unknown human remains; and, (2) report the results of quantitative matching of two-dimensional patellae images using Elliptical Fourier Analysis (EFA).

This presentation will impact the forensic science community by demonstrating the accuracy of positive identification utilizing medical radiographs of the lateral patella, as well as demonstrate the feasibility for quantified methods to match 2D images of bone scans with radiographs. Results from these studies will help bring positive identification using medical lateral patella radiographs into compliance with *Daubert* standards.

Two hypotheses were tested: (1) Experienced forensic anthropologists can accurately match lateral patella radiographs; and, (2) a 3D imaged patellae can be accurately matched with lateral patella radiographs using EFA.

The study sample was provided by the Willed Body Program, Michigan State University Department of Radiology.

Radiographs were taken using a General Electric® Amx2 portable X-ray unit. Radiographs were taken according to the standards for radiographic imaging of the patella from the lateral aspect. The distance between the X-ray source and the film was 40 inches, with an exposure of about 60kVp/5mAs. All specimens were radiographed once, then five were radiographed a second time attempting to match the angle of the first image. The first set of images served as simulated antemortem radiographs while the second set served as postmortem radiographs to enable comparisons.

An antemortem pool (n=20) and the five reset radiographs (n=5) comprised the survey radiographs. Images were blocked out with cardstock, leaving only the patella visible. Practicing forensic anthropologists and graduate students in forensic anthropology were asked to match postmortem to antemortem images, or answer "no match." The survey also collected demographic information to analyze the effect of education and experience on accuracy. At the time of abstract submission, 22 completed surveys demonstrate high rates of accuracy (99.5%), sensitivity (98.2%), and specificity (100%).

A Canon® model EOS-40D camera was used to digitize the radiographs on a copy stand with backlighting. Digital images were cropped and equalized in Adobe® Photoshop® CS5. Each patella was then outlined using the Pen tool. The outline was saved as a bitmap (BMP) file for input into SHAPE v1.3.

A NextEngine® scanner digitized each patella's surface in 3D (n=23). A series of 15 2D images were serially captured from the 3D model for comparison to the 2D radiographs. The degree of rotation spanned -15°/+15° around the antero-posterior axis and -10°/+10° around the supero-inferior axis.

The SHAPE v1.3 suite generated Fourier descriptors for all images using 40 harmonics (i.e., 345 2D images generated from the 3D scans and 22 patella radiographs). The sum of the squared differences between the Fourier descriptors for the 3D model and the radiographs was calculated and individuals ranked according to this number. The top-ranked image was accurately matched to the radiographic outline in question in 72% of cases. In an applied situation, creation of a "short list" might be preferred so an expert can then visually determine a match. In this case, note that in 20 of 22 specimens, a correct match was found within the top five of 345 images (1.4%).

Since this sample is relatively homogeneous (mostly elderly White Americans), positive results should be applicable to a more heterogeneous sample; however, increased formation of bony spurs with age may increase heterogeneity. Further studies using EFA should confirm these findings, perhaps including more young individuals.

This project has demonstrated the uniqueness of the human patella in two ways. The survey results indicate that medical radiographs of the lateral patella are valid for use in positive human identification due to individualizing trabecular patterns, bony spurs, and overall shape. In addition, this study adds to the literature on the value of EFA in positive human identification because the lateral outlines of patellae are quantitatively distinguishable, reinforcing that these structures are unique and valuable in forensic casework.

Fourier Analysis, Bone Scan, Patella

H127 Robber's Personal Identification by Superimposition and Metrical Analysis Between Recorded Images and 3D Photogrammetric Avatar of the Suspect: A Pilot Study

Francesco Introna, PhD, D.I.M., Sezione Di Medicina Legale, Piazza Giulio Cesare, 11, Bari, ITALY; Luigi Maria Galantucci, PhD, Politecnico Di Bari, Dipartimento Di Ingegneria Meccanica E Gestionale, V.Le Japigia 182, 70126 Bari, ITALY; Sergio Lubelli, MS, and Pasquale Beltempo, MS, D.I.M, Sezione Di Medicina Legale, Piazza Giulio Cesare, 11, Bari, ITALY; Gianluca Percoco, Phd, and Fulvio Lavecchia, PhD, Politecnico Di Bari, Dipartimento Di Ingegneria Meccanica E Gestionale, V.Le Japigia 182, 70126 Bari, ITALY; and Antonio De Donno, PhD, Queesland Univ of Technology, N 11, Bari, ITALY*

After attending this presentation, attendees will become familiar with the use of 3D morphometric comparison to seek a robber's personal identification.

This presentation will impact the forensic science community by showing an objective but non-invasive technique for obtaining a robber's personal identification through an analysis of recorded images and 3D photogrammetric avatar superimposition.

In the past few years, the technological advancement in personal identification systems resulted in a large production of scientific studies and an increased production of devices and commercial software. Facial identification through analysis of pictures taken from video surveillance systems still remains a difficult issue from a technical point of view.

Currently, nearly everywhere, there are video systems, webcams, digital cameras, and cell phone cameras that are able to film facial images and easily transmit, share, and store them. As a consequence, a video documentation of a criminal act often exists.

Expert analysis is then necessary to either confirm or exclude a specific individual as the subject depicted in an image. Personal identification, however, may be easy when close-up pictures are available or when the subject presents specific features or defects.

Personal identification based on 3D digital photogrammetry presents a natural evolution of previous research in this field by Parameterized Superimposition (PS). The experience was based on 2D/2D comparison between video frames taken from the surveillance camera system during a robbery and frames of the suspect brought back to the same place the robbery was perpetrated.

In the first phase, recorded images of the robber were studied and improved. Frames with a better view of the robber's face landmarks were chosen. Then, the court took the alleged offender into custody. The suspect was transported to the location of the robbery and placed in the same position as the frames from the video footage. Finally, a quantitative comparison between the image of the robber's face and the suspect's face was carried out. For that to be possible, the crime scene—often a bank or a shop—has to stay closed during the investigation and total cooperation from the suspect is necessary.

The purpose of this study is to test a new technique based on 3D photogrammetric avatar: photogrammetry currently provides the most cost-effective 3D capturing system, being fast, inexpensive, and non-

invasive; the equipment necessary for acquisition is easily transportable and offers high reliability. The technique was demonstrated to be suitable for capturing facial morphology for clinical and anthropological use.

The new technique should overcome the limits of the PS technique, while maintaining the same quality level of objectivity and accuracy. This technique involves four steps:

- **Preparatory Phase**: In which the recorded images of the robber are studied and improved. Frames with a better view of robber's face landmarks are then chosen.
- **3D Acquisition Phase:** During which a 3D photogrammetric avatar of the suspect face is created; this phase only requires four photos which are made simultaneously with a calibrated camera.
- **Superimposition Phase:** Preparatory for the final step, involves a meticulous spatial orientation of the 3D avatar in the same position taken by the offender in the selected frames. A snapshot of the 3D avatar is then taken.
- **Metric Image Analysis:** A quantitative comparison between the image of the robber's face and the snapshot obtained is used. To perform this step, it is necessary to clearly recognize at least five landmarks on the robber's face using suitable software. Landmarks are chosen and allocated on individual images in relation to the spatial position of the faces, depending on the attitude taken by the individual. The same points are marked on the suspect's face obtained at the end of the best superimposition. Repeated landmarking by different observers allows the detection of random errors and controls the quality of the landmarking practice within and between operators, minimizing variability. The absolute and relative distances between the marked points, the perimeters and the areas of the triangles obtained by connecting the points, and the compactness indexes are automatically calculated on both images in the analysis. Two series of five sets of numerical parameters can then be compared.

Promising results of a preliminary study, involving experimental subjects and cross comparisons between them are presented.

Identification, Robbery, 3D

H128 Anthropology and Disease Genetics: A New Avenue of Forensic Identification

Caitlin N. Dardenne, MS, 428 5th Ave, #6, Salt Lake City, UT 84103; and Margaret M. DeAngelis, PhD, 65 Mario Capecchi Dr, Salt Lake City, UT 84132*

After attending this presentation, attendees will better understand the potential utility of disease-specific genetic databases for forensic identification. Attendees will be introduced to the concept that features not previously considered individuating by forensic anthropologists can in fact become vital parts of the identification process with a little background research and collaboration with scientists from other fields. In addition, attendees will be shown both the methodologies required in associating anthropological and genetic practices in this type of identification, and a pilot example of how this may be employed in a real-life scenario.

This presentation will impact the forensic science community by showing how the need for more avenues of forensic identification to increase the likelihood of positive identification of highly desiccated or skeletonized remains under the purview of forensic anthropologists is important. This presentation will encourage a more productive collaboration between forensic anthropologists and geneticists and allow forensic anthropologists the opportunity to expand their avenues of identification by tapping into, until now, under-utilized resources. The concept of utilizing a specific set of medical databases discussed in this presentation provides a new avenue of research that will expand the tools available to forensic anthropologists and drive new research endeavors into exploring the forensic potential of existing medical databases.

Forensic anthropology, especially osteological analysis, has become vital to medicolegal cases in which remains are highly decomposed or skeletonized. One of the main roles of the anthropologist in such cases is the identification of the deceased through the implementation of identification methodologies and the creation of a biological profile of the remains. Unfortunately, there are still few databases to which researchers can compare their findings to help identify the deceased. Without the ability to compare the biological profiles of unidentified remains to potential matches, it is very difficult to give a name to the unknown remains: however, there are many medical patient databases with extensive areas of information that have yet to be utilized by forensic investigators. Collaboration between genetic and forensic researchers can expand skeletal identification techniques and provide new avenues for individual identification through the use of specific medical databases.

This new technique builds relationships between features of the skeleton and medical diseases through common genetic markers which affect the presentation of both aspects in the individual. The interaction of the genetic elements are analyzed for significance and then tested against a sample population. Given the genetic association between the disease and the bony manifestation, the identification of the feature on a set of remains can allow the forensic anthropologist to direct a DNA study in search of the common marker in the gene of interest. Upon finding the marker, suggesting that the individual does have the disease, the anthropologist can then search the local disease-specific patient databases using the biological profile to advance the identification process by composing a subset of potential matches.

A pilot case study on the application of this technique to the relationship between the eye disease Age-Related Macular Degeneration, which is the leading cause of vision loss in older adults, and the bone disease Ossification of the Posterior Longitudinal Ligament, which is the ossification of a ligament in the spinal column will be presented. It is encouraged that forensic anthropologists, while creating their biological profile, note features that may not be considered individuating and research any connections between these features and diseases.

Identification, Anthropology, Genetics

H129 Dental Ornamentation Among Southwest Hispanic Border Crossers at the Pima County Office of the Medical Examiner

Robin Reineke, MA, Pima County Medical Examiner, 2825 E District St, Tucson, AZ 85714; and Angela Soler, PhD, Pima County Medical Examiner, 2825 E District St, Tucson, AZ 85714*

After attending this presentation, attendees will have a better understanding of the phenomenon of dental ornamentation among some Southwest (SW) Hispanics, and a better ability to predict the geographic or national origin of decedents with varying styles of dental ornamentation.

This presentation will impact the forensic science community by increasing the understanding and identification potential of this rapidly growing demographic of American immigrants. With the recent rise in the number of SW Hispanics living in the United States, forensic anthropologists are increasingly faced with estimating ancestry in a more diverse community of Hispanic individuals. As such, an understanding of dental modification may assist in the process of predicting national, cultural, or socioeconomic affiliations of a particular unidentified decedent.

Over the past ten years, the Pima County Office of the Medical Examiner (PCOME) has examined the remains of over 2,000 individuals either confirmed to be or believed to be undocumented border crossers. A small but consistent portion of those examined have exhibited dental ornamentation to the anterior teeth in the form of metal "windows" (gold or silver lining around the tooth), gold or silver crowns, stars or letters inlayed onto incisors, and thin bars of gold or silver placed mesially between teeth. Because this is likely a cultural phenomenon, the

prevailing hypothesis is that the prevalence and type of such cosmetic dentistry will vary by geographic region of origin.

To address this question, over 1,400 autopsy reports, photographs, and/or dental charts were reviewed from all cases of undocumented migrants examined at the PCOME between 2005 and 2012. Both identified and unidentified individuals were included. For the purposes of this study, "dental ornamentation" refers to individuals who have any gold or silver dental modifications present in the teeth between either the maxillary or mandibular canines. These cases were coded as "present," whereas those without ornamentation were coded as "absent." The individuals who were missing all or part of the dentition postmortem, or when dental ornamentation could not be determined, were coded as "unknown." In addition to the presence or absence of dental adornment, sex and age were noted for all cases, and for identified individuals, the country and state of origin within Mexico, Central America, or South America were collected. For those with dental ornamentation present, further details were recorded regarding the type and location of dental ornamentation. Simple percentages, Chi-Square Tests, and Phi Coefficients were calculated using SPSS 19.

Results demonstrate that out of the 991 SW Hispanic migrants included in this study, a total of 115 (11.6%) individuals had dental ornamentation of some kind. Although a small percentage, the relatively even distribution of those examined between 2005 and 2012 demonstrates that dental ornamentation continues to be a consistent phenomenon among undocumented border crossers. Most importantly for identification purposes, the presence of cosmetic dental restorations is significantly higher among Central Americans (21.1%) when compared to Mexicans (7.8%) (x^2=.000). Additionally, a larger proportion of Central American females had cosmetic restorations (28.5%) when compared to Mexican females (16.7%) (x=.002). Cosmetic dental restorations were also present at a higher rate among Central Americans under the age of 30 years than Mexicans of the same age group (x^2=.027). Most interesting, at least 50% of all individuals with dental ornamentation did not have any associated dental work and the ornamentation was purely cosmetic.

The large percentage of individuals with purely cosmetic dental ornamentation supports the argument that this is a cultural phenomenon, as opposed to being limited to therapeutic intervention. Individuals are making a choice to have a gold or silver adornment on their front teeth. Furthermore, the higher prevalence of dental ornamentation within the Central American sample demonstrates regional variation, which also supports the cultural argument. Although additional research is needed to further clarify regional patterns, these results indicate that dental ornamentation may be used to assist forensic anthropologists in predicting region of origin when comparing unidentified decedents to missing persons, especially when there are a great number of possible matches.

Forensic Anthropology, Southwest Hispanic, Dental Ornamentation

H130 A Comparative Study of Biogeochemical Signatures in Bone From Two Groups: Deceased Undocumented Border Crossers From Mexico and Individuals From the Northeastern United States

Jennifer J. Prutsman-Pfeiffer, PhD, Univ of Rochester Medical Center, Autopsy & Neuropathology, 601 Elmwood, Box 626, Rochester, NY 14642; Lori E. Baker, PhD*, Baylor Univ, Forensic Research Lab, One Bear Place, #97173, Waco, TX 76798-7173; Thomas H. Darrah, MS, Univ of Rochester, Dept Earth & Environmental Sciences, 227 Hutchison Hall, Rochester, NY 14627; and Erich J. Baker, PhD, Baylor Univ, Dept of Computer Science, One Bear Place #97356, Waco, TX 76798*

After attending this presentation, attendees will understand the utility of incorporating bone biogeochemical studies into casework involving the analysis of unidentified skeletal remains. This research tests the hypothesis that human bones from geographically distant areas of North America (Mexico and western New York State) will reflect the respective environments of residence. The environmental regions differ based on concentrations of trace elements and lead isotope ratios. Diet differences may be reflected in the contrasting populations, as well as differences in sources of lead exposure and possibly other elements associated with occupation or medical interventions.

This presentation will impact the forensic science community by showing how the methods discussed will assist in the identification of migrant individuals in determination of their foreign origin which will impact the forensic science community.

This analysis provides a picture of the elements and isotopes that offer the most discrimination between disparate geographical populations. If it is possible to narrow a possible area of origin, whether natal or residential, this technique could provide a geographical area of focus for investigators to concentrate their efforts in resolving cold cases and the unidentified. There is a national concerted effort for medical examiners/coroners, police agencies, and families of missing persons to utilize repositories like the National Missing and Unidentified Persons System (NamUs) to associate missing persons and unidentified remains through demographic, personal, medical, and biological information. This effort also encompasses the identification work of deceased migrants along the southern U.S. border. DNA services are offered free of charge to agencies and families with the goal of finding identities for the deceased and unidentified; however, the reality of unidentified remains is that the pool of possibilities is very large and there must be a familiar sample for comparison. Biogeochemical analysis of bone may narrow the target geographic area of the unidentified person, help direct the investigation, and improve the likelihood of making an identification.

This study investigates the elemental and isotopic composition of human bones of 22 deceased undocumented southwestern border crossers with positive DNA identifications (residence of Mexico) and 38 deceased individuals from the northeastern United States (residence of western and central New York State). Inductively Coupled Plasma Mass Spectrometry (ICP-MS) was used to obtain concentrations of 31 elements and Pb isotope ratios of parietal, femoral, and tibial bone samples from Mexico (parietal N=17, femoral N=14 and tibial N=4; paired samples: parietal/femoral, N=11) and western New York State (parietal bone from autopsy series, N=32; parietal and tibial bone from anatomical gift series, N=6).

A metric Multidimensional Scaling (MDS) analysis was performed for all samples with all elements. This showed separation of the two geographically separated groups (New York vs. Mexico) when all data is considered. The significance of the differences between the groups for each element and Pb isotope ratios was then analyzed. When comparing only parietal samples, there were five elements (Al, Mn, Sn, Zn, Fe) that were significantly different between the New York State samples and the Mexico samples at the 0.01 level and one (Hg) that was significant at the 0.5 level. MDS was then performed on all of the parietal samples and included only those elements that were significantly different between the two groups. This analysis showed even better differentiation of the two groups with the elimination of nonsignificant elements. In addition, the pairing of bone samples from the same individual allowed a comparison of elemental concentration and isotopic ratios between different anatomic bone locations. The New York parietal/tibial pairs showed no significant difference, indicating that either bone would yield similar results. The Mexican parietal/femoral pairs only showed a significant difference in the concentrations of Mn with a p-value of 0.007.

A plot of lead isotopes (208PB/206Pb vs. 207Pb/206Pb) revealed both overlap and differences between the southwest and northeast parietal bones. The NY group clustered around values previously reported for individuals from this region, showing relationship to local soil, inputs from U.S. and Canadian gasoline sources, and local atmospheric ratios. Both groups revealed outliers that may be explained by different sources of environmental and anthropogenic lead.

This research was supported in part by a Lucas Grant from the Forensic Sciences Foundation.

Bone Chemistry, Geographical Pattern, Foreign Migrants

H131 Extending the Biological Profile: Using Stable Isotope Analysis as an Exclusionary Tool in Region-of-Origin Investigations of Unidentified Remains

Melanie M. Beasley, MA, 4554 Lisann St, San Diego, CA 92117; Lesley A. Chesson, MS, IsoForensics, Inc, 421 Wakara Way, Ste 100, Salt Lake City, UT 84108; Luciano O. Valenzuela, PhD, 257 S 1400 E, Salt Lake City, UT 84112; and Eric J. Bartelink, PhD, Chico State Univ, Dept of Anthropology, Butte #311, 400 W First St, Chico, CA 95929-0400*

After attending this presentation, attendees will understand the application of hydrogen and oxygen stable isotope analysis in forensic anthropology, highlighting how stable isotope analysis can contribute to the biological profile of unidentified remains by tracking the movement of a victim prior to death.

This presentation will impact the forensic science community by demonstrating how an extended biological profile that includes stable isotope data has enormous potential for aiding in the positive identification of unknown individuals.

Although anthropologists have used stable isotope analysis extensively since the 1970s to examine diet, weaning, and migration in prehistory, the technique has had limited application in forensic anthropology, demonstrated by the paucity of stable isotope presentations and publications. Stable isotope analysis offers another tool to the medicolegal community to reconstruct the movement prior to death of unidentified decedents and to exclude possible matches and narrow search areas.

Stable isotope analysis is most beneficial to forensic anthropologists in cases where standard methods of identification are unsuccessful. Although the biological profile typically consists of sex, age, ancestry, stature, and antemortem characteristics, stable isotope analysis of biological tissues can provide additional information regarding migration history, including birthplace, the last decade of life, or the weeks and months before death, depending on the tissue sampled. Previous research has demonstrated the utility of using multiple stable isotopes to identify region of origin and/or dietary patterns in border-crossers' deaths from Mexico, U.S. soldier war-dead from the Vietnam conflict, unidentified individuals from California, and the identification of a U.S. airman's remains recovered in Laos.

The application of stable hydrogen and oxygen isotope analysis of biological tissues to investigate origin is possible because stable isotope ratios of water vary systematically and predictably across landscapes due to environmental factors. These isotope distributions can be visualized using GIS maps highlighting distinct isotopic regions, or isotope landscapes (isoscapes). In turn, the isotopes of biological tissues record the isotopic composition of locally available water. For example, human hair records the isotopic composition of drinking water consumed by an individual throughout the duration of hair growth. Ehleringer et al. demonstrated that predictive models relating human hair stable isotope ratios to drinking water—and thus, geography—achieved an overall 86% success rate between observed and predicted region of origin within the continental U.S.[1]

However, the success of origin predictions based on the analysis of stable isotopes in tissues is dependent upon the quality of water isotope data used in building the foundational predictive isoscapes. Here, the impact of a fine-scale tap water collection scheme within two U.S. states on the performance of a continental U.S. tap water isoscape model originally developed by Bowen et al. was investigated. The collected sample set consisted of 186 tap water samples from several cities throughout California and Oregon. These samples were then used to develop a tap water isoscape specifically for the two coastal states.[2] The new model was then used to predict the isotopic composition of 20 validation samples randomly selected from the dataset that were not used in model generation. The agreement between measured isotope ratios and those predicted using the new isoscape was compared to agreement between measured isotope ratios and those predicted using the previous Bowen *et al.* isoscape in order to judge the accuracy of tap water predictions in the new model generated from samples collected at a finer spatial resolution.[2]

This project highlights the utility of stable isotope analysis in forensic anthropology investigations by demonstrating the application of the technique to tissues that record geographic information and by presenting methods for increasing the reliability of region of origin interpretations based on measured stable isotope data.

Stable Isotopes, Isoscapes, Biological Profile

I1 Incarcerated Foreign Minors in Italy: How to Treat Them?

Ignazio Grattagliano, PhD, Anrea Lisi, PsyD, Valentina Stallone, PhD, Roberto Catanesi, MD, Nicola Petruzzelli, PhD, Ylenia Massaro, PhD, Cristian Signorile, PhD, Anna Cannito, PhD, and Filippo Campobasso, PhD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY;*

After attending this presentation, attendees will better understand the challenges associated with tending to the needs of foreign minors by staff in Italian prisons. This presentation also looks at various alternatives to detention with the aim of reducing recidivism.

This presentation will impact the forensic science community by presenting the challenges that various juvenile detention centers throughout Italy face when confronting the treatment of foreign juvenile delinquents. In addition, this presentation highlights the importance making the most of limited funding through the formulation of innovative treatment plans aimed at this population.

Foreign minors often have problems integrating into Italian society. The two primary reasons for this are their young age and their different cultural backgrounds. The goal of this study is to provide data regarding the treatment of foreign juveniles in the Italian justice system. It is important to create secondary and tertiary prevention services in order to decrease the likelihood of recidivism, and to promote the minor's integration into the social fabric of their adopted country.

The principal motive for which minors leave their homeland is the search for a new way of life. Persichella wrote of "advance socialization," a term that refers to the expectations of well-being that a foreigner might associate with a particular place. These mental images are often generated by the mass media, as well as by relatives and friends who have already emigrated there. These youngsters are often disappointed upon their arrival in the new country, leaving them in a state of relative deprivation, frustration, and tension, which are significant risk factors for the commission of crimes.

The percentage of foreigners convicted of crimes in Italy has increased over the last decade with respect to the number of convicted Italians. This is true for all crime categories. There are many reasons for this phenomenon. Among them are the conditions in which these immigrants find themselves when they arrive in Italy (e.g., how their previous expectations measure up to the reality of their new existence, how successfully they reintegrate with their families, their ability to enter into the work force, and the influence of both Italian and foreign organized crime groups).

Foreign minors are more frequently placed in jail than their Italian counterparts. This is because it is less likely that they would have access to resources that might allow them to be spared detention (e.g., having a nuclear family, a home, steady employment, etc.). In theory, these foreign juveniles are supposed to have access to detention alternatives, but in reality, they must overcome serious obstacles in order to take advantage of them.

Cultural mediation acts to facilitate relationships between individuals from ethnic minority groups and the associated social services that are in place to serve them. The cultural mediator aids the foreigner in understanding how to behave appropriately, and attempts to sensitize him to the customs and way of life in Italy. The cultural mediator also actively participates at various phases of institutional life, for example, in helping the minor to communicate with juvenile justice officials, and with relatives. In addition, the mediator also aids the family in navigating the Italian legal system.

Some juvenile detention centers (IPMs) report a lack of resources and funding necessary to create appropriate treatment plans. They cite, for example, the under-utilization of cultural mediators who are often marginalized and relegated to the singular role of interpreter. Cultural mediators are typically only available on an hourly basis, and are not considered to be an integral part of the treatment team. Short stays in IPMs are also reported to be problematic: repeated transfers make it impossible for staff to get to know the minor in order to create an individualized education program.

When considering the usefulness of detention alternatives, the study and development of sharable management models that address the real needs of minors in the juvenile justice system are of fundamental importance. Facilitating the social integration process, appointment of a legal guardian when necessary, and providing qualified legal representation are high on the list of priorities. Only through the development of a united partnership can a welcoming network be created: one that is able to pick up on the first signs of trouble that often confront foreign minors.

Foreign Minors, Juvenile Delinquency, Incarceration

I2 Minor Perpetrators of Sexual Crimes: Personality, Coping Style, and Parental Care—Twenty-Three Italian Cases

Francesco Margari, MD, Lucia Margari, MD, Paola Lecce, PhD, Elena Lafortezza, PhD, Floriana Pinto, PhD, Francesco Craig, PhD, Andrea Lisi, PsyD, Valentina Stallone, PhD, and Ignazio Grattagliano, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will more fully comprehend the dynamics regarding sexual violence perpetrated by minors in Italy.

This presentation will impact the forensic science community by presenting some of the challenges that professionals in criminology and legal medicine face when dealing with sexual crimes committed by minors in Italy.

In the field of forensic psychiatry, any sexual behavior that occurs *without consent, without equality, or as a result of coercion* is considered to be abusive.[1] In order for sexual behavior to be considered consensual, certain criteria are necessary: comprehension of the nature of the proposal; an understanding of societal standards regarding sexuality; awareness of the potential consequences and alternatives; the presumption that agreement or disagreement will be respected in the same manner; the decision to engage is a voluntary one; and, that those involved are mentally competent.[2]

Equal relationship refers to situations in which the two people involved possess equal power within the relationship and neither of the two is controlled or coerced by the other. *Coercion* refers to situations where one party abuses authority, offers bribes, makes threats, or uses intimidation tactics in order to win the cooperation or obedience of the other. Sexual conduct during adolescence must not be considered deviant if it involves non-coercive interaction between two peers. It is not always easy to demonstrate coercion, though expert testimony evaluations often focus on this critical aspect. At times, it is also challenging to determine what age-appropriate sexual behavior is, and if the two people involved are, in fact, developmental and/or chronological peers. Studies on the topic hypothesize the inability of the adolescent to recognize the other as different from himself or herself, and the difficulties associated with entering into a sexual relationship with another person where dysfunctional coping strategies are often employed. One pilot study from 2002 revealed that the parents of adolescent sexual offenders most often employ an overprotective-affectionless parenting style.[3] "Affectionless control" parenting style is a risk factor for the development of deviant behavior. Comorbidity rates in

adolescent sexual offenders are high and involve behavioral disorders, personality disorders, and emotional-affective disorders. One recent study revealed that about two-thirds of sexual offenders meet the criteria for personality disorder. Impulsivity is one of the characteristics typical of people who exhibit aberrant and violent behavior.[4] The goal of this study is to evaluate the relationship between personality, parental care, and coping style in adolescent sex offenders.

Methods: Clinical interviews; psychodiagnostic testing (MMPI, Minnesota for Adolescents, A/2; Parental Bonding Instrument (PBI; Coping Inventory for Stressful Situations (CISS; Questionnaire I-R, frustration-aggression by Caprara et al.); and healthcare, psychological, and judicial documentation. The sample studied thus far is comprised of 23 unmarried male adolescents between the ages of 15 and 20 years at the time of the interview. The average age was 17 years ± 1.6 (standard deviation), and almost all subjects were Italian (1 Albanian), and Catholic (1 atheist, and 1 agnostic). All were investigated for perpetrating sexual violence on other minors. The sample was taken from Judicial Juvenile Social Services, which intervenes following the commission of a crime by a minor.

Preliminary results have revealed no particular pathologies on the part of the adolescent sexual offenders who were examined by the authors. The type of parenting style they received appears to have been intrusive-overprotective, which did not allow the adolescent to face typical life challenges, thus impeding his ability to develop coping skills. This type of parenting style includes intrusiveness, enmeshment, encouragement of dependence, and cutting the minor off from the outside world.

Minors, Sexual Crimes, Personality

I3 Alcohol Use and Juvenile Delinquency in Europe: Results of an International Study

Gabriele Rocca, MD, Alfredo Verde, PhD, and Uberto Gatti, MD, Univ. of Genoa, Via De Toni 12, Genoa, ITALY*

After attending this presentation, participants will be able to recognize some features of the relationship between alcohol use and delinquency among juveniles, particularly the strength and the characteristics of this association in various cultural contexts and the role of drinking patterns in the etiology of crime.

This presentation will impact the forensic science community by serving as a key aspect for understanding the relationship between alcohol use and juvenile delinquency with the aim of improving preventive interventions.

The existence of a significant correlation between alcohol use and crime has long been acknowledged in the scientific literature. Moreover, alcohol use constitutes a serious public health problem. Several studies have shown that alcohol plays a prominent role in the genesis of deviant behavior, especially among the young.

In order to ascertain the existence of significant relationship among alcohol use and delinquency among young people and to describe the nature and characteristics of such a relationship, a database was set up to record the results of the "International Self-Report Delinquency Study 2." This database was created by selecting a sample of young people (N=57,771) of both sexes, aged between 12 and 16 years, in 25 European countries (Ireland, Sweden, Denmark, Island, Norway, Finland, Austria, Germany, Holland, Switzerland, Belgium, France, Spain, Italy, Cyprus, Portugal, Bosnia-Herzegovina, Poland, Russia, Lithuania, Slovenia, Hungary, Armenia, Czech Republic, and Estonia).

The research focused chiefly on the role of alcohol use and the various modes of alcohol consumption, and sought to analyze the influence exerted by different life situations (age, sex, lifestyle, friendships, and personality traits).

Alcohol consumption proved to be a very widespread phenomenon among young people, particularly among youths who commit crimes and those who are victims of crime. Moreover, it emerged that the abuse of alcohol was the consumption modality most closely associated with both delinquency and victimization. Alcohol use was seen to correlate more closely with the involvement in violent crime than with property offenses. A possible explanation for this could be that, since alcohol exerts a pharmacological effect which simultaneously heightens aggression and blunts certain cognitive capacities, its consumption may play a greater role in the commission of unplanned offences.

The analyses conducted on the relationship between the involvement in alcohol use and various psychosocial factors, such as lifestyle, personality traits (self-control and inclination to violence), and belonging to delinquent youth groups, yielded particularly significant results.

When the results recorded in each country were examined individually, the association between alcohol use and delinquency was confirmed in all geographical settings, despite the considerable social and cultural differences. In particular, it emerged that, in all of the countries considered, alcohol use was more closely associated with involvement in violent crime than with property offenses.

The results yielded by the present study indicate that alcohol use is strongly associated with delinquency among young people in Europe and that so-called "binge drinking" is the consumption modality most closely associated with offending.

In conclusion, alcohol use and delinquency are closely related with one another. The nature and characteristics of these relationships suggest that the associations between alcohol use and delinquency are reciprocal rather than one-directional. Consequently, alcohol use constitutes a risk factor for criminal behavior. Likewise, involvement in delinquency increased the risk of alcohol consumption and, especially, of alcohol abuse.

Alcohol Use, Juvenile Delinquency, Relationship

I4 The Juvenile Psychopath: How Young Can We Diagnose Psychopathy and Is This Even Helpful or Ethical?

Shaylin P. Chock, MD, PO Box 86125, Los Angeles, CA 90086-0125*

The goal of this presentation is to offer insight into whether the diagnosis of psychopathy for juveniles can be made in light of the developing brain and normal behavior variations in childhood/adolescence. It will then discuss the arguments that favor early identification and treatment as well as those proposing that psychopathy is stable and unamenable to treatment. Finally, this presentation will discuss the ethical issues and implications.

This presentation will impact the forensic science community by fully exploring the identification of psychopathy in children and/or adolescents as it relates to diagnosis, treatment, and ethical considerations.

Psychopathy refers to a clinical construct that includes a behavioral pattern marked with risk-taking, sensation-seeking, lack of remorse for misdeeds, absence of empathy, narcissism, lack of emotionality, problems with impulse control, and involvement of criminal activities.

Looking at this definition, one can see that some of these behaviors are consistent with normal development in children and adolescents. Consequently, it may not be advisable to make a diagnosis of psychopathy for persons other than adults as several of its clinical constructs may be too common among adolescents and reflect a transient developmental state rather than a stable personality trait. However, there have been a few studies suggesting that for adolescents: psychopathy can be measured reliably, the diagnosis is the same as that for adults, and the clinical symptoms are stable across time. This presentation will examine these opposing views to help mental health clinicians decide if psychopathy should be diagnosed in children and adolescents.

Another issue to consider is whether early identification helps to decrease the risk of youth developing into adults involved in the criminal justice system. When looking at children and adolescents, the psychopathy construct may be helpful to differentiate "life-course persistent" from "adolescent limited" antisocial behavior. In theory, the importance of studying these traits will help to identify those persons who are more amenable to intervention and treatment. There have been some studies suggesting that early intervention and treatment is possible for certain components found in the psychopathy construct. Thus, intervention for these at-risk youth may be able to impede the possibility of them becoming further disturbed and engaging in more serious antisocial behaviors. However there is also evidence to show that psychopathy is stable and difficult to modify regardless of the age of the individual.

Finally, the ethical considerations of labeling a child/adolescent as a psychopath will be discussed. Taking into consideration its highly stigmatizing effect, the psychological, social, educational, and legal ramifications should be considered if a child carries this diagnosis.

Psychopath, Diagnosis, Ethics

I5 The Role of Minor Testimony in Child Abuse: Limits of Applicability in Forensic Medicine

Isabella Aquila, MD, Policlinico Univ, S. Venuta-Medicina Legale, Viale Europa, Località Germaneto, Catanzaro, ITALY; and Giuseppina Fama, PhD, Salvatore Savastano, Ciro Di Nunzio, PhD, Arianna Serra, MD, Maria Chiarelli, MD, Debora De Bartolo, Santo Gratteri, MD, and Pietrantonio Ricci, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand the forensic importance of minor testimony in child abuse.

This presentation will impact the forensic science community by discussing the possibility to evaluate capability of children to give testimony using a cognitive interview.

Introduction: Child abuse is an important public health problem for society. For this reason, the present case addresses the topic of sexual abuse against children from the expert's point of view and debates the question of applicability of clinical methodology in the forensic context.

The presentation will discuss the problem of so-called "masked" abuse, where the typical absence of objective physical evidence can make the declaration of the minor the only evidence available to the investigators.

The Case: This case stems from an allegation of abuse that concerned a group of teenagers. The investigated conduct relates to acts that could have been done by an educative figure of reference, who would have involved minors in a game having, among its rules, contact with adult genitalia. In September 2011, the judge (who in Italy is called "*Judge of preliminary investigations*") assigned to the case, appointed a board of advisors including a forensic pathologist, two psychologists, and a child neuropsychiatrist.

Objectives: The experts were asked to assess the testimonial capacity of minors. This operation was carried out through a methodological process oriented to probe the "generic skills" and the "specific skills" of involved subjects *(*Italian Guidelines on the Listening to Child Witnesses).

Methodology:

1. Gathering of evidence in accordance with the rules of the protected hearing of the minor.
2. Analysis of the quality and the accuracy of the statements.
3. Analysis of the basic psychological functions.
4. Analysis of the psychosocial context in which the complaint emerged, with particular reference to:
   - Possible elements of influence among children.
   - Possible elements of influence among adults (parents).

Procedures:

1. Use of the cognitive interview for the gathering of declarative contents.
2. Audio-video recording of interviews carried out within a neutral space (room equipped with one-way mirror).
3. Use of "Reality Monitoring" for the analysis of declarative contents.
4. Preparation of a table to compare the statements of minors.
5. Preparation of a check-list of questions for the parents' interview.

Results and Discussion: Clinical and psychosocial indicators were compatible with both the "generic skills" and the "specific skill" of each examined subject. Moreover it was necessary to partly review predisposed methodology, renouncing the use of the check-list prepared to interview minor's parents. In fact, the lawyer for defense contested the competencies of appointed experts about minor's parents' interview.

This presentation can be useful in considering the paradoxes in the work of the expert, who when called to apply the clinical methodology that makes him competent to carry out an inquiry, may have to readjust the rules of forensic science to the legal setting.

Minor Testimony, Child Abuse, Cognitive Interview

I6 Differential Diagnosis Between Munchausen Syndrome by Proxy and Overanxious Mother: A Case Report

Biagio Solarino, PhD, Univ Degli Studi di Bari, Sezione di Medicina Legale, P.zza Giulio Cesare, 11, Bari, ITALY; Pasquale Ferrante, MD, Ospedale Bonomo di Andria, Pediatric Dept, Via Fornaci,201, Andria, ITALY; and Rossella Lippolis, PsyD, and Maria Grazia Foschino, PsyD, Ospedale Giovanni XXIII, Via Amendola 207, Bari, ITALY*

After attending this presentation, attendees will be able to understand that some particular forms of child abuse such as Munchausen Syndrome by proxy need a careful scientific multidisciplinary approach.

This presentation will impact the forensic science community by demonstrating the importance of a careful approach to diagnosing Munchausen Syndrome by proxy as well as creating an informatics system that allows doctors to check how many times parents bring their babies into an Emergency Department and the medical reason of such admittances.

The term Munchausen Syndrome was commonly used to describe adults who presented themselves with a false illness story. They are affected by psychiatric factitious disorders that some recommend to re-classify as somatoform disorder in the DSM-5.

The definition of Munchausen Syndrome by proxy child abuse is: when an infant or a child is presented to doctors, often repeatedly, with a disability or illness fabricated by an adult, for the benefit of that adult.

In comparison with other forms of child abuse, this is more complex to diagnose because it involves not only a careful pediatric examination of the infant or child, but also a psychological analysis of the parent's behavior. It could be considered "normal" that a mother requires medical assessment and care for a child's presumptive illness; hence, it is never an easy task for the pediatrician to understand that the parent is

fabricating acute signs and symptoms to draw attention to himself or herself, rather than to injure the child.

The difficulty is to assess if clinicians mean that the mother is only a bit anxious about the child's health, or if she has a psychological or psychiatric disease and there is a concrete risk for the child's integrity.

Presented here is a case of a 4-year-old child who during his life was brought to the hospital at least 30 times by his mother with varying complaints. In four years, this baby presumptively manifested: diarrhea, vomiting, nausea, fever, dizziness, vertigo, absence seizures, syncope, abdominal pain, bilateral hand pain, mucus in feces, gastro-esophageal reflux disease, dyspepsia, and pollakiuria. In most of these cases, the symptoms were only reported by the mother who pretended to submit the child to accurate laboratory and instrumental examinations. The physicians did not find any kind of chronic or acute disease in the child.

In the last admittance to the hospital, the mother stated the baby showed minute and diffuse hemorrhages that suddenly appeared in the morning, coupled with bilateral ankle pain. Even in this case, the physicians did not find such signs, but the mother asked them to examine red spots on the skin. For these reason, the baby was submitted to hematological analysis because the mother was totally convinced the baby had leukemia. After four days of hospital observation, the baby was discharged without diagnosing any condition; the physicians recommended psychological consultation for the mother. The mother did not accept this recommendation and showed great anxiety and worry about her child's health. Forensic psychiatric examination was performed and diagnosed the mother's Obsessive–Compulsive Disorder (OCD). These aspects will be discussed in the following presentation, underlining that the diagnosis of Munchausen Syndrome by proxy can be elusive, especially in a young child. Health organization systems need to implement methods for better diagnosing Munchausen Syndrome by proxy.

Munchausen Syndrome, Psychiatric Disease, Forensic Medicine

I7 Forensic Science in the Islamic Legal System

Raymond H. Hamden, PhD, 2020 Pennsylvania Ave, NW, No 806, Washington, DC 20006; Manal S. Bamousa, MD*, Dammam Centre of Forensic and Legal Medicine, PO Box 476, Code 31411 Eastern Province, Dammam, SAUDI ARABIA; Hooman Keshavarzi, MA*, Argosy Univ, 939 Oak Ridge Blvd, Elgin, IL 60120; and Lama Younis, MSc*, Univ of London, 22 Cubitt Bldg, Grosvenor Waterside, 10 Gatliff Rd, London, UNITED KINGDOM*

The goals of this presentation are to: review comparative studies of religious principles and forensic activities; understand Shari'ah, the definitive Islamic law or doctrine, the source of law and moral guidance, the basis for both law and ethics; to learn about the medicolegal death investigation system in the Kingdom of Saudi Arabia (KSA) and its uniqueness, which was exclusively derived from Islamic judiciary based on Shari'ah law; review medical science in the history of the Moslem world, which is important in order to contextualize the applications of current forensic practice; to understand the role of forensic psychiatry in Islamic jurisprudence which can be traced through the Holy Qur'an and Sunnah (the teachings of the Prophet Muhammad); learn about the Islamic legal texts that give a wealth of material on mental illness, or insanity, and its existence in the Islamic literature, including law manuals and precedent/ruling (Fatawa) collections; explore the cultural, religious, and social contexts of practices of discipline and punishment in the Kingdom of Saudi Arabia; understand how disciplinary practices that are considered normative in one culture may seem neglectful or abusive in another; realize the definition of discipline means those practices (verbal, physical, emotional) intend to have children behave in specific, usually culturally normative ways will vary from culture to culture; review recent controversies that range from criminal material support of terrorism cases to civil challenges of policies of motor vehicle departments regarding the wearing of a type of Muslim veil, the hijab, in state identification photographs; and set a precedence among professionals for international understanding and to foster mutual cooperation.

This presentation will impact the forensic science community by ensuring through effective communications of the true nature of the Islamic legal system and the role of forensic science within, a better understanding of a misrepresented group of people, which will foster mutual cooperation among people globally. With this presentation, the basic premises will be presented for the participating audience to gain knowledge of the following: practice of religious principles in daily life at work—not just worship or recreation and family—differs from the secular life style. Yet, people are basically the same in corresponding the need for trust and respect, belonging and proclamation for fairness, setting rules to regulate ethics and morals, and supporting the values of liberty and humanity for everyone. With the many misconceptions of differing cultures and religious practices in people's lifestyles around the world, the audience will hear firsthand forensic science professionals speak on the practical experience in the Islamic legal systems. This session will highlight the Islamic systems in the practice of some medicolegal issues, such as medical ethics, consent, confidentiality, care of patient near the end of life, euthanasia, suicidal matters, and many other interesting aspects under the scope of Islam jurisprudence. Practices of discipline and punishment of children in Saudi Arabia families is highlighted. It is recognized within childhood studies that all societies and cultures bring infants and children into society and culture through a diversity of practices, one set of which is discipline and punishment. This presentation will review the impact of mental illness on patients in the civil and criminal legal domains regarding the application of the field of forensic psychiatry/psychology in the context of Islamic law upon Moslem populations globally. The true understanding of Islam by real people of the faith lends to best practices among experts worldwide. As globalization brings people closer in the workplace, knowing one's colleagues of different nationalities and living principles will enrich the collaboration of efforts in the paramount interest of the consumer world.

With globalization, the world has become home to an increasingly multicultural legal environment in many nations. A progressive legal system in any nation has the capability to understand and resolve the dynamics and the complex legal issues via various forensic sciences.

Cultures vary globally with varying regard for individuality and community distinction. Human beings may seek uniqueness through identity, yet the same people desire a sense of belonging with fairness and equality, regardless of cultural differences.

Different perceptions of values and traditions are based on the lack of knowledge about "The Other." Across the world, people have defined culture-specific traditions and customs, attitudes and values, and ethics and morals. These are based on religious law or civil law, or both combined.

People of westernized and assorted environments tend to have fragmented connections with traditions, religion, and beliefs, and may have a greater acceptance of forensic practices. While Eastern societies tend to have less diverse cultural groups and have more unified traditions, beliefs, and practices surrounding death, for example, they more frequently have religious issues related to various forensic sciences.

Shari'ah is the definitive Islamic law or doctrine, and it is the source of law and moral guidance, the basis for both law and ethics. The medicolegal death investigation system in the KSA is unique in the world. It is exclusively derived from the Islamic judiciary based on Shari'ah law. This is different from other Islamic countries, which have a combination of Islamic and other judiciary systems.

Forensic medicine education in KSA developed in the past few years as a result of the foundation for Saudi specialty certification in forensic medicine. The certificate is a post-graduate qualification equivalent to a doctorate degree in forensic medicine and requires completion of a four-year training program as well as passing annual evaluations and examinations.

This presentation will introduce the role of forensic psychiatry/psychology in Islamic jurisprudence and current forensic practices in the Moslem world. An analysis of the respective histories of national mental health systems, competency assessments and procedures for countries, as well as the larger Moslem world, was conducted.

The impact of mental illness on patients in the civil and criminal legal domains was observed and recommendations were offered regarding the application of the field of forensic psychiatry/psychology in the context of Islamic law upon Moslem populations globally. Additional recommendations were posited for international psychological training and a call for global practice standards.

This presentation will also highlight the practices of discipline and punishment of children in Saudi Arabian families. Discipline means simply those practices (verbal, physical, and emotional) intended to have children behave in specific, usually culturally-normative, ways. It is recognized within childhood studies that all societies and cultures bring infants and children into society and culture through a diversity of practices, one set of which is discipline and punishment.

Most research on discipline and punishment has been done in Europe and North America and has focused on child abuse (violence against the child, which is widely considered to be excessive and damaging) rather than on normative everyday practices, which is the focus of this study.

Modern day people, and some religions, reject the notion that there is an inherent conflict between science and religion. Instead they believe science and religion are two systems of knowledge. Each operating within its own sphere, they are fundamentally in harmony, mutually reinforcing, and both necessary to advance civilization (Baha'i Faith).

Global Understanding, Islamic Jurisprudence, Forensic Sciences

I8 Acculturation and the Use of the Cultural Defense

Steven M. Green, PhD, Southern California, Institute of Psychiatry, Law, PO Box 86125, Los Angeles, CA 90086-0125*

After attending this presentation, attendees will be familiar with the literature exploring how levels of acculturation can influence the notion of a "cultural defense." Case examples will be discussed to explore cultural defenses that were used previously in criminal proceedings. The appropriateness of this defense, as well as both the benefits and risks associated with "raising" such a defense, will be explored. Lastly, the presentation will address the role of the mental health professional in cases where culture may factor prominently.

This presentation will impact the forensic science community by showing how the topics covered are important in terms of understanding sentence mitigation in cases where culture is believed to have played a role in criminal offense.

Within the literature, there is much debate regarding the role of acculturation in the implementation of a cultural defense. Acculturation has been a part of the research literature since the 1930s. Over the years, the definition has evolved to describe a fluid-like process in which there is a constant flow of communication between the immigrant and the environment. As this communication transpires, the immigrant is actively internalizing and identifying with symbols of the dominant society. Consequently, the level of the individual's acculturation becomes an integral component in the assessment of a raised "cultural defense." Acculturation may provide a meaningful context from which to explore the behavior of the alleged offender, which may thus impact the severity of his or her criminal culpability.

According to some authors on this topic, a cultural defense should only be allowed for individuals who have yet to assimilate/acculturate to the values and laws of the dominant culture. Past criminal cases such as Kong Pheng Moua, a Hmong man, who abducted and raped a Hmong woman in 1984, under his culture's traditional practice of "marriage by capture," as well as other cases, have shown that culture can be an extremely important variable within the criminal justice system. There are those who question whether the use of a "cultural defense" should be allowed as a viable defense by the defendant. That is, should these individuals who retain their cultural beliefs or aspects of it, and who commit crimes based on those beliefs, be permitted to use their culture as a mitigating variable? On the other hand, there are those who support such considerations in criminal proceedings.

Some mental health professionals have argued that when considering the cultural defense as a mitigating factor, it is important to assess to what extent and degree the defendant's culture played in his or her behavior. If a cultural defense becomes an acceptable defense, what then are the implications for criminal culpability within a multicultural society? Will the nature of the crime be a significant factor? Will the specific type of cultural background of the defendant be a factor?

Most would agree that, while individuals may belong to a group in which there exists certain beliefs or practices, such individuals should nevertheless be held responsible for criminal offenses. However, in light of the undue influence that the person's cultural beliefs may have had, it may well warrant consideration for mitigation in the sentencing phase of trial.

A chief element of the presentation will be to discuss the role of the mental health professional as an expert in these cases, highlighting issues that need to be considered when conducting an evaluation where culture may be of notable importance. When culture is raised as a defense, it is important for the examiner to determine the level of acculturation and the degree to which the individual holds steadfast to the beliefs and cultural practices of his or her group, despite the possibility that the individual's cultural defense claim may be tenuous. Consequently, the complex nature of these cases in which culture may disguise true intent or mental illness, requires the mental health professional to remain sensitive and cognizant of the impact culture has on the cognitive, emotional, and behavioral functionings of the individual.

Cultural Defense, Acculturation, Criminal Culpability

I9 Measuring Preschool Children's Interrogative Suggestibility in Forensic Interviews

Laura Volpini*, PhD, Manuela Melis, MA*, and Stefania Petralia, MA, Sapienza Univ of Rome, Via Dei Marsi 78, Rome, ITALY; and Melina D. Rosenberg, MS*, 172 1st St Apt 3M, Jersey City, NJ 07302

After attending this presentation, attendees will be become familiar with the area of suggestibility in children between three and five years of age. The factors of gender, age, cognitive capacity, and the interval of time between the event and the interview will be discussed.

This presentation will impact the forensic science community by explaining how one of the most important forensic issues during the questioning of a child is the possibility of suggestibility during the interrogation of forensic cases. Ethical professionals must respect and protect childrens' rights (New York Convention 1989; Strasbourg Convention 1996). According to the international literature, childrens' cognitive development is not complete until adolescence.[1-3] Therefore, the problems inherent in children serving as witnesses are self-evident.[4] In preschool-aged children, false memories may be identified because of misinformation and insight bias. Additionally, they are generally susceptible to implanted suggestions.[5,6]

The aim of this study is to verify the possible levels of suggestibility in children between three and five years of age. The variables of gender, age, cognitive capacity, and the interval of time between the event and interview are considered. Ninety-two children were individually examined (44 male, 48 female; M=4.5 years, SD= 9.62).

The most widely used tool for assessing and evaluating levels of interrogative suggestibility are the Gudjonsson Suggestibility Scales (GSS) and the Bonn Test of Statement Suggestibility (BTSS).[7,8] All subjects completed the BTSS (which is indicated for the age range between 4 and 11 years). The duration of this test is about 30 minutes and is structured in four defined phases: presentation of the "toy duck story" with four illustrations, free report of the child, a 15-minute interval for distracting the child, and questioning (31 questions) the child about the story. The BTSS investigates the dimensions: Yield, Shift, Immediate Recall, and Total Suggestibility.[9,10]

The study hypothesizes that the younger children (three years of age) were more susceptible to the suggestibility than the older children (five years of age). Another hypothesis is that a higher score in the

dimension Immediate Recall is positive-correlated with the dimension Total Suggestibility. The last hypothesis is that a high score of Yield is correlated with the younger children and that, in contrast, an elevated score of Shift is associated with older children.

The results of this study of 92 participants concluded: (1) younger children are more susceptible to suggestibility; and, (2) no significant gender difference was observed. The dimension Immediate Recall was negatively correlated with Total Suggestibility (r=-.357).

Social compliance and source monitoring errors can contribute to presenting patterns of suggestibility because older children change their answers more often (Shift).[11,12] Social factors and memory, especially autobiographical memory, can underlie suggestibility. Children will hardly remember their early childhood (4 – 5 years) and it is also known, from numerous studies, that children can lie to avoid punishment or to get a reward.[13-15] In forensic issues, children are normally interviewed several times before a case goes to court. This study shows that repeated questions can transmit the message that they have to change their given answer.

I10 Interrogative Suggestibility in Children: Italian Validation of GSS2 in the Forensic Field

Melania Lugli, PhD, and Cinzia Gimelli, PsyD, PhD*, Science & Method and Academy of Behavioral Sciences, Italian Academy of Forensic Sciences, Viale Montegrappa 29/C, Reggio Emilia, ITALY*

After attending this presentation, attendees will be able to understand the standardization and validation of the Gudjonsson Suggestibility Scale2 (GSS2) in an Italian research sample. GSS2 is widely used, particularly in preparation of court reports, to derive information on the memory, suggestibility, and confabulation of criminal suspects, victims, and witnesses. The Gudjonsson study was twofold: (1) to present a parallel form of the Gudjonsson Suggestibility Scale (GSS, Form 1); and, (2) to study the test-retest reliability of interrogative suggestibility.

This presentation will impact the forensic science community by introducing a wide sample of subjects compared to the interrogative suggestibility and the study of the correlation among additional variables.

The hypothesis of this paper is that three variables (age, family condition, and type of attachment bond) have a significant association on the degree of suggestibility of children.

The subjects belong to three age groups: six, eight, and ten years of age. The dependent variables are: Immediate Recall; Delayed Recall; Yield 1; Yield 2; Change; and, Total Suggestibility.

Each subject submitted to two psychological tests, GSS2 with Italian translation and Separation Anxiety Test (SAT), to evaluate the way in which the child lives and the living situations (in terms of separation from their parents).

In this study, to investigate correlation measures for the corresponding variables in the two tests, about 100 children were individually examined using 30 variables for each group and all participants completed GSS2 and SAT. The investigation is ongoing. The hypotheses are:

Hypothesis 1 (Age): The higher the age, the higher the scores in Immediate and Delayed recall, and the lower the scores in Total Suggestibility, Yield 1, Yield 2, and Change.

Hypothesis 2 (Children With Divorced Parents): Children with divorced parents have higher scores in Total Suggestibility and Total Confabulation, and score equally in the Immediate and Delayed recall scores and single scores of the Immediate and Delayed recall.

Hypothesis 3 (Different Types of Attachment): Children with Attachment B have a lower Total Suggestibility score and lower total score of confabulation, the same score of Immediate and Delayed recall, which is a very high degree of association; Children with Attachment C have a higher score of confabulation, a higher Suggestibility score, and an equivalent score of Immediate and Delayed recall; Children with Attachment A have a lower score of Immediate and Delayed recall.

The presentation will focus on research related to suggestibility; in particular, time will be given to studies which show how much memory and leading questions may influence the testimony of minors. Finally, the presenters will report on studies which explore the relationship between specific variables and suggestibility interrogative degree and show how memory and testimony may be influenced by different sources of bias which need to be taken into consideration in the forensic field.

In this paper, it is believed that science is now sufficiently evolved so that such interviewing techniques can be applied to interviewing children in child custody evaluations or in cases of alleged sexual abuse.

Test Validation, Impact of Variables, Children Witness

I11 Nonverbal Reaction: Four-Phase Investigation Analysis Protocol

Luca Marzari, BS, Via Tito Livio, 5, Reggio Emilia, 42124, ITALY*

After attending this presentation, attendees will be able to study and identify every possible communicative variable, and verify the coherence of the verbal and nonverbal behavior sequence combinations (COMBO).

This presentation will impact the forensic science community by measuring objective and quantitative parameters during the forensic interview and police interrogation.

The protocol is divided into four different phases and follows rigid rules in the environmental construction of the setting, predisposed with sophisticated instrumentations of audio, video and of biophysiological measurement.

PHASE 1 – This is the phase of harvest dates inherent to the subject (medical anamnesis and structured and semi-structured checklists and includes: social position and personal beliefs, psychological evaluation, self-report list of elements that usually cause anger, disgust, contempt, sadness, surprise, happiness, fear); toxicological analysis and baseline measurement concerning usual nonverbal behaviors modality (use of manipulator's and illustrator's gestures, relax postures, involuntary nervous twitch, etc.) and subject's vocal tone. Video and audio: subject in interaction with an observer.

PHASE 2 – Neurophysiologic baseline measurement, subject verbal stimulation, and recording of potentials correlated with emotional-physiological activations to questions using the 40BSIQ (40 Brain Storm Investigation Questionnaire).

PHASE 3 – Distraction of the subject with intellectual secondary activity.

PHASE 4 – Analysis of the answers and of reactions of the subject submitted to questioning. This phase is the central point of the protocol. The subject is analyzed by four different observers. Everything will be audio- and video-recorded (four cameras, two microphones), and the observers are themselves observed by audio and video.

Nonverbal Analysis, Research Protocol, Observation Setting

I12 Child Pornography: International Cooperation and Legislation in France

Sebastien Prat, MD, Pauline Saint-Martin, MD, and; Carol Jonas, PhD, Hospital Trousseau, CHRU de Tours, Tours, FRANCE*

After attending this presentation, attendees will learn about entrapment in France and the different levels of cooperation that permit authorities to catch child pornography suspects worldwide.

This presentation will impact the forensic science community by explaining about the lack of information in this area. This presentation will also demonstrate how getting international cooperation is not a simple endeavor.

Introduction: Child pornography is a form of sexual exploitation of children. The use of telecommunication facilities, particularly the internet, has allowed child pornography to be distributed more widely. The internet is used by pedophiles for four reasons: trafficking child pornography, locating a minor for an assault, initiating communication with a minor, and communicating with other pedophiles. Today, access to pedophilic material no longer requires direct contact between supplier and consumer, but can be obtained anonymously. It is common for pedophiles, and those using child pornography, to be part of virtual groups. They can speak freely about their fantasies and their fears, thus maintaining a good image of themselves while obtaining child pornography material. The existence of these virtual groups has become a major issue, as they are not restricted by territorial boundaries.

Legislation of the Entrapment: Legislation has been passed in a number of countries to tackle the issue. Various police operations have targeted groups of child pornographers. In "Operation Icarus" by Europol in 2011, 269 suspects were identified and 112 arrested in 22 European countries. Since 2007, Article 706-47-3 of the French Penal Procedure Code legislates the actions of "cyber patrol;" however, they are limited in being able to act on this type of evidence. A case illustrates this: the *Cour de Cassation* (Supreme Court) has ruled twice on the facts of downloading child pornography images via an American police website (on February 7, 2007, and June 4, 2008). The *Cour de Cassation* came to explain that, to create a site on the internet, including those created by foreign police, was a violation of the offense. Any evidence gathered through this site is inadmissible, even if there were pre-existing violations. However, the limit also fixed by the *Cour de Cassation* is that if there were pre-existing suspicions, in this case, the challenge would not be cause for cancellation of the procedure, since it would be seen as a provocation to the evidence of the offense (which is accepted), not as a provocation to the offense (which is prohibited).

When states permit it, the police try to use fake sites in order to catch child pornographers. Trawlers and the groomers are among the different profiles of consumers of child pornography. Trawlers are individuals who are looking for sexual material without fixating on pedophilia. Groomers are individuals who seek to attract a minor, using tricks such as falsification of age or adaptation of the speech according to the speaker. The groomers usually have a pretty good understanding of how discussion forums, secure methods of downloads, and exchange of images work. Neither profile is always aware of the illegality. It does not seem difficult to intercept the trawler, who has a low potential to offend, and who does not take special precautions when using the internet. It is more difficult to intercept the groomers, whose computer skills are often high, for which there is a real interest in physical contact, and who would, therefore, have great potential for such offenses.

Conclusion: Most child pornography images are obtained via the internet, which only requires access to a site or to a chat room. Peer-to-peer networks have facilitated the exchange of child pornography, which can explain the development of the phenomenon. The technology gives the offender the opportunity to become a compulsive collector. The internet has encouraged the phenomenon of grooming, which consists of attracting someone and seducing victims. It is important to be able to locate people who use illegal pornography. One way of doing this is to track internet discussions. The principle of loyalty to the evidence can be a source of problems in apprehending child pornographers.

Forensic Psychiatry, Child Pornography, Entrapment

I13 Matricide and Mental Illness: An Italian Case Report

Felice F. Carabellese, MD, Manuela Tamma, PsyD, Egle Alfarano, PsyD, Alessio Ostuni, MD, and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will be given the opportunity to reflect on a case of matricide and the peculiarities of this case presentation.

This presentation will impact the forensic science community by emphasizing a perpetrator's lack of empathy in matricide as a sign of a mental disorder.

Introduction: A case of matricide (which came to attention for an expert opinion as commissioned by the Judge) provided the opportunity investigate this phenomenon and its peculiarities. Matricide, or the murder of one's own mother, has always been considered one of the most abhorrent crimes that can be committed, garnering intense media coverage all over the world.[1] Despite the coverage and furor that cases of matricide generate, the murder of one's own mother is a rare event. In the United States from 1976 to 2005, matricide accounted for less than 2% of all homicides in which the victim-offender relationship is known. This rate is consistent with studies from France, the United Kingdom, and Italy. Selecting only studies on matricide by adult sons, most of the perpetrators were single adult males with an intense relationship with their mother, a lack of interest in other women, a feeling of social inferiority, and an absent or passive father.[2] According to the

literature, the majority of matricidal offenders suffer from severe mental disorders. In particular, matricide seems to be more common among individuals with schizophrenia or other psychoses, to such an extent that matricide was once referred to as "the schizophrenic crime."[3] Among schizophrenic conditions, the paranoid subtype is the most common.[4] Other diagnoses include mood disorders, substance abuse, and personality disorders.[5] Very often, schizophrenic offenders were influenced by psychotic symptoms at the time of the crime. Characteristically, such "psychotic" matricides are committed with excessive force and violence, while the post-offense behavior is non-finalistic and disorganized; concealment of the crime is mostly absent or somewhat mechanical, and the perpetrators usually confess.[6] These offenders often reported feeling that their mothers were either ambivalent toward them or excessively domineering.[7] Matricides are classically committed in the victim's home, usually with a weapon, although asphyxia is also common.

Several schemes have also been proposed to classify the different types of matricidal motives. In his sample, Green reported that the apparent motives were persecutory paranoid (47%), altruistic (24%), or other (29%).[8] In a U.S. study, Hillbrand identified four scenarios: acute psychosis (47%), impulsivity (28%), escape from enmeshment (15%), and alcohol or other substance abuse (24%), with the latter being superimposed upon any of the other three. More recently, Bourget described four leading causes of matricide: mental illness, family abuse by the mother, compassion for the victim, and intoxication.[9,10]

Methods: The body of a 78-year-old woman was found on the floor in her house. Her head had been severely traumatized. Death was due to massive blunt force trauma to the head, possibly using a large hammer that was beside the body at the crime scene. The perpetrator was the victim's 48-year-old son, who lived with his mother and who had suffered from chronic paranoid schizophrenia for more than 15 years. He quickly confessed to the crime, adducing as motive the fact that he was convinced his mother was putting poison in his food, as well as practicing black magic to destroy him. The perpetrator was the third and last child, unemployed, and a bachelor with a very limited social and relational life. The man hit his elderly mother many times with a hammer and then sat in front of her all night waiting for her to die. He later explained that he wanted to be certain she was dead because, after the first blows, he had seen a demon-like vitality in her. He was found not guilty on the grounds of insanity.

Conclusions: In this case, as in others reported in the literature, the perpetrator of the matricide was a schizophrenic with a delusional disorder, and acted extremely violent. The main element of interest is the total lack of empathy with the victim while committing the crime as this is also an indicator of the mental disorder.

Matricide, Lack of Empathy, Schizophrenia

I14 Emerging Topics in Italian Forensic Psychopathology: Foreign Criminality and Cross-Cultural Assessment

Jutta Birkhoff, MD, PhD, Davide Torri, MD, and Laura Re, Univ of Insurbia, Dept. of Bio-Technologies and Life Sciences, Section of Forensic Psychiatry, Via. Rossi 9, Padiglione Antonini, Varese, ITALY; and Rosa Taratufolo, MD, and Felice F. Carabellese, MD, Univ of Bari, Section of Criminology and Forensic Psychiatry, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will be able to understand the full importance of developing a model of cross-cultural approaches to the forensic evaluation of mental disease.

This presentation will impact the forensic science community by examining the difficulty recently arising in Italian forensic psychopathology regarding the assessment of foreigners from different cultures.

Italy, located in the center of the Mediterranean Sea and close to the Balkans, represents from a geopolitical point of view, a natural gateway to Europe and which it has historically played this role for a long time.

Nevertheless in recent centuries, Italy has primarily originated emigration flows, while maintaining a homogeneously autochthonous internal population. These circumstances have changed radically over the past two decades, during which political and economic transformation globally, involving Eurasia and Africa—and also South America—has led to significant levels of immigration to Italy. Today Italy has a strong presence of foreign citizens in its own territory, both resident and transit to other European countries. This is a population with a specific age and gender constitution, according to different nations of origin, mostly consisting of workers seeking employment. Italy must now find a way to integrate both Italians and foreigners and migrants of different origins.

This presentation briefly describes quantitative and qualitative features of the foreign population living in Italy. The presentation also deals with this issue in terms of criminological survey, giving statistical information about the number and countries of origin of foreign people imprisoned in Italian jails.

According to Italian law, a judge or a lawyer can request a forensic psychiatric assessment of an offender, if there is reasonable suspicion that he/she is mentally ill. Usually the court asks the expert if the criminal is liable for his actions ("Imputabilità"), if he/she is a danger to society because of his mental disorder ("Pericolosità sociale"), and if he/she is able to participate in the criminal trial ("Capacità di stare in giudizio"). As the number of foreigners living in Italy has increased in recent years, there are currently a significant percentage of forensic psychiatric assessments being performed on criminals from very different cultures. This is new for the Italian forensic psychiatrists, who are facing new assessment difficulties and do not always have available the scientific instruments needed for a reliable cross-cultural assessment.

Case Report: This presentation is of a case concerning a double homicide committed by a foreign citizen residing in Italy as an example of the difficulty of the forensic psychiatric evaluation on persons from different cultures. The man came from sub-Saharan Africa, and had lived in Italy for about ten years before committing the crime. He killed his wife and another woman who lived with him with a sledgehammer, then went to his neighbors to report his crime. The genesis and dynamics of crime were influenced by religious and mystical beliefs which are maybe difficult to analyze and understand for a European citizen, but rather widespread and accepted in some rural areas of the country of origin of the offender. In order to answer to the judge's requests, the experts had to distinguish between physiologically different

beliefs merely due to the offender's different cultural context, and possible psychopathological convictions.

This presentation hijghlights the critical issues facing the forensic psychiatrist and points to the need to develop a model of cross-cultural approach to forensic evaluation of mental disease.

Conclusion: Italian training for psychiatrists and psychologists does not include compulsory academic courses in cross-cultural assessment. Migrants' anamnesis is mostly unknown, as it is very difficult to reach healthcare services in their country of origin. Versions of psychological tests validated for the countries of origin of the subjects to be examined are not always available. Intercultural mediators are few and are frequently not available for all migrants' ethnicities. Translation warps the content of the psychiatric interview.

Today in Italy, there are no guidelines for forensic psychiatric assessment of migrants. Experts' reliability depends on skills they have possibly acquired outside of their compulsory academic career. There is a need to develop national quality standards to ensure the individuals' equality of treatment under the law.

Foreign, Assessment, Criminality

I15 Violence and Epilepsy: The Importance of Prompt Identification of Post-Ictal Psychosis-Description of a Case

Gabriele Rocca, MD, and Roberta Carrossino, MD, Univ of Genoa, Section of Criminology and Forensic Psychiatry, Via De Toni 12, Genoa, ITALY; and Donatella La Tegola, PhD, Chiara Candelli, MD, PhD, and Felice F. Carabellese, MD, Univ of Bari, Section of Criminology and Forensic Psychiatry, Piazza Giulio Cesare, 11, Bari, ITALY*

After attending this presentation, participants will be able to recognize the features of the relationship between aggressive or violent behavior and epilepsy, with particular regard to the role of post-ictal psychosis.

This presentation will impact the forensic science community by providing understanding of the relationship between aggressive or violent behavior, epilepsy, and psychotic disorders with the aim of improving knowledge and prevention.

Aggressive behaviors occur in many different circumstances in society, and patients with epilepsy are not immune to being involved in aggressive acts. However, erroneous beliefs and prejudices linking epilepsy with violence have disproportionately emphasized the nature of this relationship. This notion acquired a highly stigmatizing value in the late 19th-century when the criminologist Cesare Lombroso promoted the association of epilepsy with aggressive sociopathic tendencies on the basis of degenerative theory. These distortions aggravate the psychosocial stigma already associated with epilepsy and have led to the questionable attribution of epileptic seizures in some cases of violent crimes or episodic aggressive outbursts.

Even today, the erroneous conviction that epileptic patients should be prone to violent actions and aggressive behavior represents a controversial subject especially in the field of forensic psychiatry.

While it is unclear that patients with epilepsy exhibit increased aggression, aggressive acts have been seen in association with seizures themselves. The prevalence of aggressive behavior in epilepsy has a rate that goes from 5% up to 50%. This significant variance depends on the different kind of sampling of patients.

Based on temporal relation of the crises, there are three different types of aggressive behavior: ictal aggressiveness, post-ictal aggressiveness, and inter-ictal aggressiveness. Most commonly, aggression may occur in the post-ictal state and can even be seen hours to days after initial periods of confusion. In particular, post-ictal violent behavior may be seen in association with Post-Ictal Psychosis (PIP).

PIP is characterized by a cluster of seizures, followed by a lucid interval, followed by the sudden eruption of a clinical disorder with a mixed affective picture, often accompanied by religious delusions and fear of impending death, lasting usually a matter of days. Episodes of PIP are comparatively common and could be dangerous, though (fortunately) are often treatable.

The following case presentation is representative of a violent act during an episode of PIP. A 29-year-old single Caucasian male was arrested and charged with attempted murders. He allegedly assaulted his mother and his brother with a knife. In the anamnesis, he had a 20-year history of paroxysmal episodes of "blanking out." At age 12, episodes of loss of consciousness began to follow these attacks. As he aged, the seizures increased in intensity as well as frequency, despite maximum drug therapy. At age 25, the first manifest post-ictal mental derangement occurred, after several bouts of untreated seizures. Thereafter, his post-ictal episodes recurred two times before the arrest, because he decided to stop the medication.

A few days before the crime, he experienced two grand mal seizures followed by the onset of multiple religious and persecutory delusions, thought broadcasting, feelings of being controlled by others, and command hallucinations. Because of a belief that the world was going to end, he left the house where he had been living and went to his parents' home. During the night, he woke up with a sensation of being persecuted by his mother and brother. He heard God and Satan arguing. God screamed, "No!" Satan bellowed, "They deserve to die." The two voices roared at each other, becoming one horrible overwhelming command, "Do it!" Fortunately, the intervention of neighbors saved the victims' lives. From a psycho-legal point of view, he was found not guilty on the grounds of insanity.

In light of the case presented, it is important to highlight that the assessment and management of violent behaviors in the patient with epilepsy requires careful consideration of several factors: whether the act is directly related to the epileptic seizure, a feature of post- or pre-ictal mental state changes, or a function of other conditions that increase the risk of aggressive behavior. Evaluation also requires appreciation of the patient's mental state and the social context in which the violent act occurs.

In the case of psychotic episodes, it is particularly crucial for the prompt identification of the relationship between the disorder and epilepsy, because patients should be treated differently according to the various pathophysiologic backgrounds, and because, in case of PIP, the most powerful and effective recipe for controlling the risk of violent behaviors is seizure reduction or elimination.

Epilepsy, Post-Ictal Psychosis, Violence

I16 Postmortem Prolactin in Suicides: Is it an Indicator of Antemortem Stress?

Tanuj Kanchan, MD, Kasturba Medical Coll, Dept of Forensic Medicine, Light House Hill Rd, Mangalore, INDIA*

After attending this presentation, the attendees will be able to recognize if postmortem prolactin levels are raised and possibly associated with antemortem stress in suicides.

This presentation will impact the forensic science community by developing an understanding of the possible trend and association of postmortem serum prolactin levels with antemortem stress and successful or completed suicides.

Stress is inevitable in today's life. A relationship between psychological stress and deliberate self-harm is well-established. Every year, over one million people commit suicide, and around 10 to 20 million non-fatal attempted suicides are reported worldwide. The World Health Organization estimates completed suicides as the 13th leading cause of death worldwide. Prolactin is a hormone secreted by lactotrope cells located in the anterior pituitary gland. It is mainly responsible for lactation, sexual arousal, myelination of neurons, surfactant synthesis in fetal lungs in humans, and is thought to play a significant role in the human stress response. The present research studies the postmortem plasma prolactin levels in completed suicides and tests the hypothesis that postmortem hyperprolactinemia is related to antemortem stress. This preliminary investigation is done to study the relationship between

completed suicides and serum prolactin, and to find if postmortem prolactin levels are raised in completed suicides.

The present prospective autopsy-based study for the biochemical estimation of serum prolactin was conducted at the Department of Forensic Medicine at Kasturba Medical College in Mangalore. An approval was received from the institutional ethical committee prior to conducting the study. Suicidal death among males during May and July 2010 were included in the study. Postmortem blood samples were collected from the right femoral vein before the start of autopsy and *in vitro* quantitative analysis of a non-hemolyzed blood sample was performed using electrochemiluminence. The normal range of serum prolactin in males (according to the chemiluminescence technology) ranges between 4.8ng/ml and 15.2ng/ml. All adult male autopsy cases of suicide with a survival period of less than 12 hours and postmortem interval of less than 24 hours were included in the study. Cases with other associated causes of hyperprolactinemia and hemolyzed blood samples were excluded from the analysis.

All the victims of suicide included in the study were males aged between 21 and 60 years. The mean age of the victims was 39.10±10 years. Most (90%) of the victims were married. Hanging was the preferred method of suicide (90%). Serum prolactin levels in cases of suicides ranged from 6.3ng/ml – 34.0ng/ml. The mean serum prolactin level among the cases was found to be 15.7±8.3ng/ml. A mean serum prolactin level of 14.97±8.3ng/ml was observed in the cases of suicidal hangings. The serum prolactin levels in cases of suicides were arbitrarily grouped into three categories: less than 10ng/ml, 10ng/ml to 15ng/ml, and more than 15ng/ml. It is observed that only 20% of the suicidal victims had a serum prolactin level < 10ng/ml, 40% had a prolactin level between 10ng/ml to 15ng/ml, and 40% had a serum prolactin levels > 15ng/ml.

The prolactin levels using postmortem blood samples in completed suicides were successfully determined. The mean postmortem serum prolactin level was found to be marginally higher in suicidal deaths, suggestive of a possible association between serum prolactin, stress, and suicides. The preliminary investigation is suggestive of a possible trend and an association of postmortem serum prolactin levels with antemortem stress and completed suicides. It is difficult to avoid stress, but suicide as the result of stress can be prevented by the early diagnosis of signs and symptoms of stress, with specific interventions toward preventing suicide. The association, however, is not strong and needs to be studied further in future studies.

Prolactin levels can be successfully determined using postmortem blood samples. This research emphasizes the importance of forensic pathologists in establishing causes of suicides at autopsy.

Suicide, Antemortem Stress, Prolactin

I17 Sidewalk Hermits: Homeless Perpetrators and Victims of Crime—Preliminary Results of an Italian Study

Ignazio Grattagliano, MD, Andrea Lisi, PsyD, and Cristian Signorile, PhD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY; Giovanni Aliquò, PhD, Daniela Poduti, PhD, Lucio Palella, PhD, and Vito Ventrella, PhD, Corso Italia 123, Bari, ITALY; and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will better understand the dynamics regarding homeless perpetrators and victims of crime in Italy.

This presentation will impact the forensic science community by presenting some of the challenges that professionals in criminology and legal medicine face when dealing with crime among homeless people.

A homeless person may be defined as "a person in a state of tangible and intangible poverty, bearer of complex, dynamic, and multiform hardships."[1] The study presented here was conducted in collaboration with the Italian Railway Police from a criminological perspective, and focuses on homeless perpetrators and victims of crime. For this research, 47 cases have been studied and the socio-demographic variables included:

Age: The majority of subjects were male (72%) and 28% were female. The average age of the subjects observed was 49.8 years. The average age for males was 48.4 years and 53.3 years for females.

Nationality: 74% were Italian; 26% were foreign (most of whom were Northern and Eastern Europeans).

Education: 47% had five years of schooling; 19% had eight years of schooling; 6% had 13 years of schooling; and in one case, 18 years of schooling. Almost 30% of the subjects had no schooling at all.

Duration of Homelessness: 40% were homeless for more than five years; 47% were homeless between one and five years; and 13% were homeless for six months.

Events Leading to Homelessness: Loss of employment (26%); departure from home (20%); immigration (10%); divorce (10%); home eviction (8%); death of a family member who was the only source of income (4%); financial failure (4%). The literature shows that divorce and poverty, as well as family and living problems, predispose women to homelessness and to being victimized by crime. The literature also notes the role that mental illness and substance abuse play. Drug and alcohol use are predisposing factors for homelessness, the commission of crimes, and being the victim of crime.[2] In addition, most mental disorders diagnosed in the homeless are correlated to substance abuse, followed by mood, psychotic, and anxiety disorders; anti-social and personality disorders; and dual diagnosis.[3-6]

Criminal Aspects of Sample: Fifty-one percent of the crimes committed generally involved offences against property or violence perpetrated against another person. This is in agreement with the literature, which reports that such crimes among the homeless are tied to the acquisition of, and selling of, illegal substances.[7] Another interesting fact taken from the literature regarding the homeless is the high percentage of crimes committed against women. This has also been confirmed by the sample. Forty-three percent of the subjects studied had no previous contact with the legal system, neither as perpetrator, nor as victim.[8] Only 20% had been previously incarcerated. This datum differs from the literature a bit, which reports higher percentages of incarceration of homeless people with respect to this sample. The relationship between homelessness and incarceration is reported in various studies: 73% of males and 27% of females had been arrested at least one time.[9] Gardiner and Cairns (2002) reported that 77% of male subjects in their study had been previously arrested.[10] Moreover, being homeless increases the chances of being detained by the police after being stopped by them. And finally, physical and sexual violence constitutes another significant risk factor that may lead to homelessness.[11] In the end, physical and sexual violence is a significant risk factor for becoming homeless.

Homeless, Crime Victims, Perpetrators

I18 Is There Such a Thing as Internet-Mediated Homicide?

Felice F. Carabellese, MD, Univ of Bari, Piazza Giulio Cesare, Bari, 70124, ITALY; Cristiano Barbieri, MD, Univ of Pavia, Via Forlanini 12, Pavia, ITALY; and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will reflect on a specific type of murder related to the use of the internet, chat lines, and chat rooms.

This presentation will impact the forensic science community by assessing the role of the increasing use of the internet in the etiology of sexual crime or homicide.

In the literature, the terms “internet homicide,” “internet chat-room killer,” and “Craig’s List killer” have been coined to indicate the scenario in which a victim of homicide is met through a chat line or chat room and lured to death at the hands of the murderer. Various criticisms have been made of this new concept, on the grounds that the outcome is no different from that of other homicides committed without the use of web resources, and so the method used has no particular influence. Indeed, it has been claimed that informatic crime just reflects a technological change in the nature of crime rather than a new form of criminal behavior attributable to the use of the internet for criminal purposes.

This scenario offers points for reflection on the nature of web-mediated victim-murderer interactions, to assess the effects on the planning and commission of the crime.

These reflections were prompted by experience as expert forensic psychiatry witnesses in a case in which the murderer had confessed to having had an exclusively virtual relationship with the victim lasting about four months, in which they spent up to 14 hours a day on a chat line. Their relationship was characterized by a strong emotional involvement of the man, who left the girlfriend he was living with because he claimed to be in love with the woman he had met on the web. Importantly, the murderer and his victim had some “online sex” experiences, but he quickly started to show conflictuality and instability motivated by jealousy, which put the woman off. After threatening to commit suicide “live” on the web (brandishing a gun – perhaps a toy) to prevent the woman from ending their virtual meetings, the man went to her home and, during their first and only real meeting, he killed her with a blunt instrument he had carried with him.

The recorded dialog between the aggressor and victim (Murderer: *“How could you do this to me?”* Victim: *“Bastard, get out! I’ll fuck with whoever I want!”*) reveals the typical victim-murderer relationship but, although this had already been expressed in a virtual reality scenario, it had never before been translated to the real world.

The man had previous convictions for drug peddling and for attempted murder of his ex-wife discovered in the act of adultery, and violence against her companion.

The case appears to be an example of the destructive potential of passage from a virtual reality to the real world. It illustrates the risks of losing both a sense of reality and a sense of limits, making it difficult to separate what is real from what is imaginary and has never been real, with all the negative consequences that can stem from this loss of the sense of reality.

The woman’s desire to end an exclusively virtual relationship was seen by the man as a real, traumatic experience. It injured his deepest emotions and his anger, symptomatic of the narcissistic wound he felt he had received, can be classified as “one of the most pernicious afflictions of the human psyche,” because “if the man who feels anger is irrational, the man who feels hate is not, regardless of whether, in the given circumstances, the hate has a rational foundation or not.”

All this demonstrates that it is possible to claim that there really is such a thing as Internet-correlated homicide, because in this case the quality and quantity of the Internet interactions progressively altered the man’s perception of the real relationship between himself and the victim. This culminated, in their first and only meeting, in murder provoked by her rejection; the pain he suffered was undoubtedly real, and all the more incomprehensible and deep to him because of the pleasure he had derived from their virtual encounters.

Virtual Identity, Sexual Crime, Homicide

I19 Psychopathy and the Cinema: Fact or Fiction?

Samuel J. Leistedt, MD, PhD, Ave Louis Go 32ET, 64, Bavdour, BELGIUM*

After attending this presentation, attendees will gain knowledge about psychopathy and about the heterogeneity of this complex syndrome through movies and cinema history.

This presentation will impact the forensic science community, especially the forensic behavioral science community, by demonstrating the utilization of fictional characters as “teaching movies” for future generations of forensic psychologists and forensic psychiatrists.

This research investigated the relationship between cinema and psychopathy. They described and analyzed the portrayal of fictional psychopathic characters in popular films and over cinematic history.

Rather than assessing their commercial success or “aesthetic efficiency” and appeal, the the degree to which the portrayal was realistic from the clinical and psychopathological viewpoint of forensic psychiatrists, forensic clinical psychologists, and mental health professionals in general was assessed. Furthermore, by focusing on psychopathy in these fictional characters, the discussion of the portrayal of mental illness in cinema and the proposal of a fictional psychopathic character nosography for film history is possible.

The following international databases and film sources were used: “The American Film Institute (AFI),” “Academy Awards,” “Archive.org,” “Base de Données Françaises du Cinéma sur Internet (BDFCI),” “British

Film Institute (BFI)," "Cinebaseinternational," "Cinefiches.com," "Cinemovies.fr," "Cinoche," "CITWF," "Les Gens du Cinéma," "Greatest Films," "Il était une fois le cinema," "Internet Movie Database (IMDb)," "Oh My Gore!," and "Western Décrypté." All of these film databases were accessible on the internet without requiring authorization.

Based on these databases from 1915 to 2010, 400 films and the fictional, psychopathic-like profile characters therein were visualized and analyzed by senior forensic psychiatrits, forensic psychologists, and movie critics. As much information as possible was obtained about each fictional character, relying primarily on the films but also using any other available sources or documentation to make an accurate psychiatric diagnosis, specifically in terms of psychopathy. Because of the heterogeneous and abstract nature of these materials, neither "classical clinical evaluation" or psychometric tests were able to be performed. That is, the diagnosis and classification were the sole results of reviewing films and any additional information on a specific character and the discussions regarding how the character evolved in a specific context (e.g., interactions with others, personal history).

In a final step, the authors proposed a clinical fictional psychopathic nosography was proposed based on two documented psychopathic classifications: (1) Primary/secondary; and, (2) Classic/macho/manipulative/pseudopsychopath. From 400 films, 126 fictional psychopathic characters (21 female and 105 male) were selected based on the realism and clinical accuracy of their profiles. Secondary (71, 43%) and manipulative (47, 62%) subtypes were the most common in the female group, while secondary (51, 43%) and prototypical (34, 28%) were the most common in the male group.

Corresponding to the increased understanding of clinical psychopathy by professional mental health providers over time, the clinical description of and epidemiological data on fictional psychopaths in popular films have become more realistic. Realistic fictional psychopathic characters do exist, but they are in the minority. Despite this, they continue to contrast with their very interesting clinical descriptions, especially since 2000. These characters, which mirror some types of our society, are very important for the cinema itself and art in general, but mostly for future generations of forensic psychologists and psychiatrists as pedagogic materials.

Psychopathy, Forensic Psychiatry, Cinema

I20 Unusual Innovative Perspectives of Research on Human Violent Behavior

Luca Massaro, MD, Via Degli Artigiani 4, Este, ITALY; and Patrizia Trapella, PhD, Via Cavour 24, Rovigo, ITALY*

After attending this presentation, attendees will be informed about the rising need to change research approach in order to deepen insight on the possible genetic bases of human violent behavior.

This presentation will impact the forensic science community by reviewing the results of most important genetic studies on violent behavior, and emphasizing the importance of the interdisciplinary scientific cooperation.

The link between genes and aggressiveness and its inheritability has been one of most debated issues in the criminologic arena, and perhaps is still a controversial topic. Among several theories on violent behavior, Darwin's Natural Selection theory, Lombroso's Intuitions, the Terrie Moffitt's developmental theory of crime, and the General Aggression Model are considered of major interest.[1-5]

Common sense questions need a proper answer: Do we all feel the same instinct to quarrel, punch, or kill? Do we observe the same aggressiveness in primary school children that punch over a trifling argument or in two males brawling, or punching, or even killing, while competing for the same female? And what about conflicts between husband and wife, or mother and son? Do we note the same kind and intensity of aggressiveness in a man resolute to rob a bank, but rapidly prone to murder the bank clerk, even before the policeman rushes to the crime scene after the alarm signal? Or in an adult subject who rapes a child; in a woman killing herself, or in twins both committing similar violent crimes?

Even if it is generally established that environmental, familiarial, educational, and cultural inputs influence the behavioral development, it's not enough of an explanation from a scientific point of view. More probable, it is: *individual genetic background* determining a sort of predisposition in aggressor habitus either in victimal status; *the circumstances* under which the violent act took place; and, *the momentary chance,* interacting together. How? This is the main question. The hypothesized existence of "warrior genes" has not ever been supported by scientific evidence. Notwithstanding, there are many investigations suggesting that genetic factors, such as hormones, neurotransmitters, enzymes, and endophenotypes have a leading role in human violent behavior.[6-10] The increasing importance of genetic factors in aggressiveness can't be undervalued any longer, and should be considered in a more complex perspective together with "the circumstances" and "the chance."

Consequently, an innovative study approach on this topic should be developed, providing a multitask research unit composed of more traditional specialties (psychiatrists, psychologists, sociologists, criminologists, and medical examiners) and also by innovative, maybe unforeseen, figures such as the anthropologist, the ethologist, the expert in non-verbal communication, and the genetic biologist. The purposed multitask teamwork should be proposed and applied with the same research program in many different countries, to share and compare the obtained findings, in order to understand any further aspect of the human violent behavior.

A brief review of the research program will be addressed with attendees.

I21 Clinical and Treatment Reality in Italian Female Perpetrators of Crimes Considered "A Danger to Society"

Felice F. Carabellese, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY; Ettore Straticò, MD, OPG, Castiglione delle Stiviere, Mantova, ITALY; Chiara Candelli, MD, PhD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY; Ilaria Rossetto, MD, Cristina Benazzi, MD, Filippo Franconi, MD, and Tiziana Sartori, MD, OPG, Castiglione delle Stiviere, Mantova, ITALY; and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will understand the importance of the real incidence of psychopathy in women for the planned treatment of new inmates.

This presentation will impact the forensic science community by assessing the rates of diagnosis of psychopathy in women affected by a serious mental disorder and considered at high risk of criminal reiteration.

The incidence of psychopathy is estimated to be 0.5% – 1% of the general population, while as many as 20% – 25% of prison populations qualify for the diagnosis.[1] The construct of psychopathy is essential in explaining criminal behavior, but unfortunately, empirical research on psychopathy in women has been inconsistent. In selected populations with a higher frequency of behavioral problems and higher rates of criminal behavior, men more often qualify for the diagnosis than women. Grann found that only 11% of female violent subjects met the criteria for psychopathy, as opposed to 31% of male violent subjects. In prison populations, other studies found rates of 16%[2] and 17.4%[3] among women, substantially lower than the rates for men in prison.

Furthermore, although men and women share most interpersonal and affective traits, as well as psychopathic behaviors, they may rely on different tactics to achieve the same goals. Considering these differences, the increase in female criminality demonstrates the need to gain a better understanding of the construct of the disorder in women in order to validate results already obtained in large samples and to develop suitable, objective evaluation tools for making reliable predictions of re-offenders, institutional facilities needs, and treatment responses.

In Italy, all women perpetrators of a crime who are not considered penally liable because they were affected by a serious mental disorder at the time of the crime, and considered at high risk of criminal reiteration (a danger to society), are hospitalized in the "Ospedale Psichiatrico Giudiziario" (OPG) (Judiciary Psychiatric Hospital) of Castiglione dello Stiviere, in northern Italy. This facility also admits men with the same characteristics. A recent research conducted in this hospital facility, using the PCL-R,[4] demonstrated a 30.7% rate of psychopathy among the inmates affected by a personality disorder, (16.9% male and 13.8% female); the mean score at the PCL-R in the sample was 28.5 for women and 26.5 for men. The research also showed that in 85% of males with a high psychopathy score, the admission diagnosis at the OPG was antisocial behavior, whereas in women a diagnosis of a borderline disorder was more common. These results are in line with those in the recent international literature that point out not only the different phenotypical manifestations of psychopathy in the two sexes, but also the likely general underestimation during risk assessment, of the violent potential and rates of female psychopathy.[5] This is also because few data are yet available on this issue.

In the light of these considerations, an observational study of the entire female population hospitalized in the OPG of Castiglione delle Stiviere was conducted to individuate the real incidence of psychopathy. In fact, it is very probable that the rates of diagnosis of psychopathy in women are too low. If this hypothesis is confirmed, admissions to the OPG failing to make a correct diagnosis of so important an element as psychopathological traits may have a negative impact on the planned treatment of new inmates.

Psychopathy, Social Dangerousness, Treatment

I22 Forensic Psychological Issues From Terrorism to Officer-Involved Shootings: U.S. Border Patrol Critical Incident Investigative Teams

Ronn Johnson, PhD, 3525 Del Mar Heights Rd, No 302, San Diego, CA 91230*

The goals of this presentation are to: (1) explore the forensic psychological factors associated with traumatic incident management, debriefing, substance abuse, self-assessment, and suicide prevention for the Border Patrol CIIT; (2) explore the culture of the Border Patrol; and, (3) fuel a foundation for additional research.

This presentation will impact the forensic science community by providing professional dialogue that will result in best practices in this area.

The federal government maintains hundreds of ports of entry. The length of the United States – Canada and United States – Mexico borders makes them convenient targets for illegal border activity. The responsibility of the U.S. Border Patrol is to no surprise directed at preventing Homeland Security breaches due to dangerous people and potentially dangerous situations. For example, following the terrorist attacks of 9/11, U.S. Homeland Security, and specifically the Border Patrol, became increasingly sensitive to border protection policy. There was intense discussion and considerable disagreement regarding immigration from the border with Mexico that added to the pre-existing concerns about drug trafficking and other border crimes. Also fueling tensions were competing economic needs reflected in Mexico's job demands and the need for a cheap work force. For example, the hourly wage in Mexico in 2000 was less than two U.S. dollars. By contrast, the earnings for unskilled undocumented workers in the U.S. are almost three times higher. Monies returned to Mexico also impacts their economy.

The USA Patriot Act was a major piece of legislation aimed at addressing the need to protect Americans from perceived threats posed by terrorists. To address those concerns, the number of Border Patrol agents increased from 3,965 in September 1993 to 12,349 in September 2006. In the fiscal year 2009, there were about 20,000 Border Patrol agents. The Border Patrol mission obviously applies not only directly to terrorists but terrorist weapons. Among the objectives of the Border Patrol is the planned use of information, integration, and rapid response that is crafted to protect the borders of the United States. The Border Patrol objectives of managing risks, increasing community engagement, and strengthening an investment in people all have underlying forensic psychological elements. The work of Border Patrol agents is hazardous and involves a significant amount of stress. For example, four Mexican nationals were charged in the shooting death of a U.S. Border Patrol agent. This incident was believed to be connected to the controversial "Fast and Furious" gun-smuggling operation. Border Patrol agents are also subjected to accusations of corruption and abuse of migrants. The Border Patrol's border enforcement has the doctrine of "prevention through deterrence" which also had implications for this unit. For example, the border stations San Diego, El Centro, Nogales, and El Paso have seen the construction of fences, lighting, and an increase in agents. Yet, some remote areas (e.g., mountains and deserts) were less

protected and resulted in more risky attempts by migrants. The U.S. Border Patrol has a unit referred to as the "Critical Incident Investigative Team" (CIIT). The CIIT has witnessed an increase in the number of migrant deaths due to dehydration, hypothermia, and being double-crossed by coyotes hired to smuggle them across the border.

In many respects, CIIT functions as an investigative nexus to address a wide range of incident issues that arise as Border Patrol agents carry out their enforcement duties. Yet, there are unique sources of tension (e.g., supervisor issues, suicidal behavior of Border Patrol agents, and Latino law enforcement cultural factors) in the U.S. Border Patrol. The first learning objective of this presentation explores the forensic psychological factors associated with traumatic incident management, debriefing, substance abuse, self-assessment, and suicide prevention for the Border Patrol CIIT. The second learning objective explores the culture of the Border Patrol. The third learning objective is designed to create a theoretical foundation for additional research. The community is expected to profit from a professional dialogue that will result in best practices in this area.

Forensic Psychology, Border Patrol, Critical Incident

I23 Testing Police Suicide Notes: Do General Population Notes and Police Testing Notes Significantly Differ?

Carole E. Chaski, PhD, Inst for Linguistic Evidence, ALIAS Technology LLC, 25100 Trinity Dr, Georgetown, DE 19947; and Robert E. Douglas, MS, National Police Suicide Foundation, 7015 Clark Rd, Seaford, DE 19947*

After attending this presentation, attendees will learn about police suicide reporting rates. Attendees will learn how the software tool SNARE provides suicide note authentication using both text-analytic, quantitative classification, and qualitative assessment based on database extraction. Attendees will learn how this method has been used to determine if police suicide notes are or are not significantly different from general population suicide notes. Attendees will also learn how validation testing is performed using behavioral and linguistic datasets, including highly sensitive data, and human subject protections for survivors of suicide.

This presentation will impact the forensic science community by showing how suicide is an international issue that affects American policing at a rate substantially higher than the general American public and only slightly lower than the American military. In the police culture, suicide is considered very shameful, which may cause an under-reporting of police suicide. Yet police officers enter their profession having met stringent standards for physical condition, mental health, and problem-solving ability, including interpersonal skill. This paper presents an empirical study of police suicide notes to determine if police suicide notes are or are not significantly different from general population notes. The method presented here, using both a computational tool and qualitative assessment, illustrates the particular human subjects protection required for validation testing using behavioral and linguistic datasets, and thus also advances the methodology of forensic science.

More than almost any other profession in the United States, policing screens its new hires for physical condition, psychological health, and problem-solving ability, including optimal interpersonal skills. Police officers begin their careers with great psychological strengths.[1] Yet it cannot be disputed that suicide occurs among police officers. Even our best can and do succumb to suicide. Miller states that "more police officers die by their own hand than are killed in the line of duty".[2]

Suicide risk is clearly related to occupational hazards of the policing profession. Such hazards include atypical schedules disruptive of circadian rhythms and long work hours, participation in violent events, constant dealings with difficult people, and prevalence of weapons.[3-8] These hazards, over time, can lead to depression, divorce or family isolation, and post-traumatic stress disorder, all of which are potential triggers for suicide.

These occupational hazards, especially the association with violent, traumatic events, help make sense of recent scholarship on the rate of police suicide. Only recently have national, empirical studies to determine police suicide rate been initiated through The Badge of Life Program.[9] Two facts can be gleaned from these studies. First, the rate of police suicide is higher than the general population. According to O'Hara and Violanti (2009), the suicide rate for police officers was 17/100,000, compared to the rate for the general public of 11/100,000 and 20/100,000 for the Army.[10] Loo had also found higher suicide rates in police than comparison populations.[11]

Second, the rate of police suicide is controversial because there may be under-reporting of police suicide. Just as the shame associated with rape in the American culture may cause actual rapes to go unreported, the shame associated with suicide in the police culture may cause actual suicides to be classified as other types of events or "undetermined." Violanti demonstrates that "male police officer deaths had a 17% increased risk of being misclassified as undetermined" than both firefighter and military occupations, and the risk of misclassification was far higher for female and African American police officers.[12]

In this context, the question is posed: are police suicide notes significantly different from general population suicide notes? This hypothesis was tested using SNARE, a suicide note assessment research tool for identifying, classifying and assessing suicide notes. SNARE combines a computational, quantitative tool and a database extraction feature for qualitative assessment. The quantitative tool in SNARE currently has obtained an accuracy rate of 80% on a dataset of 400+ real suicide notes and 500 control documents. When the real suicide note data is limited to brief notes (45 words or less), the accuracy rate increases to 86%. The statistical classifier is a linear discriminant function analysis using leave-one-out cross-validation. The reported accuracy rates are the average of true positives for the real suicide note class and the control document class. Preliminary results using only the quantitative component of SNARE have not shown differences between police and general population suicide notes.

Finally, forensic linguistic data safeguards are considered. While all suicide note research must take into account human subjects protections (44 CFR 45), research into police (as well as military) suicide must be especially cautious in collecting data, securing the data, and protecting survivors' privacy. Discussion includes how each of these issues is handled so research partnerships could be established between institutions.

Suicide Notes, Validation Testing, Human Subjects Protections

I24 Veterans' Courts: Trend for the Future?

Ziv E. Cohen, MD, 175 W 90 St, 18J, New York, NY 10024*

After attending this presentation, attendees will be able to describe the purpose and functioning of the Veterans' Court. Attendees will understand the history of attempts to address mental health issues in veterans who are entangled with the criminal justice system and will be brought up to date on current data on effectiveness of the Veterans' Court.

This presentation will impact the forensic science community by updating attendees on an important current trend in tending to the needs of veterans in the criminal justice system, a population which has vastly expanded since the Iraq and Afghanistan conflicts.

Since the inclusion of Post-Traumatic Stress Disorder (PTSD) in the DSMIII in 1980, the legal system has recognized the potential value of PTSD in shielding veterans from the criminal justice system. However, even before then, the courts had considered defendants' war experiences to assist in weighing criminal responsibility and appropriate punishment.[1] The first wave of veterans to employ the PTSD defense were Vietnam Veterans who received an often-negative response to their claims of legal insanity due to combat related PTSD.[2] With the end of the Iraq war in 2011 and the anticipated return home of most troops from the Afghanistan conflict by the end of 2014, the American mental health system is expected to be flooded with over 1.5 million veterans, with up to 35% suffering from PTSD.[3] There has been some evidence that violent crime rates are elevated among veterans returning from the Iraq war, and that violent crime is elevated among combat veterans in general.[4-5] As opposed to Vietnam Veterans, public attitudes toward Iraq/Afghanistan Veterans remain positive.[6] Thus, there is considerable interest in the utility of PTSD to help shield these veterans from the consequences of criminal behavior or to form the basis of treatment. PTSD may also be employed in arguments to reduce criminal responsibility.[7] Recently, a movement of Veterans' Courts which began in Buffalo in 2008, has expanded around the country.[8,9] In some districts, veterans convicted of felonies are eligible for services and counseling.[10] Veterans' Courts have sprung up to rectify the perceived injustice of punishing veterans for behaviors related to the symptoms of PTSD.[11] However, to date, there is little published data on the effectiveness of Veterans' Courts. Proponents argue that "treatment not punishment" both provides justice for veterans and helps reduce recidivism. However, others are troubled by the creation of a privileged class of criminal defendants. The paper presents the recent history of attempts to address the issue of veterans in the criminal justice system, the inception of Veterans' Courts, and the data available regarding effectiveness. The paper discusses the inconclusive nature of the evidence at present and suggests direction for future studies.

I25 Early Intervention Programs to Prevent Serious Juvenile Delinquency

Jessica M. May, BA, 850 Park Ave, Ste 1-B, New York, NY 10021; and Stephen B. Billick, MD, 11 E 68th St, Ste 1B, New York, NY 10065-4955*

After attending the presentation, attendees will be exposed to research-tested methods for reducing juvenile delinquency recidivism and, more importantly, to understand research supporting interventions for early prevention of this delinquency.

This presentation will impact the forensic science community by educating attendees on the status of the scientific research in the prevention of delinquency.

This presentation will discuss the prevailing failed attempts at preventing juvenile delinquency and its recidivism. The predominant method for dealing with juvenile delinquents in the last three decades has been to treat many as adults with harsh sentencing.

Recognizing the developmental aspect of juveniles as distinct from adults, the first juvenile justice system was established in 1899 in Illinois and led to the creation of the first child and adolescent psychiatry clinic in 1909 in Chicago. This clinic was specifically created to aid the newly formed family courts in their adjudication of "wayward youth." Eventually all 50 states adopted these special courts to handle juvenile delinquency outside of the adult criminal courts. The goal of these courts was to help the youth return to a healthy path of development. Hence, there was no sentencing, only adjudication of the youth "for their betterment." Until *In re Gault*, children and adolescents in family court had few of the safeguards afforded to adults charged with crimes. Since the 1970s, with the dramatic rise in violent crime committed by adolescents, many juveniles have been returned to the jurisdiction of adult criminal courts. Society was outraged to see juveniles murder and rape and be released from custody at the age of 21 years, and further to have the juvenile records sealed. In some jurisdictions, the juvenile may begin in family court and be waived up to adult criminal court. In other states, such as New York, adolescents who commit specific crimes of violence or with a weapon are immediately sent directly to adult criminal court. Society has sought to reduce juvenile crime with longer incarceration with only modest success. Unfortunately, incarcerated juveniles, when released have been fully educated to be better criminals. Spending time with more experienced criminals provides an unwanted fertile environment for teaching adolescents exactly what we do not want them to learn.

In the last three decades there has been ample research to demonstrate that instituting multisystemic therapy for serious juvenile offenders, keeping them in the community with intensive intervention, can significantly reduce recidivism. When there is recidivism, it is less severe than in released incarcerated juveniles. Multisystemic therapy provides 24-hour available parental guidance, family therapy, individual therapy, group therapy, educational support, and quite importantly, a change of peer group. In New York City, there is the new mandate through the Juvenile Justice Initiative to implement interventions to keep juvenile offenders in the community rather than sending them to be incarcerated.

However, let's look at how teaching prosocial values in early childhood can reduce the incidence of first-time juvenile delinquency. Programs such as the Perry School Project will be discussed to demonstrate that although somewhat expensive, these innovative programs nonetheless are quite cost-effective as the cost to society of adjudication, incarceration, and victim damages are significantly greater. Along with teaching prosocial values, there has been renewed interest in early identification of youth at risk for developing Antisocial Personality Disorder. An update will be given on the status of both promising approaches in early intervention to prevent serious juvenile delinquency and hence adult criminality.

Juvenile Delinquency, Prevention, Early Intervention

I26 Anti-Bullying Legislation: Have the Laws Gone Too Far or Are They Still Insufficient to Combat Bullying?

Karen B. Rosenbaum, MD, 200 W 85th St, Apt 1B, New York, NY 10024*

After attending this presentation, attendees will understand the impact of bullying on children, schools, and the community. Attendees will understand the need for anti-bullying legislation and the issues that have risen since some of the laws have been implemented.

This presentation will impact the forensic science community by providing an update of anti-bullying legislation and placing it into a clinical and forensic context.

Over the past several years, with the increase in teenage suicides, social networking, and community awareness, bullying has become recognized as a community health problem as well as a political issue. Over the past three years, there have been many high-profile cases of teenage suicides precipitated by bullying, which then prompted state laws to change. Phoebe Prince, a 15-year-old Irish immigrant, killed herself in South Hadley, MA, on January 14, 2010, after being bullied by several students in her high school. On September 22, 2010, Tyler Clementi, a Rutger's freshman, jumped off the George Washington Bridge after being outed over the internet by his roommate. Jamey Rodemeyer committed suicide in Buffalo in September 2011 after being tormented by cyberbullies.

These and many other tragic cases influenced a change in the law regarding bullying. In response to Tyler Clementi's death, New Jersey passed an "anti-bullying bill of rights." Since 2002, New Jersey had an adequate anti-bullying law in which some school districts complied and others did not. The new bill, passed in 2010, which went into effect in September of 2011, made it clear that responding to threats of bullying and intimidation was not optional. The problem with the New Jersey law and several other new state laws regarding bullying is that they did not provide the funding for schools to uphold them. In January of 2012, the law was declared unconstitutional because it was an "unfunded mandate" that funneled resources away from other programs. The law was well intentioned but did not provide the resources necessary to implement the programs mandated in the law.

In a recent article in *The Wall Street Journal* called, "Stop Panicking About Bullies," Mr. Gilespie questions whether or not America is "really in the midst of a "bullying crisis."[1] He does not believe that childhood bullying is on the rise. He also feels that the laws designed to prevent bullying are "likely to lump together minor slights with major offenses." He feels that children today are tamer and less mean than children growing up in the 1970s and 1980s. While there may be some truth to this, children growing up in the 1970s and 1980s did not have access to email, social networking sites such as Facebook and Twitter, or mobile phones. Children who were bullied thirty years ago were most likely only bullied during school hours and home served as a somewhat safe haven. Today, children can be potentially exposed to bullying every time they turn on their computer or smart phone.

After high-profile cases such as the deaths of Phoebe Prince and Tyler Clementi, there have been new state legislations mandating schools to have formal policies against bullying. This presentation will address some of the new laws designed to prevent bullying in schools, and the issues that have arisen since these laws have been in place.

Bullying, Legislation, Schools

I27 Bullying Victimization in Adolescence: A Precursor to Future Delinquency?

Shivani Chopra, MD, 2010 Zonal Ave, Outpatient Dept, 1st Floor, Ste 1p-2, Los Angeles, CA 90033*

The goals of this presentation are to: (1) understand the relationship between bully victimization in adolescence and future delinquency; (2) identify risk factors that may predispose these victims to becoming delinquent; and, (3) discuss the various types of delinquent acts that may be committed.

This presentation will impact the forensic science community by better recognizing the victims of bullying who may be at risk for developing delinquency, so that early, appropriate intervention can be implemented to deter these victims from a delinquent path.

Bullying is defined generally as a specific type of aggression which includes the following: the behavior is intended to harm or disturb; the behavior occurs repeatedly over time; and, there is an imbalance of power, with a more powerful person or group attacking a less powerful one. National surveys conducted from 2005 to 2009 indicate that up to 28% of youth, primarily during adolescence, reported having been bullied during the survey periods. It is known that perpetrators of bullying, or "the bullies," pose a significant safety risk to their fellow peers and others. In one National Institute of Child Health and Human Development survey, bullies were seven times more likely to report they carried a weapon to school in the prior month. Other studies have shown that bullies, identified by age eight are six times more likely to be convicted of a crime by age 24, and five times more likely to have serious criminal records by age 30.

Little information, however, exists about the victims of bullying and whether they engage in future delinquent behaviors. While research suggests that victims of bullying may experience serious emotional sequelae, including poor social-emotional adjustment, depression, psychotic symptoms, and even suicide, there are scant data regarding the victims' propensity for future delinquency. Does being bullied in adolescence, a critical time period for development, predispose one to engage in future delinquent behaviors?

Agnew's general strain theory endorses that adolescents who experience adverse circumstances are pressed into delinquency by negative emotional reactions, such as anger. Accepting that being a victim of bullying is an adverse circumstance, are there reasons, other than anger, that adolescent bullying victims engage in delinquent behaviors? That is, are there any identifiable risk factors that may predict the likelihood of delinquency for such individuals? Another issue to consider is the kind of delinquent conduct in which these victims may engage. In the recent past, media have shed light on school shootings, with many associating the occurrence of these acts with persons who have a history of bullying victimization. But not all victims of bullying use firearms against their peers. So what may lead a bullying victim to such extreme measures? It is important for the astute forensic practitioner to

remember that while a history of bullying is often present in such school shooting cases, most of these involve complex issues that are not simply limited to bullying victimization.

From a forensic psychiatric perspective, this presentation will review the literature to examine the aforementioned issues of whether bullying victimization in adolescence predisposes to future delinquency. In addition, it will identify potential risk factors for such a predisposition, as well as explore the various types of delinquent acts in which these victims may engage.

Bullying, Victimization, Delinquency

I28 Evolution of the Adolescent Brain: Science, Sentencing, and the United States Supreme Court

Eugene Lee, MD, 118 W Spring St, Fayetteville, AR 72701; and D'lorah L. Hughes, JD*, Univ of Arkansas, Robert A. Leflar Law Center, Waterman Hall, 1045 W Maple St, Office 130, Fayetteville, AR 72701*

After attending this presentation, attendees will be able to: (1) compare and contrast the outcomes of three recent landmark juvenile justice cases from the United States Supreme Court; (2) explain the scientific basis, reasoning, and principles which informed these opinions; and, (3) briefly describe how one state (Arkansas) is mobilizing to respond to the most recent of these landmark cases.

This presentation will impact the forensic science community by increasing awareness of how advances in the understanding of adolescent brain development are impacting juvenile justice sentencing guidelines.

The United States Supreme Court has had an active decade in the matters of juvenile justice. In *Roper v. Simmons* (2005), the Court found that the Eighth and Fourteenth Amendments forbid imposition of the death penalty on offenders who were under the age of 18 when their crimes were committed. In *Graham v. Florida* (2010), the Court held that, for non-homicide crimes, the Eighth Amendment does not permit a juvenile offender to be sentenced to life in prison without parole. And, most recently, in two cases (*Evan Miller v. Alabama* and *Kuntrell Jackson v. Ray Hobbs, Director, Arkansas Department of Correction*) which were decided together on June 25, 2012, the Court decided that the Eighth Amendment forbids sentencing schemes which mandate life in prison without possibility of parole for juvenile homicide offenders.

These three opinions have direct implications on state sentencing guidelines for juvenile offenders. This presentation will focus on the Court's use of science in formulating these opinions, and the role of factors such as an adolescent's maturity, development of sense of responsibility, vulnerability to negative influences and outside pressures, control over environment, and fixedness of character traits. As these factors can serve to inform the forensic evaluation of adolescent culpability, this presentation will include discussion through the lens of the 2011 Presidential Address at the Annual Meeting of the American Academy of Psychiatry and the Law, as well as "the evolving standards of decency that mark the progress of a maturing society" (*Trop v. Dulles* as cited in *Miller* and *Jackson*) in the context of contemporary psychiatry's bio-psycho-social framework.

Both the *Miller* and *Jackson* cases involved 14-year-olds convicted of murder and sentenced to mandatory terms of life imprisonment without the possibility of parole. Arkansas charged Jackson as an adult, and Miller was initially charged as a juvenile but his case was waived up to adult court. Discussion will include the implications of which court adolescents are tried in, as this also may hinge on the forensic evaluation of adolescent culpability.

Lastly, as the authors are faculty at the University of Arkansas School of Law, the presentation will include an opportunity for the audience to learn about how one state (Arkansas) is mobilizing to respond to the *Miller* and *Jackson* rulings, in terms of juvenile homicide offenders in Arkansas currently serving what until recently were mandatory life sentences without parole. As life-without-parole sentences are thought to "share some characteristics with death sentences that are shared by no other sentences" (*Graham*), these characteristics invite discourse when parole becomes a possibility.

Adolescent Development, Juvenile Justice, Sentencing Guideline

I29 Contemporary Neuroscience Affects Forensic Behavioral Science Standards

John L. Young, MD, 203 Maple St, New Haven, CT 06511-4048*

The goal of this presentation is to incorporate the implications of important findings from neuroscience into the daily work of advancing and applying forensic behavioral science.

This presentation will impact the forensic science community by gaining appreciation of neuroscientific discoveries, delighting in the significance for forensic behavioral science in a variety of relevant social contests.

Examinations of forensic behavioral science in response to the February 2009 report of the National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward*, point to a gratifying array of established habits that currently promote a high level of quality in both training and practice. Although its advances already impact practice, training, and research in the field, surprisingly little has been said so far about the implications of neuroscience. Yet it is a rapidly proliferating area that can be expected to command more attention in the very near future.

Experiences so far have provided a basis for high expectations as neuroscientists continue making their discoveries. This trend began during the 1970s with the establishment in cats of a distinction between two kinds of aggression, affective and predatory, each associated with changes in the activity levels of different brain structures. During the same decade, the first pharmacological agent shown to lower aggressive behavior, lithium, was documented in humans. Soon after, there appeared several associations relating brain structures and behavior, including the amygdala and emotional memory, the prefrontal cortex and executive function, and the limbic system and impulsive reactions.

As we gain information about the functions of brain structures and their connections through the use of functional Magnetic Resonance Imaging (fMRI), we increasingly recognize serious risks of oversimplification. The human brain has 100 billion neurons each connecting to a rough average of 1,000 others, and there are several glial cells for each neuron. These cells are being found not so inert as was once thought. The amygdala itself is composed of several paired nuclei, making it more than a single organ. Moreover, concerns are now arising about the validity of once-established results in neuroscience.

Appropriate concerns are being raised about the use of neuroimaging in the courtroom. Images have an inherent convincing quality unlike galvanic skin responses and similar behavioral evidence. Valid information about the developing brain is likely to have a helpful place in the evaluation of competency to stand trial. At least since the trial of John Hinckley, Jr., we have seen controversies concerning the use of neuroscientific techniques to aid in the assessment of criminal responsibility. Fascinating results are emerging with respect to the detection of malingering and other lying. A recent civil case involved the use of fMRI to demonstrate a putative association between violent video game playing and violence in order to support the claim of the state that it had a compelling interest in regulating these videos.

The study of violent behavior stands to gain much if it undertakes to link the findings of neuroscience to the social contexts in which human brains give meaning to the making of choices, including the choice to behave violently.

Another area of growing concern is medicinal enhancement, the use of substances to bolster alertness, memory, cognition, and other functions, such as physical prowess. Some compounds are new; others, mostly psychotropics, are familiar but are being proposed for off-label uses. Forensic behavioral science has a role in assessing this practice, especially as it spreads to new social contexts. As

neuroscience continues to make its advances, it is increasingly important for forensic behavioral science experts to keep pace by applying close vigilant attention to the relationships among scientists working in different but interacting social contexts.

Neuroscience, Social Contexts, Practice Standards

I30 A Typology of Parricide Offenders

Kathleen M. Heide, PhD, Dept of Criminology, 4202 E Fowler Ave, Social Sciences Bldg, Rm 107, Tampa, FL 33620-8100*

After attending this presentation, attendees will be aware of: (1) four clinical types of parricide offenders; (2) the relationship of age to parricide offender type; and, (3) specific criteria required to make the parricide offender designation, criteria that are frequently associated with this type, but that are not considered essential to making the classification, and criteria that might be present.

This presentation will impact the forensic science community by identifying four types of individuals who kill parents in terms of social history, life circumstances, typical mental health diagnoses, and motivational dynamics related to the killings.

The killing of parents, increasingly referred to as parricide, has been documented worldwide. Although matricide and patricide are rare events, mental health professionals, the justice system, and the public alike look for reasons why sons and daughters kill parents. This presentation will discuss the characteristics of different parricide offender types based on research, the evaluation of parricide defendants, discussion of parricide cases consulted on, and the extensive knowledge of the literature. This presentation will list criteria *required* to make the parricide offender-type designation, criteria that are *frequently associated* with this type but that are not considered essential to making the classification, and the criteria that *might be* present. Three of these parricide types were introduced more than 20 years ago in the book, *Why Kids Kill Parents*, and have stood the test of time as referenced by other clinicians and scholars in the field. These three types are: the *severely abused child*, the *dangerously antisocial child*, and the *severely mentally ill child*. Among children, adolescents, and young adults, the severely abused child and the dangerously antisocial child are most common. Among older adult parricide offenders, the severely mentally ill and the dangerously antisocial types predominate. The fourth type, angry children with low frustration tolerance, is found among juvenile and adult parricide offenders.

- Severely Abused Children (SAC) kill their abusive parent to end years of abuse. They kill the abusive parent because they are terrified that they or other family members will be seriously harmed or killed. SAC are typically desperate and see no other way out but murder. These individuals typically have a longstanding history of depression and meet the diagnostic criteria for Post-Traumatic Stress Disorder (PTSD).
- Dangerously Antisocial Children (DAC) kill the parent to further their own goals. In these cases, the parent is an obstacle in their path to getting what they want. These individuals, for example, may kill to have more freedom, to continue dating a person to whom the parent objects, or to inherit money they believe is eventually coming to them. DAC have a pattern of violating the rights of others when it suits them. Depending on their age, these parricide offenders are often diagnosed as having a conduct disorder or an antisocial personality disorder. This type of parricide offender is far more dangerous to society than the first in terms of re-offending and hurting other people in the future.
- Severely Mentally Ill Children (SMIC) who kill parents typically have a longstanding history of mental illness. Diagnoses commonly made include psychosis and severe depression. SMIC are typically on psychotropic medication and are most apt to kill when they stop taking it.
- Angry children with low frustration tolerance appear to be raised by parents who do not enforce limits. The parents are often lax and might be overindulgent. As the children get older, they do not accept parental authority. As parents step in and attempt to set appropriate and needed boundaries, these children aggress because they have little frustration tolerance. Often their homicidal rage is fueled by alcohol and/or drugs.

Parricide, Matricide, Patricide

I31 Sociodemographic Data of Intimate Partner Homicide-Suicide Cases in Turkish Mass Media Between 2008 – 2011 Through Judicial Records

Bunyamin Baspinar, The Council of Forensic Medicine, Yenibosna, Istanbul, TURKEY; Ipek Esen Melez, Adli Tip Kurumu Cobancesme, Istanbul, TURKEY; Deniz O. Melez, MD, Basaksehir Mahallesi, Anafartalar Caddesi, Oyakkent 2 Etap B04, Daire 45, Basaksehir, Istanbul, TURKEY; C. Haluk Ince, PhD, Ministry of Justice, Council of Forensic Science Med, Sanayi cd. Kimiz sok. No. 1, Istanbul, TURKEY; and Sakir Ozen, Adli Tip Kurumu – Cobancesme, Istanbul, TURKEY*

After attending this presentation, attendees will learn about intimate partner homicide-suicide cases in Turkey between 2008 – 2011.

This presentation will impact the forensic science community by presenting information about intimate partner homicide-suicide cases in Turkey to point out some social and legal basis of problems.

The term “Homicide-Suicide” (HS) can be explained as “the committing of suicide by the same individual after he/she has commitment a homicide.” Some authors stated that the act can be defined as a homicide-suicide if the time period between homicide and suicide is less than 24 hours while other authors use a time period of a few days to one week. Other authors have used any time period in their definition. In order to evaluate the HS cases, different methods of classification are used by different authors according to psychopathological features of perpetrators, civil status of the relationship between victim and perpetrator, or the motivation of committing a homicide.

HS is most frequently seen among intimate partners and, within this scope, is an important part of sexual violence in society. Besides, violent features of these incidences mostly find a place in mass media. Thus, this study is planned to scientifically elicit the sociodemographic features of these mass media cases which have been constituting a good “image” of the general “picture” all around the country about Intimate Partner Homicide-Suicide (IPHS). Motivation of the perpetrator has also been included in the study as a sociodemographic factor. A media monitoring agency has been used with specific keywords to detect all the incidences of IPHS which had found a place in mass media between 2008 – 2011 in Turkey. The cases were then searched in the Turkish judicial system through the judicial archives of forensic medicine units, which are organized in the structure of the Council of Forensic Medicine, an unique official forensic medical expertise institution. The judicial records were evaluated in order to have the sociodemographic data of the victims and the perpetrators. The data collected were analyzed through descriptive statistics with SPSS 16.0 software, since it had been planned as a cross-sectional study.

As a result of the data analyses, 122 incidents of IPHS including 122 perpetrators and 157 victims in a time period of 48 months between January 1, 2008 and December 31, 2011 have been detected. Among victims, 35 were a third party instead of a spouse or intimate partner. Twenty-three among 35 were the mutual children of the couples constituted by the perpetrator and the victim. Ninety-seven point 5 percent of the IPHS perpetrators were male, showing that almost all of the sexual violence in mass media, in society, is against women instead of men. The mean age of the perpetrators was 41.54 (in the range 22 – 80 years) while the mean age of the victims was 35.56 (in the range 18 – 73 years). Also, 59.8% of the perpetrators and victims were found to be married officially during the incidences, while 52% were living separately during the incidences. The education level of 54.1% of the perpetrators were found to have a secondary school level of education. A psychiatric history was found in 7.4% (n=9) of the perpetrators, among

whom only two were found to have a psychiatric diagnosis. The fact that 19 perpetrators had been committing violence to the victim before the homicide incidence was determined among 22 perpetrators for whom data related to the violence commitment status were able to be obtained. Also, 56 (45.9%) perpetrators were found to have exhibited behaviors of murder contemplation, while in 87 cases (71.3%), the time interval between the homicide and suicide was less than one hour. In addition, 89.5% of the perpetrators committed suicide using firearms while 88.6% of the victims had been murdered by firearms, all of which can also be parameters to discuss the motivation as a power ratio between the victim and the perpetrator, a violent drive-control ability, and other psychiatric basis.

The limited data can be found to be related to the past sociodemographic features, especially of IPHSs. In order to be able to obtain more data and documents, judicial units' recording more data will provide more of a chance, especially for psychiatric, sociological and criminal researches. Even with these numbers, this study can be the most comprehensive case collection in Turkey related to IPHS cases in mass media, providing some significant awareness for evaluation and prevention of further cases.

Homicide-Suicide, Intimate Partner, Sociodemographic

I32 The Psychological Autopsy as Method in Case of Suicide by Hanging

Isabella Aquila, MD, Policlinico Univ, S. Venuta-Medicina Legale, Viale Europa, Località Germaneto, Catanzaro, ITALY; Arianna Serra, MD*, Carol Pileggi, MD*, Miriam Sirianni, MD, Silvia Boca, MD, Maria Chiarelli, MD, Pasquale De Fazio, PhD, MD, Ciro Di Nunzio, PhD, Santo Gratteri, MD, and Pietrantonio Ricci, PhD, MD, Magna Graecia Univ, Viale Europa 88100 Catanzaro, ITALY*

After attending this presentation, attendees will understand the role of the psychological autopsy in a case of suicide.

This presentation will impact the forensic science community by discussing the relation between a suicide case and the choice of suicide with psychosocial, environmental, and cultural risk factors.

Introduction: Suicide is a public health problem; as a general rule it is underestimated. Prevalence of death due to suicide is greater than cancer, respiratory disorders, and other common diseases. Every year, more than 10/100,000 people commit suicide, with an alarming rise in suicides among children and women 18 to 30 years old; specifically, it is a major preventable cause of death among children. Every country has a constant trend. Specifically in Italy, there is a low risk of suicide, with the northern regions exhibiting values almost double compared to the south. It's influenced by psychosocial, environmental, and cultural risk factors. There are many risk factors: advanced age, male sex, widowhood, divorce, previous attempts or intentions of suicide, depression, schizophrenia, drugs, unemployment, social isolation, suicide among relatives, hallucinations, and delusions of persecution. Suicidal ideation is based on both cognitive substrates and personality disorders along with interactions with family as impaired parent-child relationships, emotional dissatisfaction, self-harming behavior, frustration, social marginalization experience, and inability to recognize other's complex emotional states. Even families dominated by violence and abuse can generate potential candidates for suicide. Also, there is a clear association with groups, as with psychiatric patients and persons with several mental and physical illness. In particular, adolescents with intellectual disabilities often diagnosed with comorbid psychiatric disorders are a vulnerable population who may be at risk for developing suicidal thoughts and behavior. Many different factors may influence personal decisions about the choice of suicide modality of death. There is a clear indication of restricted access to lethal means associated with a decline in suicide, especially for methods with a high fatality rate. Suicidal setting analysis is performed by forensic pathologists with "psychological autopsy." This survey includes demographics, lifestyles, personality traits, personal and psychological data of suicide's victims, and suicidal reasons. The psychological autopsy is one of the most valuable tools for research into the suicide's death.

The goals of this study are to evaluate the psychological autopsy to understand reasons and origin of suicide cases.

Case Report: This case has been tested, through the method of psychological autopsy, the case of a 17-year-old girl's death by suicide. At on-site investigations, the young girl was found hanged from a sheet attached to the railing of her apartment. The external examination of the victim revealed the presence of hanging marks: cyanosis of the face, conjunctival petechiae, soft skin neck injury, and hypostasis in both hands and feet. The examination of the victim demonstrated suicide by hanging. A psychological survey was performed on the family and friends of the victim. Measurements used were: face-to-face structured interviews, semi-structured interviews with family members of the suicide victim, or next of kin with informed consent obtained beforehand.

Results: The results showed the victim's parents were divorced. Further psychological investigations were suggestive of sexual abuse by a parent.

Conclusions: The study emphasizes the importance of psychological autopsy to detect the reasons for suicide. This survey is important especially to identify the risk of suicide victims in relation to: suicidal setting, family dynamics, previous psychiatric disorders of the victim, and any psychiatric disorders of the family. The identification of risks enhances prevention of this phenomenon.

Suicide, Psychological Autopsy, Interview

I33 False Accusations of Sexual Abuse as a Means of Revenge in Couples Disputes

Ignazio Grattagliano, MD, Univ of Bari, Piazza Cagnola, 3/B, Casamassima, ITALY; Giancarlo Di Vella, PhD, Univ of Bari, Section of Legal Medicine, Piazza Giulio Cesare, 11, Bari, ITALY; Carlo P. Campobasso, MD, PhD, Univ of Molise, Dept Medicine & Health Science, via De Sanctis, snc, Campobasso, ITALY; Graziamaria Corbi, PhD, Via Giovanni Paolo II – Loc. Tappino, Campobasso, ITALY; and Andrea Lisi, PsyD, Valentina Stallone, PhD, and Roberto Catanesi, MD, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY*

After attending this presentation, attendees will more fully comprehend the dynamics regarding false charges of sexual abuse eveled against ex-partners as a means of revenge in Italy.

This presentation will impact the forensic science community by presenting some of the challenges that professionals in criminology and legal medicine encounter when ex-partners launch false charges of sexual abuse against the other partner. Additionally, the importance of the role that Parental Alienation Syndrome (PAS) may play in such circumstances will be presented.

False accusations of sexual abuse as a means of revenge in couple diputes when carrying out forensic-psychiatric evaluations on a minor who is the presumed victim of sexual abuse, one may come across both "false positives" and "false negatives." These may be the result of honest mistakes, or are intentionally false, and the result of manipulation and exploitation. False accusations may come about under certain conditions such as in particularly bitter cases of separation and divorce where one of the parents files charges against the other, and is well aware of the untruthfulness of them. In other cases, the adult reports sexual abuse that did not, in fact, take place, but believes in good faith that it has. Such a parent's motives are protective in nature. Investigations carried out using inappropriate techniques may result in erroneous conclusions, thus confirming abuse that had, in fact, never taken place. The goals of this study are to examine the phenomenon of false accusations of sexual abuse as a form of revenge by one ex-partner against another, and to offer recommendations as to how to avoid falling into these traps.

This research examined 75 technical consultations and expert testimonials, requested by judicial authorities, and carried out between 2003 and 2009 at the Department of Criminology of the University of Bari, Italy. These cases regarded marital unrest where intrafamilial sexual abuse of a minor was reported. Twenty-two (30%) of these reports were found to be baseless and merely a result of conflict, as well as a strategic maneuver employed by one of the partners as an act of

revenge upon the other. Of these 22 baseless charges, five involved men who accused their ex-wives and/or live-in partners. The remaining 17 cases involved charges by women against their ex-husbands and/or live-in partners. This echoes what is reported in the literature. Mothers (alienating parents) often level "virtual accusations of abuse" against fathers (alienated parents). When, on the other hand, it is the father who is the instigator or the alienating parent, the accusations are usually aimed at the new partner of the ex-wife or ex-girlfriend.

Currently, technical consultants who work with separated and conflicted families are increasingly involved in court cases that follow a characteristic pattern: one parent is accused of sexual abuse or serious maltreatment. This causes harm to the youngster and the accused parent is subsequently turned out, losing all contact with the child. It is important to bear in mind how PAS is a form of violence perpetrated on minors. A parent who alienates the other commits a form of abuse that Gardner defines as "emotional," and may result in the permanent alienation of one loving parent, as well as psychiatric disorders.[1] The estranged parent who forces his or her child into a situation of continual denigration and denial of the other parent can irreversibly damage fundamental psychological bonds. When parents become estranged, a serious deficit in parental care is always a risk and should seriously be considered by the courts when they make decisions regarding child custody. Charges of abuse represent not only an instrument of protection of one's own children, but also a weapon of revenge against an ex-partner, paradoxically putting these minors into the role of victims.

False Accusations, Revenge, Sexual Abuse

I34 A Comparison of Results From Clinical and Forensic Urine Screening for Opiates in Psychiatric Patients

Daylien Casas, BS, 2920 SW 12 St, Miami, FL; Lisa J. Reidy, PhD, Univ of Miami Forensic Tox Lab, 1600 NW 10th Ave, RSMB R5, Rm 7020A, Miami, FL 33136; Patiricia Junquera, MD, Univ of Miami, Miller School of Medicine, Dept of Psychiatry and Behavioral Sciences U, 3101 JMH-Mental Health Bldg, Miami, FL; and Bernard W. Steele, MD, Jackson Memorial Hospital, Holtz Center Rm 2026, 1611 NW 12th Ave, Miami, FL 33136*

After attending this presentation, attendees will learn how clinical toxicology testing is not as accurate and as specific as they should be for patients with a history of drug abuse and psychiatric illness. Attendees will also learn that many patients who are currently using opiates would return a hospital drug screen as "negative" for opiates when this clearly is not the case. The screening methodologies currently employed in clinical laboratories are not sensitive enough to provide comprehensive toxicology results.

This presentation will impact the forensic science community by improving appropriate treatments and diagnoses for psychiatric patients.

Introduction: Patients with mental illness, such as bipolar or schizophrenia, are more likely to have substance abuse problems than the general population. If both are identified, then the individual may receive continuous treatment for each affliction. One problem associated with drug abuse lies in the detection of the drugs in a clinical setting. Patients with mental illness and drug use present a difficult challenge for physicians to determine if the causation factor for the mental illness is drug abuse or if the mental illness led them to drug abuse. If drug use is suspected, a urine sample is collected and sent to the hospital laboratory for drug screening. The drugs that are routinely screened for vary between hospital and/or institution. The screening is typically five different drug classes that include: cannabis, amphetamine(s), cocaine, opiate(s), and benzodiazepine(s). In most hospital laboratories, no confirmation for drug use is performed due to the conception that this is expensive and time-consuming. The reliability and accuracy of the urine toxicology results is a vital tool for the correct diagnosis of these patients.

Objective: This study was conducted to assess the accuracy of the clinical toxicology testing for patients with a history of drug abuse and psychiatric illness. According to the data from the National Institute on Drug Abuse, the number of opiates prescribed has dramatically increased in the last 20 years, with 131 million prescriptions written/dispensed in 2000 that had increased to 210 million in 2010. Due to this increase in use and the lack of cross reactivity with some opiates in hospital drug screening, a study was conducted comparing clinical toxicology results with typical forensic toxicology screening that combines Enzyme Linked Immunosorbant Assay (ELISA) and Gas Chromatography–Mass Spectrometry (GC-MS) to screen and confirm a wide variety of drugs.

Materials and Methods: In this IRB-approved study, 338 urine samples were collected from the hospital laboratory from patients admitted into detox or mental health institutions. Patients were comprised of males and females with ages ranging between 18 and 65 years old. The results from the hospital urine drug screening with EMIT (Enzyme Multiplied Immunoassay Technique) was obtained. The forensic toxicology testing protocol utilized a DS2 (Dynex Technologies) fully automated ELISA instrument using opiate and oxycodone ELISA kits (Neogen KY, USA). The comprehensive GC-MS screening utilized a basic LLE (Liquid-Liquid Extraction) then fast GC-MS (Agilent Technologies) analysis. These tests are comparable in pricing and in speed that is vital for routine toxicology testing in a hospital environment.

Results and Conclusions: The results of both laboratories urine drug screening are presented in Table 1. With the EMIT screening technologies; they tend to have a poor cross-reactivity to oxycodone and oxymorphone which can explain some of the differences seen. Clearly, the results demonstrate that the current screening methodologies typically employed in clinical laboratories are not sensitive enough to provide comprehensive toxicology results. The results show that many patients that are currently using opiates would return a hospital drug screen as "negative" for opiates when this is evidently not the case. The screening used at the hospital at baseline for most of the patients were inaccurate and unspecific and in this instances missed over half of the patients using opiates which is important information when trying to determine the treatment for those patients. The GC-MS data identified a wide variety of opiates in use in this population use ranging from 6-monoacetylmorphine, hydrocodone, hydromorphone, oxycodone and oxymorphone to name a few.

Table 1: The drug screening results of a clinical laboratory vs. the drug screening results a toxicology laboratory. N= 338

Drug Group	Toxicology Laboratory		Clinical Laboratory	
	Number of Positive Patients	% Positive	Number of Positive Patients	% positive
Opiates (class)	30	9	22	6.5
Oxycodone (class)	20	6	N/A	N/A

I35 An Institutionalized Elderly Sexual Offender: A Case Report

Graziamaria Corbi, PhD, Univ of Molise, Dept of Medicine and Health Sciences, Via Giovanni Paolo II - Loc. Tappino, Campobasso, ITALY; Ignazio Grattagliano, MD, Univ of Bari, Piazza Cagnola, 3/B, Casamassima, ITALY; Dario Sallustio, MD, Central Direction of Criminal Police, Ministry of Internal Affairs, Via Paolo Di Dono 149, Rome, 00142, Roberto Catanesi, MD, Univ of Bari, Section of Forensic Psychiatry, Piazza Giulio Cesare, Bari, ITALY; Nicola Ferrara, MD, Univ of Molise, Dept of Medicine and Health Sciences, Via Giovanni Paolo II - Loc Tappino, Campobasso, 86100, ITALY; Alessandro DellErba, Univ of Bari, Piazza Giulio Cesare, Bari, ITALY; Graeme Yorston, MD, Centre for Ageing and Mental Health, Staffordshire Univ, Blackheath Ln, Stafford, UNITED KINGDOM; and Carlo P. Campobasso, MD, PhD, Univ of Molise, Dept of Medicine & Health Science, via De Sanctis, snc, Campobasso, ITALY*

The goal of this presentation is to describe a case of sexual abuse perpetrated by an institutionalized patient toward a young visitor.

This presentation will impact the forensic science community by focusing on elderly sexual offenders in order to better understand the mechanisms and factors that lead to elder sexual offenses in both family and formal care settings.

Background: More commonly, older people are the victims of sexual abuse but they can be also the perpetrators. The phenomenon is complex, consisting of institutional mistreatment toward all residents or individual neglect toward a single patient. The reasons older adults commit sexual offenses, in particular against children, are still an unsolved problem that requires understanding the motivations and distinguishing between senile or pedophile. Such offenses can occur in the family as well as within the hospital, nursing home facility, or a residential care home for elderly. This case report describes an episode of sexual offense by an elderly institutionalized patient toward a young visitor.

Case Report: A 70-year-old man in a residential care home was accused of sexual abusing a 6-year-old girl who was with her mother to see the grandmother. In the late afternoon, the grandmother reported to staff members that the male resident had come to her room, promised the child some candy, and had then taken her with him to his room. Once back in her grandmother's room, the girl disclosed that the man had lowered her underwear and touched her private parts. The elderly man suffered from Parkinson's disease for several years, was first treated with dopamine agonists, then, for the appearance of long-term treatment syndrome and gambling, with atypical neuroleptics. During an interview, the child was able to mimic the abuse perpetrated, by using a doll, and by psychodiagnostic tests performed, she was found to be reliable in reporting the sexual abuse. On genital examination, no injuries were observed except for some hyperemia. The analysis of the micro-traces on her underwear gave negative results for the presence of seminal fluid but it was able to detect a DNA profile consistent with that of the elderly man. The man was found guilty and sentenced to five years in prison. A civil action was also brought against the staff of the nursing home for inadequate supervision of the resident.

Discussion: The elderly are often unrecognized victims of sexual abuse but also at risk of perpetrating abuse on vulnerable targets like children or frail elderly co-residents because of many factors associated with aging. Mental illness and cognitive disturbances (related to dementia, other neurological or iatrogenic factors), as well as a range of problems in addition to physiological or pathological sex behaviors (i.e., pedophilia) are just some of the several age-related factors that can lead to such offenders. Recently, evidence has been found linking antiparkinsonian therapy and disorders in the impulsive-compulsive spectrum including gambling and hypersexuality as well as dopamine dysregulation syndrome. A distinguishing characteristic of elderly sex offenders is that the illegal activity will usually take place in a private place, such as the home of either the offender or the victim, or in a hospital or residential care home. Because of the aging of our population, elderly sexual offenders are becoming an increasing concern to clinicians and criminal justice agencies.

Conclusions: It is important to have a fuller understanding of the factors leading to elder mistreatment and sexual offenses in both family and formal care settings. Caregivers have responsibilities to ensure the safety of dependent elders and to protect them from elder abuse and also to ensure they do not pose a risk to those they are living with and any visitors they may have. Moreover, it is necessary to better understand the motivations and psychological factors relating to elderly sex offenders, to prevent these offenses, and to define standards for surveillance of residents who are potential perpetrators.

Elderly Offenders, Nursing Home, Sexual Abuse

I36 Sex Offenders, Empathy, Aggression, and Oxytocin: A Potential Avenue for Future Exploration?

Alicia L. Bales, MD, PO Box 86125, Los Angeles, CA 90086-0125*

After attending this presentation, attendees will gain a basic knowledge of the current state of research examining effects of oxytocin on empathy and aggression. Attendees will consider the potential avenues of future research with oxytocin and sex offenders.

This presentation will impact the forensic science community and the mental health profession by suggesting that empathy deficits and aggressive behavior in sex offenders may be partially a result of oxytocin deficits in such offenders, particularly given recent research showing oxytocin's important role in increasing empathy and modulating aggression.

Intimacy deficits, cognitive distortions, and problems empathizing with victims have been factors implicated in the genesis and maintenance of sexual offending. Sexual offenders may suffer from a deficit in the ability to identify and appreciate the emotional experiences of others. Based on this framework, the development of empathy has been a central tenant in almost all sex offender treatment programs. The general principle of this emphasis is that if offenders' empathic skills can be improved, they are less likely to re-offend. Psychotherapy is the general treatment modality used to improve empathy in such offenders, but there are several challenges to this process, depending on the offender's motivation, therapist's skill, and a host of other factors. Exploring alternative ways to increase empathy in this population is warranted. If a safe and effective treatment modality can be developed to increase empathy in sex offenders, it is possible that this form of treatment may lead to a reduced risk of reoffending.

Oxytocin is currently receiving much attention from the psychiatric community, as it has been shown to play a role in bonding, attachment, peer recognition, trust, and empathy. Dubbed the "Love Drug" or the "Hormone of Love," it is a neuropeptide that is produced in the hypothalamus and released into the brain and bloodstream. Oxytocin can be given by an intranasal administration that crosses the blood brain barrier and thus has been used in several trials on humans. Several studies have focused on oxytocin's effects on empathy, as defined by the capacity to share and understand the feelings of others. For example, oxytocin has been shown to increase emotional empathy in response to both positive and negative stimuli using the Multifaceted Empathy Test. Another study found that administration of oxytocin increased mock jurors' perception of harm for the victims but did not increase the desire to punish the offenders for their criminal offenses, thus promoting the idea that oxytocin played a role in promoting emotional empathy. There is some evidence demonstrating that oxytocin may improve the accuracy of recognizing emotional state in others, particularly in individuals who would otherwise fail to make appropriate judgments based on social cues. In addition to research examining oxytocin's effects on empathy, there is evidence to show that oxytocin is an important modulator of aggression. For example, mice in which the oxytocin gene is absent from the time of conception have shown to have heightened aggressive behavior compared to normal

mice. In humans, the levels of oxytocin in cerebrospinal fluid have shown to be inversely correlated with a life history of aggression.

This presentation will review the literature regarding research on empathy deficiencies in sexual offenders and then examine the literature on oxytocin's effect on empathy and aggression. Deficits in empathy and aggressive tendencies appear to be prominent traits in sex offenders. Given this information, combined with the growing amount of evidence indicating that oxytocin may play a significant role in increasing empathy and modulating aggression, it may be hypothesized that oxytocin deficits could be one of the contributing factors involved in the genesis or maintenance of deviant behavior in sexual offenders. Based on this review of the literature to date, future research into the effects of oxytocin on empathy and aggression in sexual offenders is warranted.

Sexual Offenders, Oxytocin, Empathy

I37 False Sexual Harassment Claims in Employment Litigation: A Framework to View Internal Incentives

Alicia L. Bales, MD, PO Box 86125, Los Angeles, CA 90086-0125*

After attending this presentation, attendees will have a better understanding that some false sexual harassment allegations may arise as a result of both internal incentives and external factors motivating the plaintiff to file a claim. Attendees will understand how psychodynamic concepts such as reaction formation, displacement, projective identification, and repetition compulsion may be factors involved in cases of sexual harassment claims that ultimately may be false in nature.

This presentation will impact the forensic science community by providing a framework for the use of psychodynamic concepts to conceptualize alternative explanations for a plaintiff's perception of events and motivations behind allegations in a sexual harassment claim.

False allegations of sexual harassment in the workplace can be filed for a variety of reasons, some of which may fall into the realm of "factitious" claims. Factitious sexual harassment claims are those in which the plaintiff's wish for victim designation is a major driving force behind the claim. Factitious disorder according to the DSM-IV-TR is the *intentional* production of physical or psychological signs or symptoms with the motivation for the behavior being primarily to assume the role of one who is suffering from a medical affliction. As a corollary, factitious sexual harassment claims are those filed with the primary goal being to assume the role of a person who has been victimized in order to experience the customary social norms that surround that role.

In addition to *intentional* factors, one could hypothesize that *unconscious* internal incentives may also be factors in the development of a false sexual harassment claim. When a forensic mental health evaluator conducts an assessment of the plaintiff, both internal as well as external incentives should be explored to help identify potential motivational factors behind the claim. Being aware of potential internal and external incentives in these evaluations may be of assistance when considering alternative explanations for the plaintiff's perception of events and alternative explanations for the allegations.

This presentation proposes the use of psychodynamic principles to aid the forensic mental health evaluator in considering conscious and unconscious components that may contribute to the development of a false sexual harassment claim. For example, individuals who have a history of prior abuse may retain a sense of victimhood that is not always validated by the external world. Filing a claim of sexual harassment places the plaintiff in the role of a victim, and inhabiting this role may validate an inner experience that had been left unresolved. This may lead to a situation where the individual unconsciously seeks out another person who is in a position to potentially act as an aggressor and with whom the individual can re-enact the abusive dynamics experienced in past relationships. In these cases, the sequence of events might be hypothesized to unfold in two parts. First, the individual finds someone to re-enact a relationship where that person conforms to the role of the "aggressor" whereby the individual sees himself or herself as the "victim" of harassment. Second, when the lawsuit is filed, the plaintiff who was originally in the role of the victim can now become the "aggressor" while the defendant is now made to experience the role of being the "victim." This situation creates a dynamic that not only fits the plaintiff's internal sense of self as a victim but then goes one step further to allow the individual a chance to "master" the present and past situations by reversing roles. This is called engaging in repetition compulsion by projective identification, which is an interpersonal process whereby the individual adapts to unwelcome feelings by evoking the same feelings in another. By filing a lawsuit, the individual may cause the perceived attacker to be the person under attack, perhaps feeling humiliated, fearful, and hurt as that which the individual once experienced. The concepts of reaction formation, projective identification, displacement, misattribution, and reaction formation will be used as a framework to explore potential internal incentives operating in a plaintiff to bring about such claims.

Sexual Harassment, Factitious, Psychodynamic

I38 Cyber-Sexual Harassment and Adolescents

Simha E. Ravven, MD, Cambridge Hospital, 1493 Cambridge St, Cambridge, MA 02139; Amy Funkenstein, MD, Brown Univ, Dept of Psychiatry and Human Behavior, Box G-BH, Providence, RI 02912; and Fabian Saleh, MD, Dept of Psychiatry, Beth Israel Deaconess Medical Center, 330 Brookline Ave, Rabb 2, Boston, MA 02215*

The goals of this presentation are to: (1) understand definitions of cyber-sexual harassment; (2) learn the prevalence of adolescent Internet usage and online media as well as prevalence and effects of cyber-sexual harassment on adolescents; and, (3) become familiar with methods of risk assessment and intervention strategies to reduce cyber-sexual harassment among adolescents.

This presentation will impact the forensic science community by outlining the scope and effects of adolescent cyber-sexual harassment and suggest methods of risk assessment and intervention strategies for this important and widespread problem.

Recent attention to cases of suicide among youth victims of cyber-sexual harassment has generated interest in its prevalence, correlates, and psychological impact. While face-to-face sexual harassment is a well-known problem, understanding of the scope and implications of online or cyber-sexual harassment is emerging. Cyber-sexual harassment also is a widespread problem among youth. Adolescents have wide access to the Internet. Pew Research Center reports indicate that 93% of teens have access to the Internet and 75% have their own cell phone.[1] According to a recent survey of internet-using 10 to 15-year-olds, 33% reported online sexual harassment in the prior year, 15% reported an unwanted sexual solicitation online in the same time period, and 4% reported a sexual solicitation incident on a social networking site specifically.[2]

Cyber-bullying, generally, and cyber-sexual harassment, specifically, affect youth negatively in multiple domains. Cyber-bullying has been associated with poor school performance and psychological distress. Recent studies of cyber-harassment among middle and high school students have found that cyber-bullying is associated with poor grades in school, lower odds of planning to attend a four-year college, depressive symptoms, suicidal ideation, and self-injury as well as suicide attempts.[1,3] Being a victim of cyber-harassment was also associated with hardcore and softcore drug use and drunk driving, skipping school, and school suspension, as well as gang membership and carrying a weapon.[3] Non-heterosexually identified youth appear to be victims of cyber-bullying more frequently than heterosexually identified youth, girls more frequently than boys.[1] In offline harassment among adolescents, victimhood can predict later perpetration, or they may co-occur.[4] It is not known whether the same pattern exists in cyber-harassment or cyber-sexual harassment.

This presentation will focus on cyber-sexual harassment with respect to adolescent offenders and victims. Definitions of cyber-sexual harassment, prevalence data, and comparison with offline bullying will be discussed. Similarities and differences between offline

bullying/sexual harassment and its cyber counterpart will be considered, including whether the latter may be considered a category of sexual offending. An overview of offline sexual harassment, including landmark legal cases, will be given.

Prevalence of adolescent internet usage and online media most relevant to cyber-sexual harassment (e.g., social network sites like Twitter, Facebook, postings on YouTube, communication via email/texting) will be covered. There will also be a discussion of developmental aspects of this behavior, methodologies for assessment of risk, and intervention strategies to reduce cyber-sexual harassment among adolescents. Case studies will be used to illustrate examples.

Adolescents, Sexual Harassment, Cyber-Sexual Harassment

I39 Characteristics of Child Pornographers: A Description of a Cohort Subjected to Forensic Evaluation

Sebastien Prat, MD, and Carol Jonas, PhD, CHRU de Tours, Hospital Trousseau, Tours, FRANCE*

After attending this presentation, attendees will obtain information about child pornographers, online sex offenders, and hands-off offenders. The goal of this study is thus to identify the characteristics of people who are drawn to child pornography.

This presentation will impact the forensic science community by displaying the characteristics of an offense which increased because of the Internet. The characteristics of the classical pedophile is not what we find in child pornography.

Introduction: Child pornography is a form of sexual exploitation of children. It depicts erotic or sexual scenarios with children, either explicitly or implicitly, nurturing individuals' deviant fantasies or facilitating a move toward pedophilia. Seeking and collecting images is never a matter of chance, and the collecting process and the way the pornographer considers his collection need to be better understood. It is these psychopathological issues and the risk of the person acting out his fantasies that need to be analyzed. The use of telecommunication facilities, particularly the internet, has allowed child pornography to be distributed more widely.

Today, access to pedophilic material no longer requires direct contact between supplier and consumer. The phenomenon has increased through the use of peer-to-peer networks, which make it easier to receive images. Exchanges between collectors permit them to become part of groups that gives them a virtual social life. Some believe that downloading images does not make them criminals because they were not present at the time of the abuse. Understanding the phenomenon of child pornography is complicated, because it is sometimes a matter of deviance without leading to actual abuse, and it is this virtual aspect that appears to be encouraged by Internet. It has probably increased certain deviant behaviors that were previously limited due to inhibition.

The main question facing law enforcement agencies is the level of danger posed by child pornographers. In essence, judges need to know the likelihood that sexual abuse will occur. A number of elements indicating a risk of child sexual abuse have been identified, including participation in a virtual community, sharing images, and possession of new images, but more elements are needed for a better understanding of this problem.

Material and Method: This study was based on pre-sentencing forensic psychiatric assessments carried out at the request of the courts. The forensic psychiatric assessments have been conducted by different forensic psychiatrists in France. The main criterion for inclusion was the possession, distribution, and/or production of pornographic images of minors, and that the subjects acknowledged the charges.

Various psycho-socio-demographic elements were studied based on evidence gathered from forensic psychiatric assessments and data from the literature (e.g., sex, academic level, marital status, job, social integration, childhood, type of offense, attitude toward the offense, criminal record, addiction to images, pedophile tendency, sexuality, introspection, medical history, dominant personality traits, diagnosis, therapy).

Discussion: Child pornography is a complex phenomenon. It generally fulfills a fantasy of a pedophile nature. Different profiles of child pornographers have been proposed which help understand underlying deviant motivations, which are not always related to pedophilia. Internet offenders can be divided into those who seek online contact and those who purchase offline contacts. While the socio-demographic characteristics of these subjects have been identified, further psycho-socio-criminological elements are needed to determine the profiles in greater depth.

The sample matched the descriptions found in the literature. Subjects were almost exclusively male with an average age of forty years, which is consistent with studies that have generally reported an age range of 25 to 50 years. They appear to be younger than offline offenders. In this study, the inclusion of a 15-year-old indicates that child pornography is not just about age.

Over 80% had a diploma, and over 50% had studied at university. Half of the cases had a stable job. Overall, the data suggest that all the subjects had a sufficient level of education to pursue a career and fit into society. However, a third of the cases felt that they were not well integrated, although half of those had a stable job. Moreover, they did not consider that living with a partner was a factor of good social integration.

There is no data in the literature about the sexuality of child pornographers. Most individuals in the study were heterosexual men, and most expressed poor sexual satisfaction, although more than half lived with a partner. Most of the homosexuals in the study were single and expressed more sexual dissatisfaction than the heterosexual subjects. Living with a partner does not necessarily lead to sexual satisfaction.

Forensic Psychiatry, Child Pornography, Sex Offenders

I40 Replicating the Seigfried-Spellar and Rogers (2011) Study on Deviant Pornography Use by Age of Onset and Sex

Kathryn C. Seigfried-Spellar, PhD, Univ of Alabama, Dept of Criminal Justice, 428 Farrah Hall, Tuscaloosa, AL 35487*

After attending this presentation, attendees will have a better understanding of the relationship age of onset, sex, and pornography use. In other words, individuals who engage in adult pornography use at a younger age are at a greater risk for engaging in deviant pornography use (e.g., child porn), and whether sex is related to deviant pornography use. In addition, attendees will have a greater appreciation for the importance of empirical replication.

This presentation will impact the forensic science community by providing more information regarding the relationship between non-deviant and deviant pornography use. This study is a replication of a previous one which will extend and validate the previous conclusions of the Seigfried-Spellar and Rogers study.[1]

Although seemingly counterintuitive, research indicates the collections of child pornography users not only contain sexualized

images of children, but other genres of pornography both deviant and socially acceptable in nature.[2-3] In fact, interviews with child pornography users have suggested that some offenders move "thorough a variety of pornographies, each time accessing more extreme material" as a result of desensitization or appetite satiation, which lead to collecting and discovering other forms of deviant pornography.[2-3] Also, some consumers stated they downloaded the images simply because they were available and accessible, making the behaviors primarily a result of compulsivity rather than a specific sexual interest in children.[4]

Some child pornography consumers exhibit a complex array of sexual interests, which may be representative of a more general level of paraphilic tendencies rather than a specific sexual interest in children. In a study conducted by Endrass et al., the collection of images from 231 men charged with child pornography use also revealed other types of deviant pornography.[5] Specifically, nearly 60% of the sample collected child pornography and at least one other type of deviant pornography, such as bestiality, excrement, or sadism, with at least one out of three offenders collecting three or more types of deviant pornography.[5] This research suggests the majority of Internet child pornography users are collecting a wider range of deviant pornography, which may reflect a general level of sexual deviance rather than a specific paraphilia, such as pedophilia. In other words, some child pornography consumers may be dissidents within the normal population who exhibit a wider range of sexual interests.

The Seigfried-Spellar and Rogers sampled a panel of United States Internet respondents from the Survey Sampling International, Inc.[1] The respondents were asked their sex, age of onset for various forms of non-deviant (e.g., adult pornography) and deviant pornography (e.g., child pornography), and their level of engagement in Internet pornography (e.g., searching, downloading). Six hundred and thirty respondents completed the online survey; 33 (5%) of the sample self-reported engaging in child pornography. Results indicated that people who used adult pornography were significantly more likely to use animal and child pornography. In addition, age of onset for non-deviant pornography use (adult-only) was significantly related to deviant pornography use (child, animal). In other words, individuals who engaged in adult and deviant pornography had a significantly lower "age of onset" compared to individuals who only engaged in adult pornography.

However, this study was the first to assess whether age of onset and sex were related to deviant pornography use; thus future replications are needed to determine the validity of the findings. First, the current study will utilize a snowball sampling method by soliciting Internet respondents from various Internet websites rather than a paid panel sample of U.S. Internet users. In addition, the respondents will not only be permanent residents of the U.S. but the sample will include respondents from Canada, Australia, and United Kingdom. Again, this study will assess whether *age of onset* is a risk factor for engaging in deviant pornography. In other words, are individuals who engage in nondeviant pornography use at an earlier age more likely to engage in deviant forms of pornography use compared to late onset users? In addition, this study will explore the frequency of pornography use by collapsing the respondents into pornography categories: none, adult-only, animal-only, child-only, adult-animal, adult-child, animal-child, and adult-child-animal. This aim will assess whether self-reported child pornography users are more likely to self-report adult and animal pornography behaviors compared to the other categories of users.

Finally, a comparison in results will be made to the original Seigfried-Spellar and Rogers study to determine the validity of inferences drawn from the original findings.[1] A detailed discussion of the study's results and future implications will be discussed.

Deviant Pornography, Age, Sex

I41 Use of Clinical Mental Health Professionals in Transition Adjustment Programs for OEF/OIF Veterans as New Police Officer Recruits

Lauren McClean, MA, and JoJo Lee, MA*, Univ of San Diego, 5998 Alcala Park, SOLES-CMHC, San Diego, CA; and Ronn Johnson, PhD*, 3525 Del Mar Heights Rd, No 302, San Diego, CA 91230*

The goals of this presentation are to: (1) provide a cognitive structure that explains how this kind of project is expected to contribute to the reframing and reorganization of police officer's ability to receive information relevant to stressful transition associated with the new civilian department; (2) communicate findings that will suggest important implications for mental health transition services specifically-related to Operation Enduring Freedom/Operation Iraqi Freedom (OEF/OIF) veterans; and, (3) create a foundation for additional research on this topic.

This presentation will impact the forensic science community by describing the clinical mental health student component of a military-police cultural transition model being implemented in a large west coast police department.

There are potential negligent hire and retention risks associated with OEF/OIF veterans as new police officers. For some police departments, there has been tremendous growth (i.e., anywhere from 30 to 50 percent) in the proportion of these veterans moving into civilian police ranks. While their presence is welcomed, it has also focused increased attention on concerns about post-deployment Mild Traumatic Brain Injury (mTBI) and Posttraumatic Stress Disorder (PTSD). For example, PTSD has a predictable unwanted effect on the life course of veterans that is marked by both physical and psychological issues. A problem made worse by the presence of other psychological conditions that include the combined effects of dysphoria, as well as mTBI. Alcohol and other forms of substance abuse are also a part of the clinical picture of these veterans who are probably at a higher risk for premature departure from the military and quite vulnerable as new police recruits.

The OEF/OIF veteran clinical problems mentioned above are oftentimes inextricably linked to other sources of psychosocial stress. For example, financial pressures can occur from having psychological disorders like PTSD or other mood disorders. Most notably, they can create money-management problems, a situation made even worse if this OEF/OIF veteran had pre-existing problems managing their financial affairs. Pre-employment physicals and psychological screenings may not capture the full scope of the issues presented by these veterans. Fueled by budget cutbacks due to a declining economy, police departments are forging university partnerships with faculty that have experience in police psychology. Successful transition from the military to civilian life is important. Equally important are the transitions required from the military to police culture. The transitions from military to civilian life are exacerbated by the stress of trying to secure a job, family stress, and other financial pressures from a depressed economy. A new career as a police officer sounds like a relief, but may in many respects represent another stress on an OEF/OIF veteran who has already

carried the burden of post-deployment stress. Moving from the stress from military service, to the stress of post-military life, and then into the stress from the police world which may further compromise an already distressed OEF/OIF veteran. Some departments are fully aware of these OEF/OIF issues and have implemented resources intentionally aimed at the issues that they present as new police recruits.

The first learning objective of this presentation is to explain a cognitively-oriented approach for this OEF/OIF veteran group. This approach explains how this kind of OEF/OIF veteran-police recruit project is expected to contribute to the reframing and reorganization of police officer's ability to receive information relevant to stressful transitions associated with the new civilian department. The second learning objective is to communicate findings that will suggest important implications for mental health transition services specifically-related to OEF/OIF veterans. The third objective is to create a foundation for additional research on this topic. This presentation describes the clinical mental health student component of a military-police cultural transition model being implemented in a large west coast police department. The community benefits by decisions made to create resources that support OEF/OIF involved in civilian public safety.

OEF/OIF Veterans, Military Transition, Police Officer Recruits

I42 Collaborations Between Clinical Mental Health and Police Wellness Units: A San Diego Police Department Project

Ronn Johnson, PhD, 3525 Del Mar Heights Rd, No 302, San Diego, CA 91230; and Nick Boyd, MA*, Linh Tran, MA*, and Chris Wehrle, MA*, Univ of San Diego, SOLES-CMHC, 5998 Alcala Park, San Diego, CA 92110*

After attending this presentation, attendees will be made aware of the need to extend the support network by forging relationships with university-based mental health professionals with expertise in police psychology. At the same time, wellness unit staff must remain sensitive to the process of orienting new police officers. For example, what is not as well-known is that new police officers are probably more receptive to using department support resources early in their career as opposed to after they have been absorbed into the police culture. Attendees will also be briefed on the Peace Officer Standards of Training's (POST) psychological dimensions as an evidence-based anchoring base for mental health professionals to use while making the risk-assessment rating. A practice-relevant forensic case study is used to demonstrate how the POST psychological dimensions can be used in this risk-assessment process. It is hypothesized that attendees from this presentation will have a greater understanding of the forensic elements associated with use of the psychological dimensions of police officer functioning.

This presentation will impact the forensic science community by providing knowledge of the enhanced performance of police officers who make use of the combined resources offered through the wellness unit.

Collaborations between qualified university-based clinical mental health professionals and police wellness units offer a reasonable approach to dealing with risks (e.g., death, PTSD, suicidal behavior) police officer psychological work. Police officers have the most stressful job of any occupation. Risk assessments in the context of police work refers to the identification and psychological weighing of potential factors that are expected to compromise judgment or increase concern about stress vulnerability that can fuel misconduct. Despite the obvious need for services and available department resources, wellness units must reflexively work to achieve delicate cultural balance. The balancing act is required for negotiating the meandering contours of a police culture. The police culture includes an instinctive tendency for a male-dominated culture to avoid any revelation of what they assess as a weakness, especially those highlighted by mental health. Second, police unions are extremely leery (i.e., anonymity, fears of department, retribution, or any potential police officer negative outcomes) of any department resource (e.g., EAPs, chaplains, or senior officer mentors) that brings their members under scrutiny where they might be perceived vulnerable for being singled out. Third, the wellness unit is saddled with an onerous task of finding creative ways to assist police officers who they know are struggling with a wide range of issues. Finally, department budget cutbacks have resulted in loss of critical professional staff with the requisite expertise in responding to the stress-based concerns present by police officers.

The complexity of these police wellness issues underscores the diversity of public safety challenges. Most of these challenges on the surface appear rather obvious as to what may be required to intervene. Yet, with considerably more understanding of the dynamics of police culture, it becomes clear that gaining access to assist must be done with a unique or tailored model for a specific police department. For example, law enforcement agencies have distinct cultures (e.g., U.S. Border Patrol versus Boston Police Department) that must be first properly assessed in order to gain access for intervention. The hallmark of this work must first demonstrate the feasibility of working with the male-dominated culture posed by an otherwise hard-to-reach police population. This process is expected to be aided by understanding the beliefs and behaviors necessary for developing appropriate risk prevention and intervention programs in a department. University clinical mental health faculty with experience in working with police and public safety can be quite productive in crafting such collaborations assuming 100% buy-in (i.e., top-down cultural change) by the chief or superintendent.

In the aftermath of a high profile police misconduct incident, once the incident details are disclosed, it becomes clear that there are matters that should have previously raised red flags for the department. Police suicides are also devastating to the morale of other officers. The financial costs to departments and municipalities for a police officer's improper action reinforce the need to reduce the law suit risks where negligent hire can erode public trust. Insurance rates are also expected to rise in the wake of such cases. There are three learning objectives associated with this presentation. First, attendees are made aware of the need to extend the support network by forging relationships with university-based mental health professionals with expertise in police psychology. At the same time, wellness unit staff must remain sensitive to the process of orienting new police officers. For example, what is not as well-known is that new police officers are probably more receptive to using department support resources earlier in their career as opposed to after they have been absorbed into the police culture. The second learning objective of the presentation uses the POST's psychological dimensions as an evidence-based anchoring base for mental health professionals to use while making the risk assessment rating. The author uses a practice-relevant forensic case study to demonstrate how the POST psychological dimensions can be used in this risk assessment process. This presentation articulates a model of collaboration between university-based clinical mental health and police departments. The authors hypothesize that attendees from this presentation will have a greater understanding of the forensic elements associated with the use of the psychological dimensions of police officer functioning. The community is expected to gain from the enhanced performance of police officers who make use of the combined resources offered through the wellness unit.

Collaborations, Mental Health, San Diego Police

J1 Determination of the Age of Ink Entries From Questioned Documents With TD-GC/MS and HPLC Methods

Salih Cengiz, PhD, Istanbul Univ, Adli Bilimler Enstitüsü, Cerrahpasa Tip Fakultesi, Istanbul, 34300, TURKEY; Dilek Salkim Islek, MSc, Istanbul Univ, Institute of Forensic Sciences and Medicine, Cerrahpasa Kampus, Fatih, Istanbul, 34303, TURKEY; and Beril Anilanmert, PhD, Istanbul Univ, Adli Bilimler Enstitüsü, Cerrahpasa Tip Fakultesi, Istanbul, 34303, TURKEY*

After attending this presentation, attendees will learn how an ink entry on a questioned document is related with entrry date.

This presentation will impact the forensic science community by demonstrating how ink age determination can be accomplished using the dynamic physicochemical properties of the ink entries on a document.

Determination of the age of an ink entry from a questioned document is a difficult and controversial issue in forensic science. Lately, the studies of ink age determination done from the dynamic properties of the ink entries have shown that the phenoxy ethanol, which is one of the solvents in ink, has different behavior against the varying thermal conditions by Thermal Desorption and Gas Chromatography/Mass Spectrometry (TD-GC/MS) during methyl losses of the pigments and presents a valuable confirmatory evidence of age using High-Performance Liquid Chromatography (HPLC).[1]

The goal of this study is the enhancement of the ink age determination methods using dynamic physicochemical properties of the ink entries on a document such as the vanishing rate of phenoxy ethanol (PE) with TD-GC/MS that is used in traditional analyses of volatile organic components and the fading rate of the pigments Crystal Violet (CV), Methyl Violet (MV), Tetramethyl Para Rosaniline (TPR), and other changes in pigment constitution.

For comparison of thermal desorption properties, the sample cut in 0.5cm in length, was placed in a completely empty and clean thermal desorber tube. The sample was analyzed in two different runs for different temperatures: 90°C and 200°C.[2] The sample was desorbed for 20 minutes at 90°C. Then the sample was trapped at -10°C. The temperature of trap was increased to 300°C. The sample was held approximately three minutes then it was given into GC. Temperature of the transfer line was 140°C. The DB-VRX column used was 60m long and had an internal diameter of 0.25mm and film thickness of 1.4 µm. The oven temperature was programmed as follows; 45°C for one min, then from 45°C to 100°C at a rate of 30°C/min and from 100°C to 190°C at a rate of 12°C/min. It was held at 190°C for four minutes then increased to 200°C at a rate of 50°C/min and held for five minutes. To ensure better quantitative accuracy, the Selected Ion Monitoring (SIM) mode was employed, due to its higher sensitivity. The chosen quantifier ion m/z is 138,10 and qualifier ion 94,0. The same sample was desorbed for five minutes at 200°C. The system conditions chosen for 200°C was the same as the one chosen for 90°C. The age of ink entry was calculated by the help of the relation between the integration values at 90°C and 200°C (M_{90}, M_{200}).

For the comparison of the time dependent methyl losses of the ink pigments on the same documents, two 1.2mm punches were extracted by methanol for 15 minutes and than 10 micro liters of extract were injected to the HPLC. The chromatograms of the questioned inks were compared to find age differences in between.

By the present methods proposed, as a result of one year work and approximately 300–350 experiments the aging curve of ink (V%) was plotted and the feasibility of ink age determination in the laboratory clear. The HPLC chromatograms have been used for prediction and/or confirmation. Two examples of the use of the proposed method in caseworks is given.[2,3]

Ink Age, HPLC, TD-GC/MS

J2 The Use of Attenuated Total Reflectance Fourier Transform Infrared Spectrometry (ATR-FTIR) in the Analysis of Paper

Sheila Kwong, BA, 2100 I Street NW, Room 507A, Washington, DC 20052; and Walter F. Rowe, PhD, George Washington University, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the potential for the use of the Attenuated Total Reflectance Fourier Transform Infrared Spectrometry (ATR-FTIR) spectrometer in the field of forensic science in discriminating different brands of white multi-use and copier paper. Attendees will also understand the use of principal component analysis (PCA), hierarchal cluster analysis (HCA), and discriminant analysis (DA) in analyzing infrared spectra.

This presentation will impact the forensic science community by introducing questioned document examiners and other forensic scientists to the power of ART-FTIR combined with multivariate statistical methods such as principal component analysis and linear discriminant analysis.

Determining the sources of sheets of paper can facilitate in cases involving fraudulent documents, threatening letters, ransom notes, and other cases of questioned documents. A number of methods have been applied to the analysis and comparison of paper samples, including transmitted light imaging, laser speckle imaging, light microscopy, scanning electron microscopy, X-ray diffraction, pyrolysis-gas chromatography, Raman spectroscopy, ultraviolet-visible-near infrared spectrometry, FTIR, and ATR-FTIR. Some of these methods require the destruction or significant alteration of the sample examined. Some of the methods are also lengthy and time-consuming. ATR-FTIR has many attributes that commend its use for the analysis of paper: it is non-destructive; it can analyze small areas (thus avoiding areas of paper which bear printing or writing); it requires virtually no sample preparation; and, it is very fast (individual spectra being obtained in under one minute). Moreover, ATR-FTIR instruments are becoming more widely available in forensic science laboratories.

ATR-FTIR has been applied in the past to paper pulps and to a limited number of finished papers. This study involved the analysis of ten reams of white multi-use and copier paper, representing seven different brands. The brands of paper were ones that are widely available in office supply stores, big-box department stores, and online. These brands are those that would be encountered in many offices and homes, in use as computer printer paper, copy paper, or stationery. Such papers consist of cellulose, often with fillers such as calcium carbonate, sizing agents such as starch, and optical brighteners (fluorescent compounds that contribute to the whiteness of sheets of

paper). All of these components have infrared absorptions in the range 600cm^{-1} to 4000cm^{-1}. Samples taken from each ream included the top five, middle five, and bottom five sheets. Each paper sample was pressed against the ATR crystal of the FTIR spectrometer and a spectrum was scanned. The spectra obtained from this procedure were then converted to/from percent transmittance units and absorbance units. Only the infrared region from 600cm^{-1} to 1800cm^{-1} showed significant absorption peaks; therefore, only this region was analyzed further. Some of the infrared spectra displayed anomalous baseline offsets. To deal with these, all of the spectra in the 600cm^{-1} to 1800cm^{-1} range were smoothed and then converted to first derivative spectra using the Savitsky-Golay method. The first derivative spectra from 604cm^{-1} to 1300cm^{-1} were analyzed using principal component analysis (PCA), hierarchal cluster analysis (HCA), and discriminant analysis (DA). Features of interest in the first derivative spectra were confined to this spectral range.

It was observed that there the infrared spectra displayed a high degree of consistency within a ream of paper. In PCA eight factors were required to account for more than 90% of the variance in the data. The factor plot of the first two extracted factors indicated that the ten reams of paper could be placed in four groups: a group of seven and three groups of one each. DA using the first eight extracted factors and these four groups resulted in 94.3% correct classification of the infrared spectra and 93.8% correct classification on cross-validation. Two paper brands could be differentiated from the others and two different grades of paper belonging to the same brand could be differentiated from each other. While ATR-FTIR proved not be highly discriminating among paper brands, the simplicity of the technique, its non-destructive nature, and the increasing availability of ATR-FTIR instruments make this technique a useful addition to the methods of paper analysis.

Paper, FTIR, Chemometrics

J3 The Forensic Language-Independent Analysis System for Handwriting Identification (FLASH ID)

Gabriel D. Watts, BA, FBI, Questioned Documents Unit, Rm 2160, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will have an understanding of the purpose and capabilities of FLASH ID.

This presentation will impact the forensic science community by providing information on a new system that can facilitate research on handwriting examinations and expedite handwriting comparisons involving voluminous evidence.

The Forensic Language-Independent Analysis System for Handwriting Identification (FLASH ID) is an automated handwriting comparison system that allows document examiners to compare voluminous pages of handwriting in a fraction of the time it would take using conventional manual methods. FLASH ID uses graph theory to measure topographic and geometric characteristics in handwriting and generates a confidence score that is used to rank suspect writers (similar to the Automated Fingerprint Identification System). This ranking is then utilized by document examiners to narrow down the list of potential authors of the questioned writing, thereby potentially eliminating the need to compare the writing of every writer in a given database. This software could prove useful for cases similar to the Weinberger kidnapping of 1956, whereby it took a team of people over six weeks to examine nearly two million pages of handwritten public records before identifying Angelo John LaMarca as the writer of the ransom notes. FLASH ID "sees" writing as graphemes, not characters, and therefore can conduct comparisons on any language. Operating FLASH ID begins by either scanning a document in or selecting one from a file for comparison against a pre-loaded database. Once the metadata for the selected document has been entered, the user selects one or multiple databases for the document to be compared. Depending on the size of the database(s) and the performance of the computer, this could take anywhere from 30 seconds to hours. After the comparisons are complete, the ranked results are displayed along the right margin, and the user can double click on any of the documents for side-by-side view. Other select features of the FLASH ID user interface include the ability for users to select regions of interest for comparison, load multiple documents at one time for comparison (bulk load), and view the "heat map" of a document, which color-codes the strongest areas of similarity between the questioned and known writing. Current challenges include successfully extracting "clean" handwriting from a document for comparison. This is currently accomplished using over-the-counter image processing software; however, FLASH ID provides a "line removal" tool that eliminates concentric lines typically found on ruled notebook paper. Preprocessing of document ensures that scores are based on the comparison of handwriting and not extraneous markings or background noise on the page. Another challenge is interpreting meaning from the confidence scores. If a document scores relatively higher than the next closest score, then this can be interpreted that there is a significant amount of distinction. However, because each comparison depends on the quantity and style of handwriting, the scores cannot yet be used to establish a unilateral threshold for identity versus non-identity of handwriting. For the field of document examination, FLASH ID is a significant step toward the quantification of handwriting comparisons, and can be an invaluable tool for further research and validation of the principles of handwriting identification. For the forensic document examiner, FLASH ID has the potential to facilitate expeditious examinations of voluminous evidence, and may some day be used for objective verification of conclusions.

FLASH ID, Handwriting, Handwriting Analysis

J4 Stone Paper: An Overview of its Characteristics and the Impact They May Have on Forensic Document Examinations

Haley A. Elliott, MFS, and Lisa Stadmeyer, MSFS, Forensic Laboratory Services, 22433 Randolph Dr, Dulles, VA 20104-1000*

After attending this presentation, attendees will become familiar with a few of the stone papers (FiberStone®, Gartner®, Oxford®, TerraSkin®, ViaStone™) available on the commercial and retail markets for purchase. Attendees will understand the limitations involved in stone paper exams as well as what modifications may be needed when conducting certain questioned document examinations. These examinations include: indented impressions, typewriting, non-destructive ink (writing instruments, toner and inkjet printing) examination, tearing, folding, and stapling. The information gleaned from the latter three studies may be useful in alteration cases. An overview of water and grease interaction with inks on the stone paper, as well as the effect of environmental exposure on stone paper, is also discussed.

This presentation will impact the forensic science community by increasing the depth of knowledge regarding stone paper, a relatively new product available for purchase that may eventually appear in casework. Stone paper's general characteristics and modifications or work-arounds that are needed during questioned document examinations will be discussed. The goal is that this presentation will encourage members of other disciplines to develop their own studies regarding whether or not special considerations need to be taken for cases involving stone paper.

Stone paper (FiberStone®, Gartner®, Oxford®, TerraSkin®, ViaStone™) is comprised mainly of calcium carbonate and plasticizers. Unlike pulp paper, it is manufactured without large amounts of water and chemicals. Due to its unique composition and manufacturing process, stone paper manufacturers claim it is: more environmentally friendly than traditional pulp paper, 100% recyclable, water, grease, and tear resistant, and bio-degradable. Stone paper has been commercially available for ten years and is used by the packaging and marketing industries as gift bags, boxes, labels, and other wrapping materials. Many of these stone paper products are touted as being "greener" and, therefore, are used by a few environmentally conscious companies

whose products can be found on store shelves. In the past three years, stone paper has become increasingly available in household consumer-use products, including notebooks and inkjet photo paper, which are available at various office supply, novelty, and "big box" stores, among other sources. For this study, supplies were obtained through manufacturer donations and purchase. As stone paper becomes more available, the forensic community will likely encounter stone paper in casework.

This study seeks to introduce and educate the forensic document community and the forensic science community at large, about stone paper characteristics, evaluate some of the manufacturers claims outlined above, and describe special considerations that must be taken during forensic document examinations involving stone paper. Actions and associated examinations undertaken include: indented impressions, typewriting, non-destructive ink (writing instruments, toner and inkjet printing) examination, tearing, folding and stapling, water and grease interaction, and environmental exposure. Results of the current study will show that examination of stone paper can be conducted in a manner similar to traditional pulp paper, with a few exceptions regarding indented impression examinations and fracture matching.

Stone Paper, Paper Examination, ViaStone™

J5 The Case of Different Documents and Different Conclusions

Ted M. Burkes, BS, FBI Laboratory, 2501 Investigation Pkwy, Rm 2174, Quantico, VA 22135; and Ronald N. Morris, BS*, 307 Springhill Cir, PO Box 905, Bedford, VA 24523*

The goal of this presentation is to show why the reports of two different Forensic Document Examiners (FDEs) cannot be compared if they did not examine the same exact writings.

This presentation will impact the forensic science community by demonstrating how the examination and comparison of different writings on purportedly the same documents can lead to different conclusions. This is especially true when one set of the questioned documents was fabricated using the second set of documents, eventually examined by another laboratory, as the models for the creation of the first self-serving set of documents.

This case originated when Dennis "Chip" Harrup's company, Central Virginia Aviation, sold an aircraft and led the buyer to believe that the annual airworthiness inspection had been completed. Upon delivery, the aircraft did not contain the FAA mandated aircraft maintenance records. Mr. Harrup assured the buyer that the airworthiness inspection had been done. The FAA requested Mr. Harrup send them the maintenance paperwork on the airplane. Mr. Harrup sent five forms to an FAA inspector in Memphis and the inspector made copies of those forms (unknown to Mr. Harrup) before returning them.

Later, the FAA again requested the forms from Mr. Harrup, who sent the FAA photocopies of the documents, claiming that the originals had been lost. The second set of forms sent to the FAA contained signatures different from those on the original forms. The signatures on both sets of documents sent to the FAA were in the name of Tracey Helvey, the mechanic who purportedly performed the work on the airplane.

The FAA submitted the first set of photocopies, made by the Memphis FAA Inspector, along with undictated (collected) signatures of Mr. Harrup and Mr. Helvey, to the FBI Laboratory for a handwriting comparison. After conducting the handwriting examinations, he issued an opinion that no conclusion could be reached regarding Mr. Harrup preparing the questioned signatures due to the very limited amount of comparable known writing submitted for examination. The FDE also issued an opinion that there were limited characteristics to indicate Mr. Helvey may not have prepared the questioned signatures imaged on the submitted questioned documents.

Upon receiving the forensic document examiners report, the FAA contacted the FBI Laboratory and requested assistance in obtaining exemplars from Mr. Harrup. The FDE traveled to Richmond, Virginia and briefed the FAA personnel on what type of exemplars to obtain, how to obtain them, and to not let Mr. Harrup see the questioned writing before or during the collection of the exemplars. The FAA collected over forty exemplars from Mr. Harrup. They also collected over 40 exemplars from Mr. Helvey on a separate occasion.

The exemplars from Mr. Harrup and Mr. Helvey were then submitted to the FBI Laboratory for another handwriting comparison to the first set of photocopies of the questioned documents. After conducting this examination, the FDE issued an opinion that there were significant characteristics in common between the image of the questioned signatures and the known writing of Mr. Harrup, indicating that Mr. Harrup may have prepared the questioned writing. Additionally, characteristics were observed to indicate that Mr. Helvey may not have prepared the signatures imaged on the questioned documents.

The attorney for Mr. Harrup contacted a second FDE about examining some documents in the case. The documents submitted initially were photocopies of marginal quality. The questioned signatures were nothing more than a sawtooth style of writing with virtually no significant characteristics, qualities, and features. Additionally, each submitted questioned document consisted of the signature portion of two different documents. The known writings consisted of both copies and originals by two different writers.

The examination and comparison of the writings was significantly influenced by the quality of the copies of the questioned writing. Portions of the pre-drawn baseline and questioned signatures appeared to be missing. Additionally, the spelling of the name of the signer printed below the pre-drawn baseline was different than the spelling of the name of the submitted known writer by that name. The reason for their absence could not be accurately determined with the available copies. One of the factors considered was alteration of the writing; another was the generation of the copies.

The result of the examination and comparison of the questioned and known signatures was inconclusive. No evidence of significance was noted to indicate that either of the known writers wrote the questioned signatures.

Later, a second submission of five questioned documents was received for comparison to these new questioned signatures. The examination and comparison of the questioned signature on these resulted in the conclusion that Mr. Harrup probably wrote the questioned "Tracy Helvey" signature on those documents. A verbal conclusion was reported to the attorney and he did not want a written report.

This case describes the pitfalls associated with the examination of copies of unknown generation, evidence on some copies that could be associated with more than one possible explanation for its occurrence, and some of the reasons for two forensic document examiners reaching what some could say are different conclusions. In every case where documents are examined and a report is written, only reports based on exactly the same evidence can be compared with each other. If both forensic document examiners are reviewing some of the same documents together with different documents, it cannot be expected that the conclusion reached will be identical. If both forensic document examiners are examining exactly the same documents, they should come to virtually the same conclusion, based on the evidence within the writings examined.

Handwriting, Documents, Conclusions

J6 The Forensic Examination of Non-Original Documents and Images: Is It Reliable to Make Conclusions About the Printing Process and the Type of Ink Used to Create the Original Document?

Gerald M. LaPorte, MSFS, National Institute of Justice, Office of Inv & Forensic Science, 810 Seventh St, NW, Washington, DC 20531*

The goals of this presentation are to: (1) determine if a Forensic Document Examiner (FDE) can reliably make conclusions about the printing process and the type of ink used to create the original document when presented with copies and image files; and, (2) determine what impact file format and resolution have on text-based documents.

This research will impact the forensic science community by providing more information about non-handwriting features that can be assessed from a non-orginal document.

Sometimes, a FDE is provided with copies and/or digital images of an original document that may not be available for examination. There have been extensive discussions in the literature regarding possible limitations when conducting examinations to determine authorship, but very little focus on non-handwriting features such as printing processes and ink type. Specifically, copies, low quality, or monochrome images, and Portable Document Format (PDF) documents are often discounted as insufficient if information is requested about the creation of the original document. Images of text-based documents may be submitted for examination and can be captured in various formats (e.g., PDF, GIFF, TIF, JPG, BMP) at different resolutions. The objective of this study is to determine if an FDE can reliably make conclusions about the printing process and the type of ink used to create the original document. Moreover, what impact does file format and resolution have on text-based documents.

A series of documents were created using various types of laser printers, photocopiers, and inkjet printers bearing ballpoint inks, roller ball pens, gel pens, and felt tip writing instruments. From the original images, copies and scans were produced using various file formats and resolutions. Physical characteristics of the copies and images were evaluated visually and using stereomicroscopy to determine if there were any gross morphological differences in the printing processes and writing inks. Finally, the documents created using the various file formats were compared to ascertain features that should be considered when rendering a conclusion.

The production of digital images and PDF documents in the course of forensic document examinations is becoming more common due to electronic storage of documents. Indeed, there is information that can be obtained from a computer forensic examination, but information about printing processes and writing inks used for the original document is in the prevue of an FDE. Depending on the circumstances in a case, the evidence that can be gleaned from this type of examination can be extremely probative.

Non-Orignal Document, Ink, Copies

J7 Role of Automation in the Forensic Examination of Handwritten Items

Sargur Srihari, PhD, CEDAR, Univ of Buffalo, 520 Lee Entrance, Ste 202 UB Commons, Buffalo, NY 14228; and Kirsten A. Singer, MFS, Dept of Veterans Affairs, OIG, Office of Investigation, 51L, 801 Eye St NW, Washington, DC 20001*

After attending this presentation, attendees will be updated on the research on automation of examination procedures.

This presentation will impact the forensic science community by providing the status of research regarding automation of a forensic handwriting analysis.

The most common task in Forensic Document Examination (FDE) is the examination of handwritten items. Procedures for handwriting examination developed by the FDE community have been refined over several decades, and described among several standards published by the American Society for Testing and Materials (ASTM). During the last few years, the artificial intelligence community has also developed several software automation tools for FDE. Some of these tools attempt to replicate human FDE procedures, e.g., for determining whether a given handwriting specimen can be attributed to the writer of the known writing. As with expert systems in other manually intensive procedures, such as medical diagnosis, current automation tools are useful only as part of the overall procedure. Incorporating the computational approach within the standard FDE procedure not only places these tools in context but also helps validate and improve existing manual procedures. The standard work flow in FDE of handwritten items is considered and the steps where automation is available or possible is annotated. In this instance, the well-known Lindbergh kidnapping case is considered. The case involved multiple, handwritten ransom notes which were tested for the presence of multiple writers on the same, and all, documents; determining whether the writing is disguised; consideration of the effect of comparing formally-written known writing with informally-written questioned writing, etc.

The necessary groundwork has already been laid down with the ASTM document Standard Guide for Examination of Handwritten Items which lists steps that forensic document examiners follow when examining and comparing bodies of writing. Hereinafter, this will be referred to as the standard procedure, as it represents the knowledge engineering necessary for an expert system. For the validation purpose, the standard procedure has been vetted and accepted by the FDE community. When following the standard procedure, the examiner often needs to make several decisions, since every case has special needs, e.g., ransom notes could be written by multiple writers, thus requiring comparison of document sub-parts; with historical manuscripts; different writers may be more similar to each other than with contemporary writers; thus requiring recalibration of individualizing characteristics; and, there is always the potential for disguised writing. The standard procedure will be described and steps will be annotated where existing and future computational tools are useful. The well-known Lindbergh ransom note case was chosen as it is familiar to the forensic community, and illustrates the range of problems to be considered, including extended writing, addressed envelopes, disguise, poor quality images, writer training, and, finally, expression of an opinion.

The CEDAR-FOX system is an interactive tool for FDEs which assists in performing several steps of the standard procedure. First the questioned and known documents are scanned, then several interactive tools are available for preparing the document for processing, which would assist in isolating particular words, reducing image noise, and removing unwanted artifacts. The standard FDE procedure for handwriting can then be cast in computational terms, and used to systematize and validate expert human procedures. Automation tools are available to perform many of the steps. The findings for the particular ransom note case using the tools are given. Observations are made for developing a more fully automated approach to FDE.

Handwriting, Automation, Computer

J8 Judicial Decision Making on the Admissibility of Forensic Document Examination Testimony: A Twenty-Year Review

Melissa Pickett, Cierra I. Alexander*, and TaJa Sneed*, Kentucky State Univ, 400 E Main St, Frankfort, KY 40601; Victoria Springer, MA, Univ of Nevada, Reno, Grant Sawyer Ctr for Justice Studies, MS 313, Reno, NV 89557; and Mara L. Merlino, PhD, Dept of Psychology, Kentucky State Univ, 400 E Main St, Frankfort, KY 40601*

After attending this presentation, attendees will have an understanding of how judges have treated challenges to proffers of expert testimony in which the admissibility of forensic document examination during the twenty years following the U.S. Supreme Court decisions *Daubert vs. Merrell Dow Pharmaceuticals, Inc. (509 U.S. 580, 1992), General Electric Co. vs. Joiner (522 U.S. 136, 1997),* and *Kumho Tire Co., Ltd. vs. Carmichael (199 S.Ct. 1167, 1999)*. Attendees will gain an understanding of how judges have interpreted the requirements of these decisions and their impact on the field of forensic document examination as described by fellow document examiners.

This presentation will impact the forensice science community by offering an understanding of how judges evaluate the admissibility proffers of forensic document examination under the guidelines established by *Daubert, Joiner, Kumho*, Federal Rule of Evidence 702, and subsequent case precedents.

Judges' interpretations of their gatekeeping responsibilities under the *Daubert* trilogy have imposed more objective, stringent requirements (relevancy, legal sufficiency, and reliability) for the admissibility of some kinds of evidence which for 70 years had been considered admissible under the *Frye* decision's general acceptance standard, while other

kinds of evidence have remained relatively unaffected by the *Daubert* trilogy. Confronted with challenges to the admissibility of evidence from their various fields, forensic practitioners have responded to the questions about the reliability of their testimony by seeking ways to both improve their disciplines and demonstrate to judges, attorneys, academicians, and fellow experts that their underlying assumptions, methods, and conclusions meet the requirements of the *Daubert* trilogy. This discourse among practitioners, judges, attorneys, law professors, and evidence scholars about how the admissibility of expert testimony from the forensic fields should be determined illustrates an issue relevant to all expert testimony.[1]

A summary of findings from an empirical content analysis of published judicial decisions concerning cases in which forensic document evidence was challenged following the 1993 *Daubert* decision will be presented. The purpose of this study of case law was to empirically examine patterns of cases and the variety of factors that judges discuss when describing the reasons for their admissibility decisions.

Criminal and civil cases containing codeable proffers in which the admissibility of forensic document examination was challenged were identified. The forensic document examination proffers were divided into two groups according to whether the case was decided before or after the *Kumho* decision, investigated whether there were any differences in judges' discussions of admissibility in terms of various rules of evidence. Significant differences pre- and post-*Kumho* in the number of mentions of the reliability of the basis of the testimony, the reliability of the principle or method upon which the evidence was based, falsifiability, error rate, and peer review and publication were found.

Bivariate correlations revealed significant relationships between the number of evidence characteristics mentioned by judges and the length of time post-*Daubert* that the decision was handed down. The number of evidence characteristics judges discussed increased as the length of time post-*Daubert* increased (a significant positive correlation).

The data available in this sample suggest that judges differentially focus on characteristics of the experts and the evidence depending on the type of case. Judges in civil cases who discussed forensic document evidence discussed a greater number of both expert characteristics and evidence characteristics than judges in criminal cases. The impact of *Daubert* on the field of forensic document examination from the point of view of two experts, and the steps which have been taken by forensic document examiners to meet the requirements of the *Daubert* trilogy will be discussed. The empirical data and the discussion by forensic professionals in the context of the sociology of science, and a discusstion of how the tenets of this sociological perspective are demonstrated in the discourse surrounding the social construction of evidentiary reliability and the admissibility of forensic expert testimony is examined.

Document Examination, Admissibility, Judicial Decisions

J9 U.S. Questioned Document Examiners: A Nationwide Survey of Background, Education, Training, and Experience

Victoria A. Springer, MA, Univ of Nevada, Reno, Grant Sawyer Ctr for Justice Studies, MS 313, Reno, NV 89523; Veronica B. Dahir, PhD, Univ of Nevada, Reno, Center for Research Design and Analysis, 1664 N Virginia St, Reno, NV 89557; and Mara L. Merlino, PhD, and Tierra M. Freeman, PhD, Kentucky State Univ, Dept of Psychology, 400 E Main St, Frankfort, KY 40601*

After attending this presentation, attendees will become knowledgeable of the typical background that is characteristic of forensic document examiners currently practicing in the U.S., including educational attainment, training, certification, experience, and other aspects of their professional preparation.

This presentation will impact the forensic science community by presenting a snapshot of background training, experience, and qualifications of forensic document examiners that are currently practicing in the U.S. This includes their perception of the strengths and weaknesses in training, based on their response to open-ended questions presented in the survey. This is informative for those still in training and helpful for those who offer continuing education or training courses for document examiners.

This presentation presents the findings from Phase I of a national study of forensic document examiners, sponsored by the National Institute of Justice (NIJ). The purpose of the study is to inform and expand the extant empirical research on forensic document examiner expertise in signature analysis. In Phase I, Forensic Document Examiners (FDE) from across the United States participated in a multi-mode (phone and web) survey to gather background information from the professional examiners and their opinions regarding the strengths and weaknesses of education and training in forensic document examination. This presentation presents a summary of the survey results (e.g., background and education) including a thematic analysis of their views on training programs.

The sampling frame was derived from the contact information on file with various regional and national professional organizations in which participant FDEs are members. Examiners who participated in this study were currently employed in the United States, over the age of 18, and English-speaking. Potential participants received an advanced letter describing the purpose of the study at the mailing address on file with the professional organization. Two weeks after they received an advanced letter, phone interviewers at the Center for Research Design and Analysis at the University of Nevada, Reno (UNR), in collaboration with researchers at Kentucky State University (KSU), contacted potential respondents to participate in the phone survey or web survey if they preferred.

The survey probed examiner background, including their educational attainment, membership in professional organizations, certifications, training, and other professional preparation. The survey also documented the type of lab in which FDEs are employed, as well as other positions that examiners have held (including specializations outside of forensic document examination). The survey also included questions regarding examiner experience in providing expert testimony and engaging in proficiency testing as part of their training. The survey concluded with open-ended questions regarding the perceived strengths and weaknesses of examiner training. Themes from these open-ended responses are summarized and presented in this poster.

The results of this survey will inform Phase II, the experimental portion of the study, which is currently in the ongoing data collection phase at KSU. Phase II involves the examination of various handwriting samples in questioned documents by both forensic document examiners and lay participants. The background information of examiners from the Phase I survey data is informative in and of itself as an indication of the contemporary background, education, and experience of forensic document examiners who are currently practicing in the United States. It will also serve as a fundamental set of statistical controls for differences in examiner backgrounds, as well as a platform for analyzing patterns in individual differences between examiners and their performance in Phase II at KSU.

Questioned Document, QDE Training, QDE Education

J10 Statistical Basis to Determine Probabilities of Occurrence of Handwriting Characteristics

Sargur Srihari, PhD, CEDAR, Univ of Buffalo, 520 Lee Entrance, Ste 202 UB Commons, Buffalo, NY 14228; and Kirsten A. Singer, MFS*, Dept of Veterans Affairs, OIG, Office of Investigation, 51L, 801 Eye St, NW, Washington, DC 20001*

After attending this presentation, attendees will be informed of preliminary results of computerized assessment of specific handwriting characteristics and their frequency in a general population database.

This presentation will impact the forensic science community by providing an example of frequency determination of handwriting analysis that may be applicable to other kinds of pattern analyses that are observer dependent with subjective conclusions.

This research proposes to supplement the existing research conducted in the publication, *A Statistical Examination of Selected Handwriting Characteristics*.[1] That research involved the statistical analysis of specific handwriting characteristics for the "th" combination. This and other previous studies focused on the "th" combination because of its frequency of use in the English language, as well as its role in the most commonly used English word, "the." Based on a survey by www.AskOxford.com, the next most common English words are "of" and "and." The current study will seek to examine handwritten characteristics of the selected word "and" in both its hand printed and handwritten (cursive) form, as well as occurrences of the symbol for "and" (e.g., ampersand). The intent of this research is to determine the feasibility of studying aspects of the selected word, and quantify observed characteristics into statistically useful information.

When Forensic Document Examiners (FDE) render conclusions based on their comparison and examination of handwritten items, they tend to assign probative values to specific handwriting characteristics and their combinations. Their judgments are usually based entirely on the examiners experience and power of recall. Statistical data concerning frequency of occurrence of characteristics and their combinations offer promise for providing a quantitative basis for forensic document examiner conclusions. If the frequency of occurrence of combinations of particular handwriting characteristics is available, then the probability of the observed characteristics can be determined. Such objective information would not only support the examiner's conclusions, but would provide additional scientific credence in courtroom testimony.

In the present research, a computer-executable "truthing" tool was developed to more easily allow the consulting FDEs to evaluate each instance of the written word "and," then select specific characteristics observed from drop-down menus. The "truthing" tool works in conjunction with images of handwriting and hand printing specimens in a database consisting of supervised handwritten and hand printed specimens from over 1,500 individuals representative of the United States population. Examples of observable characteristics are whether the "a" staff is: (1) retraced; (2) looped; (3) a single line; or, (4) no fixed pattern. These characteristics and their most frequent combinations will then be used to determine their frequencies in the database. Since the number of combinations can be very large, a probabilistic graphical model is used to calculate the probability of any given combination will be determined. The probabilistic models are then used to infer the desired probabilities. The number of characteristics is necessarily limited in order to establish preliminary frequency characteristics without requiring an overwhelming amount of labor-intensive effort from the consulting forensic document examiners. The resulting methods will be incorporated into a software system to aid the forensic document examiner. The database and selected characteristics can be expanded for future research projects that may focus on additional characteristics of the word "and" or other words and their selected characteristics.

Handwriting, Frequency, Computer

J11 Exhibit Design and Presentation

Suji Lee, BFA, and Barbara Torres*, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032*

After attending this presentation, attendees will understand how a well thought-out visual account of an expert's results can best be used in case reports and courtroom exhibits to make effective visual exhibits that aid verbal communication.

This presentation will impact the forensic science community by reviewing how forensic document examiners can use the various computer software options and tools to their best advantage and effectively present complex information in a clear and concise manner.

As experts, we are expected to simplify complicated questioned document examinations. Understanding the perspective of the jury and having a basic knowledge of color theory, composition, and content selection will aid the expert in the communication of his or her findings.

When testifying before a jury in today's crime drama obsessed society, the use of exhibits is not only beneficial, but expected. It has been expressed by attorneys that the most effective expert witnesses are excellent teachers. As such, visual aids are critical to demonstrating evidence and findings. This presentation will share the research behind what juries respond to and expect from experts in this regard. The advantages and disadvantages inherent in the various presentation options available will be discussed such as the static poster format vs. a slideshow presentation (software format) or individual handouts for the jurors vs. one central poster.

Exhibits can support the expert's testimony and make it more impactful and memorable. For decades, forensic document examiners have used photographs, photocopies, or drawings to demonstrate handwriting and other evidence. The digital age has ushered in a variety of software programs with capabilities that far exceed the simple formats of the past.

Many elements compose the basics of design such as: visual hierarchy, positive and negative space, font choices, annotations, and color influences. Software programs provide forensic document examiners with many design options in these areas. Some of these elements overlap. Visual hierarchy includes the use of emphasizing scale, colors, font style, placement, and opacity. Positive space is the subject matter area and negative space is the remaining surrounding areas. Knowing how to compose the content/subject matter on a blank canvas will make a difference in keeping the jurors' attention and their eyes inside the frame of your exhibit. Font choices are pertinent for legibility and speed in which the jurors can read the information without hesitation. When the font is difficult to read, this can deter the jury members from reading on further. It is common that forensic document examiners create annotations on their exhibits. These annotations may be made with multiple colors that can potentially lead to confusion in the courtroom. Organizing notations and choosing the right colors can make an inviting environment for the viewer. Therefore, jury members will spend less time trying to comprehend what the annotations are conveying and focus more on what is important. Having a better understanding of these topics will facilitate a foundation for a straightforward and powerful chart that best demonstrates your evidence.

Exhibit, Design, Testimony

J12 The Wills of Michael Renslow

David S. Moore, MEd, 9010 Barrhill Way, Fair Oaks, CA 95628*

After attending this presentation, attendees will gain an understanding of the various types of forensic document examinations that were relevant during the evaluation of the hand-printed holographic wills of Michael Renslow. Each area of consideration provides critical evidence that led to the ultimate conclusion of the wills authenticity. The various considerations in this case example are relevant to the examinations of many similar questioned documents that are challenged in legal proceedings.

This presentation will impact the forensic science community by providing overwhelming evidence that addressed the issue of genuineness that existed between the contested wills. This evidence will be presented in a logical, cogent sequence within a framework and understanding that the author, who was trained in a formal, conventional manner consistant with ASTM standards, was opposed by two, less formally trained individuals who had arrived at diametrically opposite findings.

This case example involves the various holographic hand printed wills of Michael Renslow and the various forensic document examinations that were conducted to determine the authenticity of these wills.

In this matter, the author was opposed by two examiners who arrived at findings totally opposite from the author. When such a condition occurs, it is a legitimate endeavor to consider why this happened and whether formal training — or the lack of it — might be the underlying cause. The author was formally trained as a forensic document examiner in the mid-1970s in accordance with the requirements outlined in ASTM Standard E-2388 (*Standard Terminology for Expressing Conclusions of Forensic Document Examiners*), which requires — among other things — a minimum of two years of formal training in this field. The training of the opposing examiners did not meet the requirements of this ASTM Standard (indeed, one of them was originally a graphologist and was primarily self-trained in forensic document examination). Additionally, the author has been certified by the American Board of Forensic Document Examiners (ABFDE) since it's inception in 1978; while one of the opposing examiners was certified by the American Board of Forensic Examiners (ABFE). Although both Boards have received accreditation by the Forensic Specialty Accreditation Board (FSAB), only ABFDE was initially sponsored by the American Academy of Forensic Sciences (AAFS) and other national and international prestigious forensic document examiner organizations. In many ways, this case is a perfect example why formal training should be a prerequisite for individuals who claim expertise in this field.

A total of three wills were purportedly written and signed by Mr. Renslow over a two-month time span in latter 2010. Each will bequeathed all of Mr. Renslow's money, property, and other valuable assets to his girlfriend/fiancé of eight years, Ms. Susan Pinar Ilkin. Mr. Renslow's relatives, who were not mentioned in the wills, challenged the authenticity of the wills and retained an attorney to represent them. In turn, the author was retained by that attorney. The opposing examiners were retained on behalf of Ms. Pinar Ilkin.

This hand printing and signature case involves considerations such as disguise, simulation, tracing, alterations, erasures, indentations evidence, erasable ink and pencil writing, multiple authors, and other important aspects that, ultimately, led to a determination of the authenticity of the wills. Often, holographic will contests involve only several of these considerations; however, this case involved all of these and more. Attendees will be provided with the overwhelming evidence that was available for consideration all of which led directly to the determination of genuineness.

Each of the relevant aspects that were considered and explored in the examination of these wills will be discussed. While each of these aspects directly addressed the issue of the wills' authenticity, the opposing examiners apparently either did not consider these various aspects or they discounted them.

Holographic wills, to be considered authentic by the court, must be written and signed in their entirety by the decedent. Critical to the evaluation of the authenticity of such wills is the body of known writings. A sufficient quantity of comparable genuine (known) handwriting, hand printing and signatures is a pre-requisite for such an evaluation. In this case, a significant quantity of the "known" writings was provided by the proponent of the wills, Ms. Pinar Ilkin. Section 7.10 of ASTM Standard E 2290 (*Standard Guide for Examination of Handwritten Items*) requires, among other things, that the known writing must be inter-compared to assure that it was all written by one individual. Had this guide been considered and appropriately employed by the opposing examiners, they would have discovered that the known documents contained the writing of more than one individual. Had such a discovery been made, presumably their findings would have been different.

Finally, this presentation will consider that possibility that, if Michael Renslow didn't write and sign his purported holographic wills, then who did?

Holographic Will, Forgery, Simulation

J13 Examination of Text on Carbon Paper

George Virgin, MFS, and Elaine Wooton, MFS, DHS ICE Forensic Document Laboratory, 8000 Westpark Dr, HSI FDL Stop 5116, McLean, VA 20598-5116*

After attending this presentation, attendees will learn about methods used to decipher text on sheets of carbon paper.

This presentation will impact the forensic science community by familiarizing attendees with a questioned document case involving carbon paper and the methods used to decipher text on the carbon paper. These methods might be applicable to other questioned document cases involving carbon paper.

This presentation will document a questioned document case study of a carbon paper examination and the steps applied to decipher and report the text content on sheets of carbon paper. Sheets of carbon paper were submitted for examination to the Homeland Security Investigations (HSI) forensic laboratory as part of a criminal case. The sheets of carbon paper had been used to make copies of, and distribute, a secret newsletter to members of a prison gang. The carbon paper was a key piece of evidence in the case against one of the defendants. Decipherment of the text on the carbon paper was important in order to show the information contained in the newsletter.

The carbon paper submitted had been used to make typewritten copies of a few different documents. The carbon paper had been well handled and contained hard-to-read typewritten and handwritten text. The sheets of carbon paper were filled with lines of text prepared using both the English and Spanish languages. Some of the sheets of carbon paper had been used to copy more than one document. Lines of typewritten text were typed overtop of other lines of typewritten text. Notations had been handwritten overtop of the typewritten text and overtop of other handwritten notations. The overprinted text on the carbon paper was not clearly observed. There was some success in deciphering the overprinted text through image subtraction and analysis techniques performed using the Foster & Freeman VSC® (Video Spectral Comparator 6000) and Adobe Photoshop® (version CS5). This was accomplished by collectively examining the sheets of carbon paper using the VSC and Photoshop. This resulted in the decipherment of almost all of the text on one of the sheets of carbon paper. Image processing resulted in the decipherment of additional text on the carbon paper that would not have been deciphered otherwise, helped to verify the accuracy of hard-to-read text, and enhanced the readability of the text.

Another aspect of the case was centered around whether it was a decipherment or a transcription. Discussions between questioned document examiners revealed that some viewed the carbon paper examination as a transcription, while others viewed it as a decipherment. Additional discussions arose on how to report the results. Some examiners favored presenting the results to the case submitter as images for the case submitter to interpret. Others favored presenting the interpreted results to the case submitter in the form of a transcription of the text. In addition, other questions arose during the review process, after seeing whether a second examiner could independently reach the same conclusion. The case ended up as a decipherment. A transcription of the deciphered text was provided to the case submitter. A second examiner independently reached the same conclusion for the majority of the deciphered text. The text was reported as unable to decipher where no agreement between the two examiners could be reached.

Questioned Documents, Carbon Paper, Decipherment

J14 Characterization and Differentiation of Document Papers Based on Element Profiles

Emily G. Riddell, BS, and Ruth Waddell Smith, PhD, Michigan State Univ, Forensic Science Program, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will become familiar with the use of element profiles as a means to characterize document papers, as well as the use of statistical procedures to differentiate the papers based on these element profiles.

This presentation will impact the forensic science community by demonstrating an additional method for questioned document comparisons. The elemental profiles potentially offer greater discriminating power than the current methods used, and statistical analysis of the profiles provides a more objective method of comparison.

Currently, the analysis of document papers typically involves a comparison of physical and chemical features such as dimensions, color, and brightness. However, with advances and improvements in the paper-making process, differentiation based solely on these features can be limited. As a result, alternative methods that exploit different properties of the paper would be beneficial in the analysis and comparison of document papers. Recently, the potential of trace elements for the differentiation of paper samples has been investigated. These elements originate in the paper as a result of impurities in the raw materials, as well as from processes used during manufacture. Thus, it is possible that a profile of the elements present may be used to not only differentiate paper types, but also to associate paper of the same type produced by the same manufacturer.

Since the elements are present at trace levels, sensitive instrumental techniques are necessary for the analysis. Previous research has used inductively coupled plasma mass spectrometry (ICP-MS) to analyze trace elements in paper samples. This multi-element technique meets the requirement for high sensitivity; however, the instrumentation is complex and high running costs are associated with the analysis. An alternative technique is inductively coupled plasma optical emission spectroscopy (ICP-OES), which is a less expensive multi-element technique. While not as sensitive as ICP-MS for many elements, ICP-OES may offer a viable alternative for element determination in document papers.

The purpose of this research was to further investigate the differentiation of document papers based on the trace element profiles generated using ICP-OES. Three reams of four different types of paper (copy, laser inkjet, multipurpose, and office paper) produced by the same manufacturer were obtained. Samples were microwave digested in nitric acid and hydrogen peroxide prior to analysis. The resulting digests were analyzed by ICP-OES to identify characteristic elements for each paper type. The elements selected were those that were present above the instrument detection limits, were not present at significant levels in the blank digest, and did not vary significantly within a ream of paper. The selected elements were then quantified using ICP-OES. The sample digests were also analyzed by ICP-MS, quantifying the same elements.

The element concentrations determined were firstly normalized to the initial mass of paper used in the digestion. The element profiles that were generated using each instrument were treated as two separate data sets and each data set was firstly subjected to hierarchical cluster analysis (HCA). This is a multivariate statistical procedure used to identify similarities among samples in a data set. The dendrograms generated were used to assess similarity among reams of the same paper type, as well as dissimilarity of different paper types, based on the concentrations of the elements present.

Profiles in each data set were also subjected to principal components analysis (PCA). While this procedure is also multivariate in nature, PCA identifies sources of variance in a data set, rather than similarities, as is the case in HCA. The two main outputs of PCA are scores plots and loadings plots. The former plots are scatter plots in which chemically similar samples are positioned closely and distinctly from chemically different samples. Loadings plots are used to identify the variables contributing to the variance described by the principal components. In this research, the scores plots were used to assess the association of reams of paper of the same type and differentiation of different paper types. The loadings plots were then used to identify the elements responsible for the differentiation observed.

Finally, results from HCA and PCA were compared to determine if one technique, ICP-OES or ICP-MS, offered improved association and differentiation of the paper samples based on the elemental profiles generated.

Trace Elements, Questioned Documents, Statistics

J15 Analysis of Eye Movements While Observing Handwriting

Yoko Seki, MA, National Research Institute of Police Science, 6-3-1, Kashiwanoha, Kashiwa, JAPAN*

After attending this presentation, attendees will understand: (1) the strategies that a forensic document examiner takes to extract characteristics from handwriting by visual inspection; and, (2) the importance of the observation from various perspectives in handwriting examination.

This presentation will impact the forensic science community by demonstrating the relationship between the examiner's eye movements and the correctness of the identification results.

Eight forensic document examiners participated in the experiment. They were instructed to watch the monitor displaying two handwriting samples, one of which was the questioned handwriting and the other was the known handwriting, and decide whether two samples were written by the same person or not. Sixteen writers participated in the preparation of handwriting samples. They were asked to write the same person's name in square style. One out of sixteen writers was asked to prepare five samples, two of which were used for the known handwriting and other three were used for the questioned handwriting. Another fifteen writers were asked to prepare one sample, which were used for the questioned handwriting. The handwriting pair, used as a stimulus, consisted of a known handwriting and a questioned handwriting. So, there were eighteen handwriting pairs used as stimuli. Three out of eighteen pairs were the same writer's pair and the other fifteen were different writers' pair. Procedure of the experiment was as follows: known handwriting pair was firstly presented to the subject for extracting characteristics of the known handwriting; then 18 stimuli were presented to the subject respectively in random order; subjects were instructed to click the mouse to display a stimulus, observe it as long as necessary to identify the writer, and click the mouse to express their opinion as to the identity of the writer; and, eye movements of the subjects during the observation and the time necessary to their decision making were measured. An eye-tracking system was used for the measurement.

Answers obtained from the subjects were either correctly identified or inconclusive. Average ratio of inconclusive was higher in the case of the different writer than the same writer. Average time necessary to the decision making was significantly longer in the case of inconclusive than conclusive. Observing manner was roughly common to the subjects, that is, subjects observed some point of the first character of the known handwriting and then observed the corresponding point of the questioned handwriting. Then, observation point moved to the next point of the known handwriting and then the corresponding point of the questioned handwriting. The same procedure was taken throughout the entire observation. All the subjects observed almost the same points in the case where the stimulus was undertaken; short response time and unanimous answer. All the subjects observed characteristics on shape such as terminating manner of a stroke, curvature, and relation between two strokes. One subject observed the space between characters along with the shape and all his answers were correct.

The fact that longer time was necessary to the decision making in inconclusive cases suggests that the distinct difference or similarity between the two handwritings makes the decision making easier. This

also suggests that there is a possibility of the commonality of the document examiner's knowledge on the typical or large intra-individual difference. Higher inconclusive ratio in different writers than the same writer was, however, different from the expectation because the number of the same writer samples was smaller than that of the different writer samples. This may suggest that the examiner unconsciously avoids type 1 error. The fact that the observation on the spacing had an influence on getting the correct answer suggests the necessity of various viewpoints in the identification task for reaching the correct opinion. These results show the importance of the inspection from various perspectives, the choice, and the processing of the adequate information in the handwriting examination.

Handwriting, Eye Movements, Eye-Tracking System

J16 Preliminary Trends in Frequency Occurrence of Handwriting and Hand Printing Characteristics

Thomas W. Vastrick, BS, 380 S State Rd 434, Ste 1004-132, Altamonte Springs, FL 32714-3866*

After attending this presentation, attendees will have an understanding of how the results of this project will benefit their daily work and court presentations. The objective of this presentation is to provide a pilot preview of early results of a frequency occurrence study. In addition, attendees will receive a brief tutorial of the use of the database system used for characteristics classification.

This presentation will impact the forensic science community by putting the judiciary and critic communities on notice as to the advancements of strengthening the statistical basis of handwriting conclusions used in court.

In 2010, the National Institute of Justice (NIJ) awarded a research grant for the study of the frequency occurrence of selected handwriting and hand printing characteristics. This study is a statistic-driven project requiring exacting methodological precision that will withstand an expected onslaught of criticism from those who have created a cottage industry out of such attacks.

The NIJ study is designed to classify approximately 2,000 handwriting or hand printing characteristics of approximately 5,000 writers. The population sampling is being collected using a stratified sampling representative of the population within the United States and taking into account instrinsic and extrinsic factors that may affect handwriting as described in *Handwriting Identification: Facts and Fundamentals* by Huber and Headrick.[1] Factors considered include age, ethnicity, sex, handedness, region of early elementary education, and location of collection. The percentages of each factor must fall within a range (such as plus or minus five percentage points) of what is recognized as the makeup of the United States population. For example, if twelve percent of the United States population is left-handed, then the stratified sampling must be within a range of seven to seventeen percent.

The handwriting specimens form content is a modified version of the specimen form used by Dr. Sargur Srihari in earlier published studies of handwriting and pattern recognition.

The handwriting characteristics have been selected and tested for objectivity and repetitiveness of results in order to avoid unnecessary integral error rate increase. Each feature has undergone, among other tests, an Attribute Agreement Assessment study in which multiple examiners have classified the same handwriting forms and have themselves classified the same handwriting forms more than once. Characteristics that are found to bear variances of results, either from the multiple forensic document examiners or by the same examiner in two different classification exercises, is either modified to eliminate the issue causing the confusion or has been excluded from the study as being unnecessarily subjective.

A database system has been specially developed for this project. Every feature bears a brief description with most accompanied by an image illustration. By design, a classifier need only click their computer mouse in the check box in order to note the presence of a denoted feature. The database will automatically record the result. Multiple handwriting specimens can be recorded on a database and the results will then be sent to the database specialist who will integrate all databases and submit the results to the statisticians for analysis. It should be noted here that the forensic document examiners have no part in this portion of the study and this is by design. The project is a statistical study and is driven by statistical methodologies. Any decisions as to procedures in this study are the sole responsibility of the statisticians.

Trained forensic document examiners are used for the purposes of classification in the database. The reason for this is that it will be forensic document examiners who will be the end users of the project as they will be able to enter features from writings in question in actual casework and collect frequency results to their case-specific entries. As part of the presentation, attendees will be guided through a tutorial on the use of the database as volunteer classifiers are an essential need of this project and will be solicited from amongst the attendees who are practicing forensic document examiners with documented training meeting the ASTM training guideline.

As part of the pilot projects, the statisticians have arranged for a pilot study of a small number of writers in order to test the complete system for seamless integration. Since the pilot study will also yield actual results, it is the purpose of this presentation to present the results along with presenting idiosyncrasies that have thus far been observed during the study.

This research was funded by the National Institute of Justice (NIJ) research grant (2010-DN-BX-K273).

Statistics, Handwriting, Frequency

J17 Some Reasons for Qualified Conclusions

Ronald N. Morris, BS, 307 Springhill Cir, PO Box 905, Bedford, VA 24523*

The goal of this presentation is to provide some reasons why a forensic document examiner cannot always reach a definite conclusion in a handwriting or hand printing examination.

This presentation will impact the forensic science community by explaining why handwriting and hand printing evidence is not always conclusive when attempting to identify a writer.

Frequently, recipients of reports from Forensic Document Examiners (FDE) expect the FDE to be able to determine with absolute certainty the authorship of handwriting and hand printing material they are examining. Under no circumstances is this possible. Every FDE is limited by the evidence contained in the writings they are examining.

The evidence in the writings may be the result of a lack of sufficient individuality in the writing, a limited quantity of writing, copies of documents or writing that is not original, or any number of other factors. This paper discusses some of the reasons for qualified conclusions and how different factors can affect the certainty of the conclusion reached.

Identification or elimination of a writer is based on the cumulative effect of all the available observable evidence in the writing examined and not on the presence or absence of any single characteristic, quality, or feature in that writing. The identification or elimination of a writer requires conclusive supporting evidence.

The presence of a single, significant, or irreconcilable difference does not provide a basis for concluding that two writings are by different writers. It does provide a basis for non-identity of the writer whose known writing is compared with the questioned writing. Non-identity is not the same as eliminating a writer. Additionally, the presence of what is thought to be a single, significant similarity does not provide a basis for concluding that two writings are by the same writer.

The paper includes examples of writers that have more than one style of writing. These writers are able to write without incorporating features of one style into features of the other style. The writer may be able to do this using their unaccustomed hand, while some writers can do it using the same hand. Although style is one factor, the details of the writing of the different styles can be completely different.

Another factor discussed in the paper is the limitation imposed by the adequacy of the submitted writing. The submitted writing may be insufficient for comparison purposes. A writing sample can be insufficient due to disguise, a lack of sufficient individuality or limited writing, evidence of simulation or tracing, completely different styles of writing submitted for comparison, etc.

Some transitory factors that can result in qualified conclusions are also discussed. Transitory factors can include, but are not limited to, injury to the writing hand, use of drugs, other temporary physical conditions, etc. One transitory factor that is discussed is referred to as an accidental feature resulting from a single event that temporally affected the writer.

All copies of writing are problematic. If only a copy is available and the original has purportedly been destroyed, it is not always possible to say with certainty that the copied writing is an accurate reproduction of the original writing. Additionally, it is not possible to conclude, based on the examination of the copy alone, that the writing on the copy is actually written on the original document. Because of the increasing reliance on electronic documents used by banks, government offices, corporations, etc., originals are frequently destroyed. Many times the FDE is working from a printout of a scanned document that has the word "original" stamped on it. Such documents are not "originals" as defined by the FDE.

In summary, it is not possible to reach an unqualified conclusion in every case the FDE examines. Various factors in the writings combine to limit the significance that can be attached to the characteristics, qualities, and features of the examined writing to support a conclusion that it is or is not written by the same writer.

Handwriting, Qualified Conclusion, Evidence Evaluation

J18 Decision Making When Dealing With Blood Soaked Documents

Gary A. Licht, MS, Iowa DCI Crime Lab, 2240 S Ankeny Blvd, Ankeny, IA 50023-9093*

The goal of this presentation is to present for discussion the decision-making process involved in the forensic document examinations of blood soaked documents.

This presentation will impact the forensic science community by reinforcing the knowledge that critical thinking is necessary in dealing with blood soaked documents, particularly in how those decisions may affect the presentation of the documents within the judicial system.

Death investigations may involve document evidence which is obscured by products of decay, blood and bodily fluids, and other environmental substrates. The forensic document examiner (FDE) is faced with a decision-making process which must take into consideration the items which comprise the documents, and what role these items may play in the future of the case at hand, biological safety factors, and the limitations of the laboratory equipment available. Investigators who submit items to a crime laboratory are asked only for brief information about the items and requested examinations. When dealing with deteriorating documents, more information is necessary, and typically involves discussions with the investigator. The final product of the FDE work will likely be hardcopy prints made from digital images from cameras, video images, or scanners. The use of these products in a courtroom, or in discussions with those involved in the investigation, may be a factor in deciding what examinations will be conducted. Blood and body fluids present a potential safety risk, but, their removal allows for future viewing and presentation of the original exhibits. A complicating factor is that removal of contaminants may be deleterious to the items which comprise the exhibits. It is therefore necessary to gather as much information about the documents as is feasible before proceeding with examinations beyond nondestructive imaging.

The case presented for discussion involved a two-page document which was handwritten, and for which no pen was available as the likely source of the ink. The color of the ink was important. The documents were heavily stained with body fluids which obscured roughly two-thirds of the information. Infrared imaging yielded good results, but not the critical words and phrases that mattered to the investigator and the decedent's family. Microscopic examinations provided only limited information about the pen ink. A careful evaluation of the effects of the body fluids allowed decisions to be made about subsequent limited testing of the ink-blood-paper composite. Limited testing and infrared imaging followed, and allowed for a decision to remove the blood and still retain readable original documents. The resultant images and documents allowed for every word on the two pages to be read. Images of the original documents with stains, accurately reproducing the color of the pen ink, were retained in file. Images of the documents as the examinations proceeded were also kept in file. Black and white composite infrared fluorescence images, and grayscale images of the resultant documents, were provided to the investigator for his information and for discussions with the decedent's family.

Document Examination, Death Investigation, Obscured Writing

J19 The Case of the Staple Mark

Sandra R. Lines, BA, 6200 E Cholla Ln, Paradise Valley, AZ 85253*

After attending this presentation, attendees will have a better understanding of the importance of literature review when examining unusual cases with limited evidence and providing the court with supporting documentation from the literature along with exhibits.

The presentation will impact the forensic science community by demonstrating the importance of literature from professional source material when testifying in court on an unusual case.

A check for more than one million dollars was sent by a title agency to a finance company. The finance company claimed they never received the check. A staple mark on the check along with testimony from the title agency's employees allegedly would prove the finance company did receive the check. Staple marks are often part of the examination process in cases involving medical records, business records, contracts, and wills. However, it is not common for a forensic document examiner to receive an examination involving only a staple mark. In this case, the original check was destroyed and the forensic document examiner was asked to determine if three marks on copies of the front and back of the check were the result of a single staple mark. There was some concern by the plaintiff's attorney and client that this may not be within the purview of the examiner. To allay the attorney's concerns, a literature review of respected tomes was conducted and several applicable sources were documented.

The examination of the two sides of the questioned check then commenced. Due to the obvious enlargement of the questioned check copies, a request was made to provide an original blank check from the title company to use in the comparison process. Based on the size of the original requested check, the questioned copies were reduced to 87% to match the known check size. Transparencies and copies were made of the 87% copies to assist in the alignment process. Two marks on the reverse side of the questioned check were found to be in close alignment and consistency with a standard ½-inch staple. One small hole was observed on the face of the check. Unfortunately, the copying process of the original check left artifacts that obscured the area on the front of the check where a second hole would be expected. Using a standard stapler with ½-inch staples, staples were placed on copies of the questioned 87% checks in the same locations. The staples were found to be in relative alignment and width as the marks produced on the questioned check. It was determined that it was highly probable the marks on the check were the result of a staple mark; i.e., the examiner was virtually certain the marks on the check were from a staple.

In 2011, upon appearance in court, the defendants' attorney objected to testimony concerning the staple mark, stating that a forensic

document examiner has "no special knowledge" of staple marks. A copy of the chapter written by Tom Vastrick titled "Staples" in the *Scientific Examination of Questioned Documents* was provided to the court.[1] The court accepted the testimony and ruled that the forensic document examiner does have special knowledge regarding staples and/or staple marks. The case was adjudicated successfully for the plaintiff. It should be noted the original check sent to the finance company was cashed by a third party who should not have received the check. The third party spent all the money and there was no avenue to recoup the loss.

Staple Marks, Questioned Documents, Forensic

J20 Signatures of the Arabic-Speaking Writer in the United States: Are There Class Characteristics?

Linda L. Mitchell, BS, 243 S Escondido Blvd, No 304, Escondido, CA 92025-4116*

The goals of this presentation are to provide forensic document examiners with insight into signature styles used by Arabic-speaking writers of English, and to discuss results of a preliminary study regarding the effect of right-to-left writers who later learn to write English and whether or not there are class characteristics peculiar to this group of writers.

This presentation will impact the forensic science community by providing a preliminary look into the English handwriting of the Arabic-speaking population. It will serve as a catalyst for further study into the handwriting characteristics, and may provide additional criteria for the analysis of handwriting of this population category.

The intent of this presentation is to provide insight into signatures as they are used in Arabic-speaking countries and how Arabic-speaking writers sign their name in the United States. The information gleaned from background research and analyses of requested signatures collected for this study (written by writers whose first language is Arabic) will provide Forensic Document Examiners (FDEs) with additional criteria for the forensic examination of signatures produced by such writers.

As foreign cultures continue to blend into our American and Canadian societies, FDEs are increasingly asked to authenticate signatures of writers whose first language does not use the Roman alphabet. Among these writers, the Arabic-speaking population is well-represented. Since the Arabic alphabet bears no resemblance to English script and is written from right-to-left, FDEs will be introduced to the some of the issues that impact signature analysis of both Arabic and Anglicized versions. Another consideration is that the Arabic custom regarding signatures is not the same as American custom. In keeping with this theme, the author will illustrate customary uses of the signature in Arabic-speaking cultures. Topics include: (1) styles of signatures used in Arabic-speaking cultures; (2) the purposes of different signature styles; and, (3) adaptations of Arabic signatures for use in the United States.

The training of a FDE in the United States and Canada focuses mainly on the habits of native English-speaking writers and does not necessarily cover handwriting traits of foreign writers, such as Arabic-speakers who have learned an alphabet that is entirely new to them. It is the author's hypothesis that characteristics present in Arabic script could affect the English writings and thereby provide additional criteria for establishing authorship of signatures. Hence, another aspect of this study is to identify whether or not there are specific habits (i.e., class characteristics) within the signatures that could be attributed to this category of writer.

The results of this preliminary study were based on the examination and analysis of signatures provided by 100+ writers. Each writer was asked to write the "English" spelling of his or her name along with samples of the signature styles they use in their native country. Next, each writer was requested to sign in the style he or she uses in the United States for: (1) casual communications, such as a note or letter; (2) transactions that involve money, such as a charge card; and, (3) an official document, such as a passport. The signatures gathered for this study were then inter-compared to determine whether or not any class characteristics could be identified.

Results of this study will be presented as to: (1) the number of signature styles per writer; (2) the styles used and for which purposes; (3) the frequency of use of Anglicized signatures; and, (4) the class characteristics noted among study specimens. Observations and tentative conclusions will be presented, along with suggestions for further study on this topic.

It is expected that the results of this study will provide forensic document examiners with a more reliable basis upon which to form an opinion regarding the identification/authentication of signatures written or purported to have been written by Arabic-speaking writers signing documents in the United States.

Handwriting, Arabic Signature, Document Examiner

J21 A Novel Method of Interpreting Evidence When First Attempts Fail

Carolyn Bayer-Broring, MFS, Immigration & Customs Enforce, OI FDL Stop 5116, 8000 Westpark Dr, Ste 325, McLean, VA 20598-5116*

After attending this presentation, attendees will understand a novel method of approaching an examination when the initial attempts at interpretation fail. A case study will be presented highlighting the efforts used.

This presentation will impact the forensic science community by encouraging attendees to think outside the box during examinations.

The Homeland Security Investigations Forensic Laboratory (HSI-FL) is the investigative arm of U.S. Immigration and Customs Enforcement dedicated to the forensic examination of international travel and identity documents. In the course of working a case, a document examiner at the HSI-FL might examine one document or thousands, to include such things as passports, identity cards, driver's licenses, and birth certificates. A wide variety of instruments are available at the HSI-FL, including the Video Spectral Comparator (VSC), X-ray, microscopes, loupes, and light boxes.

During the course of an examination of three foreign passports, it was determined that all three passports had been bio-page-substituted; meaning the biographical data pages of each were not original, but rather were an "overlay," where an adhesive-backed substrate was utilized to place a false page into the booklet. Indications were that the original pages still were present underneath. Two of the three passports were Electronic Passports ("E-passports" as indicated by the ICAO symbol embossed on the front cover), which meant that there should be an electronic chip somewhere in the book, bearing personalized data relating to the carrier of the book.

Under normal circumstances, specialized software in the VSC 6000 can be utilized to interpret the Machine-Readable-Zone (MRZ) appearing on the biographical data page of a passport, and in the instances of E-passports, the information from the MRZ can then be used to "unlock" the electronic chip, revealing the information encoded on the chip. Visual comparison of the MRZ and the resulting chip data can then be made, to determine if the information is the same—which it should be in instances of booklets that have not been tampered with or altered. Ostensibly, if the MRZs of these page-substituted passports could be interpreted, and if the electronic chips were present and operational, the identities of the true bearers should be easy to determine for comparative purposes.

The machine-readable-zones in the two E-passports were not visible on the substituted pages; however, there was reason to believe they should still be present on the original pages underneath. So what to do? One option would have been simply to pull the substituted page off and see what was underneath; however, examiners at the HSI-FL are not allowed to conduct destructive examinations. So that wasn't an option. Use of an X-ray determined that the electronic chips were

present in the books, and they appeared intact and undamaged (chips and antennae are often removed or otherwise damaged during alterations), so finding some method of interpreting the MRZ and opening those electronic chips was important.

Ultimately, strong transmitted light and the spot-illumination function of the VSC were utilized, along with plain old pencil and paper, to hand-interpret the MRZs of the true biographical data pages still present under the substituted pages. After a little trial and error, the right numbers and letters were determined, the data was hand-typed into the VSC and – voila! The MRZs worked. The data was then utilized to "open" the chips and the images and data of the true bearers became readily apparent, further supporting the finding that the booklets had been altered.

Travel Documents, MRZ, E-Passports

J22 A Crosscut Shredded Document Case Made Easier — Predicting Where the Pieces Go

Larry A. Olson, MFS, IRS National Forensic Lab, 525 W Van Buren, Ste 400, Chicago, IL 60607*

After attending this presentation, attendees will learn some of the characteristics of crosscut paper shredders and shredder "chad" (the shredded pieces), and more importantly, understand some of the techniques that can facilitate the manual re-assembly of shredded documents.

This presentation will impact the forensic science community by proposing a methodology to make the process of manually reassembling a shredded document easier.

A small bag of crosscut shredded documents was received for reassembly in the hopes of providing evidence in a case of identity theft and the filing of false tax returns. Several of the documents shredded were self-adhesive memos. Some of the notes had apparently been stuck to each other before shredding, and some had been attached to other documents. Due to the random position of the notes, they became shredded in different orientations to the shredder "mouth," which resulted in bits and pieces of the same type of paper in various sizes and shapes.

Little could be found in the literature outlining a practical methodology for reassembling shredded documents. Some of the difficulties encountered in reassembling shredded documents are: (1) many pieces are of the same size and shape; (2) many pieces are very small, deformed and/or stuck together; (3) some pieces are likely to be missing; (4) paper chad are often very delicate and difficult to handle; and most significantly, (5) the examiner typically has no final design to work toward (this problem is akin to attempting to complete many different picture puzzles thrown together on same table).

The hypothesis presented is that it is possible to predict the precise pattern into which a document was shredded. This can be done by first making some rudimentary measurements of the shredded chad. Next, the pattern observed that is formed by the crosscuts on even a small portion of reassembled chad can be extrapolated to predict the overall pattern into which the document was shredded. Several preliminary steps for sorting the chad (based on size, shape, shred direction, border angles) eventually allow for the more rapid location of a desired piece to fit into the pattern.

A methodology for the complete (ideal) reassembly of a shredded document is proposed. This includes, in part, the following steps: (1) sorting chad by color and type of paper, and by markings present; (2) making measurements or comparisons of the chad width, chad length, and the angles formed by the machine-cut edges and the shredded edges; (3) orienting the chad in the shredder direction, (4) creating a template for assembly and a grid for aligning the chad; and, (5) creating a grid of the pattern of the shred over the entire document.

Through the use of the methodology described, at least nineteen documents in the case were able to be either totally or partially re-assembled.

Also presented will be some results of a related research project of examining the chad produced by shredders of several makes and models.

Paper Shredder, Shredded Documents, Document Reconstruction

J23 Cognitive Theoretical Perspectives in Studies of Forensic Document Examination

Mara L. Merlino, PhD, and Tierra M. Freeman, PhD, Kentucky State Univ, Dept of Psychology, 400 E Main St, Frankfort, KY 40601; Victoria Springer, MA, Univ of Nevada, Reno, Grant Sawyer Ctr for Justice Studies, MS 313, Reno, NV 89557; Veronica B. Dahir, PhD, Univ of Nevada, Reno, Center for Research Design and Analysis, 1664 N Virginia St, Reno, NV 89557; Derek L. Hammond, BA, U.S. Army Criminal Investigation Laboratory, 4930 N 31st St, Forest Park, GA 30297-5205; Adrian Dyer, PhD, RMIT Univ School of Media and Communication, Bldg 5.2.36, City Campus, Melbourne, Victoria 3000, AUSTRALIA; and Bryan Found, PhD, Victoria Police Forensic Services Department, Office of the Chief Forensic Scientist, 31 Forensic Dr, MacLeod, Victoria, AUSTRALIA*

After attending this presentation, attendees will understand some of the principles of cognitive psychology, and the use of eye-tracking technology to study attention and feature-matching processes as they relate to decision-making processes in forensic document examination.

This presentation will impact the forensic science community by demonstrating the importance of engaging in theoretically-based, multidisciplinary research to an understanding of the nature of the methodology and expertise in forensic document examination (FDE).

A substantial portion of FDE training is devoted to signature comparisons, handwriting, and hand printing. FDEs seek those features and characteristics which may be characterized as the document's identifying attributes or characteristics. Examiners first determine the presence or absence of features, and then qualitatively assign these features some degree of evidentiary weight in order to reach their decisions. Examiners are trained to look not only for substantial similarities or differences among writing samples, but also for repeated small characteristics which may be sufficient to establish clearly that writings are the work of two individuals even though they may contain a considerable number of general similarities. The number and quality of these features allow FDEs to make assertions about the authorship of the specimen and the extent of their confidence in their decisions.[1]

A substantial body of research addresses the cognitive mechanisms involved in attention and visual search. This paper discusses the application of cognitive theory to understanding the nature of attention, feature extraction and weighting, and decision-making in forensic document examination. Data from a national study of forensic document examiners will be used to illustrate the ways in which cognitive psychology can contribute to an understanding of the decision-making processes of experts in the field compared to lay those of lay people.

Many current theories of attention propose that attention is based on the relationship between a bottom-up, saliency-based attentional system and a top-down, feature-specific selection mechanism. Attention is guided by relational information about the target, or information about how the irrelevant information of a non-target differs from the features of the target. Relational models of visual search demonstrate that visual attention can be guided by attending to specific feature values such as color, size, or intensity, by inhibiting attention to irrelevant features, or by directing attention to how stimuli differ. Relational models place the target in relation to its context, offering more specific (e.g., directional) information about differences. This relational aspect of attention may be influenced by the presentation formats of stimuli.[2]

Tversky pointed out that most stimuli seem to be effectively described by the presence or absence of qualitative features. He and others argued that an object is represented by a set of features or attributes, and that judgments of similarity are achieved through a process of feature matching. Tversky's "Contrast Model" systematizes this "feature" approach, and proposes that similarity depends on the

proportion of features common to the two objects, and also on their unique features. Feature matching occurs by establishing differences in quality or quantity, such as differences in color or size, or the presence or absence of the features upon which the judgment is based, usually in terms of binary variables.[3] This feature-matching process, along with the deployment of attentional resources, is a core process of forensic document examination.

This research was supported by Award No. 2010-DN-BX-K271 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice.

Feature Matching, Attention, Handwriting

J24 Validation of Quantitative Measures in the Non-Destructive Differentiation of Black Ballpoint Pen Inks

Jeremy Lindley, BS, 6130 Carvel Ave, Apt 5, Indianapolis, IN 46220; and Derek L. Hammond, BA, and Brigid O'Brien, PhD, U.S. Army Criminal Investigation Laboratory, 4930 N 31st St, Forest Park, GA 30297-5205; 4930 N 31st St, Bldg 925-S, Forest Park, GA 30297*

After attending this presentation, attendees will understand the use and application of the measurement feature within Adobe® Photoshop® CS5 Extended as applied in the quantitative differentiation of black ballpoint ink samples.

This presentation will impact the forensic science community by demonstrating the validity and reliability of newly introduced objective measures in traditional qualitative non-destructive ink differentiation tasks involving the analysis of black ballpoint inks.

A previous published study conducted at the U.S. Army Criminal Investigation Laboratory demonstrated the use of L*a*b* color mode as a valid and reliable method in the non-destructive differentiation of black ballpoint pen inks. However, the results obtained through the use of L*a*b* color were based on visual observation and qualitative in nature. To extend the utility and discriminatory power of L*a*b* color as a tool in forensic document examination, this study investigates the use of L*a*b* color mode combined with analysis tools available within Adobe® Photoshop® CS5 Extended (APCE) as a new quantitative-based approach for non-destructive ink differentiation.

In the current study, the measurement feature within APCE was utilized via two different collection methods (manual and automated) to obtain the means of the gray values of each inked sample within a set of pen-pair samples previously converted from an RGB image to a processed L*a*b* color mode image. Theoretically, a statistical difference in the gray value (means) between two inks would provide quantitative support that the two inks were from different populations (i.e., different inks). Conversely, if the gray value (means) of two inks were not statistically different then this would provide quantitative support that the two inks were from the same population (i.e., indistinguishable ink(s)).

For the manual method of analysis, which requires the examiner to manually select the area of interest (AOI) within a given sample, 138 black ballpoint ink pen-pair samples were analyzed after converting the RGB images into L*a*b* color ("a" channel) images. These samples consisted of the following pen-pair types: (1) same ink/pens (N=35); (2) close non-match (N=70); and, (3) different ink/pens (N=33). As the names suggest, when the ink samples were produced, they were created either by using the same pen to create a pen-pair sample (control samples) or with different pens/inks. The close non-match samples are samples that are known to have been created using different pens that utilize different ink formulas but were not previously differentiated by optical examination of the resulting L*a*b* color image of the pen-pair sample. Quantitative analysis outperformed the previously conducted qualitative analysis (i.e., visual inspection of L*a*b* color images of the pen-pair samples) of the close non-match samples. However, qualitative analysis outperformed the quantitative analysis of the pen-pair samples written using the same ink. In the analysis of the pen-pair samples created using different inks, both methods were equally successful in correctly differentiating all of the samples tested.

For the automated method of analysis, the AOI within a given sample is selected automatically using a saved action script within APCE. One hundred and twenty-eight black ballpoint ink pen-pair samples were analyzed after converting the RGB images into L*a*b* color ("a" channel) images. These samples consisted of the following pen-pair types: (1) same ink/pens (N=35); (2) close non-match (N=70); and, (3) different ink/pens (N=23). Automated quantitative analysis outperformed the previously conducted qualitative analysis (i.e., visual inspection of L*a*b* color images of the pen-pair samples) of the close non-match samples. However, qualitative analysis outperformed the automated quantitative analysis of the pen-pair samples written using the same ink. In the analysis of the pen-pair samples created using different inks, both methods were equally successful in correctly differentiating all of the samples tested.

Preliminary findings suggest that this new, low-cost and nondestructive method for ink differentiation has a higher discriminatory power than the qualitative analysis of L*a*b* color images involving different and/or close non-match inks. However, in the absence of establishing a minimum gray value threshold, necessary to prevent or reduce Type I errors (i.e., false positives), manual quantitative analysis using the measurement feature within APCE falls short of the higher performance results produced using qualitative analysis of pen-pair samples produced with the same ink formulas.

J25 Empirical Differentiation and Profiling of Processed Colored Inkjet Inks Using Fourier Transform-Infrared Spectroscopy

Rashmi Sharma, Central Forensic Science Laboratory, CFI's Complex, Hyderabad, INDIA; Rajeev Kumar, MSc, 5/300 New Ram Nagar, Agra, INDIA; Kavita Goyal, MSc, Forensic Science Laboratory, Sector-14, Rohini, INDIA; and A.K. Gupta, DSc, School of Forensic Science, SHIATS, (formerly Allahabad Agriculture Institute), Allahabad, INDIA*

After attending this presentation, attendees will understand the factors which differentiate the processed inkjet inks and the features which are similar in inkjet inks of different printers of same brands and different brands. This presentation will show the significant use of Fourier transform-infrared spectroscopy in the examination of the cases related to inkjet printer.

This presentation will impact the forensic science community by providing information which could be used to create a database and could be applied to actual case work due to very good sensitivity and reproducibility of the technique.

Processed ink from 208 samples was taken from printouts printed by different types of printers manufactured by someof the leading companies. The samples were taken in the form of printouts from printers of different manufacturers and models. The same substrate has been taken for the collection of samples. All the four primary inks are considered. The sample collection includes the printout from printers

containing both cartridges (i.e., refilled and original cartridges). The random sample collection has been done from different local markets of India. Samples were prepared by keeping cyan, magenta, yellow, and black content constant for each sample using a commercial word pallet software. The samples were collected in the form of colored rectangular blocks. A known quantity of section was removed from the surface of the document and ink was extracted from the substrate by using standard extraction procedures. The samples were dissolved in a constant amount of suitable solvent and kept for some constant time. A series of solvents which are suitable to dissolve the inkjet inks was also given. The samples were then scanned by preparing KBr palettes. The IR spectra were recorded using FT-IR spectrophotometer. The significant peaks were selected and identified to indicate the chemical difference in inkjet inks. Based on characteristic absorption bands in IR, the inks were classified into a few distinct groups. The obtained spectras and all the available information could be used to create a database and could be applied to actual case work due to very good sensitivity and reproducibility of the technique. An attempt has been done to give the ink profiling of inkjet printing inks. The technique is destructive in nature but it will provide a great helping held to the forensic community in the examination of cases related to inkjet printer inks.

Inkjet, Absorption, Refilled

J26 Detecting Altered and Counterfeit Travel and Identity Documents by Utilizing State-of-the-Art Instrumentation

Karen Cox, BS, DHS/HSI/FL Stop 5116, 8000 Westpark Dr, Ste 325, McLean, VA 20598-5116*

After attending this presentation, attendees will become aware of the various methods used to detect counterfeit and altered foreign and U.S. travel and identity documents.

This presentation will impact the forensic science community by providing information and awareness of the challenges the Forensic Document Examiner (FDE) encounters in todays casework. With the sophisticated methods used in counterfeiting and altering travel and identity documents, the use of state-of-the-art instrumentation within the laboratory has become vital in the detection of document fraud techniques.

The Homeland Security Investigations Forensic Laboratory (HSI-FL) is the only U.S. crime laboratory specializing in the scientific authentication and research of foreign and domestic travel and identity documents. The HSI-FL provides document and latent print forensics, intelligence, and investigative support services for the Department of Homeland Security and other law enforcement agencies. The presentation will illustrate various counterfeiting methods and alterations detected in the examination of travel and identity documents using state-of-the-art instrumentation at the HSI-FL.

Technology in today's world is ever evolving; computer technology has become extremely sophisticated, and, as we examine questioned documents for authenticity and fraud, it has become readily apparent that the increase in these capabilities has given the casual counterfeiter many new capabilities to produce a higher level fraudulent document. There are various components involved in the examination of a questioned document. Depending on the type of substrate (paper, hybrid paper, and plastic), the appearance and characteristics of the printing process can be greatly affected. In addition, security features are constantly advancing in the area of questioned documents. The traditional printed security features used in identity cards and passport pages are being supplemented with much more sophisticated secure printing techniques, i.e., iridescent and non-iridescent inks. Security printing incorporates multiple levels of security features such as latent images, guilloche patterns, and rainbow fountain printing. Further, covert security features, i.e., microscopic metallic particles, microstructures, and optically variable devices which contain data, are being incorporated within many security inks. With the use of sophisticated instrumentation, high-quality counterfeits can be detected.

The HSI-FL analyzes travel and identity documents from all over the world; therefore, the range of quality of counterfeiting seen in casework varies. Grommets used in passports for the prevention of photograph substitution have been replaced with more secure and tamper-resistant security measures incorporating holographic laminates, digital encoding, laser engraved tactile features, and embossing techniques. In an effort to increase the efficiency of passenger processing, an increase in the use of machine-readable travel documents is much more prevalent. The use of radio frequency identification devices within travel and identity documents now requires the use of X-ray technology to determine the presence of these devices and to determine attempts of alteration.

Keeping up with advances in document security technology and maintaining a heightened level of awareness of counterfeiting techniques and production methods used by document vendors is crucial in identifying and deterring document fraud.

Counterfeit, Altered, Documents

J27 An Evolution of Document Security: A Case Study of the United States Permanent Resident Card

Hillary M. Hoover, MFS, and Kristen E. Welch, BA*, Immigration and Customs Enforcement, HSI FDL Stop 5116, 8000 Westpark Dr, Ste 325, McLean, VA 20598-5116*

After attending this presentation, attendees will gain an understanding of the evolution of the United States Permanent Resident Card to include the advancement of its security features. Furthermore, this presentation will educate attendees on the significance behind the reform of these security features over the last half century.

This presentation will impact the forensic science community by cultivating awareness of how an identity document and its security features evolve as technology continues to advance. The opportunity for most laboratories to study these advancements may be infrequent; therefore, this presentation will provide visual examples and methodologies for examinations leveraging a wide array of tools.

The U.S. Permanent Resident Card, informally known as a "Green Card," designates the permanent resident status of a non-U.S. citizen authorized to live and work within the United States. It is known as a "Green Card" because of the green background printing used in previous designs. The Permanent Resident Card is commonly encountered as a means to obtain a myriad of benefits such as social services, driver's license or identification cards, school registration, and bank accounts.

There are multiple ways in which to acquire a U.S. Permanent Resident Card, and as a sought-after immigration benefit, the U.S. Permanent Resident Card has been subject to countless attempts at unlawful replications and alterations over the years. With readily available access to digital printing methods such as thermal, inkjet, and laser printers, document mills have proliferated around the world. As a result, the United States Government has constantly worked to reinforce the security of the Card to frustrate and deter those who would seek to gain the benefits of the Card through unlawful means. Nevertheless, each year, the Homeland Security Investigations Forensic Laboratory (HSI-FL) examines a multitude of counterfeit Permanent Resident Cards.

The HSI-FL has a library that is home to thousands of genuine standard travel and identity documents including, but not limited to, passports, birth certificates, social security cards, and permanent resident cards. Because of the vast number of counterfeit Permanent Resident Cards received at the HSI-FL each year, United States Citizenship and Immigration Service (USCIS), the issuer of the Permanent Resident Card, has continually solicited HSI-FL support by means of counterfeit deterrence evaluations and adversarial analysis in order to design a more secure document.

Older generations of the Permanent Resident Card were unsophisticated, making them more vulnerable to counterfeiting or

alteration. The older cards simply contained a paper substrate with an attached photograph held within a laminated pouch. Newer versions of the card have incorporated an integrated photograph, holographic laminate, and an ultraviolet feature. As of May 2010, the Permanent Resident Card consists of a polycarbonate layer that is receptive to laser engraving. After the polycarbonate substrate has been fused by heat and pressure and the personalized data has been laser engraved, convincing alterations become difficult. The laser engraving becomes intertwined with the polymer of the card, making its removal unlikely, whereas in the older generations of the card, the paper substrate could more readily be separated and altered. Further, this newest version of the Permanent Resident Card contains a complex combination of Level 1 and Level 2 security features. (Note: A Level 1 security feature is one that can be observed without the use of instrumentation, whereas a Level 2 security feature requires the use of a simple tool). The Level 1 security features found within the Permanent Resident Card include an optically variable device, or hologram, optically variable ink, personalized data with tactility, and an optical memory stripe on the reverse side of the card. The Level 2 security features found within the Card include high resolution microprinting and an ultraviolet feature.

Document, Security Features, Counterfeit

J28 On the Forensic Value of Non-Original Signatures on Travel and Identity Documents

Samiah Ibrahim, BSc, 139 Riverdale Ave, Ottawa, ON K1S 1R1, CANADA*

After attending this presentation, attendees will have a better appreciation of the widespread use of non-original signatures as a security feature, including its limitations.

This presentation will impact the forensic science community by alerting policy makers and designers of secure travel and identity documents by highlighting the limitations of a common security feature.

The universal function of a signature is to provide evidence of: (1) the provenance of a document; or, (2) consent. Forensic document examiners are routinely called upon to analyze signatures for the purpose of determining authorship. In recent years, there has been a trend in the production of travel and identity documents toward inclusion of an image of the document-holder's signature; typically captured from a digital scan of an original ink-on-paper signature from the application document. Although promoted as a security feature, this image is more often than not a liability rather than an added feature of protection or personalization on the card.

There are many elements of a signature that are evaluated in the course of a forensic examination. Features such as the relative size, slope, and the ratio of glyph size can be assessed from an image or copy of a document, provided that the copy or image quality is not overly degraded. There are far more features that require viewing with the aid of magnification in order to properly assess. These features include line quality, tremor or hesitation, direction and sequence of stroke, retouching, pen stops or lifts, and relative speed. Even the evaluation of glyph design often requires some magnification.

National identity cards, passports, drivers' licenses, and health cards all are examples of identity documents that include some level of personalization. Typically, each of these documents includes a visible, printed image of a signature, and in recent years this image has been reproduced with very poor quality. The limitations on quality are not with technology since micro-printing on many different media and using various inking techniques is commonplace. The limitation is with popular understanding of the use and abuse of the signature.

As the evolution of travel/identity documents progressed from original ink on substrate signatures to digital reproductions, the actual affect of having a signature printed on an identity document has become a liability. These documents cannot be used to forensically compare signatures with legitimate, known sample signatures for the simple reason that so many elements critical to the evaluation of the signature are not present. They also may not be able to be used as legitimate, known samples of an individual's signature for that same reason.

Furthermore some travel/identity document issuing processes allow for alterations to genuine signatures. When images are resized to fit into a predetermined window or space (e.g., under a photograph) they are often compressed along either their *x* or *y* axis without respect to the original aspect ratio. Some signatures are cropped so that portions are deleted or removed in order to fit into this artificially constrained space. The resultant signature image does not even display those superficial features of a signature such as size and ratio that are relied upon by primary validators at ports of entry, for example. The signature portion of many travel/identity documents is unable to meet the requirement for validation to which similar on-board data such as biographical information and photographs are routinely subjected.

The goal of this presentation is to highlight the issues and limitations surrounding the forensic examination of these signature images from travel/identity documents.

Travel Document, Identity Document, Signature

J29 Alternative Methods for Dry Seal Analysis

Robin P. Cessna, MFS, and Rachel A. Voiles, MSFS*, HSI FDL Stop 5116, 8000 Westpark Dr, Ste 325, McLean, VA 20598-5116*

After attending this presentation, attendees will gain a better understanding of traditional and unconventional non-destructive methods to examine dry seal impressions.

This presentation will impact the forensic science community by demonstrating new and different types of methods that can be used when traditional methods of dry seal examination are unsuccessful or insufficient. The goal of this research is to determine under what circumstance each technique will demonstrate an advantage over the other.

A dry seal is a non-inked mechanical device which embosses a design on a substrate. A dry seal impression is fixed on the substrate by application of two complementary metal plates, one a positive die with the design of the seal raised on its surface, the other a negative die with the depressed design.[1] Historically, dry seal devices have been used by notaries to verify legal documents, as stationers' embossments to identify the paper manufacturer or business, on architectural or engineering construction documents, or land survey drawings, to certify the identity of the licensed professional who supervised the development.[2,3,4] Dry seals continue to play a role in the forensic science community and are used by forensic document examiners to assist in authenticating passports and other identification documents. They can be used as a security feature, associating a photograph, text, or signature to a page, by compressing or permanently affecting the paper fibers, making alteration or replacement difficult. Some forgers, rather than attempting to replicate the design of a genuine seal, use a similar seal to make a weak impression in hopes that no one will detect the deception.[1,2] The Homeland Security Investigations Forensic Laboratory (HSI-FL) is tasked with determining if a document has been altered, which may include authenticating dry seals on passports, birth certificates, and other types of identification documents.

The dry seal impressions used for this research will be obtained from a variety of sources, including laboratory casework, specimens from the forensic laboratory reference library, and self-generated specimens. This experiment will strive to incorporate impressions of varying degrees of quality and depth. The dry seal impressions will be placed into three categories based on the clarity of the impression. Impressions that have all of the details including the texts and pictographic elements distinctly visible will be placed into Category I, impressions that have some of the details visible will be placed into Category II, and Category III will include impressions with no observable details. The categorization will be reviewed by other examiners not associated with this research project. A diverse selection of methods and instrumentation, including the traditional methods using oblique lighting, the Video Spectral Comparator 6000 (VSC), microscopy and unconventional techniques using the Electrostatic Detection Apparatus (ESDA), and Reflectance Transformation Imaging (RTI) will be applied in this research. The toner bead cascade method, the toner pad, the

aerosol development hood, and a dry erase marker will be used in conjunction with the ESDA equipment. Reflectance Transformation Imaging (RTI) is a new imaging technique based upon the combination of multiple digital images of an object illuminated from different angles. The object and the camera are in a fixed position which allows for the creation of a composite image from several images. The results obtained from this research will expose forensic document examiners to other techniques available for dry seal examination.

J30 Application of Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy (ATR-FTIR) to the Analysis of Red and Green Permanent Marker Inks

Robert B. Ge, BS, 5400 Joshua Rd, Mechanicsburg, PA 17050; and Walter F. Rowe, PhD, George Washington Univ, Dept of Forensic Science, 2100 Foxhall Rd, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the forensic potential of Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy (ATR-FTIR) as a method of analysis for permanent marker inks. Attendees will also understand how Principle Component Analysis (PCA), Discriminant Analysis (DA), and Hierarchical Cluster Analysis (HCA) can be used to demonstrate the discriminatory capabilities of ATR-FTIR.

This presentation will impact the forensic science community by increasing awareness of the capabilities of ATR-FTIR for the analysis of inks.

The analysis of inks serves many important functions in forensic science, including the determination of document authenticity and the comparison of document sources. The tests often require identification of the manufacturer and the specific formula of the ink. A marker is classified as a permanent marker if its ink adheres to most surfaces, has water-resistant properties, and uses dyes or pigments. Permanent markers typically contain three main components: colorants, carriers, and resins.

Numerous analytical methods have been used in the analysis of inks, and particularly of their dyes and pigments. These methods include Thin-Layer Chromatography (TLC), Liquid Chromatography (LC), Capillary Zone Electrophoresis (CZE), Infrared spectroscopy (IR), Raman spectroscopy, surface-enhanced Raman spectroscopy, Mass Spectrometry (MS), and Gas Chromatography–Mass Spectrometry (GC/MS). Various combinations of these analytical techniques may also be used.

In this study, ATR-FTIR and TLC were used for the analysis of the inks from both red and green permanent markers from eight different brands. ATR-FTIR is rapidly becoming the preferred method for acquiring infrared spectra, because little sample preparation is required: samples may simply be placed on the ATR crystal and an infrared spectrum scanned. In this instance, permanent marker inks were applied to the dull side of a sheet of aluminum foil. After the inks had dried, the inked spots on the foil were pressed against the ATR crystal. The FTIR spectra were analyzed using principal component analysis (PCA), linear discriminant analysis (DA), and agglomerative hierarchical cluster analysis (HCA). PCA is a multivariate technique that analyzes a data set in which observations are described by many inter-correlated quantitative dependent variables. Its goal is create a new, smaller set of variables that represent the meaningful variation in the original data set.

After scaling and baseline corrections, the spectra of each brand of permanent marker ink showed remarkably high consistency. Each brand had a unique infrared spectrum. For PCA, the green permanent marker inks required five components to account for more than 90% of the cumulative variance. The red permanent marker inks required six components to account for more that 90% of the variance. In DA, both red and green attained 100% correct classification for the original groupings and 100% correct classification in cross-validated groupings. TLC was performed by making “scribble” sheets on filter paper. Seven millimeter punches were taken from each “scribble” sheet. One-half of each punch was extracted into 40 µL of methanol and the extracts were spotted on silica gel TLC plates. The TLC plates were developed with a mobile phase consisting of ethyl acetate:ethanol:water (75:35:30). The developed TLC plates were examined under both normal room light and under long wavelength ultraviolet light. For each color of permanent marker, each brand of marker produced a unique chromatogram. The discriminating power of TLC and ATR-FTIR were found in this instance to be identical.

This study demonstrates that high-quality ATR-FTIR spectra of permanent marker inks can be easily obtained and that these spectra readily discriminate different brands. Further research needs to be done on alternative sampling methods, on obtaining ATR-FTIR spectra *in situ,* and on the effects of the environment on the infrared spectra of the inks.

Infrared Spectra, Ink, Chemometrics

J31 An Experimental Study on Methods to Reveal the Pen Pressure Dynamic of Chinese Signatures

Ning Liu, MA, 128 Andemen Rd, Jiangsu Police Inst, Nanjing, PEOPLES REPUBLIC OF CHINA; and Lei Pei, 101 Baixia Rd, Nanjing, PEOPLES REPUBLIC OF CHINA*

J32 ESDA Visualization of Marks Imparted by Postal Service Processing

Elaine Wooton, MFS, OI FDL, Stop 5116, 8000 Westpark Dr, Ste 200, McLean, VA 20598-5116; and Jordan C. Brough, MFS*, 605 Valley View Ave, SW, Leesburg, VA 20175*

After attending this presentation, attendees will understand what types of indentations can be left by postal processing and how they may or may not differ from other indentations.

This presentation will impact the forensic science community by increasing understanding of all of the indentations found on document evidence, and being more informed as to the value of such markings.

Electrostatic Detection Apparatus (ESDA) examinations commonly reveal bands and/or lines on the documents being examined. Work done previously has established that the relative placement of some of those features corresponds to components in digital printing or photocopying processes (specifically, roller/feed mechanisms). A recent case at the Homeland Security Investigations–Forensic Laboratory (HSI-FL) involved numerous letters and envelopes, which were processed for indented handwriting using Foster & Freeman’s ESDA-2. Only one of the documents actually had indented handwriting, and that writing appeared to have been made by administrative staff who had received the item. In addition to the indented writing, a variety of bands and lines were revealed in the ESDAs, the significance of which was initially unknown to the examiners involved. A review of professional

meeting presentations and publications revealed the prior work about printer-generated marks.[1,2] Many of the marks in the case documents were consistent with the existing assessments of their likely sources. However, many of the items contain qualitatively different marks such as a wide band in the center of each half of the opened and flattened envelopes, and a wide band in the center of each third of the folded letters. It seems likely that those bands are artifacts of processing equipment used by the US Postal Service, since they had to have been created when the letters were inside the envelopes, and there are likely no other automated processes between sealing an envelope and its being sorted by the Postal Service's automated equipment in this particular case. Knowing that something is "likely" is not a sufficient understanding of the origin of these indentations and an analysis of the components of the processing equipment with an eye toward establishing what produces the wide band is required. Additionally, this type of analysis could reveal whether other Postal Service components could be producing other artifacts that would be revealed by an ESDA examination.

The experimental protocol includes preparing a number of test samples to include blank sheets of paper pulled from a common ream of paper, folding the sheets twice, and inserting them into addressed envelopes. A group of the samples are mailed from different locations using the United States Postal Service. Some samples from this group are mailed locally and some are mailed from the western United States, all of which arrive at the same location. Another group of samples is taken to the local Postal Service sorting facilities (including the regional Dulles sorting facility), and with the facility's permission, inserted into the sorting equipment to observe which specific mechanisms physically touch the samples in order to better understand what impressions are made. Finally, a third group of samples is used as a control. These samples are not exposed to any sorting equipment and are not put through the Postal Service at all. ESDAs are developed for all samples in each group and assessments are made as certain indentations are revealed.

This study is not meant to be exhaustive as it is not feasible to send mail through all Postal Service facilities. There are also countless combinations of equipment that a piece of mail can encounter, depending on the sending and receiving locations.

Questioned Documents, Indentations, Postal Service

K1 Effects of Hair Bleachers in the Analysis of Amphetamine(s) and Bath Salt Drugs

Jeffery Hackett, PhD, UCT, Inc, 2731 Bartram Rd, Bristol, PA 19007; Albert A. Elian, MS, and Kerrie Donovan, MS, Massachussetts State Police Crime Laboratory, 59 Horsepond Rd, Sudbury, MA 01776; and Michael J. Telepchak, MBA, UCT, Inc, 2731 Bartram Rd, Bristol, PA 19007*

After attending this presentation, attendees will learn about the effects of hair bleaching in the analysis of amphetamines and synthetic cathinones in hair using readily available Solid Phase Extraction (SPE) cartridges and tandem mass spectrometry.

This presentation will impact the forensic science community by offering analysts operating in forensic facilities information about the impact of bleaching materials used on hair analyzed for amphetamines and synthetic cathinones (bath salt) drugs analyzed by Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) and solid phase extraction.

Method: Samples of decontaminated hair (10mg) containing amphetamines and bath salt-type drugs (amphetamine, methamaphetamine, methylenedioxyamphetamine (MDA), methylenedioxymethamphetamine (MDMA), butylone, ethylone, flephedrone, mephedrone, methylone, methedrone, methcathinone (4-MEC), methylenedioxypyravalerone (MDPV), and pyravalerone were treated with 10% aqueous sodium hypochlorite solution (bleach), 3% aqueous hydrogen peroxide solution, or 3% aqueous ammonium hydroxide solution for 2 hr before being removed, washed, and dried. The samples were then digested in 0.1M NaOH (containing deuterated analogues) for 0.5 hr at room temperature. Each solution was adjusted to pH6 with 0.1M phosphate buffer (4mL) and applied to a conditioned SPE column. The samples were extracted on commercially available SPE columns (C8/SCX). After loading the sample, the sorbent was washed with deionized water, acetic acid (0.1M), and methanol (3mL of each, respectively). Each SPE column was dried and eluted with 3mL of a solvent consisting of methylene chloride/isopropanol/ammonium hydroxide (78:20:2). After elution, 200µL of mobile phase was added to the collection tube. The samples were then evaporated to the mobile phase for analysis by LC/MS/MS in positive Multiple Reaction Monitoring mode (MRM). Data is presented for MRMs of amphetamine, methamphetamine, MDA, and MDMA, butylone, ethylone, flephedrone, mephedrone, methylone, methedrone, methcathinone (4-MEC), methylenedioxypyravalerone (MDPV), and pyravalerone (and deuterated analogues), respectively.

Liquid chromatography was performed in gradient mode employing a 50 x 2.1mm C_{18} analytical column and a mobile phase consisting of acetonitrile and 0.1% aqueous formic acid. The gradient was programmed to run from 5% to 90% acetonitrile in 4.0 min and then back to 5% for re-injection. The total run time for each analysis was less than five minutes.

Tandem mass spectrometry was performed in using positive MRM mode. The following transitions were monitored (quantification ions underlined): Amphetamine m/z: 136.1 to 91.0, 65.0, Amphetamine-d_5: m/z 141.1 to 124.0, 93.0, Metamphetamine: m/z 150.1 to 91.1, 119.1 Methamphetamine-d_5: m/z 155.2 to 92.1, 121.2, MDA: m/z 180.2 to 163.1, 105.1, MDA-d_5: m/z 185.2 to 168.1, 110.1, MDMA: m/z 194.2 to 163.1. 105.1. MDMA-d_5: m/z 199.2 to 165.1, 106.8, Butylone: m/z 222.1 to 174.2, 204.2, Ethylone: m/z 222.1 to 174.2, 204.2, Flephedrone: m/z 182.1 to 164.2, 149.1, Mephedrone: m/z 178.1 to 145.1, 160.1, Methylone: m/z 208.1 to 160.1, 132.1, Methedrone: m/z 194.1 to 176.2, 161.1, Methylethylcathinone (4-MEC): m/z 192.1 to 174.2, 144.1, Methylenedioxypyravalerone (MDPV): m/z 276.2 to 135.1, 126.1 and Pyravalerone: m/z 246.2 to 105.1, 175.2, respectively. In this presentation, representative chromatograms are shown to illustrate the efficiency of the chromatography and analysis of amphetamine and synthetic cathinones

Results: The limits of detection/quantification for the SPE method were determined to be 0.05ng/mg and 0.1ng/mg, respectively for the amphetamines (amphetamine, methamphetamine, MDA, and MDMA) and synthetic cathininones (butylone, ethylone, flephedrone, mephedrone, methylone, methedrone, methcathinone (4-MEC), methylenedioxypyravalerone (MDPV), and pyravalerone). The method was found to be linear from 0.1ng/mg to 10ng/mg (r^2>0.999). Data is presented to show that recoveries of amphetamine were found to be greater than 90%. Interday and Intraday analysis of amphetamine were found to <7% and <10%, respectively. Matrix effects were determined to be <5%. Degradation of the amphetamines ranged from 77% to 45%, while the degradation of the synthetic cathinones ranged from 25% to 100% for the bleaching agents.

Conclusion: The use of the information given in this new procedure for the analysis of amphetamine and synthetic cathinones will be of great use to analysts in the field of forensic hair analysis as it demonstrates the use of SPE/LC/MS/MS to provide valuable data from about the effects of bleaching agents in hair analysis.

Hair, LC/MS/MS, SPE

K2 Extraction and Analysis of AM2201 Metabolites in Urine: A Drugs and Driving Case

Albert A. Elian, MS, Massachusetts Police State Crime Laboratory, 59 Horse Pond Rd, Sudbury, MA 01776; and Jeffery Hackett, PhD, UCT Incorporated, 2731 Bartram Rd, Bristol, PA 19007*

After attending this presentation, attendees will learn about the extraction and analysis of the hydroxy metabolites of AM2201 (a newer fluorinated synthetic cannabinoid) from urine using readily available Solid Phase Extraction (SPE) cartridges and tandem mass spectrometry.

This presentation will impact the forensic science community by offering forensic toxicology analysts and chemists involved with drugs and driving cases more information about the analysis of this synthetic cannabinoid (AM2201 hydroxylated metabolites) employing LC/MS/MS and solid phase extraction.

Method: In this method, urine (1mL samples (calibrators, controls, and test samples)) containing internal standard (THC-d_3/AM2201-OH-d_5) was enzymatically hydrolysed with β-glucuronidase before being adjusted to pH6 with 0.1M phosphate buffer. The samples were then applied to pre-conditioned SPE mixed mode columns (C_8-Weak Anion Exchange). The SPE columns were conditioned with methanol, dionized (DI) water, and 0.1M pH6 phosphate buffer (3mL, 3mL, 1mL, respectively). After loading the samples onto the columns, the SPE sorbents were washed with DI water and pH6 phosphate buffer containing 20% acetonitrile (v/v) (3mL of each) and then SPE columns were dried under full vacuum for 5 min. The analytes were eluted with 3mL of a solvent mixture consisting of ethyl acetate containing 10% methanol. The eluates were evaporated to dryness using nitrogen gas at 40°C and dissolved in 100µL of a mixture of: 95% aqueous formic acid (0.1%) and 5% acetonitrile (containing 0.1% formic acid). The samples were

analyzed by tandem mass spectrometry using positive Multiple Reaction Monitoring mode (MRM) and gradient liquid chromatography. Liquid chromatography was performed on a 50x2.0mm C_{18} analytical column with a guard column of the same chemistry. The mobile phase employed consisted of **A** aqueous formic acid (0.1%) and **B** acetonitrile (containing 0.1% formic acid). The gradient was started at 5% **B** and increased 90% **B** in 4 min, after which it was decreased to 5% **B** and kept until 5 min. The flowrate of the mobile phase was 0.5mL per min. Each analytical run was completed in 5 min.

In this presentation, representative chromatograms and calibration curves are shown to illustrate the efficiency of the chromatography and analysis of AM2201 and its metabolites.

Results: The limits of detection/quantification for the SPE method were determined to be 0.5ng/mL and 1.0ng/mL, respectively for the analytes The method was found to be linear from 1.0ng/ mL to 100ng/ mL (r^2>0.999). Data is presented to show that the recoveries of the AM2201 metabolite were found to be greater than 90%. Interday and intraday analysis were found to <7% and <10%, respectively. Matrix effects were determined to be <5%. No parent drug was found in the test sample. Results of the metabolite concentrations are shown in the presentation.

Conclusion: The use of the information given in this new procedure for the analysis of the metabolites AM2201 will be of great use to analysts in the field of forensic toxicology as it demonstrates the use of SPE/LC/MS/MS to provide valuable data regarding the metabolites of one of the newer synthetic cannabinoids

AM2201, SPE, LC/MS/MS

K3 Methylenedioxypyrovalerone (MDPV) Postmortem Blood Concentrations: A Series of Suicide Case Reports

George S. Behonick, PhD, Kevin G. Shanks, MS, and Andrea R. Terrell, PhD, AIT Laboratories, 2265 Executive Dr, Indianapolis, IN 46241*

The goal of this presentation is to gain an understanding of the analytical methods employed to qualitatively identify and quantitatively analyze postmortem specimens for the presence of MDPV and other related “bath salt” compounds. Additionally, attendees will gain insight into the interpretive relationships of MDPV postmortem blood concentrations in deaths where drugs were not a factor.

This presentation will impact the forensic science community by emphasizing these unique case histories and circumstances, frequently characterized with atypical or bizarre decedent behaviors, which can direct postmortem toxicological testing strategies to the analyses of MDPV and other “bath salt” compounds.

Methylenedioxypyrovalerone (MDPV), a synthetic beta-ketone resembling methylmethcathinone (mephedrone) and its analogs (commonly termed “bath salts”), has a worldwide distribution and is promoted as a “legal high.” Dubbed “not for human consumption,” these stimulant agents are easily purchased from a number of sources to include convenience stores, “head shops,” and the internet. The agents are identified as “bath salts,” “plant food,” “jewelry cleaner,” and “pipe cleaner” in an apparent attempt to circumvent laws regulating psychostimulant substances. MDPV is a stimulant chemically related to methylphenidate and methylenedioxymethamphetamine (MDMA); its pharmacological mechanism of action is similar to cocaine in acting as a dopamine and norepinephrine re-uptake inhibitor. The products are marketed with clever trade names (e.g., “Ivory Wave,” “Vanilla Sky,” “Hurricane Charlie,” and “Bolivian Bath”) and colorful creative packaging. Emergency departments and poison control centers throughout the United States have reported epidemic-like encounters characterized as sympathomimetic toxidromes accompanied by profound mental status and behavioral changes in users. Clinical case reports have also described paranoid psychosis and hallucinatory delirium following the use of MDPV. Persons intoxicated or under the influence of MDPV or other “bath salts” pose keen interest in forensic postmortem and human performance cases; however, routine toxicology screening techniques may not be adequate for detection and identification of these compounds. This study reports an analytical technique for the qualitative and quantitative analyses of MDPV in postmortem specimens. The method is suitable for the analyses of other “bath salt” compounds and is performed routinely by some laboratories in postmortem and human performance cases. The toxicological findings are presented for five postmortem cases submitted to a laboratory between February and November 2011, which include the quantitative analyses of MDPV in blood. The manner of death in all cases was suicide. Three of the cause-of-death classifications involved self-inflicted gunshot wounds, while two cases were attributed to hanging. Three of the five cases were male, with an age range of 25 – 36 years for the five decedents. The range observed for the concentration of MDPV in postmortem blood is 68.3 to 1,044ng/mL. MDPV and other “bath salt” compounds were extracted via a protein precipitation extraction with acetonitrile. Instrumental analysis utilized in identifying and quantifying MDPV was Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS). Three of five cases exhibited other positive toxicological findings (ethanol, benzodiazepines, THC-COOH, opiates and opioids); one case included detection of mephedrone in blood and other postmortem specimens.

Apparent recreational use of MDPV and other “bath salt” derivatives and analogs is an emerging substance abuse problem. The index of suspicion should be high among forensic pathologists, medical examiners/coroners, and toxicologists when a case history is characterized by bizarre, delusional, and hallucinatory decedent behavior. Profound, intentional self-harm with fatal consequence is described for the five cases in this series of reports; MDPV was quantitatively reported for postmortem blood in all cases, and witness accounts for two of the cases confirmed decedent use of “bath salts” prior to death.

MDPV, Blood, Suicide

K4 Fatal Overdose With the Anti-Diarrheal Medication Loperamide

Teresa R. Gray, PhD, 700 N 5th St, Richmond, VA 23219; and Kymberly Carr, BS, 830 Southampton Ave, Ste 400, Norfolk, VA 23510*

After attending this presentation, attendees will be briefed on an apparent suicidal overdose involving loperamide, including analytical parameters used for confirmation and quantitation.

This presentation will impact the forensic science community by describing lethal loperamide concentrations and autopsy observations. This case also highlights the importance of scene investigation and communication between the toxicology laboratory and medical examiners.

Loperamide is a Piperidine Opioid (PO) found in several over-the-counter anti-diarrheal preparations. Doses range from 2 – 4mg PO in adults, not to exceed 16mg daily and expected plasma concentrations are <0.01mg/L. At therapeutic doses, loperamide does not produce typical opioid effects on the central nervous system because of low systemic availability, high protein binding, and poor accumulation in the brain. Loperamide and its primary, inactive metabolite desmethylloperamide are almost immediately pumped out of the brain by P-glycoproteins. Adverse effects are rare, but can include cramps, nausea, drowsiness, dizziness, headache, and dry mouth. Overdoses are usually accidental, nonfatal, and occur in children under age three. Here is reported an apparent suicidal overdose involving loperamide.

A 20-year-old White male with a history of pain and depression was found dead at home along with eight empty 72-count bottles of 2mg loperamide hydrochloride tablets and a receipt of purchase dated

one day prior. No suicide note was found. Significant autopsy findings included clear, frothy fluid at the lips and slight vomitus on the face. Biological tissues and fluids collected at autopsy were submitted for toxicological analysis with loperamide noted as a suspected factor in death.

Femoral blood and urine were negative for ethanol, methanol, acetone, and isopropanol. Enzyme-linked immunosorbent assay screening for cocaine metabolite, opiates, methamphetamine/MDMA, phencyclidine, barbiturates, carisoprodol/meprobamate, fentanyl, methadone, zolpidem, amphetamine/phentermine, acetaminophen, and salicylate was negative in femoral blood. HPLC-UV analysis tentatively identified 7-aminoclonazepam, but was not confirmed by mass spectrometry. Alkali-extractable drug screening by liquid-liquid extraction and GC/MS was also negative.

Given the numerous empty bottles on scene and autopsy findings suggesting overdose, it was assumed that loperamide may be present in this case but instrument settings precluded identification as loperamide and desmethylloperamide are reportedly late eluters. As hypothesized, loperamide fortified into drug-free blood, extracted and analyzed by a normal GC/MS screen was not detected. By extending the final hold time, loperamide eluted with substantial tailing. Modifying the temperature ramp further improved peak shape and loperamide was confirmed in femoral blood and urine. Desmethylloperamide was tentatively identified by spectral library match in both matrices, but a reference standard is not commercially available for comparison.

This study successfully quantitated loperamide by GC/NPD using a less polar column and the optimized GC/MS chromatographic conditions. The linear dynamic range was from 0.1 – 6mg/L and accuracy was greater than 85%. Loperamide results obtained in blood, urine, liver, and gastric contents were 0.4mg/L, present, 7mg/kg, and 30mg/kg, respectively; urine was evaluated qualitatively per department policy.

The medical examiner ruled the death a suicidal overdose of loperamide. Two suicidal loperamide overdoses are reported with loperamide concentrations of 2.6mg/L (blood), 12.5mg/kg (liver), and 3mg/kg (gastric contents) in one case and 0.084mg/kg (blood) and 0.87mg/kg (liver) in the other. Blood concentrations in this case and the literature greatly exceed expected therapeutic concentrations. Presumably in overdose, the P-glycoprotein efflux mechanism is overwhelmed, allowing loperamide to exert typical opioid CNS effects leading to euphoria and ultimately death.

Internet-user forums debate the effectiveness of high-dose loperamide to achieve euphoria, ward off withdrawals, and potentiate other opioid receptor agonists. If euphoria is achieved, the high is reportedly not as intense as other prescription opiates/opioids and does not justify the cost or gastrointestinal side effects. Still, since loperamide is easily accessible, the potential for abuse exists and laboratories should evaluate whether their basic drug screens are capable of detecting this late-eluting compound.

Loperamide, Suicide, Death Investigation

K5 Analysis of a Group of Volatile Compounds With Forensic Interest: Validation of an Analytical Method by HS-GC/FID

Carla Monteiro, BS, Miguel Franco, MSc, Cristina Cordeiro, MSc, Alda Claro, BS, Paula Proença, BS, Carla Mustra, MS; and Francisco Corte-Real, PhD, Instituto Nacional de Medicina Legal, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; and Duarte N. Vieira, PhD, MD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

After attending this presentation, attendees will understand the potential contribution of a new method for detection and quantification of volatile substances in different biological matrices with interest in forensic contexts.

This presentation will impact the forensic science community by allowing toxicology experts to understand the specificities and difficulties of validating an analytical method developed for the analysis of volatile compounds with different solubilities like toluene or acetone.

Although pharmaceutical products, drugs of abuse and ethanol (alcohol) are the most common poisons encountered in clinical and forensic toxicology, the possibility of poisoning with a wide range of other compounds has to be taken into account. These include pesticides, volatile substances, metals and anions, and natural toxins.

The purpose of this work was the optimization and validation of a sensitive and rapid analytical procedure to the detection and quantification of some volatile organic compounds (acetaldehyde, ethyl acetate, acetone, acetonitrile, 1-butanol, diethyl ether, methanol, 2-propanol, chloroform, toluene and xylene) in different matrices (blood, urine and vitreous humor) using a gas chromatograph, equipped with a flame ionization detector coupled to a headspace injector of fixed volume (1mL loop) Headspace/Gas Chromatograph/Flame Ionization Detector (HS/GC/FID).

The substances under study were divided and grouped according to their solubility and working range. For substances with high water solubility, a mixture was created (acetaldehyde, ethyl acetate, acetone, acetonitrile, 1-butanol, diethyl ether, methanol, 2-propanol). The other substances, whose solubility in water was practically non-existent but had a good solubility in methanol, were divided according to the working range.

Prior to gas chromatographic analysis, all specimens, including the calibrators, were diluted 1:10. By volume, i.e., 100µL of urine, vitreous humor, or blood were diluted with 1mL aqueous solution of n-propanol (100mg/L), used as internal standard.

The chromatographic separation was performed using two capillary columns with different polarities, in order to ensure fulfillment of the identification criteria recommended for this type of analysis (Flanagan *et al*., 1997; Kugelberg *et al*., 2007).[1,2] Chromatographic analysis conditions were as follows: an initial oven temperature of 40°C, held for 5 min, followed by a rise to 130°C with a gradient of 10°C/min. At the end of each analytical cycle, the initial conditions were resumed and maintained for 3 min. The injector temperature was maintained at 150°C, with a split ratio of 4:1, with detectors set at 250°C. The carrier gas was helium at a constant flow rate of 2.7mL/min.

All compounds studied, including n-propanol (internal standard), eluted in a time interval of 15 min and were all well resolved with no interference of metabolites, degradation products, or other substances, such as t-butanol, formaldehyde, ethylene glycol, methyl and ethyl formate, etc. In the concentration ranges analyzed, and for all compounds, the analytical response proved to be linear with a correlation coefficient greater than 0.9962. The limits of detection varied between 1mg/L (1-butanol, toluene, and xylene) and 10mg/L (chloroform) and the limits of quantification between 2mg/L (xylene) and 31mg/L (chloroform). The coefficients of variation obtained for intermediate precision varied from 0.8% (acetonitrile) to 7.0% (xylene). The accuracy of the method varied between 87.8% (acetaldehyde) to 106.3% (xylene).

The study focused on all parameters included in the validation procedure for quantitative methods, in place at the forensic toxicology laboratory of Centre Branch—Portuguese National Institute of Legal Medicine. These included the study of selectivity, linearity, limits of detection and quantification, precision, accuracy, robustness and carryover, having the method shown to be suitable for the intended purpose.

HS-GC/FID, Volatile, Validation

K6 Applications of Hydrophilic-Interaction Chromatography in Forensic Science

Thomas A. Brettell, PhD, and James N. Anasti, BS, Cedar Crest College, 100 College Dr, Allentown, PA 18104*

After attending this presentation, attendees will have a better understanding about hydrophilic interaction liquid chromatography and review of literature displaying how this method can be used for the forensic science community.

This presentation will impact the forensic science community by providing information on the application of Hydrophilic Interaction Liquid Chromatography (HILIC) to the separation of analytes in different matrices including forensic drug and toxicological samples.

HILIC is a mixed or multi-modal partition chromatography designed specifically to separate polar, ionic, or weakly acidic and basic compounds. The aqueous/organic mobile phase is passed over the more polar stationary phase. Columns consist mainly of bare silica or chemically bonded silica such as simple amide, cyano, and diol to complex alkyl and polymeric coatings. The columns can be particle packed or monolithic. The bonded moieties can range in thickness to allow for specific aqueous saturation. The aqueous layer creates electrostatic repulsion and other intermolecular forces to aid in the separation process of more similar compounds such as isomers.

The highly organic mobile phase is composed mainly of acetonitrile and can be controlled through gradient or simple isocratic elution. High concentrations of organic modifiers allow for proper ionization of analytes and, therefore, are compatible with an electrospray ion source of a mass spectrometer. Due to advances in mass spectrometry, this is the detector type of choice when looking at low concentration of analytes and analytes in difficult matrices such as whole blood. As an alternative to normal and reverse phase liquid chromatography, HILIC sustains selectivity and prominent peak shape while using rapid isocratic methods.

Reversed reverse-phase or aqueous normal phase chromatography was coined HILIC by A.J. Alpert in 1990. The first applications of HILIC were primarily of bio analytics such as proteomics and metabolomics because of the ability to purify bio markers, amino acids, and other proteins. In the pharmaceutical industry, the use of HILIC has grown for purposes such as quality control and processes pertaining to research and development. Although HILIC is not a new technique, this form of chromatography is beginning to become more prevalent because of stationary phase developments. Advances in stationary phase preparation, including nanostructures within polymeric scaffold, create efficient preparation and productive permeability. The new production techniques allow not only for a variety of moieties, but also lower cost and create a more consistent product. The separation efficiencies and increased production of HILIC columns has significantly amplified research and applications. Today, HILIC can be seen to be applied to broader applications. HILIC has been applied to many fields, including forensic science and forensic toxicology. Designed for polar metabolites, HILIC is a valuable asset to forensic toxicologists for the analysis of such polar drug metabolites.

Reviews of forensic HILIC applications are seen in such studies as comparison of ethyl-glucuronide distribution in pubic and head hair. Other topics include body fluid and tissue distribution of cocaine and associated metabolites. Estimations of *g*-hydroxybutyrate levels in serum also use HILIC. A method for screening and confirming stimulants, narcotics, and beta-adrenergic agents in urine used the capabilities of HILIC. A comprehensive review for HILIC of seized drugs and related compounds by the Drug Enforcement Agency is also cited. The advantages of HILIC separation of isomers such as morphine-6-glucurinde and morphine-3-glucuronide are also presented. This presentation will review general theory and forensic applications of HILIC for the past 10 years.

HILIC, Forensic, HPLC

K7 Analysis and Characterization of the First- and Second-Generation Raving Dragon Novelty Bath Salts

Justin L. Poklis, BS, VCU Dept of PhramTox, 410 N 12th St, Rm 746, PO Box 980613, Richmond, VA 23219-0613; Carl E. Wolf, PhD, Virginia Commonwealth Univ, PO Box 980165, Richmond, VA 23298-0165; Omar I. ElJordi, BS, 3940 Oakleys Ln, Richmond, VA 23223; Kai Liu, PhD, Virginia Commonwealth Univ, PO Box 980581, Richmond, VA 23298-0581; Shinjun Zhang, PhD, Virginia Commonwealth Univ, PO Box 980540, Richmond, VA 23298-0540; and Alphonse Poklis, PhD, VCU/MCVH Station, Medical Coll of Virginia, Box 98-165, Richmond, VA 23298*

After attending this presentation, attendees will see an example of how quickly a single brand of bath salts can change its ingredients as well as the spectroscopic characterization of 3,4-methylenedioxy-N-methylcathinone (methylone) and 2-methylamino-1-phenylpentan-1-one (pentedrone).

This presentation will impact the forensic science community by illustrating an example of the change in active ingredients found in bath salt preparations after the administrator of the Drug Enforcement Administration (DEA) issued a temporary schedule for three synthetic cathinones under the Controlled Substances Act (CSA). These substances were: 4-methyl-N-methylcathinone (mephedrone), 3,4-methylenedioxy-N-methylcathinone (methylone), and 3,4-methylenedioxypyrovalerone (MDPV). Also presented will be the Mass Spectrum, Nuclear Magnetic Resonance (NMR), Ultraviolet (UV), and Infrared (IR) spectroscopic characterization of the first-generation methylone and the second-generation 2-methylamino-1-phenylpentan-1-one (pentedrone), the lone ingredients found in the bath salts sold under the brand “Raving Dragon.”

Introduction: In recent years, a large number of new, uncontrolled designer drugs have appeared on the market. Several of the new synthetic drugs that are sold as bath salts belong to one of the classes of β-ketophenylethylamines or phenethylamines. These drugs are available in small packets containing milligrams to gram quantities. They are available via the internet or at various convenience stores, gas stations, truck shops, tattoo parlors, and discount tobacco outlets and are often sold as bath salts with the disclaimer, “Not For Human Consumption.”

In February of 2011, several packets containing 0.3g of an off-white powder sold under the name Raving Dragon Novelty Bath Salts were obtained via a website of the same name. This product was removed from the market in October of that year, coinciding with the DEA issuing a temporary schedule of mephedrone, methylone, and MDPV under the CSA. Four months later in February of 2012, a new bath salt was released from the same company under the new name Raving Dragon Voodoo Dust; again several packets were obtained containing 0.5g of a fine white powder.

Methods: Both products were subjected to various spectroscopic techniques: mass spectroscopy (Shimadzu MDGCMS QP-2010 Ultra), NMR spectroscopic (Bruker Ultrashield Plus-400MHz), UV (Shimadzu UV-1601 UV-Visible Spectrophotometer), and IR spectroscopy (Thermo Scientific Nicolet IS10), for the characterization and identification of the active ingredients in the packets. Once the spectroscopic techniques results were obtained for the active ingredients, these results were compared to reference standards in order to confirm their identity and purity.

Results: It was determined that the first-generation Raving Dragon Novelty Bath Salts contained methylone, one of the three compounds added to the banned substance list in October of 2011. The second-generation novelty bath salt, Raving Dragon Voodoo

Dust, was found to contain pentedrone. At the present time, pentedrone is unscheduled by the DEA. The purity of the bath salts was determined by UV using the specific absorbance (defined as the $A_{1cm}^{1\%}$ value) of the reference standard vs. the bath salt. Methylone with an $A_{1cm}^{1\%}$ of 550 at λ= 235 was determined to be 89% of the ingredients of the Raving Dragon Novelty Bath Salts. Pentedrone with an $A_{1cm}^{1\%}$ of 579 at λ= 256 was calculated to be 100% of the ingredients of the Raving Dragon Voodoo Dust.

Discussion: Recently, numerous articles relating to the pharmacological and toxicological effects of methylone, including several postmortem cases, have been published. Pentedrone has been previously identified in samples intercepted by the Canada Border Services Agency, customs in Berlin, and police organizations in several federal states of Germany. No specific pharmacological and toxicological data is available.

Conclusion: Once a synthetic compound or group of synthetic compounds are added to the DEA list of scheduled compounds, new analogs appear in their place. In the case of the Raving Dragon Novelty Bath Salts, methylone was replaced within four months of its scheduling with pentedrone as the active ingredient. Pentedrone should be added to the fast-growing group of "Legal High" (designer) drugs that can be expected to be found in bath salt products. The analysis of the Raving Dragon Brand Bath Salts illustrates the rapidly changing active ingredients in "Legal High" preparations that are readily available to the public.

This project was supported by the National Institute on Drug Abuse (NIDA) Center for Drug Abuse Grant P50DA005274.

Bath Salts, Methylone, Pentedrone

K8 Characteristics of Toxicology Laboratories Performing Drug-Impaired Driving Casework

Jennifer L. Turri, BS, W 3901 Johnson Rd, Vulcan, MI 49892; Kayla Lowrie, MS, 520 Stevens Dr, Apt 208, King of Prussia, PA 19406; Jillian K. Yeakel, MS, 105 Revere Dr, Harleysville, PA 19438; and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the characteristics of U.S. laboratories performing toxicological analysis in drug-impaired driving cases, focusing on their size, workload, turnaround time, and level of engagement in training. The purpose of presenting this data is to allow attendees to evaluate the findings of a survey of toxicology laboratory users and compare how their own laboratory performs relative to others in terms of size, requests for testimony, and available instrumentation.

This presentation will impact the forensic science community by improving the understanding of expectations and needs of clients of Driving Under the Influence of Drugs (DUID) testing laboratories and standards of service delivery within the field.

Cases involving suspected DUID contain several important elements, including: an officer trained in documenting observations regarding the driving and subject behavior as well as the collection of a biological specimen for comprehensive toxicology testing; a toxicology lab to analyze the specimen for illicit substances; and a prosecutor to utilize the data in the court system. Three surveys were conducted, in collaboration with the National Safety Council, to poll State's Drug Recognition Experts (DREs), Traffic Safety Resource Prosecutors (TSRPs), and toxicology labs with the purpose of gathering information about the needs of the traffic-safety community regarding drug testing and testimony in DUID/DRE cases. TSRPs, DREs, and toxicology lab directors from each state at various jurisdictional levels were surveyed to identify areas of need in the scope and sensitivity of testing available, turnaround time, training, expertise for trial or preparation, meeting court-imposed deadlines, and other service factors of unmet need in training and research for scientists, law enforcement, and prosecutors.

In terms of staffing, the reported mean (median) size of the labs surveyed was 8 (6.5) analysts per lab (range 1-200), with a reported mean (median) of 74 (25) DUID/DRE cases each month per laboratory (range 1-1800). As expected, the size of the lab and the resources available affected the average. In terms of turnaround time, both DREs and TSRPs reported an average turnaround time of eight weeks with respect to drug analysis, and corresponding satisfaction ratings started to decrease among the DREs and TSRPs when turnaround time reached six to eight weeks. According to prosecutors, toxicologist's testimony affects trial outcome a reported average of 63% of the time, and there has been an increase in toxicologist appearances in court due to the confrontation clause issues which in turn contributes to an increase in the analytical backlog in the lab due to analysts being called to testify.

When asked about whether toxicologists are involved in DRE or TRSP training, only 53% of the respondents said they were involved. This type of training entails educating the DREs and prosecutors of what type of testing is provided, specific drugs that are tested for, understanding reports, statistics on drugged driving, and, for prosecutors in particular, how results in a given case are interpreted. When asked why a toxicologist isn't involved in DRE or prosecutor training, the majority reported that they haven't been asked, while others reported that it wasn't seen as necessary or there is insufficient staffing, funds, or resources. In addition to training among the DREs and prosecutors, toxicology labs also reported an additional need for training among the staff. The greatest areas of need for training include instrumentation, uncertainty determination, confirmation testing, and mock-trial training. Other high priorities for additional resources reported by the toxicology laboratories include additional staffing, instrumentation for confirmation, and upgrading or obtaining a new facility.

DUID, Lab Management, Testimony

K9 Sertraline in Postmortem Blood and Liver: Deaths in North Carolina (2002 – 2011)

Sandra C. Bishop-Freeman, PhD, 1001 Brinkhous-Bullitt Bldg, Campus Box 7580, Chapel Hill, NC 27599-7580; Ruth E. Winecker, PhD, OCME, Campus Box 7580, Chapel Hill, NC 27599-7580; Laura W. Friederich, BS, 613A Pleasant Dr, Durham, NC 27703; and Erin M. McIntee, MS, OCME, 1001 Brinkhous-Bullitt Bldg, Univ of North Carolina, Campus Box 7580, Chapel Hill, NC 27599*

After attending this presentation, attendees will have greater insight into the different types of postmortem casework associated with sertraline and norsertraline at therapeutic and toxic concentrations.

This presentation will impact the forensic science community by providing information regarding sertraline and norsertraline concentrations as it relates to cause and manner of death determinations.

Sertraline (Zoloft®) is a Selective Serotonin Reuptake Inhibitor (SSRI) used in the treatment for depression in typical, daily adult doses ranging from 50 – 200mg. Patients on chronic oral daily doses of as much as 300mg reached a steady-state plasma level averaging 0.206mg/L (0.099-0.309mg/L). Sertraline undergoes N-demethylation to norsertraline which has about 10% – 20% the pharmacologic activity of its parent.

At the North Carolina Office of the Chief Medical Examiner, cases suspicious for toxicological cause or with essentially negative autopsy findings are routinely screened for common over-the-counter, prescription, and illegal drugs via various laboratory techniques. A search of the database for sertraline/norsertraline liver data with or without corresponding blood data revealed upwards of 200 cases over a 10-year period. Decedents were divided into three groups

according to the classification of the effect of sertraline as it impacts the cause of death. The pathologist considered sertraline to be either the primary cause of death (below), additive to the cause of death, or not implicated in death. The foci of the study are the overdose cases where sertraline was determined to be the primary cause of death regardless of other drugs and their concentrations (N=30) and non-overdose cases where sertraline received no classification (N=140). The latter focus may be considered postmortem normal concentrations.

Sertraline metabolism and elimination could be altered by the health of the patient, drug-drug interactions, and genetic deficiencies. The concentrations of sertraline and norsertraline, as well as the parent/metabolite ratio, were reviewed in light of pathological findings and co-intoxicants. Case studies involving significant postmortem redistribution and potential drug interactions will be highlighted.

Sertraline Overdose Cases (Suicide)

Specimen Location	N	Range		Average		Median	
		Sertraline	Norsertraline	Sertraline	Norsertraline	Sertraline	Norsertraline
Central (mg/L)		0.49-25	0.32-8.2	4.19	2.28	1.85	1.5
Peripheral (mg/L)		0.74-9.2	0.27-4.6	2.86	1.79	1.75	1.55
Liver (mg/kg)	20	27-490	5.4-940	137	127	94	72.5

Sertraline Overdose Cases (Accident)

Specimen Location	N	Range		Average		Median	
		Sertraline	Norsertraline	Sertraline	Norsertraline	Sertraline	Norsertraline
Central (mg/L)		0.61-3.1	0.93-4	1.16	1.92	0.82	1.6
Peripheral (mg/L)		0.74-1.8	0.36-3.7	1.21	1.71	1	1.3
Liver (mg/kg)	10	20-279	15-518	90.2	166.8	63.5	155

Sertraline, Death Investigation, Toxicology

K10 The Effects of Burn Injury on Tissue Ethanol and Ethyl Glucuronide Concentrations

Trista Haupt Wright, PhD, 700 N 5th St, Richmond, VA; and Kenneth E. Ferslew, PhD, East Tennessee State Univ, Section of Toxicology, Box 70422, Johnson City, TN 37614*

After attending this presentation, attendees will better understand the effects of burn injury on tissue ethanol and ethyl glucuronide concentrations after using a series of burn injury experiments to mimic a residential house fire and determine if visual appearance or core body temperature correlates to changes in analyte concentrations.

This presentation will impact the forensic science community by providing insight to the potential changes in ethanol and Ethyl Glucuronide (EtG) concentrations after burn injury and potential inaccuracies for determining impairment using post-incineration tissue ethanol concentrations.

Ethanol is a popular, legal drug and its deleterious cognitive effects cause an increased risk for residential house fires. Currently, there is no known data available to validate tissue ethanol and EtG concentrations and their interpretations in fire-related death victims. Tissues collected at autopsy must be used for toxicological analysis when blood is not available. The literature does not address the possibility that antemortem tissue ethanol or EtG concentrations maybe altered in fire deaths.

The main objective was to determine if exposure to a house fire causes changes in postmortem ethanol and EtG concentrations from antemortem concentrations.

Methodology included a Sprague Dawley rat model being used to determine the effect of burn injuries, using two fire-related models, on liver, kidney, and heart ethanol and EtG concentrations. The rodents were gavaged with ethanol (4g/kg) then euthanized after three hours by carbon dioxide. Burn injuries from fire deaths were mimicked using the reported average response time by local fire departments and two types of burn injury using a fire pit and a gas grill with these conditions:

Flame burn injury (Fire Pit) (n=9 per group, 3 groups) Temperature: >1000°F	Duration (minutes): 2, 5, and 8
Thermal burn injury (Gas Grill) (n=9 per group, 9 groups) Temperature: 200°F, 400°F, or 600°F	Duration (minutes): 2, 5, or 8

Homogenized specimens were analyzed for ethanol by Gas Chromatograph/Flame Ionization Detector (GC/FID) and EtG by enzyme immunoassay. Tissue ethanol and EtG concentrations from burn injury groups, non-ethanol dosed controls, and non-burn injured controls were compared to determine if any differences occurred in analyte concentrations due to flame and/or thermal burn injury. Core body temperatures were monitored using a rectal probe to determine if a correlation existed between changes in analyte concentrations and maximum core body temperatures.

The result was a significant time/temperature increase in tissue ethanol concentrations from both burn injury models. Only the greatest exposure to burn injury with both models produced a significant increase in EtG concentrations. Lesser time/temperature exposures produced a significant decrease in liver ethanol and kidney EtG concentrations. Tissues collected from non-dosed controls did not have detectable ethanol or EtG concentrations produced by burn injury. Changes in ethanol and EtG concentrations and organ weights did not correlate, but changes may be related to maximum core body temperature. Maximum core body temperatures ranged from 96°F – 151°F for burn injury groups.

In conclusion, the burn experiments using a rodent model suggest that caution should be used when predicting ethanol impairment from postmortem fire victim tissue ethanol and EtG concentrations because ethanol and EtG concentrations maybe altered from burn injury. In addition, it was determined that false positives are unlikely in individuals who have not consumed ethanol. This study was unable to determine the mechanism by which the changes in analyte concentrations were altered in corpses exposed to flame or thermal burn injury.

Burn Injury, Ethanol, Ethyl Glucuronide

K11 Blood Glucose Concentrations After Burn Injury

Trista Haupt Wright, PhD, 700 N 5th St, Richmond, VA; and Kenneth E. Ferslew, PhD, East Tennessee State Univ, Section of Toxicology, Box 70422, Johnson City, TN 37614*

After attending this presentation, attendees will have a better understanding of burn injury effects on fire victims' blood glucose concentrations.

This presentation will impact the forensic science community by providing an understanding of the potential changes that can occur in post-incineration blood glucose concentrations compared to antemortem blood glucose concentrations in fire-related deaths after burn injury.

Changes in postmortem biochemistry make interpreting toxicology results difficult when attempting to predict antemortem concentrations. Blood glucose concentrations are known to rapidly decrease in the hours following death; however, postmortem vitreous humor glucose concentrations are stable and can be used to determine if hyperglycemia was a factor in the decedent's death. There does not appear to be any literature investigating if burn injury changes antemortem blood glucose concentrations in post-burn injury blood specimens.

The main objective was to determine if post-burn injury blood glucose concentrations are altered by excessive thermal and/or flame burn injury compared to antemortem blood glucose concentrations.

Methodology included a Sprague Dawley rat model being used to determine the effects of burn injuries with two fire-related models, thermal and flame burn injury. The burn injuries produced by the different burn injury groups ranged from scorched hair to loss of limbs. One hundred twenty-six male rats were gavaged orally with 4g/kg of ethanol then placed in metabolic cages for three hours until carbon dioxide euthanization. Burn injuries from fire deaths were mimicked using the reported average response time by local fire departments and two types of burn injury, using a flame and thermal injury, with these conditions:

Flame burn injury (Fire Pit) (n=9 per group, 3 groups) Temperature: >1000°F	Duration (minutes): 2, 5, and 8
Thermal burn injury (Gas Grill) (n=9 per group, 9 groups) Temperature: 200°F, 400°F, or 600°F	Duration (minutes): 2, 5, or 8

Pre- and post-burn injury blood glucose concentrations were measured in the heart blood using a Relion Ultima point-of-care blood glucose monitor. Post-burn injury heart blood was collected after refrigeration of the burn injured corpses upon reaching a core body temperature of 50°F. A short duration between death and post-burn injury blood collection and refrigeration was implemented in this procedure to minimize experimental glucose changes. Pre-burn injury core body temperatures and maximum core body temperatures were measured using a rectal probe to determine if there was any correlation between core body temperatures and changes in blood glucose concentrations.

Results revealed maximum core body temperatures ranged from 90°F – 15545°F after flame or thermal burn injury. Post-burn injury blood glucose concentrations in higher maximum core body groups, flame burn injury for eight minutes, and thermal burn injury at 600°F for eight minutes were 30% and 36% greater respectively, compared to pre-burn injury blood glucose concentrations ($p<0.05$). Lesser time/temperature exposures produced a significant decrease in post-burn injury blood glucose concentration ($p<0.05$). Low maximum core body temperature groups had a 50% – 69% decrease in post-burn injury blood glucose concentrations compared to pre-burn injury concentrations. The rate of blood glucose decrease was lessened as time/ temperature exposure increased. Groups that had some of the hotter maximum core body temperatures (thermal burn injury at 400°F for eight minutes, thermal burn injury at 600°F for five minutes, and both burn injury controls) had a much smaller decrease (0% – 27%) in post-burn injury blood glucose concentrations compared to pre-burn injury concentrations.

In conclusion, the burn injury experiments using a rodent model suggest that blood glucose is altered by excessive burn injury. Despite efforts to minimize the loss of blood glucose in post-burn injury, the results indicate that at lower maximum core temperatures, post-burn injury blood glucose concentrations were significantly decreased compared to pre-burn injury concentrations. The natural decline of blood glucose was observed in lower burn injury groups. The decrease in postmortem blood glucose concentrations was disrupted as the burn injury increased in the experiments. The natural process is overshadowed by increasing blood glucose concentrations at higher maximum core body temperatures/longer exposure to burn injury. Blood glucose was significantly elevated in the Sprague Dawley rats that had excessive burn injury/higher maximum core body temperature (thermal burn injury 600°F for 8 min). The literature describes a relationship between hyperglycemia and burn patients. The severely burn-injured corpses exhibited elevated glucose concentrations and suggests that burn injury alters normal postmortem pathological changes. Time and temperature of exposure correlate to core body temperature change and result in a corresponding change in post-burn injury blood glucose concentration.

Blood Glucose, Burn Injury, Rodent Model

K12 Evaluation of the Chemical Derivatization of Nine Different Cathinone Bath Salts Analogs

Omar I. ElJordi, BS, 3940 Oakleys Ln, Richmond, VA 23223; Carl E. Wolf, PhD, PO Box 980165, Richmond, VA 23298-0165; Justin L. Poklis, BS, VCU Dept of PhramTox, 410 N 12th St, Rm 746, PO Box 980613, Richmond, VA 23219-0613; and Alphonse Poklis, PhD, VCU/MCVH Station, Box 98-165, Richmond, VA 23298*

The goal of this presentation is to provide the forensic community the optimal derivative to be used in the identification and quantification of bath salts.

This presentation will impact the forensic science community by providing the optimal derivatizing agent, to date, for the drugs cathinone, methcathinone, methylone, methedrone, mephedrone, ethcathinone, ethylone, pentedrone, pentylone, and butylone to utilize in the everyday work of identifying submitted substances. Over the past few years, so-called bath salts drugs have become a major substance-abuse problem in the United States. Cathinone is a naturally occurring stimulant found in *Catha edulis*. It is a beta-keto derivative of amphetamine with similar psychological and behavioral effects. Methcathinone, methedrone, methylone, mephedrone, ethcathinone, ethylone, pentedrone, pentylone, and butylone are designer drugs of cathinone. The beta-keto phenethylamine side-chain varies in length of the alkyl chain at the gamma carbon while the phenyl ring either has no attachment, a methyl group, a methoxy group, or a methylene dioxy ring attached. While cathinone, methcathinone, mephedrone, and methylone are Schedule I drugs, the rest have not yet been controlled. Due to the structure resemblance, highly specific analytical methods such as Mass Spectrometry are necessary to accurately identify these abused bath salts.

A Multidimensional-Gas Chromatography/Mass Spectrometry (MD-GC/MS) (Shimadzu Scientific, Inc.) equipped with a Rtx-5 (20m x 0.18mm ID x 0.2df) and a Rtx-50 (10m x 0.18mm ID x 0.2df) columns (Restek Corporation), a Dean's switch, and a 2010 Ultra GC/MS system with EI ionization was used. The oven temperature was programmed from 150°C, initial hold 0.1 min, to 320°C at 25°C/min. The inlet temperature and transfer temperature were 275°C and 280°C, respectfully. The drugs were initially evaluated underivatized and then derivatized using 5µg of standard in methanolic solution and evaporated to dryness under N_2 at room temperature. The residue was derivatized using either Heptafluorofutyric Anhydride (HFBA), Propionic Anhydride (PA), Acetic Anhydride (AA), Trimethylsilane (TMS, BSTFA + 10% TMCS), t-butyl (MTBSTFA, MTBSTFA + 1% TBDMCS), MethElute, or N-trifluoroacetyl-*l*-triprolyl chloride (*l*-TPC).

The underivatized bath salts analysis resulted in poor chromatographic characteristics and small base peak fragment ions. The optimal derivative was determined to be HFBA, which demonstrated the best chromatographic resolution, characteristic fragmentation, and symmetrical peak shape. HFBA required a lower temperature and shorter reaction time to obtain the derivatives as compared to PA, AA, TMS, and MTBSTFA. Flash derivatization was performed with MethElute. The HFBA derivative results are as follows:

Drug	R_t (min)	Base Ion (m/z)	Qualifier ion m/z (relative abund.%)	Molecular Weight (m/z)
Cathinone	4.5	105	240 (30), 77(4)	345
Methcathinone	4.6	105	254 (29), 77 (81)	359
Ethcathinone	5.0	268	373 (0.2), 134 (2), 105 (50), 77 (21)	373
Mephedrone-D3	5.1	119	257 (21), 91(18)	376
Mephedrone	5.2	119	373 (0.1), 254 (20), 91 (20)	373
Pentedrone	5.2	282	387 (1), 105 (61), 77 (26)	387
Methedrone	5.9	135	254 (8), 107 (6)	389
Methylone	6.4	149	254 (18), 121 (11)	403
Methylone-D3	6.4	149	406 (3), 257(19), 121 (11)	406
Butylone	6.6	149	417 (4), 268 (27), 121 (11)	417
Ethylone	6.7	149	417 (2), 268 (33), 121 (11)	417
Pentylone	6.9	149	431 (3), 282 (21), 121 (10)	431

The shift in retention times of the PA and AA derivatives showed successful derivatization, but the mass spectrum contained uncharacteristic 44m/z and 58m/z base ions. The MTBSTFA, TMS, and MethElute derivatives revealed incomplete derivatization resulting in up to two peaks; a derivatized drug peak and underivatized drug peak or only the completely underivatized. The *l*-TPC derivative was successfully synthesized, resulting in two peaks in mixtures where the solution contained a racemic mixture of the drug.

The HFBA derivative was determined to be the best overall derivative for the identification of the listed bath salts. Bath salts can also be derivatized using *l*-TPC, which can assist in differentiating steroisomers if needed.

Bath Salts, Derivatization, Mass Spectroscopy

K13 "Benzofury" Also Known as 6-APB (6-(2-Aminopropyl)-2,3-Dihydrobenzofuran): A Recent Fatality Involving an Unusual Drug

Kimberly McCall-Tackett, BS, Diane J. Mertens-Maxham, BS, Robert E. Lyon, DO, and Norman A. Wade, MS, Maricopa County MEO, Forensic Science Center, 701 W Jefferson St, Phoenix, AZ 85007*

After attending this presentation, attendees will be alerted to a popular new "research chemical" being sold over the internet, 6-(2-aminopropyl)-2,3-dihydrobenzofuran or 6-APB, commonly referred to as "Benzofury" and being used as an ecstasy substitute. This presentation will aid forensic toxicologists in the identification of this unusual compound and provide quantitation data from a recent postmortem case.

This presentation will impact the forensic science community by providing scientific literature from a recent postmortem case involving 6-APB. There is little to no toxicological data available at this time and the presentation of this case may help in compiling such data.

Benzofury (6-(2-Aminopropyl)-2,3-dihydrobenzofuran) or 6-APB, has become a popular "research chemical" available for sale over the internet. It is being marketed as "plant food" and has recently become available in its pure powder form. It is gaining popularity among recreational users for its reported euphoric and psychedelic properties, which are thought to be similar to Methylenedioxyamphetamine (MDA). It is in the phenethylamine class of drugs and an analog of 3,4- MDA, with an oxygen atom within the methylenedioxy portion of MDA being replaced with a methylene group. It is thought to be an entactogen, stimulant, and psychedelic drug and is currently unscheduled in the United States. However, it may be covered in the Federal Analog Act and is still currently legal in several other countries. Dr. David Nichols and his team first investigated 6-APB around 1993 at Purdue as a potential antidepressant which could also possibly be used in conjunction with psychotherapy.

A 21-year-old male had been drinking and using drugs over the course of an evening with two friends at a local motel in Peoria, AZ. They purchased nine pills of what they thought were ecstasy, each consuming three of the pills. During the night, the decedent became aggressive and violent and the friends feared they would be removed from the property. One of the friends put the decedent face down on the bed and straddled him in an effort to calm him. The attempt to restrain him lasted approximately 15 minutes and ended with the friend putting the decedent in a choke hold. The decedent was then found to be unresponsive and emergency medical services were summoned. He was transported to a local hospital where his death was pronounced in the emergency department.

The decedent was transported to the medical examiner's office where a full autopsy was performed. The only notable findings were contusions from the restraint. Multiple postmortem samples including vitreous, cardiac blood, urine, bile, and gastric contents were collected and sent to the toxicology laboratory for testing. Blood and urine specimens were subjected to a qualitative analysis using a basic pH screen with a liquid/liquid extraction and analyzed by Gas Chromatography/Nitrogen Phosphorus Detection (GC/NPD), then confirmed by Gas Chromatography/Mass Spectrometry (GC/MS). Volatiles were assayed on vitreous and cardiac blood using Gas Chromatograph/Flame Ionization Detector (GC/FID). The blood was also screened by Enzyme-Linked Immuno-Sorbent Assay (ELISA) for barbiturates, benzodiazepines, benzoylecgonine, opiates, methamphetamine, and fentanyl. The methamphetamine screen reacted at a low positive level. A sympathomimetic amine quantitation was performed on the cardiac blood by GC/MS Selected Ion Monitoring (SIM), with a large unidentified peak seen on the Thermal Imaging Camera (TIC). A significant peak was also seen on the GC/NPD screen as well as the GC/MS/TIC, which also was unidentified. The peak was subsequently identified as 6-APB and a known standard was obtained courtesy of the DEA Special Testing Laboratory. The 6-APB was quantitated using a sympathomimetic amine method and the concentration was determined by comparing the peak area ratios of 6-APB to the internal standard (MDA-D5) against a standard curve, with linearity demonstrated up to 1.0mg/L. Fractional volumes were used for samples exceeding linearity. The concentration of 6-APB in the decedent's cardiac blood was found to be 2.15mg/L. Ethanol was found in the decedent's cardiac blood and vitreous at 0.05mg% and 0.09 mg%, respectively.

The cause of death was listed as external compression of the neck and the manner of death was homicide. Benzofury (6-APB) was listed a contributing factor. In its pure powder form, 6-APB is usually ingested orally with the onset of effects reported within 30 – 90 min after ingestion. Scant information regarding this drug is available; therefore, little is known about its dosing and toxicity.

Benzofury, MDA, Postmortem

K14 Phenazepam and Driving Impairment: A Case Report

Paige L. Hinners, BS, 1000 Gladstell Rd, #508, Conroe, TX 77304; Monica Brady Mellon, MS, 8301 New Trails Dr, Ste 125, The Woodlands, TX 77381; and Sarah Kerrigan, PhD, SHSU Regional Crime Lab, 8301 New Trails Dr, Ste 125, The Woodlands, TX 77341*

After attending this presentation, attendees will understand the potential for phenazepam, a lesser known 1,4-benzodiazepine to impair driving performance.

This presentation will impact the forensic science community by providing an increased understanding of phenazepam impairment, specifically the extent to which it may impair some individuals at low dose.

Phenazepam is a 1,4-benzodiazepine that is structurally related to lorazepam and bromazepam. It originated in the Soviet Union in the 1970s and recently emerged as a drug of abuse. It is reported to be one of the most frequently prescribed benzodiazepines in Russia and other Commonwealth of Independent State (CIS) countries. Although it has no legitimate clinical uses in the United States, it has been used therapeutically for its sedative hypnotic, anticonvulsant, muscle relaxant, anxiolytic, and for the treatment of alcohol withdrawal overseas. When used therapeutically, it is available as 0.5mg and 1mg tablets, injectable solutions (0.1% and 0.3%) and transdermal patches. Oral doses of 0.5mg (2 – 3 times daily) may be prescribed, but doses up to 10mg/day are reported.

Several eastern European countries have taken steps to control phenazepam. Here in the United States, it is not controlled at the Federal level, although two states (Arkansas and Louisiana) enacted recent legislation to control the drug. Illicitly, it is available as a powder, tablet, and blotters (similar to LSD). Recreational users report doses of 2mg – 10mg of the drug. There have been relatively few pharmacological or toxicological studies involving phenazepam. In one study involving doses of 3mg – 5mg, peak plasma concentrations of 24 ng/mL – 38ng/mL were observed at approximately 4 h with a half-life of approximately 60 h. When 2mg doses were administered intramuscularly in epileptic patients, the half life was estimated to be 15 h. Adverse effects may include somnolence, dizziness, incoordination, and asthenia.

In a report from Finland, 3.4% of all Driving Under the Influence of Drug (DUID) cases were found to contain phenazepam. In the vast majority of cases (77 of 83 positive cases), other drugs were also detected. Multiple drug use can complicate interpretation, particularly for drugs that are less studied. Performance deficits attributed to phenazepam include unstable gait, confusion, impaired balance, slurred speech, memory loss, ataxia, and pupils that are slow to react to light.

A case is reported of a 24-year-old male apprehended for impaired driving. The subject failed to stop at an intersection and was involved in a two-vehicle crash. The subject had slurred speech and profound psychomotor impairment. His balance was poor; he

staggered, and after being placed in a chair, was unable to stand without falling. Blood toxicology was initially negative at another laboratory. The sample was sent to SHSU Regional Crime Lab for additional testing due to the inconsistent results. Comprehensive toxicology testing by Solid Phase Extraction (SPE) and Gas Chromatography/Mass Spectrometry (GC/MS) revealed the presence of phenazepam at a concentration of 76ng/mL in blood. No other drugs were detected. Phenazepam was quantitated using an Agilent HP 5975 MSD/6890 GC with a HP-5MS capillary column (30m x 0.25mm x 0.25µm). In the absence of deuterated phenazepam, prazepam was used as the internal standard.

The immunoassay cross-reactivity of phenazepam was investigated and found to be >250% using the immunalysis benzodiazepine Enzyme Linked Immuno-Sorbent Assay (ELISA) used in the laboratory. Due to the high cross-reactivity, the sample screened presumptively positive at the 50ng/mL (oxazepam) cutoff. Initial screening at the first laboratory by Enzyme Multiplied Immunoassay Technique (EMIT) was negative, resulting in no further testing. This case report highlights the importance of cross-reactivity in immunoassay and the need to perform more extensive, broad spectrum screening for impaired driving cases, especially when impairment and toxicology results are inconsistent. In this case report, severe impairment was observed in an individual following phenazepam use. The concentration detected was consistent with a single dose of the drug. Phenazepam is a lesser known low-dose benzodiazepine with the potential for significant traffic safety consequences.

Phenazepam, Impairment, Immunoassay

K15 Identification and Quantification of Tapentadol and N-Desmethyltapentadol in Human Urine Using Gas Chromatography-Mass Spectrometry

Shannon Cassatt, MS, 310 Sleepy Hollow Rd, Richmond, VA; and Carl E. Wolf, PhD, and Alphonse Poklis, PhD, VCU/MCVH Station, Medical Coll of Virginia, Box 98-165, Richmond, VA 23298*

After attending this presentation, attendees will learn about a Gas Chromatography-Mass Spectrometry (GC/MS) method developed to identify and quantify tapentadol and its main metabolite N-desmethyltapentadol (NDT) in human urine. Attendees will also understand that preliminary investigations demonstrated that the NDT metabolite does not have the same extraction characteristics and chemical derivatization properties as the parent drug. Therefore, special considerations were necessary when developing a method for simultaneous identification and quantification of tapentadol and NDT in human urine.

This presentation will impact the forensic science community by describing to forensic toxicologists and chemists the first GC/MS method developed and validated to identify and quantify tapentadol and its main metabolite NDT in human urine.

Chronic pain is one of the most persistent health care problems in the United States. When physicians fail to properly address pain in patients, it can lead to additional health problems or decrease the patient's quality of life. In many health care settings, opiate and opioid drugs have become the treatment of choice for pain management because of their effective analgesic properties. Tapentadol (Nucynta®) is a relatively new drug that is approved for treatment of both immediate and chronic pain. Tapentadol causes analgesia by acting as an agonist at the brain's mu receptors and as a norepinephrine reuptake inhibitor. Combining these two mechanisms of action makes tapentadol different from "traditional" opiate and opioid drugs, which do not act as norepinephrine reuptake inhibitors. As an analgesic drug, it is likely that incorporation of tapentadol into pain management and pain-monitoring programs will become more widespread, and it will be necessary for toxicology laboratories to be able to identify and quantify the drug and its metabolite in human urine specimens.

The development and validation of the first GC/MS assay developed for the identification and quantification of tapentadol and its major metabolite NDT in human urine samples will be described. Method development studies were initially performed to design an assay that was optimized for the extraction, identification, and quantification of tapentadol and NDT. The optimized procedure involved sample alkalinization with saturated borate buffer (pH 9.5) and extraction into chloroform: isopropanol (9:1) solvent. Samples were evaporated to dryness under a stream of nitrogen and derivatized with 25µl MTBSTFA + 1% TBDMCS: acetonitrile (1:2) at 55°C for >2h.

Quantification of tapentadol and NDT required two internal standards. Deuterated tapentadol-d3 was used for tapentadol quantification and 4-(2-methylamino)propyl)phenol was used for NDT because deuterated NDT was not commercially available. Two internal standards were needed because of the extraction differences between tapentadol and NDT, arising from the metabolite's secondary amine structure. The secondary amine structure of NDT also limited the compound's solubility in MTBSTFA + 1% TBDMCS derivatizing reagent, making it necessary to solubilize the metabolite with acetonitrile to maximize silation derivatization.

Glucuronide conjugates are the primary route of tapentadol and NDT elimination. Hydrolysis studies were performed to liberate the glucuronide conjugates from urine samples. Tapentadol-β-D-glucuronide and NDT were analyzed using the developed GC/MS program and no free tapentadol was detected. Overnight hydrolysis with helix pomatia H-2 was found to be the optimal hydrolysis method, with approximately 50% tapentadol liberated at concentrations of 150ng/ml, and 47% at concentrations of 600ng/ml.

The assay met all laboratory validation criteria with respect to linearity, sensitivity, accuracy, inter-assay precision, intra-assay precision, selectivity, matrix effects, process efficiency, recovery, bench-top stability, and instrument stability. The Limit of Detection (LOD) and Limit of Quantification (LOQ) for tapentadol and NDT were administratively set at 10ng/ml and 50ng/ml, respectively.

Five quality-control samples were run in triplicate over an eight-day validation period with tapentadol and NDT at concentrations of 50, 150, 600, 1500, and 2500ng/ml. The accuracy of the quality-control samples were within ±16% of the target value and the precision %CV values (inter and intra) were <16%. Matrix effect, process efficiency, and recovery were assessed by analyzing six replicates of tapentadol and NDT at concentrations of 150 and 600ng/ml. At both concentrations, tapentadol recovery was 100% and NDT recovery was 83% at 150ng/ml and 96% at 600ng/ml. The validated method allows for the identification and quantification of tapentadol and NDT in human urine.

Tapentadol, N-Desmethyltapentado, GC/MS

K16 Deaths Involving the Recreational Use of α-PVP (α-pyrrolidinopentiophenone)

Lauren L. Richards-Waugh, PhD, Kristen M. Bailey, MS, David J. Clay, BA, Myron A. Gebhardt, MS, Christina L. Newsome-Sparks, BS, Hahmada E. Mahmoud, MD, Susan E. Venuti, MD, and James C. Kraner, PhD, OCME, 619 Virginia St, W, Charleston, WV 25302*

After attending this presentation, attendees will gain a better understanding of potentially fatal consequences involving the stimulant hallucinogen α-pyrrolidinopentiophenone (α-PVP). Attendees will also obtain information addressing the measurement of this compound in human autopsy samples.

This presentation will impact the forensic science community by providing useful information regarding the toxicological analysis of cases involving designer stimulants, highlighting the need to consider the potential involvement of such drugs when presented with suggestive incident circumstances.

Until recently, the most common stimulant hallucinogen used illicitly in the United States was MDMA. However, the rapidly escalating availability of a variety of highly potent analogues has resulted in drug-related morbidity and mortality including violent confrontations, motor vehicle accidents, suicides, and fatal drug toxicity. A group of these compounds, collectively referred to as "bath salts," have been sold via the internet and through a variety of retailers including gas stations, convenience stores, and so-called "head shops." Typically, the compound present in these preparations has been 3,4-methylenedioxypyrovalerone (MDPV). Over a three-month period beginning in March 2012, the West Virginia Office of the Chief Medical Examiner has investigated three deaths involving a similar drug, α- α-PVP. The mechanism of action of this drug is thought to involve inhibition of the reuptake of norepinephrine, dopamine, and serotonin. Here is reported case circumstances and toxicological findings in three deaths involving α-PVP in which the decedents exhibited aggression, paranoia, violence, and homicidal behaviors.

Samples obtained at autopsy underwent routine postmortem toxicological testing. This included blood alcohol analysis by Gas Chromatograph/Flame Ionization Detector (GC/FID), drugs of abuse by immunoassay, Liquid Chromatography/Time Of Flight/Mass Spectrometry (LC/TOF/MS) screening of blood precipitates, and Gas Chromatograph/Mass Spectrometry (GC/MS) screening of alkaline and acidic/neutral blood extracts. GC/MS analysis of alkaline extraction of urine utilizing Toxi tube A was helpful in identifying the presence of α-PVP. Confirmation and quantitation of α-PVP was performed by GC/MS analysis of an alkaline liquid-liquid extract (without derivatization).

The decedents were adult males aged 31, 35, and 51 years. The oldest male was found deceased on his bathroom floor. Empty packages of bath salts were discovered at the scene with yellowish-tan powder noted within the nostrils. The most significant toxicological finding was α-PVP at a concentration of 0.10mg/L in the blood. THC and carboxy-THC were also present at 2.6 and 25ng/mL, respectively. The second fatality involved witnessed seizure activity preceding the demise. A history of bath salt and prescription drug abuse was reported. Toxicology results included α-PVP at a concentration of 0.52mg/L in the blood in addition to sertraline (0.16mg/L), oxycodone (0.02mg/L), and 7-aminoclonazepam (<0.01mg/L). The youngest male died from firearm injuries during an armed confrontation with law enforcement involving aggressive and paranoid behavior, as well as suicidal threats. Vials believed to contain bath salts were found in the decedent's pockets. Drugs confirmed in the blood included α-PVP and pentedrone at concentrations of 0.29 and 0.48mg/L, respectively. In all three cases, α-PVP was deemed to be the primary cause of death or a significant contributory factor.

Current routine postmortem toxicological analysis may not detect many of the designer stimulant compounds that present an increasing challenge in forensic pathology and toxicology. Often, cases in which the history documents bizarre, aggressive, hallucinogenic, or paranoid behaviors, and/or symptoms consistent with overstimulation of the sympathetic nervous system are positive for compounds such as α-PVP or other cathinone derivatives upon targeted analysis. Similar to other sympathomimetic drugs, establishing toxic and lethal concentrations for α-PVP will likely be difficult. These drugs often demonstrate significant overlap between concentrations tolerated by individuals and those reported in drug-related fatalities. Investigative history, autopsy findings, and toxicology results must be fully assessed to most accurately determine the cause and manner of death in cases involving designer stimulants such as α-PVP.

α-PVP, Bath Salts, Postmortem

K17 Two Cases of Suicide in Nurses by Atracurium: Revealed by LC/ESI/MS

Carmela Fiore, MD, Viale degli Aviatori, 1, Dept of Forensic Pathology, Univ of Foggia, Foggia, Italy 71100, ITALY; Francesca Giannelli, Ospedale Colonnello D'Avanzo, Foggia, ITALY; Palmira Fortarezza, Ospedale Tatarella, Cerignola, ITALY; Eugenia Di Stefano, MD, Ospedale Colonnello D'Avanzo, Foggia, ITALY; and Fabio Centini, BS, Policlinico Le Scotte, Siena, ITALY*

The goal of this presentation is to show two suicidal cases of atracurium in nurses, revealed by Liquid Chromatography/Electrospray Ionization/Mass Spectrometry (LC/ESI/MS). The analytical method and the postmortem toxicological concentrations of atracurium and laudanosine revealed in both fluids and tissues are discussed.

This presentation will impact the forensic science community by showing the importance of an analytical method developed for simultaneously quantifying postmortem of atracurium and its metabolite laudanosine in two suicidal cases.

Atracurium is a non-depolarizing skeletal muscle relaxant. It is a derivative of curare, a plant extract prepared from many different plants of the Amazon forest, used by the natives of the area as a poison arrow for hunting and war. It is used to facilitate endotracheal intubations and to relax skeletal muscles during surgery or mechanical ventilation. It is available as a 1% solution of the besylate salt for intravenous administration. It can be fatal in any concentration due to respiratory failure, so controlled ventilation is necessary. Following an intravenous dose, the muscles begin to relax within about two minutes and the effect lasts for 15 min – 35 min, depending on the dose. The drug is excreted in urine and bile, and its elimination half-life is around 20 min.

This presentation concerns two lethal cases of polydrug intoxication, both positive for the atracurium:

- The first case (named "A") involved a nurse of the Emergency Unit found dead in his home. Near his body, a syringe containing few cc's of colorless liquid and an empty blister pack of tablets of midazolam were found.
- The second case (named "B") involved to a nurse found unresponsive in the hospital where he was employed. Near his body, a syringe containing 11cc's of colorless liquid and an empty bottle showing the words "sodium pentothal" were found.

A comprehensive toxicological screening was performed on postmortem cardiac blood, urine, bile, and tissue homogenates (liver, heart, and kidney) using a combination of immunoassay and chromatographic techniques.

In detail, in both cases, lethal concentrations of midazolam were confirmed in biological fluids and tissues of the body A, while the presence of thiopental was revealed in biological fluids and tissues of the body B.

Since atracurium degradation occurs rapidly *in vitro* by the same hydrolysis mechanism observed *in vivo*, and it is accelerated by an alkaline pH and high temperatures, and given its simultaneously precharged yet lipophilic nature, detecting low atracurium levels in human postmortem samples is a challenge.

A method was developed for simultaneously quantifying low levels of atracurium and its less polar metabolite laudanosine in postmortem blood, bile, urine, and tissues by LC/MS in an ion trap mass spectrometer under positive ion ESI conditions. Analytes were isolated from blood and tissues by solid-phase extraction using Bond-Elut Certify columns. The method proved selective and sensitive, and was validated in postmortem blood, bile, urine, heart, kidney, and liver in the range of 1 – 2000ng/mL (blood) and 5 – 5000ng/g (tissues). The proposed method was fully validated with respect to previously published LC/MS methods.

Lethal concentrations of atracurium and laudanosine were confirmed in all the biological fluids and tissues of both bodies. The presence of atracurium was also confirmed by toxicological examination of the colorless liquid found in syringes.

Based on the autopsy findings, case history, and toxicology results, the forensic pathologists ruled that the cause of death in both cases was an overdose of atracurium in combination with midazolam for body A and thiopental for body B; the manner of death was suicide.

Atracurium and Laudanosine, Liquid Chromatography, Toxicological Finding

K18 Direct Analysis in Real Time (DART®) Analysis With a Modified GC/MS System for Rapid Drug Screening

Brian Musselman, PhD, 999 Broadway, Saugus, MA 01906*

After attending this presentation, attendees will learn about complete rapid screening for drugs of abuse using Direct Analysis In Real Time (DART®) screening capability with their Gas Chromatograph/Mass Spectrometry (GC/MS). This is important since traditionally the DART® technology has required a more complex Liquid Chromatography/Mass Spectrometry (LC/MS) for operation.

This presentation will impact the forensic science community by enabling more rapid screening of samples with existing GC/MS systems that are prevalent in the community. This technology can speed identification of drugs of abuse, reduce turn-around-time, and reduce sample backlogs.

DART® is an ambient ionization method that provides rapid determination of sample composition with little sample preparation. Samples are directly sampled and ionized merely by placing the material in the flow of heated ionizing gas. Solids or liquids are readily analyzed, often without any manipulation or purification of the sample. The ionization usually occurs by the excited helium atoms reacting with ambient water to form protonated water clusters. These water clusters attach a proton onto the molecule of interest, producing a spectrum that is very simple and often composed of one peak per compound. This leads to the facile interpretation of the spectra and the ability to analyze mixtures without the complexity of many fragment ions.

Several major forensics laboratories including FBI, Secret Service, the FDA Forensic Chemistry Center, and the Virginia Department of Forensic Science, have utilized DART® for rapid detection and characterization of unknowns. Published papers show analysis of gamma-hydroxybutyric acid, synthetic cannabinoids, analysis of sexual assault evidence, alprazolam tablets, methamphetamine, bank security device and pepper spray components, explosives trace detection, ricin activity assay, iodine and red phosphorus, and chemical warfare agents.[1-10]

However, this time-saving ambient ionization technology has not gained a wider audience in the forensic community for several reasons. A major reason is the fact that the DART® source requires a mass spectrometer equipped with an Atmospheric Pressure Inlet (API) typically supplied with an LC/MS system. Since this technology is limited to more specialized laboratories, the analysts cannot readily access the current DART® technology. In this current effort, an API has been integrated into an Agilent Mass Selective Detector (MSD), which is widely used in state and federal laboratories for trace forensic analysis. Secondly, the sampling process has been left to the analyst, allowing for flexibility, but also encumbering the analysts with additional method development. The sample preparation process has been simplified with a new device composed of a card-containing metal screen that holds the liquid or solid sample. The sample is placed on the screen, the card is inserted into the source, and the spectrum acquired in less than 10 seconds.

Facilitating DART® analysis with the low cost Agilent mass analyzer should enable more laboratories to add this capability, speeding analysis and reducing backlogs. This presentation will demonstrate the application of this modified DART®-MSD for determination of the presence of drugs in urine with a simple solid phase extraction for sample preparation. This reduces analysis time of 30 – 60 min to less than one minute. Additionally, the direct analysis of solid dosage forms of drugs of abuse will be illustrated, showing how DART® can identify these materials in seconds.

Drugs of Abuse, DART®, Mass Spectrometry

K19 Survey of Practices in Toxicological Investigation of Drug-Impaired Driving

Kayla Lowrie, MS, 520 Stevens Dr, Apt 208, King of Prussia, PA 19406; Jennifer L. Turri, BS, W 3901 Johnson Rd, Vulcan, MI 49892; Jillian K. Yeakel, MS, 105 Revere Dr, Harleysville, PA 19438; and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to compare their laboratory's practices with peer laboratories and evaluate typical cutoffs used for drug screening and confirmation. This presentation will describe data from a survey carried out to evaluate the practices of forensic toxicology laboratories performing analysis in the investigation of Driving Under the Influence of Drugs (DUID) cases. The survey was sponsored by the National Safety Council's Committee on Alcohol and Other Drugs (NSC CAOD).

This presentation will impact the forensic science community by providing data to support updating of general recommendations for laboratory testing in DUID investigations in order to improve consistency and standards of screening and confirmation.

The purpose of this survey was to evaluate scope and sensitivity of testing, compliance with the current recommendations for DUID testing, and changes in patterns of drug use by drivers in DUID investigations that might warrant updating of previous recommendations. This research aimed to assist in critically reviewing and updating the current guidelines and recommendations for the toxicology community.

An online web-survey instrument was used. The survey questions focused on scope and sensitivity for drug screening and confirmation, analytical methods, and ability to meet previously published recommendations.[1] The final revised survey was sent to confirmed participants via the online survey. Follow-up emails and phone calls were used to obtain additional information or clarify responses. In spite of these efforts, some participants did not respond to all questions; therefore, the data represents 96 surveys completed to the point where they were deemed sufficiently complete for inclusion in the data analysis.

It was indicated that 80% of responding labs test blood samples and 68% reported testing urine samples in DUID casework. Few labs reported testing oral fluid, and not consistently. Screening methods for blood testing were mostly Enzyme-Linked Immuno-Sorbent Assay (ELISA) (34%), Gas Chromatograph/Mass Spectrometry (GC/MS) (28%), Liquid Chromatography/Mass Spectrometry (LC/MS) (17%), and Enzyme Multiplied Immunoassay Technique (EMIT) (13%). No labs reported using Liquid Chromatography Time-Of-Flight (LCTOF) screening for blood. For urine, 29% reported GC/MS screening, ELISA (27%), EMIT (23%), and LC/MS (14%). For confirmatory testing, 52% of labs reported using GC/MS, while 36% used LC/MS. Labs were asked about reporting unconfirmed results, and 33% indicated they would report those under some circumstances, including insufficient sample, lack of a confirmatory procedure (with a recommendation to have testing sent out), and emphasized the inclusion of disclaimer about the presumptive nature of the result.

Respondents were asked whether their laboratories practices were consistent with the 2007 recommendations. Responses varied by drug and matrix. For screening purposes, the majority of labs reported meeting or exceeding the guideline recommendations for drugs of abuse, including carboxyTHC, benzoylecgonine, benzodiazepines, MDA, barbiturates, methadone, opiates, and PCP. The majority did not meet the recommendations for amphetamines. Drugs for which the majority of laboratories did not meet the recommendations for confirmatory testing were mostly therapeutic drugs including trazodone, nortriptyline, carisoprodol, zolpidem, topiramate, and methadone.

Participants were asked to indicate which additional drugs should be included in the recommendations for routine screening and confirmation. At least 75% of the 68 participants who responded to this question indicated that mephedrone, zopiclone, and buprenorphine should be included in future recommendations for blood sample screening. Additionally, at least 50% of the participants indicated that methylone, MDPV, JWH-073, JWH-250, JWH-081, JWH-122, JWH-210, JWH-019, JWH-200, AM-2201, benzylpiperazine, trifluromethylphenylpiperazine, dimethyltryptamine, modafinil, quetiapine, and zaleplon should be included in the future recommendations for blood sample screening.

Based on this input, the NSC CAOD is updating the guidelines for distribution early in 2013.

DUID, Cutoffs, Guidelines

K20 Simultaneous Quantification of Amphetamines, Ketamine, and Opiates in Urine Using SPE and LC/MS/MS

ChuAn Yang, MA, Institute of Forensic Medicine, 123, Min-An St, Zhonghe Dist, New Taipei City, Taiwan, TAIWAN, ROC; Hsiu-Chuan Liu, MS, Taipei, TAIWAN, ROC; Ray H. Liu, PhD, 3737 Rivera St, San Francisco, CA 94116; and Dong-Liang Lin, PhD, Institute of Forensic Medicine, 123, Min-An St, Zhonghe Dist, New Taipei City, Taiwan 23548, TAIWAN, ROC*

After attending this presentation, attendees will learn of a Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) technique for analyzing amphetamine, methamphetamine, MDA, MDMA, morphine, 6-acetylmorphine, codeine, 6-acetylcodeine, ketamine, and norketamine in urine.

This presentation will impact the forensic science community by developing a simple, accurate, and fast analytical method of LC/MS/MS capable of quantifying ten analytes in urine that are abused drugs.

Heroin, methamphetamine, and ketamine have historically been the most commonly abused drugs in Taiwan and are routinely monitored in the laboratory by Gas Chromatography/Mass Spectrometry (GC/MS) methods. The purpose of this study was to evaluate whether the LC/MS/MS-based approach can be more effectively applied to the simultaneous quantitation of amphetamine (AM), methamphetamine (MA), MDA, MDMA, morphine (MOR), codeine (COD), 6-acetylmorphine (6-AM), 6-acetylcodeine (6-AC), ketamine (K), and norketamine (NK) in postmortem urine specimens.

Samples (1mL) were extracted via solid-phase extraction, evaporated, and reconstituted in the mobile phase for injection onto the LC/MS/MS system. Deuterated analogues of the analytes of interest were used as internal standards. Chromatographic separation was achieved using an Agilent Zorbax SB-Aq (100mm ´ 2.1mm i.d., 1.8-□m particle) analytical column at 50°C. The mobile phase consisted of 0.1% formic acid (v/v) in water (A) and methanol (B) at a flow rate of 0.32mL/min. The initial gradient composition (A/B 90:10, v/v) was held for 1.5 min, then decreased to 0% A in 8.5 min and held for 2 min, then increased to 90% A in 1 min and held for 2 min. MS analysis was performed by an electrospray ionization in positive-ion Multiple Reaction Monitoring mode (MRM) with optimized collision energy for the precursor ion selected, monitoring two transitions for each analyte.

Validation was performed by extracting drug-free urine fortified with 50 – 1000ng/mL of the 10 analytes, yielding the following results: (1) average extraction recovery (n=5) was >80%, except for MDMA (70%) and MOR (74%); (2) inter-day and intra-day precision ranges (%CV) were 1.59 – 9.13% and 0.57 – 3.89%; (3) calibration linearity (r^2), detection limit, and quantitation limit were >0.997, 1ng/mL and 5ng/mL for all analytes, respectively; and, (4) matrix effects: ion suppression was lower than 20% for all analytes; it was compensated by using deuterated internal standard. Compared with traditional GC/MS methods, the conclusion arose that this relatively simple protocol can be used for routine and reliable identification and quantitation of AM, MA, MDA, MDMA, MOR, COD, 6-AM, 6-AC, K, and NK in urine. This method was successfully applied to the analysis of postmortem and antemortem specimens from forensic cases.

Drugs of Abuse, Urine, LC/MS/MS

K21 Fatal Cases of Aconitum Alkaloids Poisoning in Korea

Sujin Jeong, MS, 139 Jiyang-ro Yangcheon-gu, Seoul, Korea 158-707, KOREA; Seungkyung Baeck, PhD*, 139 Jiyang-ro Yangcheon-gu, Seoul, Korea 158-707, KOREA; Sangki Lee, PhD*, 139 Jiyang-ro Yangchun-gu, Seoul, Korea , KOREA; Hee-Sun Chung, PhD*, 1402-703 Mokdong Apt, Shunjung-dong, Yangchon-ku, Seoul, Seoul 158-774, KOREA*

After attending this presentation, attendees will gain knowledge regarding concentration levels in fatal cases of aconite poisoning and detection methods.

This presentation will impact the forensic science community by showing how this method was successfully applied to detect aconitines in various specimens of related aconitum alkaloids poisoning cases.

Aconitum alkaloids have been occasionally used in Korean herbal medicine because of pharmacological effects such as analgesic, anti-epileptic, and anti-inflammatory, but they can lead to sudden death by their cardiotoxins and neurotoxins. In traditional medicine, aconite roots are used only after processing to reduce the toxic alkaloid content. Soaking and boiling during processing will hydrolyze aconite alkaloids into less toxic and non-toxic derivatives; however, the use of a larger-than-recommended dose and inadequate processing increases the risk of poisoning. Every year, several causes of death were contributed to aconite toxicity. The high levels of toxicity of aconite are considered to be derived from aconitine, mesaconitine, and hypaconitine. The lethal dose of aconitine in human adults is estimated to be only 1mg – 4mg.

There have been reported cases of homicide, suicide, and accidental ingestion. Severe aconite poisoning can occur after accidental ingestion of wild plants or consumption of herbal decoction-made aconite roots. Some fatal cases were caused by unrefined herbal medicine prepared from aconite. Aconitum alkaloids have been indentified in various samples such as traditional prescribed herbal medicine, aconite infusion water, aconite liquor, wild greens mixed aconite, and their biological specimens from five cases related to aconite poisoning this year.

A rapid, specific, and sensitive Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method was developed for simultaneous identification of aconitine, mesaconitine, and hypaconitine. The determination of aconitum alkaloids in specimens was performed by LC/MS/MS after liquid-liquid extraction using trimipramine-d3 as an internal standard. Samples of each, 1mL or 1g, were extracted with 5mL of ethyl acetate in alkali of NH4OH. The organic layer was dried with a stream of nitrogen at 45°C. The residues were reconstituted with methanol and injected into LC/MS/MS. The separation was applied on Agilent XDB C18 column (1.8 micron, 4.6×50 mm). The injection volume was 5µL and the retention time was less than 8 minutes. A gradient elution of acetonitrile and water of 0.1M ammonium formate and 0.1% formic acid were used as mobile phase. Flow rate was 0.4mL/min. LC/MS/MS system (ABSciex, ABI 3200QTrap) coupled with an Electrospray Ionization (ESI) source was performed in multiple reaction monitoring(MRM) mode. The transitions of the Aconitum alkaloids executed as follows: m/z 646.3→586.0 for aconitine, m/z 632.3→572.4 for mesaconitine, m/z 616.3→556.3 for hypaconitine, and m/z 298.3→103.0 for trimipramine-d3 as internal standard. This method was successfully applied to detect aconitines in specimens. The validation results of selectivity, matrix effect, recovery, linearity, intra- and inter-assay precision, and accuracy were satisfactory.

It is well known that aconite poisoning can cause various symptoms, including arrhythmia and death, but specific autopsy findings are not configurative. There is a potential risk to overlook the death by aconite ingestion without advance information. When given more information about the scene, this method is useful to investigate aconite poisoning. At the same time, the public should be warned of the danger of eating wild plants and be educated on the potential hazards from self treatment with aconite root. In addition, it is necessary to have institutional restrictions on aconite medicine.

Aconitine, Fatality, LC/MS/MS

K22 Flight Activity and Drug Use: Legislation and Toxicological Statistics From 2006 – 2012 at the Rome Medical Legal Institute of the Italian Air Force

Paola Frati, PhD, Dept of Anat Histol Forensic and Orthop Sciences, Univ of Roma, La Sapienza, Viale Regina Elena 336, Roma, 00161, ITALY; Angelo Landolfi, Via Atene 59, Ciampino, Roma 00043, ITALY; Paola Mancarella, and Arianna Giovannetti, Viale Regina Elena 336, Rome, ITALY; Francesco P. Busardo, MD, Via Del Vespro, 129, Palermo, ITALY; Giuseppe Ciniglio Appiani, MD, and Raffaele Cresta, MD, Via Piero Gobetti 2/A, Roma, ITALY; and Domenico Abbenante, MD, Via Largo Claudio Monteverdi, Cerveteri, ITALY*

After attending this presentation, attendees will understand the medical assessment of commercial pilots and cabin crews, which has two main purposes: (1) to assess their functional ability; and, (2) to ascertain whether they are physically able to safely exercise the privileges of their licenses and to verify the risk of incapacitation during the period of validity of the medical certificate.

This presentation will impact the forensic science community by demonstrating the importance of continuous surveillance of commercial pilots and cabin crews. As this study confirms, the percentage of drug users in this category of workers is very low.

The goal of this presentation is to describe the experience of the Italian Air Force Medicolegal Institute of Rome and the Forensic Laboratory of the Catholic University regarding the medical assessment of commercial pilots and cabin crews.

Materials and Methods: The total number of Class 1 and 2 medical examinations undertaken during a six-year period from January 2006 to the first semester of 2012 was taken from the Italian Air Force Medicolegal Institute of Rome medical records database.

The normative references in the relevant period regarding personal fitness to fly are: Italian Presidential Decree n. 566 November 18, 1988; JAA JAR-FCL 3 Flight Crew Licensing (medical) Amendment 5, December 1, 2006.

Urinary screening for the qualitative detection of drugs was carried out using the immunochemical technique Kinetic Interaction of Microparticles in a Solution (KIMS). The following substances were tested for: amphetamines, barbiturates, benzodiazepines, cannabinoids, cocaine, and opiates. All samples were processed to guarantee chain of custody, obliging operators to document the different stages of the sample. Samples were separated into two aliquots (sample and counter-sample) and closed in front of the patient with a tamper-proof seal signed by the healthcare operator and the patient. The counter sample of urine that tested positive in a preliminary analysis was kept in the freezer at -20°C for 60 days, to be used in case any medical-legal disputes arose.

Results: The results of preliminary analysis of the urinary specimens were then examined and elaborated. Data review allowed the evaluation of the sample distribution by gender, age, drug substance type, with subsequent confirmation by Gas Chromatography/Mass Spectrometry (GC/MS). Within the positive samples, analyzed using the KIMS, the gender distribution is almost equal (five male subjects, compared to four female subjects) with an age range of 19 – 50 years.

In the relevant period, of 7,530 subjects tested for drug use (only extraordinary medical examination), nine were positive to KIMS screening. Among the positive subjects, none were polydrug users. Distribution of positive results for drugs indicated a clear prevalence of cannabinoids (eight subjects, or 89%). Only one positive case was detected for cocaine (11%) and no samples were positive for barbiturates, benzodiazepines, amphetamines, or opiates.

The cases that were positive after urinary screening, and their samples, were then subjected to confirmation by GC/MS. Of the nine positive cases, five cases (equal to 56% of all positive) haven't been confirmed. In the four confirmed cases, one was detected for cocaine and three for cannabinoids.

Discussion and Conclusion: Thanks to the continuous surveillance of commercial pilots and cabin crews, the study shows that the percentage of drug users is very low; therefore, this result indicates that it is appropriate to continue this strict type of monitoring. This phenomenon should not be underestimated since it can influence the ability of individuals who are responsible for the safety of others.

Substances of Abuse, Italian Air Force, Toxicological Investigation

K23 Blood Transfusions and Their Influence on the Evaluation of Postmortem Alcohol Levels in Biological Fluids in Road Traffic Accidents: Case Report And Review of Literature

Francesca Pepe, MD, Viale Europa, Località Germaneto, Catanzaro, Italy 88100, ITALY; Isabella Aquila, MD*, Viale Europa, località Germaneto, Policlinico Universitario, S. Venuta- Medicina Legale, Catanzaro, 88100, ITALY; Ciro Di Nunzio, MFS, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Legal Medicine, Catanzaro, 88100, ITALY; Silvia Boca, MD, Viale Europa 88100 Catanzaro, Catanzaro, 88100, ITALY; Maria Chiarelli, MD, and Gratteri, MD, Viale Europa, Germaneto, Catanzaro, 88100, ITALY; and Pietrantonio Ricci, PhD, Viale Europa, Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand the relationship between blood transfusions and postmortem alcohol levels in biological fluids.

This presentation will impact the forensic science community by discussing drunk driving and its social consequences.

Introduction: Traffic accidents are an important cause of death, particularly among young people. To drive under the influence of alcohol and/or drugs is the cause of many of these accidents. In particular, the alcohol concentrations are measured in a corpse through the toxicological postmortem analysis on the body fluids. The blood represent the biological liquid that allows verification of drunk driving at the time of the accident. In particular, the concentration of alcohol in the blood is subject to variations due to different etiological factors. Blood alcohol levels in the corpse are altered by the putrefactive phenomena. Also, blood transfusions may influence the concentration of blood alcohol levels. This medical practice is performed to restore hemodynamic parameters in patients with critical conditions, usually after a traffic accident. The exact determination of blood alcohol levels is very difficult to determine during the autopsy examination of the corpse which has been exposed to the blood transfusion procedure.

Objective: The goal of this study is to examine the influence of blood transfusion on blood alcohol levels in cases of deaths from traffic accidents. In particular, the focus is on the reliability of postmortem toxicology data in subjects during the last stages of life who have been transfused to be resuscitated.

Case report: The study investigates a 36-year-old subject, hospitalized in the emergency room for traumatic shock after a traffic accident. He underwent surgery for left nephrectomy because of renal laceration, but died of these injuries: left temporo-parietal hemorrhage with subarachnoidal hemorrhage; bilateral hemothorax; fracture of the right clavicle; multiple rib fractures with bilateral pulmonary parenchymal contused injuries; fractures of the fifth dorsal vertebra without spinal cord injury; and, liver and intestinal lesions.

Results of Toxicological Investigations: Toxicological analysis performed on body fluids showed high levels of ethanol in bile, vitreous humor, and blood, as well as high levels of methadone. The values of ethyl alcohol in the blood were of 2.29g/l. Because of blood transfusion, the concentration of alcohol in vitreous humor had to be estimated. In effect, the vitreous humor levels should be in equilibrium with blood levels. The vitreous humor levels were the lesser affected of the two because the blood had been diluted by transfusion. Additionally, because the value of ethyl alcohol in the vitreous humor reaches a chemical equilibrium with a ratio of about 1:1 including the lymph and circulatory fluids, the vitreous humor levels were less affected. Many calculations were carried out to evaluate the value of ethyl alcohol in the blood at the time of the first transfusion. This result is shown through the application of appropriate correction factors that have considered the amount of blood transfused (1400ml), the weight of the subject, the metabolism of alcohol, the metabolic capacity medium, and the time elapsed from ingestion to accident. These calculations have determined the value of hypothetical blood alcohol at the time of the car crash before transfusion (1.28g/l).

Conclusions: In this case, it was possible to determine the concentration of blood alcohol levels over and above the cut-off. It has been concluded that the person was driving under the influence of alcohol. This investigation is essential for judicial purposes, in particular when it comes to an accident involving people who are the driver's responsibility. The study allows evaluation of a theme that has great social impact—it is very important to evaluate the conduct of the driver at the time of the incident.

Alcohol, Blood Transfusion, Toxicological Investigation

K24 Preclinical Investigation of CP47,497: A Widely Abused Synthetic Cannabinoid

Kimberly Samano, MFS, 6731 Forest Hill Ave, Richmond, VA 23225-1801; Aron H. Lichtman, PhD, 1220 E Broad St, Richmond, VA 23298; and Alphonse Poklis, PhD, VCU/MCVH Station, Medical Coll of Virginia, Box 98-165, Richmond, VA 23298*

The goal of this presentation is to educate attendees about CP47,497 (2-[(1R,3S)-3-Hydroxycyclohexyl]-5-(2-methyloctan-2-yl)phenol), a synthetic cannabinoid recently banned by the DEA. The pharmacology of this compound was first described in the scientific literature in 1982, but prior to its ban was being sold for consumption primarily through internet sources or head shops and was associated with a large spike in emergency department visits. CP47,497 activates the cannabinoid receptor 1 (CB_1R) and dose-dependently elicits cannabimimetic effects that are more potent than effects produced from Δ^9- tetrahydrocannabinol (THC). Importantly, these studies provide novel evidence using a whole animal model that the CB_1R antagonist rimonabant reverses the potent cannabimimetic effects of CP47,497

This presentation will impact the forensic science community by providing a direct comparison of synthetic cannabinoid and THC behavioral data in whole animal studies.

CP47,497 and other synthetic cannabinoid compounds were originally synthesized as tools to investigate the mechanism by which marijuana affects the brain as well as for the development of potential therapeutic agents to treat pain and other disorders. However, studies addressing the behavioral consequences of synthetic cannabinoids are scant. Synthetic cannabinoids pose an enhanced risk for abuse, toxicity, and addiction due their increased potency and efficacy over THC. The goal of the present study was to determine whether the pharmacological effects of CP47,497 are achieved in a dose-dependent and time-dependent manner. Since CP47,497 binds to CB_1 receptors and elicits THC-like effects, it was investigated whether rimonabant would attenuate its pharmacological actions *in vivo*.

All mice received intraperitoneal injections of CP47,497, THC, or vehicle. To test for cannabimimetic subjective effects, a tetrad model was utilized that consisted of four outcome measures: catalepsy; antinociception (tail flick latency); hypothermia; and, locomotor activity. Although many pharmacological agents can produce one or

a subset of these effects, drugs that activate CB_1 receptors produce measurable effects in all four parameters of the tetrad. Immediately following behavioral testing, mice were humanely euthanized and blood and tissue were harvested for CP47,497 quantification. Samples are currently being analyzed on an Applied Biosystems Liquid Chromatograph/Tandem Mass Spectrometer (LC/MS/MS) interface utilizing electrospray ionization and selective ion monitoring, using an acetonitrile liquid-liquid extraction procedure that the laboratory has previously developed validated methods for quantification of THC and other cannabinoids in blood and tissue.

In the cumulative dose-response experiment, mice were treated with THC (3, 10, 30, 100, and 200mg/kg), CP47, 497 (0.3, 1, 3, 10 and 30mg/kg), and vehicle control. Potency ratios for comparison of CP47,497 to THC were calculated including 95% confidence limits for each: catalepsy 7.49 (5.72 – 9.76), antinociception 9.11 (3.76 – 21.98), and hypothermia 7.68 (4.55 – 12.83), which clearly demonstrate CP47,497's enhanced potency and efficacy. In the final component of the tetrad, 30mg/kg CP47,497 produced a statistically significant increase in locomotor depressing effects versus control. Based on the data obtained from the dose-response study, 30mg/kg CP47,497 and 100mg/kg THC were used in subsequent antagonism studies. Both 30mg/kg CP47,497 and 100mg/kg THC produced statistically significant increases in catalepsy, hypothermia, antinociception, and a decrease in locomotor activity versus control. CP47,497 and THC-induced catalepsy and hypothermia were reversed by pretreatment with 3mg/kg rimonabant. Although 3mg/kg rimonabant antagonized the antinociceptive effects of 100mg/kg THC, 10mg/kg rimonabant was required to block the antinociceptive and locomotor depressing effects of 30mg/kg CP47,497.

This study's results provide the first *in vivo* evidence that the cannabimimetic effects of CP47,497 are CB_1 mediated as blockade of these effects is achieved with the CB_1 antagonist, rimonabant. Given that CP47,497 elicits dose-dependent cannabimimetic effects that are markedly (7 – 9 times) more potent than THC-containing substances, these data are consistent with the large number of abusers of this compound presenting with severe cannabis-related adverse effects that require emergency department interventions.

CP47,497, Spice, THC

K25 DART® AccuTOF™: A New Drug Screening Protocol for Biological Specimens

Rachel C. Beck, BS, 2026 Valleyday Rd, Hoover, AL 35244; Maggie W. Morgan, HSD, 806 Hillyer High Rd, Anniston, AL 36207; and Tracy Segrest, PhD, and Erin M. Shonsey, PhD, 2026 Valleydale Rd, Hoover, Alabama 35244*

After attending this presentation, attendees will learn how the DART® AccuTOF's™ technology can be utilized as a comprehensive screening technique of whole blood.

This presentation will impact the forensic science community by expanding the scope of analysis of whole blood drug screening to include targets not covered by traditional immunoassay techniques.

The field of forensic toxicology is never stagnant; preferences for a specific drug and/or drug combination fluctuate within the population. Meanwhile, scientists in the field are charged with providing timely, comprehensive, and accurate results while enduring dwindling personnel and financial resources, which often necessitates a limited scope covering only the staples. In order to comply with the duty of identifying both conventional and emerging drugs that are problematic in society, new methodology must be adopted in the screening of biological samples.

Current drug screening practices utilize both traditional immunoassay methodology and Gas Chromatography/Mass Spectrometry (GC/MS) technology. Immunoassays have been successful for the analyses of conventional drugs; however, immunoassays are costly, making scope expansion outside common drugs of abuse monetarily impractical. Additionally, immunoassays are limited for their ability to adapt quickly in the analysis of new and/or additional compounds due to kit production and/or validation. The GC/MS has less scope limitations when compared to the immunoassay but is a great deal more costly with respects to time. GC/MS technology requires tedious sample preparation prior to data collection and consumes multiple days of a scientist's time to complete the extraction, collection, and analysis of the data. Moreover, when used for drug screening purposes, any positive findings must then be confirmed by repetition. The Direct Analysis in Real Time (DART®) ionization source coupled to an AccuTOF™ mass spectrometer offers a solution to the restricted budget, available personnel, and drug screening limitations currently faced. Furthermore, DART® AccuTOF™ technology offers a second methodology for the screening of targets that have been traditionally identified and confirmed by repetitive GC/MS analyses. The robust, open air DART® ionization allows for comprehensive analysis by producing protonated molecular ions for all mode specific (positive mode) ionizable components of the specimen sampled via surface ionization, while the AccuTOF™ mass spectrometer allows for continuous data collection.[1,2] This hybrid instrumentation allows for the putative identification of both parent and metabolite compounds alike via a molecular formula database search with a total instrument analysis time of a couple of minutes per sample.

The application of the DART® AccuTOF™ technologies in the field of toxicology for the screening of whole blood, an exceedingly complex matrix, has realized the necessity for sample preparation prior to analysis.[3] To combat the complexity of the whole blood matrix, Disposal Pipette Extraction (DPX™) tips utilizing a cationic sorbent, featuring sulfonic acid groups, were employed for analysis of basic drugs spiked into porcine whole blood.[4] The amount of blood needed for the analysis was based upon the Limit Of Detection (LOD) study performed with neat standards. Porcine blood was screened for 35 different targets spanning a multitude of drug classes. Detected target coverage included basic and amphoteric compounds in the following classes: cathinones; sympathomimetic amines; select opiates; select benzodiazepines; dextromethorphan; carbamazepine; carisoprodol; select barbiturates; zolpidem; cocaine metabolite; citalopram; tapentadol; and, select tricyclic antidepressants. These detected targets were identified at therapeutic levels ranging from 10ng/mL to 400ng/mL.

Based on the experimental data collected, comprehensive screening can be accomplished with DART® AccuTOF™ technology. This study expanded the current drug screening scope of whole blood beyond the classical impairing drugs and even identified emerging select cathinones (bath salts). In conclusion, DART® AccuTOF™ technology has provided a promising solution to the current drug screening limitations encountered by forensic toxicologists.

K26 More Bang for Your Buck—An Alternative Approach to Blood and Tissue Screening That Saves Time and Money

Mary E. Zaney, BS, 1851 NW 10th Ave, Miami, FL 33136; Diane Boland, PhD, Miami Dade County MEO, Toxicology Laboratory, Number One Bob Hope Rd, Miami, FL 33136; George W. Hime, MS, Miami Dade County MEO, 1851 NW 10th Ave, Miami, FL 33136; and Joseph H. Kahl, BS, 1044 Abell Cir, Oviedo, FL 32765*

After attending this presentation, attendees will have seen an alternative automated solid phase extraction technique to blood and tissue screening as compared to Liquid-Liquid Extraction (LLE) of basic drugs. Better recovery of designer drugs such as "bath salts" will also be shown.

This presentation will impact the forensic science community by demonstrating how more information can be obtained from the same sample volume, while saving time and money.

The Toxicology Laboratory at the Miami-Dade Medical Examiner Department recently changed the blood and tissue screening methodology from a multi-step LLE of basic drugs to a dual-Elution Solid Phase Extraction (SPE) of acidic/neutral and basic drugs. This was done to achieve a more cost-effective comprehensive blood drug screen, which utilizes smaller solvent volume and reduces sample preparation time.

The objective is to present data comparing the previously utilized LLE procedure to the newly implemented automated SPE method. Examples will include spiked controls, proficiency samples, and postmortem cases.

The LLE procedure (described by Forrester et. al in JAT) applies strictly to the extraction of basic drugs from 1mL of sample. The extract is then analyzed by dual column Gas Chromatography with Thermionic Sensitive Detection (GC/TSD).

The SPE method is a modified version of United Chemical Technologies Procedure Code: DRB200DAUZ120392 using UCT Clean Screen® cartridges and an automated Zymark Rapid Trace® system. The procedure uses 1mL sample volume yet yields two distinct fractions. The acidic/neutral extract is submitted for analysis by dual column Gas Chromatograph-Flame Ionization Detector (GC-FID), and the basic extract is analyzed by GC/TSD. GC-Ion Trap/MS is performed to confirm any positive findings.

The SPE method detected all 113 spiked control drugs and showed improved recovery for certain drugs, particularly the sympathomimetic amines and benzodiazepines. Co-elution of doxylamine and etomidate with caffeine was prevented since caffeine now elutes in the acidic/neutral extract.

The improved detection of ephedrine, in addition to the detection of acetaminophen in the acidic/neutral extract was noted in two separate proficiency samples in which these drugs were missed when screened using the former LLE method.

Screening of postmortem case samples utilizing the SPE method has led to detection of drugs in the acidic/neutral extract such as propofol, topiramate, levetiracetam, acetaminophen, and valproic acid which would have previously been missed. Newer drugs detected in the basic extracts include BZP, TFMPP, 5MeoDIPT, methylone, and MDPV, which could have been missed due to decreased recovery by LLE. In addition heroin, 6-MAM, morphine, and benzoylecgonine were detected in the initial GC/MS screening, as opposed to having to be specifically targeted in other confirmatory assays.

With the constant evolution of designer drugs, it is important for laboratories to respond and adapt accordingly, even though funding for consumables and staff may be limited. By adopting an SPE protocol, the laboratory is now equipped to screen for a variety of tryptamines, as well as the components of the ever-so-popular "bath salts." Additionally, the laboratory has become more efficient due to the reduction in solvent usage and sample preparation time. Other advantages include safety improvements and prevention of errors from multi-step procedures.

More information is obtained from the same sample volume via the dual elution which provides a much more comprehensive screen.

SPE, Comprehensive Screen, Basic Drugs

K27 Advanced Automated Library Searching for Compound Identification in Forensic Toxicology Samples

Adrian M. Taylor, PhD, 71 Four Valley Dr, Concord, ON L4K 4V8, CANADA*

After attending this presentation, attendees will learn about the different complimentary screening techniques that can be performed on a hybrid quadrupole linear ion trap to confidently identify targeted and unknown compounds. Attendees will learn about using acquired Tandem Mass Spectrometry (MS/MS) data to search against MS/MS libraries and utilizing a new advanced automated library searching with the capability to dynamically review the collected MS/MS information. Attendees will see that the software substantially improves the "data mining" process and provides an elegant solution to automated processing of the forensic toxicology screening data to confidently identify compounds.

This presentation will impact the forensic science community by demonstrating the advantages of the new automated library-searching approach in improving typical forensic toxicology screening workflows.

Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) utilization in forensic toxicology screening for drugs and drug metabolites has become increasingly popular due to the selectivity, sensitivity, and the speed of LC/MS/MS analysis. MS/MS confirmation with automated searching against available spectral libraries has proven to add a superior level of confidence to the compound identification. One of the key factors of the complete solution for forensic toxicology screening is automation of the library searching with the advanced capability to dynamically review the acquired data. Solutions need to be accurate and robust. The ability to search multiple libraries, create subsets of libraries, adjust and refine search parameters as well as re-search acquired data provides the user with the substantial flexibility. Setting mass tolerance, intensity thresholds, and searching multiple collision energies enhance the data under revision. The ability to search or re-search entire data files or a specific mass spectrum with different parameters can improve overall data quality and throughput. Additionally, reporting tools allow the information to be disseminated to the end user.

Forensic toxicology samples were analyzed using generic sample preparation procedures with two AB SCIEX LC/MS systems: a hybrid linear ion trap-triple quadrupole system and a hybrid quadrupole-time-of-flight instrument. The tandem mass spectrometric measurements were performed using the Collision Energy Spread (CES) feature which ensures the detection of the fragment ions generated in low-, medium-, and high-collision energy regimes. All the collected MS/MS spectra were searched against an AB SCIEX Forensic Drug Spectral Library comprised of over 1,250 compounds. The data processing was performed with the new AB SCIEX prototype library searching tool equipped with two library search algorithms. The accuracy, flexibility, speed, and robustness of the new library searching approach was successfully demonstrated in the processing of the data specifically acquired in different experimental set-ups. The ion trap screening data were collected in three screening workflows that consisted of several looped experiments as follows:

1. Multitargeted Screening:
    a. MRM detection of 300 analytes with the *Scheduled* MRM™ algorithm.
    b. Enhanced Product Ion (EPI) dependent scans set to automatically collect MS/MS fragmentation spectra for the targets detected in experiment 1.

2. General Unknown Screening:
    a. Enhanced Mass Spectrum (EMS) monitoring for the detection of the unknown analytes.
    b. EPI dependent scans set to automatically collect MS/MS fragmentation spectra for the unknowns detected in experiment 1.
3. Combined multitargeted and unknown screening:
    a. MRM detection of 300 analytes with the *Scheduled* MRM™ algorithm.
    b. EMS monitoring for the detection of the unknown analytes.
    c. EPI dependent scans set to automatically collect MS/MS fragmentation spectra for the targets identified in experiment 1 and unknowns identified in experiment 2.

The hybrid quadrupole-time-of-flight data collected using a TOF/MS survey scan with IDA-triggering of up to 20 product ion scans was also processed. In all specified cases, both targeted and unknown drugs and metabolites were identified in selected samples with a high level of confidence (based on the values of purity, fit, and reverse fit). Utilization of the new advanced automated library searching with the capability to dynamically review the collected MS/MS information has been demonstrated to substantially improve the "data mining" process and provide an elegant solution to automated processing of the forensic toxicology screening data.

LC/MS/MS, Library Searching, Hybrid Linear Ion Trap

K28 An Easy, Fast, and Reliable Workflow to Perform Real Forensic/Toxicological General Unknown Screening

Adrian M. Taylor, PhD, 71 Four Valley Dr, Concord, ON L4K 4V8, CANADA*

After attending this presentation, attendees will learn about a comparative screening workflow that allows the comparison between a sample and control in which significant differences in the sample are automatically extracted resulting in a reduction of several hundred peaks down to identifying only the significant components of the sample. Learning outcomes will include how high resolution accurate mass instrumentation can be successfully used to provide comprehensive and valuable information in identification of unknowns. Currently real General Unknown Screening suffers from complexity of biological matrices, which makes it almost impossible to identify relevant compounds in an easy and fast way. This presentation will present an easy-to-use generic workflow for General Unknown Screening. As an example, Tramadol in urine will be shown to be easily detected with only two injections in a Comparative Screening workflow using a hybrid quadrupole/time-of-flight instrument.

This presentation will impact the forensic science community by showing a fast, confident, and easy-to-use workflow to perform real non-targeted screening. The General Unknown Comparative Screening workflow provides basic sensitivity in Mass Spectrometry (MS) and Tandem Mass Spectrometry (MS/MS) modes for a clear identification of compounds, high resolution to overcome selectivity issues, and mass accuracy to capitalize from the provided resolution.

Method: ekspert™ ultraLC device was coupled to a fast-scanning high resolution MS system providing fast and sensitive MS/MS capabilities. Information-dependant acquisition with dynamic background subtraction and dynamic exclusion triggered 10 MS/MS experiments. The resulting total cycle time ensured that the compounds had more than 10 data points across extracted ion chromatograms (peak width 4 – 5 sec). Total LC runtime was 10 minutes using 6 min gradient (95% de-ionised water to 0% de-ionised water) with Phenomenex Kinetex 2.6µm C18 Column, 100 Å, 50 x 2.1mm column.

Results: The Comparative Screening workflow required two injections; a control injection was followed by the sample injection. The control was a urine sample of approximately comparable matrix to the sample without any drugs. Both data were loaded into PeakView™ software and automatically evaluated by an additional software add-on. All peaks overcoming a defined threshold were evaluated for retention time similarities in both sample and control. Significant differences in the sample due to, for example, absence or lower abundance of the same peak in control were automatically extracted and MS as well as MS/MS information was displayed (defined by second threshold). Thus, a reduction of several hundred peaks down to what is specific to the sample only were identified; Tramadol and its related major metabolites (demethylation). Sensitive MS/MS information can be used for confident identification by automatic searching MS/MS forensic library (1,250 entries). In case of missing conformity of a detected mass with any compound in any library, additional built-in software tools help to identify formulas by accurate mass, isotopic ratio, and sensitive MS/MS information. Finally, potential structures of calculated formula can be verified by fragment-predictive software tools.

Comparative General, LC/MS/MS, Accurate Mass

K29 Analysis of the Rate of Decay and Dispersion of Pentobarbital in Soil by Liquid Chromatography/Mass Spectrometry

Chasity D. Suttle, BS, 414 Thomas Jefferson Cir, Madison, TN 37115; and Paul Kline, PhD, 1301 E Main St, Murfreesboro, TN 37132*

The goals of this presentation are to: (1) become familiar with the principles of extracting pharmaceuticals, specifically barbiturates, out of a complex matrix, particularly soil; (2) apply the use of this method to determine the initial concentration of the contaminated area and the focal point of contamination; and, (3) understand the significance of this method in order to determine the time of contamination based on the rate of decay and dispersion dynamics.

This presentation will impact the forensic science community by showing an effective method for extracting barbiturates out of complex matrices, specifically soil, is necessary for analytical analysis and has significant impact in the field of forensics and environmental science.

A method for detecting the barbiturate pentobarbital in soil previously developed was utilized to determine its application to the decay rate and dispersion rate of pentobarbital and similar barbituric acid derivatives in soil.

Pentobarbital is a pyrimidine derivative in a class of organic drugs called barbiturates. Several thousand derivatives of barbituric acid have been synthesized with far-reaching effects and flexible durations of action. Duration of action refers to the length of time the drug affects the target system, and in the case of humans or animals, it is the Central Nervous System (CNS). Pentobarbital is categorized as a fast-intermediate sedative-hypnotic drug. Barbiturates are highly stable organic compounds that are released into the environment via multiple pathways. Barbiturates have been extensively used throughout the United States. Euthanized animals are a growing contamination source in addition to the contribution of barbiturates from a wide array of pharmaceutical use, misuse, and abuse.

The method was developed to quantify the rate of decay of pentobarbital in contaminated soil. Pentobarbital in addition to other barbituric acid derivatives were extracted from separate soil samples, each separately spiked with the respective barbituric acid derivative. Clean-up procedures involved centrifugation, reverse-phase Solid Phase Extraction (SPE), microfiltration, and lastly, analysis by Liquid Chromatography/Mass Spectrometry (LC/MS). Concentration determination and recovery were determined utilizing a deuterated isotope method, Pentobarbital-D5, and an internal standard method. Satisfactory recoveries of the barbituric acid derivatives indicate this is an effective method for analysis and detection. Further, pre-

concentration via solid phase extraction allowed for 0.001mg of barbituric acid derivative per five grams of soil (200 parts per billion) to be detectable at limits of quantification using LC/MS. This method can be suitable for larger quantities of soil and applicable for a wide range of soil types.

The development of extraction methods for pharmaceuticals out of soil has multiple applications in the scientific community. Additionally, the application of this extraction method as to the determination of the source of contamination, date of contamination, and amount of contamination has significant impact in the field of forensics.

Barbiturate, Soil, Decay

K30 Method Development and Validation of Dimethylamylamine (DMAA, Methylhexanamine) by Gas Chromatography-Mass Spectrometry

Brittany D. Pasierb, BS, 700 Lower State Rd, Bldg 25, Unit A8, North Wales, PA 19454; Jillian K. Yeakel, MS, 105 Revere Dr, Harleysville, PA 19438; Celeste Metzger, MS, 2300 Stratford Ave, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will understand how a method was developed and validated for the detection of Dimethylamylamine (DMAA, methylhexanamine) in nutritional supplements and urine samples using Gas Chromatography/Mass Spectrometry (GC/MS).

This presentation will impact the forensic science community by providing a method for the detection of the emerging drug of abuse, and banned stimulant drug DMAA, and raise awareness of its use and presence in over-the-counter supplements and "legal highs."

Marketed as a nasal decongestant in the 1940s, DMAA, also known as methylhexanamine, currently has no recognized medical use. In 2006, the compound began to be added to nutritional supplements such as weight-loss preparations and pre-exercise pills. DMAA is a central nervous system stimulant which in excess produces effects similar to, but not as intense as, amphetamine. Combined with its availability and perceived low toxicity, DMAA is highly susceptible to abuse. DMAA use was recently associated with the death of two United States soldiers, was added to the World Anti-Doping Agency's Prohibited List, and is currently restricted in several countries.

As the compound is restricted in a number of countries worldwide, it is important to have an established, reliable method for its detection. Quantifying the concentration of DMAA in popular nutritional supplements will also benefit the forensic science community to the extent of determining just how potent and dangerous these supplements are to the public.

The objective of this research was to develop and validate a method for the detection of methylhexanamine in nutritional supplements and urine samples using GC/MS.

The analysis of DMAA is more challenging due to its two diastereomers and reactive primary amine group. After reconstitution studies with methanol, acetonitrile, isopropanol, ethyl acetate, and dichloromethane, DMAA was determined to be insufficiently stable for proper analysis on the GC/MS without derivatization. Following time and temperature studies, a successful derivatization method using 4-carbethoxyhexafluorobutyrl chloride (4-CB) that produced the two expected DMAA chromatographic peaks was developed. Extracts were derivatized by addition of 4-CB with ethyl acetate at 70°C for 20 min. Detection was performed by selected ion monitoring by GC/MS, using amphetamine-d5 as an internal standard.

A Liquid-Liquid Extraction (LLE) technique was used to isolate DMAA using concentrated ammonium hydroxide and chloroform/isopropanol/n-heptane (50:17:33) as the organic extraction solvent. The solvent was removed and evaporated at 33°C under a stream of nitrogen gas. Successful calibration curves have been established across the concentration range 1 – 20µg/mL. The curves generated acceptable r^2 values of 0.997 for DMAA peak 1 and 0.998 for DMAA peak 2. Successful calibration curves have also been established across the concentration range of 10 – 100ng/mL. These curves generated acceptable r^2 values of 0.994 and 0.993 for DMAA peak 1 and DMAA peak 2 respectively. In addition, the limit of detection and limit of quantitation were both preliminarily determined to be better than 10ng/mL, which is determined to be acceptable for both the analysis of solid dosage materials and expected concentrations in biological fluids.

The method is being applied to analysis of DMAA in nutritional supplements containing the drug and to biological samples. The presentation will also review the pharmacology of DMAA and reported adverse effects.

DMAA, Supplements, GC/MS

K31 Profiling of Inhalants and Common Blood Alcohol Interferences Using Headspace-GC/FID and Headspace-GC/MS

Amanda Rigdon, BS, and Jonathan Edelman, BS, 110 Benner Cir, Bellefonte, PA 16823; Frank Dorman, PhD, 107 Whitmore Labs, University Park, PA 16802; and Kristi Sellers, BS, and Jim Whitford, BS, 110 Benner Cir, Bellefonte, PA 16823*

WITHDRAWN

K32 A Proposed Means for the Detection and Quantification of Bath Salts From Blood

Sarah E. Sims, BS, 144 Interstate 45 N, #1216, Huntsville, TX 77320; and Chris Heartsill, BS, and Elizabeth L. Todd, PhD, 2355 N Stemmons Fwy, Dallas, TX 75207*

After attending this presentation, attendees will understand the potential for Gas Chromatography/Flame Ionization Detection (GC/FID) use as a means of detecting and quantifying synthetic cathinones (bath salts). In addition, attendees will be aware of an assay that successfully extracts bath salts from blood samples. Finally, attendees will be aware of the stability of these extracts over a short period of time.

This presentation will impact the forensic science community by demonstrating a method for the extraction, detection, and quantification of a subset of novel drugs of abuse, specifically bath salts. As these drugs are quickly being banned at both the state and federal level, it is critical that laboratories develop appropriate assays in a timely fashion. Adoption of the method described in this study, rather than in-house method development, would allow laboratories to more quickly add bath salts to the drugs of abuse which they can report. In addition, the stability study performed on the extracts will provide valuable information for validation studies that must be performed in each laboratory.

Drug abusers often attempt to circumvent controlled substance legislation by manufacturing and using novel compounds. Recently, synthetic derivatives of the natural alkaloid cathinone, more commonly known as bath salts, have been used by drug abusers seeking legal alternatives to more common drugs of abuse such as amphetamines. Because these compounds are novel, few laboratories have validated methodologies for the extraction, detection, and quantification of these compounds. This study proposes a method for this purpose.

This study utilized a basic alkaline extraction procedure to extract methcathinone, mephedrone, pentedrone, 4-methylethcathinone (4-MEC), methylone, α-pyrrolidinopentiophenone (α-PVP), butylone, and

methylenedioxypyrovalerone (MDPV) from spiked blood samples. These extracts were then subjected to both GC/FID and Gas Chromatography/Mass Spectrometry (GC/MS). Retention times were noted for the samples on GC/FID and compared for possible co-elution. The compounds separated well with the exception of the co-elution of α-PVP and butylone on channel one. However, there was clear separation on the second channel between these two compounds, allowing all compounds to be combined into a single master mix for curve generation. GC/MS results were used to verify the identity of the compounds. Both GC/FID and GC/MS showed a good response from all compounds, demonstrating that the methods used on the instruments were appropriate for detection of bath salts. Calibrators were then created for each compound at 0.02mg/L, 0.05mg/L, 0.15mg/L, 0.50mg/L, and 1.00mg/L. The calibrators were run on the GC/FID and the area ratio compared to the internal standard alphaprodine was used to create standard curves that could be used to calculate the concentration of each of the compounds. These curves were linear over the 0.02mg/L – 1.00mg/L range using all five points. Each curve achieved a minimum R^2 value of 0.995.

Following the establishment of curves on the GC/FID, a stability study was performed on the extracts to determine the stability of each compound at each concentration over a period of one week. The extracts were run each day for a week and their concentrations were charted to determine any change over time. The overall trend indicates that the compounds begin to degrade at concentrations greater than or equal to 0.15mg/L after a 24-hr period.

Samples from cases in which bath salts were previously detected were then re-extracted to determine for which matrices the assay was suitable. Samples included antemortem and postmortem blood, urine, muscle tissue, and vitreous fluid, all of which are common sample types available in forensic analysis. The compounds of interest were both detected and quantified via the assay, demonstrating the suitability of these matrices.

Synthetic Cathinones, GC-FID, Quantification

K33 Capillary Electrophoresis and Capillary Electrochromatography Mass Spectrometry for Charged and Neutral Drug Detection

Hanzhuo Fu, BS, Florida International Univ, Dept of Chemistry, 11200 SW 8th St, Miami, FL 33199; and Bruce R. McCord, PhD, Dept of Chemistry, Florida International Univ, University Park, Miami, FL 33199*

K34 Comprehensive Toxicological Examination in a Case Involving Alleged Use of Bath Salts: The Importance of a Negative Result

Barry K. Logan, PhD, and Sherri L. Kacinko, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to define the appropriate scope of testing for alleged “Bath Salts” intoxication cases, and appreciate that negative toxicology findings can only be properly interpreted when the scope of testing is understood.

This presentation will impact the forensic science community by providing an approach to rule out drug intoxication with emerging hallucinogenic drugs as part of a complex death investigation. It will also emphasize for the public and the press the importance of waiting for completion of toxicological testing before making assumptions about the role for intoxicants in criminal or death investigations.

In the assessment of crimes of extreme violence or where there is evidence of delusional or psychotic behavior, increasingly suspicion falls on the possible role of emerging designer stimulants and hallucinogens. Similar behaviors, however, can result from mental illness, schizophrenia, or even intoxication with traditional recreational drugs or drugs of abuse.

The importance of a structured escalating set of analytical protocols for these types of investigations cannot be overstated. Once routine toxicological analysis rules out traditional recreation drugs of abuse, the routine testing can begin. A recent case involving a violent assault provides a good example of how the application of routine tests can be supplemented by tests for additional drugs relevant to the fact pattern of the investigation

In this case, routine drug testing did not reveal the presence of any drug which could explain the extremely violent nature of the attack. Further testing was needed. Additional testing for the common “bath salts” compounds, MDPV, mephedrone and methylone, was performed. In addition a comprehensive screen for a wide variety of both traditional and emerging stimulant and hallucinatory drugs (67 in total) was performed using Liquid Chromatography-Time Of Flight-Mass Spectrometry (LC-TOF/MS). This included tryptamines, designer phenethylamines, other stimulants, cathinones, traditional stimulant drugs including cocaine and its metabolites and amphetamines, methoxy derivatives of phenethylamines, LSD, mescaline, psilocin, and bufotenin. Additional gas chromatography-mass spectrometric analysis was performed and compared to additional libraries containing over 10,000 known designer drugs and their analogs. The chromatographic data were further scrutinized for the presence of unidentified peaks; however, none were found.

Further testing for a comprehensive scope of emerging synthetic cannabinoid compounds was performed also. These drugs have been linked to adverse effects including paranoia, anxiety, psychosis, and violent assaults. A total of 20 synthetic cannabinoid drugs were tested for, including JWH-018, JWH-073, JWH-250, AM-2201, JWH-200, RCS-4, JWH-210, AM-694, JWH-122, JWH-081, JWH-019, RCS-8, JWH-203, JWH-022, JWH-018 5-chloropentyl, UR-144, XLR-11, AM-2233, AM-1248, and A-796,260. None were detected in the blood samples from the case.

Some of these emerging designer drugs, especially in the 2C series and derivatives of MDPV, as well as traditional hallucinogens like LSD and psilocin, are known to have limited stability in biological fluids, so appropriate collection and storage conditions are important in investigation of some of these more labile compounds. Consequently, their use cannot be ruled out even when toxicological tests are negative, and this places more of a burden on the results from a thorough investigation of the scene and history and circumstantial evidence of drug residue and paraphernalia when they exist.

In this case, comprehensive testing of available blood samples starting with routine analytical tests, and the addition of more specialized tests targeted to the compounds of concern, showed the presence of no drugs. No physical evidence from the scene or from the history revealed the presence of specific esoteric drugs that might have been ingested. The reasonable conclusion when the history, scene, autopsy, and toxicological evidence is considered in this case is that designer drug use was not a factor in this case.

Bath Salts, Designer Drugs, Drugs of Abuse

K35 Death by "Legal Psychedelic Piperidines and Phenethylamines": Postmortem Tissue Distribution of Desoxypipradrol (2-DPMP) and 4-Chloro-2,5-Dimethoxyamphetamine (DOC)

Eric S. Lavins, BS, Cuyahoga County MEO, 11001 Cedar Ave, Cleveland, OH 44139; Mary Pietrangelo, MD, 1160 Oakwood Ln, Saint Clair, MI 48079; Kevin G. Shanks, MS, 2265 Executive Dr, Indianapolis, IN 46241; Cassandra E. Cushman, West Virginia Univ, Morgantown, WV 26505; Sofalvi Szabolcs, MS, and; Joseph A. Felo, DO, Cuyahoga County MEO, 11001 Cedar Ave, Cleveland, OH 44106; John F. Wyman, PhD, Cuyahoga County Regional Forensic, Toxicology Section, 11001 Cedar Ave, Cleveland, OH 44106; and Thomas P. Gilson, MD, Cuyahoga County MEO, 11001 Cedar Ave, Cleveland, OH 44106*

After attending this presentation, attendees will have a better understanding of the piperidine and amphetamine class designer drugs desoxypipradrol (2-DPMP) and 4-chloro-2,5-dimethoxyamphetamine (DOC) and their concentrations in postmortem matrices.

This presentation will impact the forensic science community by informing forensic professionals on new abuse trends for amphetamines and designer drugs, particularly in our youth. It adds to the relatively sparsely published data concerning the potential toxicity of these stimulant drugs and provides a comprehensive approach to extraction, detection, and quantification of these substances.

These type of compounds have recently achieved "epidemic" status for abuse by young people. 2-DPMP exhibits a cocaine-like binding profile while DOC is a long-acting agonist of serotonin receptors; the fluoroamphetamines stimulate release and prevent reuptake of dopamine, serotonin, and norepinephrine.

Toxicities observed are similar to amphetamine toxicity: tachycardia, nausea, hypertension (vasoconstriction), insomnia, hyperthermia, mydriasis, panic attack, and seizures with the added predominant neuropsychiatric features of hallucinations, paranoia, and agitation.

A 30-year-old White male called a friend and advised him he had been snorting "DOC," 4-chloro-2,5-dimethoxyamphetamine, and was "tripping" and needed assistance. EMS and police were called and found the individual lying face down, breathing, but unresponsive, convulsing, extremely warm to the touch, and sweating heavily. He was conveyed to the hospital with an initial diagnosis of an acute drug overdose. The decedent had a history of selling, manufacturing, and using illegal drugs. All indications were that the overdose occurred within the last three hours. The individual died 42 hrs later at the hospital. A collection of narcotics and drug paraphernalia were confiscated from the residence as evidence and later submitted for analysis.

An autopsy was performed at the Cuyahoga County Medical Examiner's Office. Autopsy findings included dilated cardiomyopathy with a 460-gram heart, cerebral edema, and edematous lungs. Heart and femoral blood, vitreous humor, bile, liver, brain (medulla), and gastric were submitted for a comprehensive toxicology analysis.

The heart blood was positive for amphetamine 0.058mg/L, methamphetamine 0.170mg/L, fentanyl 2.0ng/mL; norfentanyl 0.44ng/mL, acetaminophen, atropine, caffeine, cotinine, lidocaine, and nicotine. The femoral blood was not sufficient in volume for analysis. No antemortem admission blood samples were available for subsequent analysis.

Because of the decedent's drug history, further testing was performed to determine the presence of other possible phenethylamine and amphetamine class drugs. Samples were extracted at a basic pH into ethyl acetate. 2-DPMP, DOC, and the fluoroamphetamines were separated and detected by an Agilent GC/MS-EI in full scan mode with a Restek-DB5 capillary column.

Further confirmatory testing was performed at AIT Laboratories, Indianapolis, IN, for the 2-DPMP, DOC, and fluoroamphetamines. Specimens were extracted at a basic pH into n-butyl chloride. Separation and detection was completed by a Waters Acquity UPLC coupled to a Waters LCT Premier XE TOF mass spectrometer as well as a Waters Acquity UPLC coupled to a Waters Tandem Quadrupole Detector (TQD). The analytical column for both analyses was a Waters BEH C18, 2.1 x 100mm, 1.7µm particle size.

The concentrations for the subsequent testing are as follows: desoxypipradrol (2-DPMP) concentrations (mg/L) were 0.283, heart blood; 0.236, vitreous humor; 1.98mg/kg, liver; 0.817mg/kg, brain (medulla); >1.0, bile, and negative, in the gastric.

4-chloro-2,5-dimethoxy amphetamine (DOC) concentrations (mg/L) were 0.466, heart blood; 0.380, vitreous humor; 1.40mg/kg, liver; 1.09mg/kg, brain (medulla); and 2.04 in the bile. Fluoroamphetamine and fluoromethamphetamine were qualitatively present in all the specimens.

2-DPMP and DOC was found to be distributed among multiple matrices with values ranging from 0.236 to >1.0mg/L for 2-DPMP and 0.380 to 2.04mg/L for DOC. Tissues responsible for detoxification/excretion had higher concentrations of the drugs. 2-DPMP, DOC, and the fluoroamphetamines were present in all tissues analyzed except gastric.

Drug chemistry results from submitted drug and drug paraphernalia exhibits were found to contain the following: 2-fluoromethamphetamine; alprazolam; 2-(1-pyrrolidinyl)-(4-methylphenyl)-1-propanone (MPPP); methamphetamine; dimethyltryptamine (DMT); psilocin; cannabis; fluoromethamphetamine; 4-chloro-2,5-dimethoxyamphetamine (DOC); phencyclidine; and, lysergic acid.

This case was consistent with the suspicion that this was an acute drug exposure. The cause of death was ruled toxic metabolic encephalopathy due to mixed drug intoxication. The manner of death was ruled as accidental.

Desoxypipradrol (2-DPMP), 2,5-dimethoxyamphetamine (DOC), Designer Drugs

K36 *In Vitro* Formation of Acetylmorphine From Morphine and Aspirin in Gastric Contents and Water

Claire K. Kaspar, BS, Cuyahoga County MEO, 11001 Cedar Ave, Cleveland, OH 44106; John F. Wyman, PhD, Cuyahoga Co Regional Forensic, Toxicology Section, 11001 Cedar Ave, Cleveland, OH 44106; Cassandra E. Cushman, West Virginia Univ, Morgantown, WV 26505; Leon Glass, PhD, 3978 Mack Rd, Fairfield, OH 45014; and Eric S. Lavins, BS, and Thomas P. Gilson, MD, Cuyahoga County MEO, 11001 Cedar Ave, Cleveland, OH 44106*

After attending this presentation, attendees will understand that it is possible to form acetylmorphine *in vitro* by incubating human gastric contents or Deionized (DI) water with morphine and aspirin.

This presentation will impact the forensic science community by suggesting that detection of 6-acetylmorphine (6-AM) may no longer solely be an indicator of heroin use.

Forensic toxicologists across the world have considered detection of 6-AM to be definitive evidence of heroin use. 6-AM was detected in an 85-year-old female with a history of a witnessed arrest in bed at a nursing home. The decedent was under hospice care for failure to thrive, and had a history of multiple strokes, syncope, hyperkalemia, osteoporosis, anemia, and osteomyelitis. There was no history of illicit drug use and the decedent was prescribed morphine sulfate elixir (Roxinol®). Whether she was taking aspirin (acetylsalicylic acid) was not recorded and salicylates were not detected by colorimetry. The manner of death was natural and the cause of death was ruled as bronchopneumonia due to hypertensive atherosclerotic cardiovascular disease with remote myocardial and cerebral infarcts.

What about the 6-AM? Is it possible that an individual may be taking morphine (pain management) and aspirin (anticoagulant), and the aspirin may acetylate morphine to produce acetylmorphine? In the present study, the possibility of formation of acetylmorphine when morphine is mixed in solution with aspirin was investigated.

Two opioid negative, postmortem gastric specimens were selected for this study, along with morphine sulfate-Extended Release (ER) tablets (15mg) and coated-aspirin tablets (325mg). Morphine and aspirin tablets were placed into 50mL samples of the two separate gastric specimens, as well as deionized water. The three morphine/aspirin solutions were incubated at 37°C for increasing lengths of time. A separate experiment was run in gastric contents using 15mg morphine sulfate powder in lieu of morphine extended-release tablets. One milliliter aliquots were taken from all samples at 10 min intervals up to one hour, and then at 90 min, two hours, and ultimately 26 hrs. Aliquots were extracted using a previously published UCT solid phase opiate procedure, and analyzed by GC/MS in SIM mode.

Acetylmorphine was detected in all of the samples containing morphine and aspirin in combination. Levels of acetylmorphine were greater in gastric contents than in DI water during the same incubation period. After 120 min, the 6-AM concentrations for the samples containing aspirin and an ER tablet were 21ng/mL and 25ng/mL in the gastric solutions, compared to 7ng/mL in water. After 26 hrs at room temperature, the gastric concentrations were 124ng/mL and 121ng/mL, and in water 27ng/mL. The increase in concentration of acetylmorphine in gastric was linear (R^2 = 0.99 and 0.98), while formation in water was non-linear (R^2 = 0.63). The results for morphine sulfate powder were essentially identical to those observed for ER tablets. The initial pH of the two gastric samples were 4.74 and 5.27, respectively; following the addition of the morphine/aspirin tablets and two hours incubation, final pH values were 3.86 and 3.92. The final pH of the water solution was 2.88. This study demonstrates that it is possible to form acetylmorphine *in vitro* by combining morphine and aspirin tablets in both postmortem gastric contents and deionized water. The compound produced in this study was identified as 6-AM by GC/MS. Further investigation must be done to determine whether the compound is actually 6-acetylmorphine, 3-acetylmorphine, or a mixture of the two compounds.

Does acetylmorphine form *in vivo*? In addition to the case described above, 10,602 specimens were assayed for opioids by a pain management laboratory using Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS). Three cases containing acetylmorphine were found to be inconsistent with heroin usage. A single specimen was listed as having a prescription for morphine and contained codeine, morphine, and 6-AM; the other two specimens contained 6-AM but not morphine or codeine. Although *in vitro* formation of acetylmorphine has been demonstrated, these data indicate that *in vivo* formation from the co-administration of aspirin and morphine is unlikely to occur. This may be attributed to inconsistencies in elimination half-lives; half-lives are 13 – 20 minutes and 1.3 – 6.7 hours for aspirin and morphine, respectively.

Morphine, Acetylsalicylic Acid, Acetylmorphine

K37 An Investigation of the Binding of Benzodiazepines to Human Serum Albumin and the Effect on Quantitation in Blood Samples

Kristina M. McNerney, BS, Cedar Crest Coll, 100 College Dr, Box 956, Allentown, PA 18104; and Marianne E. Staretz, PhD, Cedar Crest Coll, Dept of Chemical & Physical Sc, 100 College Dr, Allentown, PA 18104*

After attending this presentation, attendees will understand how the binding of benzodiazepines to Human Serum Albumin (HSA) can affect the quantitation of benzodiazepines in blood samples. Attendees will also be made aware of how the varying binding affinities of different benzodiazepines for human serum albumin can affect quantitation within specific sample preparation methods.

This presentation will impact the forensic science community by providing further pharmacological/toxicological information on benzodiazepines, a class of drug that is commonly used therapeutically and is increasingly being abused in social settings.

Benzodiazepines are commonly prescribed central nervous system depressants which are found in a wide variety of different medications, from sedatives and hypnotics to amnesiatics and anticonvulsants. Benzodiazepines are increasingly being used as recreational drugs, often in combination with other drugs such as opiates and alcohol. HSA is the most abundant plasma protein in humans. Many drugs, including benzodiazepines, bind reversibly to albumin with albumin then acting as a carrier for the drug. This binding can increase the apparent solubility of the drug in the plasma and can influence the distribution, metabolism, and excretion of the drugs. Quenching of albumin fluorescence can be used to study the interactions of these drugs with albumin and characterize the binding affinities and other important binding characteristics. In a preliminary investigation, the binding affinities and other binding characteristics for alrazolam, bromazepam, diazepam, flunitrazepam, flurazepam, lorazepam, oxazepam, temazepam, and triazolam to HSA were tabulated. The binding constants of the nine benzodiazepines ranged from $1.14x10^2$M for diazepam, having the lowest binding affinity, to $8.05x10^6$M for flunitrazepam, with the highest binding affinity. The binding of these drugs to HSA and the binding affinity of each benzodiazepine derivative may affect the quantitation of these drugs in blood. In the current research, different preparation methods were utilized on samples spiked with known amounts of benzodiazepine. Quantitation was accomplished using an Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) method with Multiple Reaction Monitoring (MRM) which utilized a C18 column and isocratic elution with 0.1% formic acid in methanol (60%) and 0.1% formic acid (40%) at a total flow rate of 0.3500mL/min. The temperature range was 40°C – 95°C. Within a preparation method, the effect of differing binding affinities on the quantitation was studied. In a dilute and shoot method, flunitrazepam, a benzodiazepine which was shown to have a high binding affinity for albumin, showed a significant difference when quantitated in samples containing human serum albumin compared to samples without human serum albumin. Samples containing HSA had calculated concentrations that were 31% – 50% lower than samples without HSA. Diazepam, which was shown to have a lower binding affinity for albumin, also showed a significant difference when quantitated in samples containing HSA compared to those without. Samples containing HSA had a calculated concentration that was 40% – 60% lower than samples without HSA. Other preparation methods were used; a comparison of these results will also be presented.

Benzodiazepines, Human Serum Albumin, Quantitation

K38 Intraosseous Fluid as Alternative Biological Specimen in Postmortem Toxicology Case Evaluations

Justin A. Volk, OCME, and Chinyere M. Williams, BS, OCME, 850 Bryant St, San Francisco, CA 94103; Ellen Moffatt, MD, San Francisco OCME, 850 Bryant St, N Ter, San Francisco, CA 94103; Alan H. Wu, PhD, Rm 2M27, 1001 Potrero Ave, San Francisco General Hospital, San Francisco, CA 94110; Amy P. Hart, MD, San Francisco OCME, 850 Bryant St, N Ter, San Francisco, CA 94103; and Nikolas P. Lemos, PhD*, OCME, Forensic Lab Division, Hall of Justice, N Ter, 850 Bryant St, San Francisco, CA 94103*

After attending this presentation, attendees will understand the usefulness and value of Intraosseous Fluid (IOF) as a possible toxicologic specimen in postmortem cases of medicolegal interest.

This presentation will impact the forensic science community by providing valuable information on the collection of IOF during autopsy as well as its analysis by Enzyme Linked Immunosorbent Assay (ELISA) for several commonly encountered drugs in postmortem toxicologic evaluations.

In San Francisco, sudden, unexpected, or violent deaths are investigated by the Office of the Chief Medical Examiner. Autopsies are performed and biological specimens are collected for laboratory tests. Such specimens commonly include blood (central/cardiac and peripheral), urine, liver, and vitreous humor. Blood and vitreous humor are routinely screened for ethanol and related compounds by headspace gas chromatography equipped with flame ionization detection. Blood (central/cardiac) and urine specimens are further screened by ELISA for amphetamines, barbiturates, benzodiazepines, cannabinoids, cocaine, fentanyl, methadone, opiates, oxycodone, phencyclidine, and tricyclic antidepressants using commercially available ELISA kits and by Gas Chromatography/Mass Spectrometry (GC/MS) in full scan mode for over 100 common drugs and metabolites. Confirmations and quantitations are normally carried out in blood (peripheral) and urine as necessary to complete the toxicologic evaluations.

After evisceration, IOF specimens were collected from 30 decedents and from four different parts of the body (right tibia, left tibia, right humerus, and left humerus) together with other standard autopsy specimens. IOF specimens were collected using donated EZ-IO® intraosseous systems by Vidacare in 10mL syringes with continuous suction provided by holding back the commercially available plungers with mosquito forceps. IOF specimens were then transferred into clean gray top test tubes. All specimens were refrigerated until the time of analysis.

Blood (central/cardiac) and urine specimens were screened by ELISA per the Office's standard testing protocol. Additionally, IOF specimens were screened by ELISA using commercially available kits donated by Venture Labs, Inc. The kits used in the IOF experiments were designed and validated for blood analyses and the analysis took place using blood drug cut-offs. The ELISA drug screening results in IOF specimens for cocaine, amphetamine, methamphetamine, opiates, oxycodone, methadone, tricyclic antidepressants, fentanyl, and phencyclidine closely correlated with the ELISA drug screening results in blood. Correlation between blood ELISA and IOF ELISA results was 100% for cocaine, opiates, methadone, phencyclidine, and fentanyl, over 90% for tricyclic antidepressants (91%), and oxycodone (93%) but dropped to 89% for cannabinoids, 75% for methamphetamine, and 69% for amphetamine. Additionally, it appears that body origin of the IOF specimen may contribute to the correlation between IOF ELISA results and blood ELISA results since IOF from the left humerus and the left tibia showed slightly higher correlation to the blood ELISA results (93% and 93%, respectively) than those from the right humerus (91%) and the right tibia (86%).

Further studies are needed to fully investigate the potential of IOF in postmortem toxicology including quantitation of drugs in IOF and evaluation of this fluid's susceptibility, if any, to postmortem redistribution and interval, two issues that often arise when dealing with drug concentrations in postmortem blood specimens. This limited study suggests that IOF specimens appear to be relatively easy to collect at autopsy using commercially available collection devices, permit the collection of enough specimen volume for ELISA testing and appear to closely mimic blood ELISA drug screening results. For these reasons, intraosseous fluid should be considered as an alternative biological specimen by forensic pathologists, coroners, medical examiners, and forensic toxicologists for drug screening by ELISA in postmortem toxicology investigations.

Intraosseous Fluid, Toxicology, ELISA

K39 Quantitative Analysis of Endogenous Levels of Gamma-Hydroxybutyric Acid (GHB) in Hair Samples Using Different Extraction Techniques

Megan E. Crowley, BS, 213 Race St, Macungie, PA 18062; Marianne E. Staretz, PhD, Cedar Crest Coll, Dept of Chemical & Physical Sc, 100 College Dr, Allentown, PA 18104; and Michelle Schmidt, MS, Cedar Crest Coll, 100 College Dr, Allentown,PA, PA 18104*

After attending this presentation, attendees will understand how a series of freeze/thaw cycles can be used to extract Gamma-Hydroxybutyric Acid (GHB) from human hair samples. Attendees will learn how freeze/thaw cycles can be a quick and reliable method for the analysis of hair samples from individuals suspected of illicit drug use.

This presentation will impact the forensic science community by providing a quick extraction method to use for hair analysis of GHB. It is thought that in the future this extraction method can be used to extract other drugs from human hair samples. This extraction method will help to decrease the analysis time of hair samples when they are encountered in the forensic science community.

GHB is a short chain fatty acid that was originally used for medicinal purposes such as the treatment of alcoholism and clinical depression. In 2005, GHB was approved under the trade name Xyrem® to treat narcolepsy and cataplexy. Despite its approved medicinal applications, GHB is primarily associated with being a recreational drug and drug of abuse. Within the forensic science community, GHB is most often observed in cases of drug-facilitated sexual assaults. Due to its synergistic effects with alcohol and quick onset of amnesia, GHB is an attractive drug of abuse for criminals attempting sexual assault.

The half-life of GHB in a healthy individual is only 20 – 53 min, which leaves a narrow and abrupt window for detection. Urinalysis, a conventional technique for detecting illicit drug use, is difficult to use because GHB is undetectable in urine within twelve hours after ingestion. This presents an additional obstacle for forensic scientists because many sexual assaults are not reported within this twelve-hour time window. Hair analysis of GHB may prove useful in the detection of drug-facilitated assaults involving GHB by allowing for a longer detection window. Most current hair extraction techniques are time-consuming and require a significant amount of sample preparation. Extraction using freeze/thaw cycles requires less time and less sample preparation. The freeze/thaw cycles consist of first washing the hair and then placing the hair into ethanol, which is used to extract the GHB from the hair. Once the hair is placed into the ethanol, the samples are then placed in liquid nitrogen until the ethanol is frozen (about 30 sec). The sample is then left to thaw, which usually takes about 2 min. This process is repeated for a total of five times. Once the sample is dried down, it is then derivitized and reconstituted in acetonitrile and then analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). Quantitation of GHB extracted from hair was accomplished using a pulsed-splitless GC/MS method, which had a pulse pressure of 30.0psi that was held for 1.75 min. This method was determined to be sensitive and robust for analysis of GHB.

The current research indicates that freeze/thaw cycles are comparable to other extraction techniques. The freeze/thaw extraction has worked on multiple types of hair and has allowed for efficient detection and quantitation of endogenous levels of GHB in human hair samples. This method has been shown to detect endogenous levels of GHB at 0.1ng/mg of hair. This method should also prove useful in the analysis of hair samples where illicit GHB use is suspected.

Endogenous GHB, Hair Analysis, Freeze Thaw

K40 Development and Validation of an LC/MS/MS Method for the Detection of the Metabolites of JWH-018 and JWH-073 in Human Urine

Moonhee Jang, PhD, National Forensic Service, 331-1 Sinwol-7-dong, Yangcheon-gu, Seoul, Korea 158-707, KOREA; Wonkyung Yang, PhD, 139 Jyangno Yangcheon-Gu, Seoul, 158-707, KOREA; Eunmi Kim, PhD, 139 Jiyangno Yangcheon-gu, Seoul, KOREA; and Hee-Sun Chung, PhD, 1402-703 Mokdong Apt, Shunjung-dong, Yangchon-ku, Seoul, 158-774, KOREA*

After attending this presentation, attendees will learn the analytical method for the determination of major metabolites of JWH-018 and JWH-073 in human urine, and the quantification results of authentic urine samples.

This presentation will impact the forensic science community by presenting the fully validated analytical method for the detection of the main metabolites of new designer drugs, JWH-018 and JWH-073, in urine.

Due to their cannabis-like effect, synthetic cannabinoids have attracted much public attention since 2008. Thus, elucidation of the metabolic pattern as well as detection of the intake of these drugs has been of major concern. In the present study, a sensitive and reliable analytical method was established and validated for the simultaneous determination of the metabolites of JWH-018 and JWH-073 in human urine. For the routine screening in urine, (ω) and (ω-1)-hydroxyl, carboxyl, and hydroxyindole metabolites were selected as target drug metabolites. The samples were prepared by solid-phase extraction and analyzed using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). The LODs were 0.025ng/mL or 0.1ng/mL and the LOQs were 2.5ng/mL for all analytes. The results of the intra- and inter-day precision and accuracy were satisfactory: <10% for precision and within ±10% for accuracy at low (2.5ng/mL) and high (75ng/mL) concentrations. In this analytical method, no significant matrix effect was observed and high recoveries for all metabolites were achieved. The described method was applied to 52 authentic urine samples suspicious of JWH-018 or JWH-073 abuse and the quantification results among samples were compared. Twenty-one of the samples (40%) were found positive for at least one metabolite of JWH-018 or JWH-073. Carboxylated metabolite of JWH-073 was detected in all analyzed samples, which could be due to the metabolism of JWH-018 in humans. However, (ω) or (ω-1)-hydroxyl metabolite of JWH-073 was detected in only 12 samples. And only a small amount of these metabolites was detected compared with JWH-018 metabolites in most of the analyzed samples. In 14 samples of a total of 21 samples, (ω-1) hydroxyl metabolite of JWH-018 was the most abundant metabolites, with a mean concentration ranging from 2.9 to 671.2ng/mL; however, in the rest of the samples, the relative concentration of (ω-1) hydroxyl metabolite of JWH-018 was very low (<LOQ-23.4ng/mL) compared with that of the most abundant metabolite in the respective sample. It can be assumed that herbal mixtures used by the suspects contain JWH-073 as an impurity. 6-hydroxyindole metabolite of JWH-018 was detected in samples where (ω-1) hydroxyl metabolite of JWH-018 was the most abundant metabolite. Similarly, 6-hydroxyindole metabolite of JWH-073 was detected in only two samples which contain (ω-1) hydroxyl metabolite of JWH-073 with a concentration of more than LOQ. These results suggest that at least three metabolites including (ω) and (ω-1)-hydroxyl and carboxyl metabolites should be simultaneously monitored to prove intake of JWH-018 or JWH-073. The variation in the concentrations of detected metabolites could be due to the dosage of the drug and time intervals between the use of the drug and urine collection. However, the absence of detailed information such as dosage, content of synthetic cannabinoids in herbal mixture, and urine collection time makes it difficult to interpret the variation of concentrations between metabolites in the pharmacokinetic aspects. Thus, further study for the estimation of the profiles of metabolite concentrations after JWH-018 or JWH-073 intake versus time will be essential. The developed analytical method will be useful for confirmation and quantification of the metabolites of JWH-018 and JWH-073 in urine in the field of forensic toxicology.

JWH-018 & JWH-073, Metabolite, LC/MS/MS

K41 Carisoprodol and Meprobamate Incidence in DUID Cases in the City and County of San Francisco

Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Ter, 850 Bryant St, San Francisco, CA 94103; and Eric A. Ingle, BA, Cecilia O. Medina, BS, Glenda M. Easterling, BS, Pavlos Karamanidis, BS, and Chinyere M. Williams, BS, OCME, 850 Bryant St, San Francisco, CA 94103*

After attending this presentation, attendees will understand the reasons carisoprodol and meprobamate can impair one's ability to safely operate a vehicle, the incidence of these two drugs in DUID cases during a three-year period (January 1, 2009 to December 31, 2011), the blood concentrations measured in these drivers, and the identity of other drugs found in the blood of these drivers.

This presentation will impact the forensic science community by adding to the existing body of literature information regarding driving behavior, drivers' symptomology, blood concentrations, and other drugs found present in the blood of drivers driving under the influence of carisoprodol and meprobamate.

Carisoprodol and meprobamate are medications that are available only by prescription in the U.S. Carisoprodol is a muscle relaxant and meprobamate is a central nervous system depressant and a major metabolite of carisoprodol. Most patients are prescribed these medications for muscular pain management or anxiety, but abuse may develop due to the sedative-hypnotic effects these compounds produce.

In San Francisco, blood evidence is screened for ethanol and related compounds by Headspace/Gas Chromatography equipped with Flame Ionization Detection (HS/GC/FID). Blood is further screened by enzyme-linked immunosorbent assay for barbiturates, cannabinoids, cocaine, methadone, methamphetamine, opiates, and phencyclidine and by Gas Chromatography/Mass Spectrometry (GC/MS) in full scan mode for over 100 drugs and metabolites. Following a positive screening result for carisoprodol and/or meprobamate by GC/MS, a fresh aliquot of blood is extracted by liquid-liquid extraction and reanalyzed by GC/MS using quantitative calibrators freshly prepared in drug-free swine blood.

For the purposes of the present study, the in-house computerized database was interrogated, and 21 driving cases in which the laboratory had reported carisoprodol and/or meprobamate in blood specimens were identified during the three-year period of interest. Police reports were reviewed and information regarding the date/time of driving, the observed driving, and field sobriety test performance was collected. The 21 drivers with reportable carisoprodol/meprobamate in their blood comprised of 6 females and 15 males. The mean age of all drivers was 32 (range: 19 – 50). The mean age in females was 38 (range: 25 – 50) and 28 (range: 19 – 44) in males. Police reports indicated that drivers freely admitted to taking carisoprodol/meprobamate, did not exhibit breath odor of alcoholic beverage, displayed glossy, watery eyes, and slurred speech. Their demeanors were described as calm and relaxed. During the horizontal gaze nystagmus, clues observed included inability to follow the object, inability to keep head still and track only with eyes, lack of convergence, and lack of reaction to light. During the Romberg test, clues observed included eyelid fluttering, opening of the eyes during the test, and estimation of 38 – 95 sec for 30 sec. The clues observed during the "one leg stand test" included poor balance, inability to keep the foot off the ground, and raising arms up to six inches to maintain balance. Clues observed during the "finger count test" included

touching the finger pads instead of the tips and miscounting the steps and the number of steps performed.

Carisoprodol was reported in all 21 driving cases while meprobamate was reported in 20 of the 21 cases. The mean carisoprodol and meprobamate concentrations and associated ranges in all 21 drivers were 11mg/L (0.8 – 26mg/L) and 20.4mg/L (3.2 – 38mg/L), respectively. Carisoprodol and/or meprobamate were the only drugs detected in one-third of the cases included in this study (7 of 21 cases). In these seven cases, the mean carisoprodol and meprobamate concentrations were 12.3mg/L (7.3 – 16mg/L) and 30.4mg/L (19 – 36mg/L), respectively. In the remaining 14 cases where carisoprodol/meprobamate were not the sole compounds detected, drivers' blood specimens were found to contain on average two more psychoactive compounds including benzodiazepines (n=3), cannabinoids (n=3), oxycodone (n=3), ethanol (n=2), methadone (n=2), hydrocodone (n=2), cocaine/benzoylecgonine (n=2), methamphetamine (n=1), MDMA (n=1), citalopram (n=1), and tramadol (n=1).

Carisoprodol/meprobamate occurrence in driving under the influence cases in the City and County of San Francisco is a significant and on-going challenge. Often these drugs are present with other psychoactive compounds in drivers, making it difficult to assign specific signs and symptoms to them. Carisoprodol/meprobamate were the only drugs found in the blood of drivers in the minority of these 21 cases whereas in most of the cases, they were present together with several other compounds, primarily benzodiazepines, cannabinoids, and oxycodone.

Carisoprodol, Meprobamate, DUID

K42 Cannabinoids in 113 Driving Under the Influence of Drugs (DUID) Forensic Toxicology Cases

Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Ter, 850 Bryant St, San Francisco, CA 94103*

After attending this presentation, attendees will understand the ranges of concentrations at which cannabinoids are often detected in DUID cases.

This presentation will impact the forensic science community by providing valuable information on cannabinoid incidence among drivers and by offering blood reference concentrations of common cannabinoids in DUID case investigations.

The Forensic Laboratory Division of the Office of the Chief Medical Examiner performs DUID and other human performance forensic toxicology cases investigations on behalf of 14 law enforcement agencies routinely operating within the City and County of San Francisco. Specifically for cannabinoids, commercially available Enzyme Linked Immunosorbent Assay (ELISA) kits by Venture Labs, Inc. are employed to screen blood and urine. The ELISA cannabinoid cutoffs used for blood and urine are 5 ng/mL and 50ng/mL, respectively. Following a positive ELISA, confirmation and/or quantitation takes place on a new specimen aliquot by Gas Chromatography/Mass Spectrometry (GC/MS) with a limit of quantitation of 1ng/mL for Δ^9-tetrahydrocannabinol (THC) and 5ng/mL for 11-hydroxy-Δ^9-tetrahydrocannabinol (THC-OH) and 11-nor-9-carboxy-Δ^9-tetrahydrocannabinol (THC-COOH) for both blood and urine. The deuterated compounds THC-d_3 and THCCOOH-d_3 are used as internal standards. For THC-d_3, the target (underlined) and qualifier ions are 389 and 374. For THCCOOH-d_3, the target (underlined) and two qualifier ions are 374, 476, and 491. For THC, the target (underlined) and qualifier ions are 386 and 371. For THC-COOH, the target (underlined) and two qualifier ions are 371, 473, and 488. Finally, for THC-OH, the target (underlined) and two qualifier ions are 371, 459, and 474.

Between July 1, 2010, and June 30, 2011, the Division performed toxicologic evaluations in 919 DUID cases including the cannabinoid protocol described above. Cannabinoids were consequently reported in 113 of the 919 cases (12.3%). Five of these cases involved urinalysis and 108 involved blood analysis.

Drivers averaged 29.7 years of age (range: 14 – 68 years) and were predominantly male (n=100; 88%) which represents a higher proportion of male drivers as compared to the overall sex distribution of drivers whose toxicology was performed by this Division during the same time period (750 males, 82%; 169 females, 18%).

Among all 108 blood DUID cases, mean concentrations and associated ranges in ng/mL for THC, THC-OH, and THC-COOH were 5 (1 – 33), 9 (5 – 14) and 52 (5 – 320), respectively.

In 64 of the 108 cases involving blood evidence, ethanol was also found at a mean concentration of 0.13% (w/v) which ranged from 0.01 – 0.38% (w/v). In four of these 64 ethanol-cannabis cases, additional drugs were also detected (diazepam/nordiazepam in two cases, alprazolam in one case, methadone in one case, and MDMA/MDA in one case). In the 64 cases where ethanol was reported in addition to cannabinoids, mean concentrations and associated ranges in ng/mL for THC, THC-OH, and THC-COOH were 4 (1 – 23), 9 (8 – 12), and 44 (5 – 150), respectively.

Cannabinoids were reported in combination with drugs other than ethanol in 15 cases. In those 15 cases, drugs found in addition to cannabinoids were codeine (four cases), cocaine/benzoylecgonine (three cases), methamphetamine/amphetamine (three cases), MDMA (three cases), oxycodone (two cases), alprazolam (two cases), methadone (one case), and hydrocodone (one case). In these 15 cases where cannabinoids were found in combination with drugs other than alcohol, mean concentrations and associated ranges in ng/mL for THC, THC-OH, and THC-COOH were 7 (1 – 33), 8 (7 – 10), and 65 (13 – 290), respectively.

Cannabinoids were the only compounds reported in 29 of the 108 blood DUID cases. In these 29 cases, mean concentrations and associated ranges in ng/mL for THC, THC-OH, and THC-COOH were 7 (1 – 26), 8 (5 – 14), and 62 (6 – 320), respectively.

In the five cases involving urinalysis, THC-COOH was the only cannabinoid confirmed present. Only in one of the five urinalysis cases, cannabinoids were the only compounds reported. Cocaine/benzoylecgonine, cocaethylene, and codeine were each confirmed present in two urinalysis cases, whereas morphine, phencyclidine, carisoprodol, meprobamate, promethazine, norpromethazine, and levamisole were each confirmed present in one urinalysis case. Per professional guidelines, drug concentrations are not measured/reported in urine specimens.

This study offers a significant insight into the blood cannabinoid concentrations of drivers involved in DUID investigations in San Francisco. The reported mean concentrations suggest that drivers who concurrently consume ethanol with cannabis have on average lower THC blood concentrations than drivers who use cannabis by itself or with drugs other than ethanol and one may infer these drivers may be changing their cannabis use patterns (i.e., consuming lower cannabis doses and/or extending the waiting times before drinking) when they combine cannabis with alcohol. This type of epidemiological data provides reference concentrations for forensic toxicologists, law enforcement agents, and attorneys who are required to evaluate cannabinoid concentrations in human performance toxicologic specimens when involved in DUID investigations.

Cannabinoids, Toxicology, DUID

K43 Toxicology Result of Drivers of Fatal Motor Vehicle Accidents in Harris County, Texas, in 2011

Fessessework G. Guale, DVM, HCIFS, 1885 Old Spanish Tr, Houston, TX 77054; and Ashraf Mozayani, PhD, PharmD, Texas Southern Univ, 3100 Cleburne Ave, Houston, TX 77004*

After attending this presentation, attendees will have relevant information about the involvement of illicit, prescription, and over-the-counter drugs in causing the majority of fatal traffic accidents.

Attendees will learn the importance of extensive standardized testing of biological specimens for different classes of drugs in addition to alcohol.

This presentation will impact the forensic science community by raising awareness on the prevalence of fatal motor vehicle accidents caused by drugs alone with no alcohol involved. The involvement of drugs in fatal traffic accidents other than alcohol have not been adequately explored, partly due to lack of information in police training and most of the crime laboratories are neither mandated nor equipped to perform confirmation and quantitation of illicit, prescription, and over-the-counter drugs in biological specimens, especially blood. The other reason is the high cost of drug confirmation in biological specimens and the possibility of obtaining convictions based on only blood alcohol levels.

Driving under the influence of alcohol and drugs has been the main cause of fatal and non-fatal accidents for drivers and other occupants in the car, as well as pedestrians. In 2011, the medical examiner of the Harris County Institute of Forensic Sciences performed autopsies of 214 victims of fatal car crashes. All drivers of fatal motor vehicle accident cases were subject to alcohol screening and confirmation, nine-panel Enzyme-Linked Immuno-Sorbent Assay (ELISA) screens for drug of abuse, standard basic drug screen for prescription and over-the-counter drugs using Gas Chromatography/Mass Spectrometry (GC/MS), screens for 11 synthetic marijuana (Spice/k2) drugs, 8 methylcathinones (bath salt) drugs, and three hypnotic Z-drugs using Time-Of-Flight/Liquid Chromatography/Mass Spectrometry (TOF/LC/MS). All identified drugs by screening methods were subject to confirmation and quantitation by GC/MS, GC/MS/MS, and LC/MS/MS instruments. Out of 214 victims, 134 (63%) had ethanol and other drugs in their system. Out of 134 cases, 86 cases were positive for ethanol with quantitation result greater than 0.08gm/dl in 77 (89%) of cases and less than 0.08gm/dl in 9 (10.4 %) of cases. Out of 134 cases, 46 (34%) were positive for illicit, prescription, and over-the-counter drugs with no ethanol. Next to ethanol, the most common drug identified was marijuana in 30 (22%) of the cases with and without ethanol present. Ten (17%) of the cases had alprazolam, 9 (6.7%) cases had cocaine, 7 (8.9%) cases had hydrocodone, and 5 (3.7%) cases had PCP. The prevalence of alcohol and drugs among the deceased drivers' cases indicate alcohol and marijuana being the most common findings followed by benzodiazepines, opiates, cocaine, PCP, muscle relaxants, and other prescription drugs. Out of 134 drug-positive cases, 100 (74%) are male and 26% are female drivers, 63 (47%) are White, 48 (35%) are Hispanic, 27(20%) are Black, 3 (2%) are Asian and 2 (1.4%) are unknown race. The most common age group is in the range of 21 – 30 (35%), followed by 31 – 40 (20%), 41 – 50 (15%), 51 – 60 (17%), >60 (8.2%), <21 (11%). White male drivers, 21 – 30 years of age, are the most identified victims of fatal alcohol and drug related accidents.

The importance of screening and confirmation of illicit, prescription, and over-the-counter drugs in the biological specimen of motor vehicle accident victims is discussed.

Drugs, Driver, Fatality

K44 Using Pharmacology to Screen Your DWI-Drug Cases

David M. Benjamin, PhD, 77 Florence St, Ste 107N, Chestnut Hill, MA 02467-1918*

After attending this presentation, attendees will be able to describe the pharmacologic criteria necessary for a prosecutor to meet the burden of proof to establish DWI-Drugs and apply these criteria to the findings of the presence of a drug in the urine.

This presentation will impact the forensic science community by presenting pharmacologic criteria which will help prosecutors select meritorious cases and defer going forward on cases when the pharmacology clearly will not support guilt beyond a reasonable doubt. An awareness of these criteria should minimize the prosecution of unwinnable cases, save valuable court time, improve the quality of justice in the courts, and protect innocent citizens from unnecessary mental anguish and monetary expense. A prototypical case will be discussed.

In order to successfully prosecute a DWI-Drugs case, the State must show that the defendant driver was impaired, and that the impairment was proximately caused by a previously ingested drug. The drug could be an illicit drug, a prescription drug, an over-the-counter drug, or an inhalant of some type. An admission by the driver that he/she took a drug earlier, or the positive results of a urine drug test, only indicate prior exposure, but do not demonstrate that the previously ingested drug proximately caused impairment at the time of the police stop. Evidence of impairment is best established by observations of erratic behavior by fact witnesses, and testing of balance, coordination, and cognitive function by professionals qualified to administer such tests.

Example of an Unwinnable DWI-Drug Case: In a Commonwealth of Massachusetts case (Com), a young woman, E.D., was stopped for crossing a road line. Her urine screen was positive for a small amount of butalbital, a barbiturate found in common prescription anti-migraine medications.

Many drugs remain in the body long after the time interval of their pharmacologic activity has elapsed (biosphere). Thus, determining the presence of a drug in a biological fluid is not a sufficient basis to opine that an individual is impaired. Instead, one must determine the biosphere of that drug, that is, the duration of time the drug exerts its pharmacologic effect on the individual, rather than its residence time in the body. Moreover, only certain drugs show a good correlation between the magnitude of their blood level and the extent of the effect they produce on the individual. Other drugs, called hit-and-run drugs, produce an effect long after they have left the body and are no longer detectable in blood or urine. A good example of such a drug would be the glucocorticoid, prednisone, which produces major changes in the hypothalamic-pituitary-adrenal axis, which may persist for weeks or months.

The half-life of butalbital is 1.5 – 3.5 days. Based on generally accepted pharmacokinetic principles, it takes 6 – 10 half-lives to rid the body of a drug. This means that E.D. could have taken the drug more than a month earlier and still had a positive urine test on the day she was stopped, even though the pharmacologic effects on migraine relief and possible impairing effects last only a few hours, and tolerance to barbiturates is known to occur after repeated use.

The COM planned to have a Drug Recognition Expert (DRE) testify at trial that the defendant had been impaired, an opinion that could not be proven beyond a reasonable doubt, and one to which the DRE was not percipient, as she had never met or assessed the defendant. A DRE is basically a fact witness, not an expert, and according to *U.S. vs. Horn* (Motion Hearing, 2001) testifies under FRE 701 not FRE 702, and cannot offer opinion testimony on scientific or technical issues. However, on the day of the *Daubert* hearing to strike the DRE, the COM reconsidered its position, and agreed to let the defendant off with probation.

In this case, a simple pharmacokinetic analysis would have indicated the very low likelihood that the prosecution could have proved its case beyond a reasonable doubt, or that a jury would have convicted. The defendant was subjected to unnecessary anxiety and considerable expense, without an adequate basis for prosecution of this case.

Pharmacokinetics, Lay Witnesses, Expert Witnesses

K45 Cannabinoids in Exhaled Breath Following Controlled Administration of Cannabis

Sarah K. Himes, BS, National Institute on Drug Abuse, Biomedical Research Center (BRC), 251 Bayview Blvd, Ste 200, Rm 05A721, Baltimore, MD 21224; Karl B. Scheidweiler, PhD, 251 Bayview Blvd, Ste 200, Rm 05A721, Baltimore, MD 21224; Olof Beck, PhD, Karolinska Universitetssjukhuset Huddinge, 141 86 Stockholm, SWEDEN; and Marilyn A. Huestis, PhD, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Blvd, Rm 05A721, Baltimore, MD 21224*

The goal of this presentation is to offer a greater understanding of the applicability and relevance of measuring cannabinoids in breath following controlled smoked cannabis. The hypothesis is that the detection window of cannabinoids in breath will be several hours. This would be an appropriate timeframe for detecting driving under the influence of drugs, as this is similar to the window of acute drug impairment.

This presentation will impact the forensic science community by supporting the application of cannabinoid breath testing, particularly in the drugged driving field.

Methods: Breath specimens were collected using SensAbues (Huddinge) devices prior to and following *ad libitum* smoking of a single 6.8% Δ^9-tetrahydrocannabinol (THC) cigarette for 10 min in occasional and chronic cannabis users. This study was Institutional Review Board- (IRB) approved and written informed consent was obtained from participants. Breath specimens were collected during a 3 min period at -18, -1, 0.5, 1, 2, 3, 4, 5, 6, 8, 10.5, 13.5, and 21 hr post-smoking. Sample preparation involved a 20 min methanolic extraction, followed by solid phase extraction on polymeric SSTHC columns (UCT). THC, 11-nor-9-carboxy-THC (THCCOOH), and cannabinol (CBN) were quantified by Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) similar to a method proposed by Beck *et al*. with minor modifications.[1] Limits of Quantification (LOQs) were 50pg/pad for THC and CBN and 100pg/pad for THCCOOH. Linearity extended to 10,000pg/pad for all analytes. Extraction efficiencies for THC, THCCOOH and CBN were 33.8 34.6%, 58.1-63.0%, and 67.1-73.5% across the linear range. Matrix effects ranged from -34.6 to 12.3%. Extraction efficiencies and matrix effects were similar for matched deuterated internal standards. To date, breath specimens from one occasional and five chronic smokers were tested.

Results: Following controlled administration of THC, breath pads were positive only for THC; CBN and THCCOOH were not detected in any specimen at the method's LOQs. Breath pads were positive only at the 0.5, 1, and 2 hr post-smoking collections. Following cannabis smoking, dry mouth frequently occurred, making the collection of oral fluid difficult. As oral fluid collections occurred just prior to breath collection, breath collection times were delayed early in the time line due to prolonged oral fluid collection times. Mean (range) times for breath collection were 0.9 (0.78-0.98), 1.4 (1.30-1.45), and 2.4 hr (2.25-2.58) post-smoking. All but one participant had detectable THC in breath at 0.9 hr with a median (range, n) THC breath concentration of 147.0pg/pad (117-409, n=5). At 1.4 hr post-smoking, all but one participant had THC-positive breath with a median concentration of 122.2pg/pad (71.4-209, n=5). Only three participants still had detectable THC in breath at 2.4 hr post-smoking with a median concentration of 67.6pg/pad (54.0-86.3, n=3). For two participants, only one breath collection was positive for THC: 109pg/pad at 1.37 hr and 118pg/pad at 0.9 hr. Participants with multiple positive specimens (n=4) showed decreasing THC breath concentrations over time. In all participants, once breath specimens were negative for THC, they remained negative for the duration of the study.

Conclusions: The cannabinoid detection window in breath was short, ranging from 0.9 – 2.4 hr after cannabis smoking. Only parent THC was present; CBN and THCCOOH were not detected. Breath is an alternative matrix to oral fluid for a short cannabis detection window. Future research should determine if THC is present in breath during sustained cannabis abstinence in chronic daily cannabis smokers. During prolonged abstinence after chronic daily cannabis smoking, large THC body stores were slowly eliminated in the blood, plasma, urine, oral fluid, and sweat. The low THC concentrations in breath after cannabis smoking suggest that prolonged excretion will not occur. These data support the suitability of cannabinoid breath testing in the field of forensic science, particularly in the drugged driving field.

Breath, Cannabinoids, THC

K46 Determination of Synthetic Cannabinoids in Whole Blood From Recreational Users

Robert Kronstrand, PhD, and Markus Roman, BSc, Nat'l Board of Forensic Med, Dept of Toxicology, Artillerigatan 12, Linkoping, SWEDEN*

After attending this presentation, attendees will understand how synthetic cannabinoids may be analyzed and will have an insight in the common findings in recreational users as well as the challenges these compounds present to the forensic toxicologist. This paper presents a Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) method for synthetic cannabinoids in whole blood and toxicological findings from recreational users.

This presentation will impact the forensic science community by adding findings for substances that have paucity in data.

Analysis was performed on a Waters ACQUITY ultra performance LC connected to an API 4000 triple-quadrupole instrument equipped with an electrospray interface. The following compounds were included in the method: JWH-007, JWH-015, JWH-018, JWH-019, JWH-020, JWH-073, JWH-073-methyl, JWH-081, JWH-098, JWH-122, JWH-147, JWH-200, JWH-203, JWH-210, JWH-250, JWH-251, JWH-398, AM-694, AM-2201, AM-1241, RCS-4, RCS-8, and WIN 55,212-2. JWH-018-d_{11} was used as internal standard. The analytes were chosen because they either were scheduled by the Swedish government or because they were reported as possible drugs of abuse.

To 1g whole blood was added 0.5mL TRIS-buffer (0.5M, pH=8.5) and 3mL of tert-butylmethylether:chlorobutane (50:50). The organic phase was transferred to new tubes, evaporated to dryness, and reconstituted in 100µL of 10mM ammonium formate and acetonitrile (50:50). 5µL was injected into the LC/MS/MS. Chromatography was performed using an ACQUITY high-strength silica T3 column (1.8µm, 50 x 2.1mm, Waters) and operated at 0.6mL/min with a total run time of 6 minutes. Mobile phase A consisted of 0.05% formic acid in 10mM ammonium formate and phase B was 0.05% formic acid in acetonitrile. The chromatographic system was run in a linear gradient from 35% to 70% phase B.

Method validation included selectivity and matrix effect studies, investigations of calibration models, accuracy, within and between day precision, and dilution integrity. The method was applied to 1,609 authentic cases where the police had requested synthetic cannabinoids.

The method validation experiments showed overall good results for the 23 analytes. Matrix effects were seen especially for the late eluting compounds and an interference for the transitions of RCS-8 appeared in most chromatograms close to the retention time of RCS-8. All analytes were best fitted to quadratic calibration curves between 0.05ng/g to 5.0ng/g.

The overall positive rate was approximately 30% with AM-2201 as the most common finding. The positive findings changed over time, sometimes so that substances that were scheduled decreased to be

replaced by new unscheduled analogs. Eleven of the analytes were found in one or more cases.

Analyte	*N*	Median (ng/g)	Mean (ng/g)	Range (ng/g)
JWH-018	80	0.10	0.62	0.05 – 9.7
JWH-019	7	0.65	0.44	0.07 – 0.78
JWH-081	8	0.20	0.24	0.06 – 0.65
JWH-122	51	0.42	3.6	0.05 – 88
JWH-203	3	13	27	0.06 – 68
JWH-210	31	0.75	1.6	0.07 – 11
JWH-250	3	0.48	0.45	0.14 – 0.73
AM-694	10	0.12	0.43	0.05 – 1.5
AM-2201	290	0.34	1.0	0.05 – 29
RCS-4	5	0.23	0.80	0.06 – 3.4

Concentrations were typically in the subnanogram range, but some cases had very high concentrations (see table). It has been reported that synthetic cannabinoids, in comparison to cannabis, seem to be more dangerous and potent, causing several unwanted symptoms in the users. In the material, case histories were not received in more than a few cases where the subjects had suffered from severe side effects and been brought to hospital. These subjects presented with unconsciousness, vomiting, incontinence, and hallucinations and relatively high concentrations of JWH-018, JWH-203, or JWH-210, sometimes in combination with another synthetic cannabinoid. This study concludes synthetic cannabinoids appear in very low concentrations and the changing panorama of substances requires a flexible approach to the analytical methodology.

Cannabinoids, LC/MS/MS, Recreational Users

K47 Driving Under the Influence of Alprazolam

H. Chip Walls, BS, Forensic Toxicology Lab, 1600 NW 10th Ave #7025A, Miami, FL 33136-1015; and Nicholas B. Tiscione, MS, Ilene K. Alford, MS, Xiaoqin Shan, PhD, and Dustin Yeatman, MS, Palm Beach County SO, 3228 Gun Club Rd, West Palm Beach, FL 33406; and Brianna Peterson, PhD, 2203 Airport Way, S, Seattle, WA 98134*

After attending this presentation, attendees will have a better understanding of the prevalence of alprazolam in DUID cases and the lack of correlation between blood alprazolam concentrations and impairment.

This presentation will impact the forensic science community by adding to the body of knowledge regarding alprazolam concentrations found in Driving Under the Influence of Drugs (DUID) cases, observed impairment, and comparison to the indicators for central nervous system depressants in the Drug Recognition Expert (DRE) matrix.

Alprazolam, a high-potency benzodiazepine, is FDA approved for the treatment of anxiety and panic disorder and is one of the most prescribed medications and abused drugs worldwide. Sedation and impairment of cognitive function and psychomotor performance are some of the main problems associated with the use of benzodiazepines as anxiolytics. Patients using alprazolam commonly report adverse events, such as drowsiness, dizziness, and reduced alertness, especially in the first month of use. Alprazolam is commonly used with alcohol and other recreational drugs, presumably to achieve increased intoxication and manage undesirable drug withdrawal symptoms such as the downside or dysphoric phase of stimulant use and to alleviate the panic and paranoia caused from using high potency cannabis. The pharmacology of alprazolam will be reviewed as an attempt to understand why Alprazolam is such a popularly abused drug in suspected intoxicated driver cases across the United States.

Between 2007 and 2012, 28% of all blood DUI drug cases submitted to the Palm Beach County Sheriff's Office Crime Laboratory contained alprazolam, making this the most commonly detected drug. Of the 205 cases analyzed during this period containing alprazolam, only nine contained alprazolam alone (4.4%). The nine subjects were composed of six males and three females with a mean age of 45 years (range 17 – 72). Seven out of nine involved traffic crashes. Alprazolam concentrations ranged from 22 to 437ng/mL.

During the first six months of 2012, 13% of all DRE cases submitted to the Washington State Patrol Toxicology Laboratory contained alprazolam. Of the 64 DRE cases analyzed during this period containing alprazolam, only seven contained alprazolam alone (10.3%). The seven subjects were composed of four males and three females with a mean age of 38 years (range 24 – 57). Alprazolam concentrations ranged from 10 to 210ng/mL.

Summary data from all sixteen alprazolam-only cases followed by detailed information for four cases from Palm Beach County and seven Washington State cases will be presented. Detailed information will include testing protocol, analytical results, and case synopsis including observed impairment and clinical indicators of drug use. The indicators for central nervous system depressants in the DRE matrix will be compared and contrasted with these case investigations.

Alprazolam, DUID, DRE

K48 Prevalence of Tetrahydrocannabinol in Oral Fluid Collected From Drivers in California

Christine Moore, PhD, DSc, and Cynthia Coulter, BS, Immunalysis Corporation, 829 Towne Center Dr, Pomona, CA 91767; and Mark Johnson, PhD, John Lacey, MPH, and Tara Kelley-Baker, PhD, Pacific Institute for Research and Evaluation, 11720 Beltsville Dr, Calverton, MD 20705*

After attending this presentation, attendees will be aware of the prevalence of marijuana in the oral fluid of California drivers. Attendees will appreciate the utility of oral fluid in traffic safety situations.

This presentation will impact the forensic science community by showing that oral fluid is a viable alternative to blood for the analysis of drugs in specimens taken from drivers.

Recent roadside surveys conducted in the United States have determined that cannabis is the most prevalent drug detected in drivers randomly stopped and voluntarily tested. The 2007 National Roadside Survey reported that 7.7% of nighttime weekend drivers tested positively for tetrahydrocannabinol (THC) in their oral fluid, indicating recent ingestion of cannabis.

This presentation will focus on data collected from drivers in various locations in California during 2010 and again in 2012.

In 2010, researchers attempted to recruit 1,784 drivers who were stopped at random during nighttime hours on Friday and Saturday evenings. Due to age or type of vehicle, 282 were not selected. Of the 1,502 eligible drivers, 297 either refused to be part of the survey, or only completed part of the process. In total, oral fluid was collected voluntarily from 900 drivers. Subjects were predominantly male (63.2%), White (60.5%), and had a median age of 29. A total of 14.4% of drivers tested positively for illegal drugs with 8.5% testing positively for THC. Only 1.3% of the drivers were positive for both THC and alcohol, a combination known to significantly increase the odds of traffic accidents. Compared to the 2007 National Survey, the percentage of marijuana positives in California drivers had increased overall (from 4.9% to 7.8%) and in three of the four comparable jurisdictions; only one showed a lower percentage of positive drivers in 2010. In 2010, the prevalence of cannabis varied throughout the state with Fresno showing the lowest prevalence of 4.3% and Eureka, Humboldt County, having the highest prevalence of drivers positive for marijuana, 18.3%. The concentration range for THC in oral fluid was 2 – 1284ng/mL; mean 199ng/mL; median 30ng/mL. Part of the

impetus for the 2010 study was the potential for decriminalization of marijuana in California Proposition 19—also known as the Regulate, Control, and Tax Cannabis Act of 2010—which was on the ballot in November 2010. If it had been approved, the proposition would have legalized various marijuana-related activities in California (although not under federal law), allowing local governments to regulate these activities, permitting local governments to impose and collect marijuana-related fees and taxes, and authorizing various criminal and civil penalties. The ballot initiative was defeated 53.5% to 46.5%. However, medical marijuana is legal in California (Proposition 215, 1996) and as part of the survey, drivers were asked if they held a permit for its medical use. While only 36 drivers admitted to having permits for medical marijuana, 38.9% of them tested positively for THC, compared to 7.5% of those without permits. When controlled for driver age, race, and including jurisdiction as a random variable, drivers holding permits for medical marijuana were significantly more likely to test positively for THC than nonpermit holders.

In 2012, the California Study was repeated with data collected from nine locations including Anaheim (Orange County), Chula Vista (San Diego County), Eureka (Humboldt County), Fresno (Fresno County), Gardena (Los Angeles County), Ontario (San Bernardino County), Modesto (Stanislaus County), Redding (Shasta County), and San Rafael (Marin County). Four of the nine sites were the same as the 2010 study (Anaheim, Eureka, Fresno, and San Rafael). Researchers recruited over 1,000 drivers during weekend nighttime hours to provide oral fluid specimens voluntarily. Cannabis use throughout the state was again different, depending on geographical location.

The difference in marijuana prevalence in drivers between 2007, 2010, and 2012 will be presented. The effect of medical marijuana availability and potential decriminalization of marijuana in the state of California will be discussed.

Oral Fluid, Marijuana, Driving

K49 Can Oral Fluid Cannabinoid Testing Differentiate Cannabis Smoking From Intake of Oral THC and Oromucosal Sativex® Administration?

Dayong Lee, MS, National Institute on Drug Abuse, 251 Bayview Blvd, Ste 200, Baltimore, MD 21224; Erin Karschner, BA, NIDA Intramural Research Program, Chemistry & Drug Metabolism Section, 5500 Nathan Shock D, Baltimore, Maryland 21224; Allan J. Barnes, BS, NIDA Intramural Research Program, 5500 Nathan Shock Dr, Rm 373, Baltimore, MD 21224; Garry Milman, PhD, National Institute on Drug Abuse, 251 Bayview Blvd, Ste 05A.505.16, Baltimore, MD 21224; Robert S. Goodwin, DO, PhD, NIDA Intramural Research Program, Chemistry & Drug Metabolism Section, 5500 Nathan Shock Dr, Baltimore, MD 21224; and Marilyn A. Huestis, PhD, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Blvd, Rm 05A721, Baltimore, MD 21224*

After attending this presentation, attendees will be informed about cannabinoid disposition in Oral Fluid (OF) after a single oral Δ^9-tetrahydrocannabinol (THC) or Sativex® oral mucosal administration. Dronabinol, synthetic THC, is approved in the U.S. for treating anorexia caused by AIDS and chemotherapy-associated nausea/vomiting. Sativex®, a cannabis oromucosal spray containing approximately 1:1 THC and cannabidiol (CBD), is in phase III trials for cancer pain in the U.S. and approved for multiple sclerosis symptoms in several European countries, Canada, and New Zealand. While several studies investigated OF cannabinoid pharmacokinetics following cannabis smoking, there is only one with multiple oral THC doses and none with Sativex®. This presentation characterizes OF cannabinoid time-course profiles, windows of detection, and cannabinoid ratios after the oral and sublingual drug delivery routes. Differences from cannabis smoking were evaluated for possible approaches to identifying relapse and compliance with cannabinoid pharmacotherapy.

This presentation will impact the forensic science community by providing the first data defining cannabinoid disposition in oral fluid after single-dose medicinal cannabinoid products. These data will improve interpretation of oral fluid cannabinoid testing and aid in formulating policy and legislation for oral fluid testing and in effectively managing patients undergoing cannabinoid pharmacotherapy.

Methods: Fourteen cannabis smokers (aged 19 – 43 yrs, 79% male, 64% African American) provided written informed consent for this double-blind, double-dummy, within-subject, Institutional Review Board-approved study. The participants resided on a closed research unit at least 10h prior to each drug administration. Five or 15mg synthetic oral THC; two (low dose, 5.4mg THC, and 5.0mg CBD) or six (high dose, 16.2mg THC, and 15.0mg CBD) actuations of Sativex®; or placebo oral THC and six placebo Sativex® actuations were administered in random order. Dosing sessions were separated by at least five days. OF specimens were collected with the Quantisal™ collection device, 0.5 hr before and 0.25, 1, 4.5, 7.5, and 10.5 hr after dosing initiation. THC, CBD, cannabinol (CBN), 11-hydroxy-THC (11-OH-THC), and 11-nor-9-carboxy-THC (THCCOOH) were quantified by 2D Gas Chromatography/Mass Spectrometry (GC/MS). If analyte concentrations exceeded the upper limit of linearity, participants' OF specimens were diluted with drug-free OF-Quantisal™ buffer mixture. Limits of quantification were 0.5ng/mL for THC, CBD, and 11-OH-THC, 1ng/mL for CBN, and 7.5pg/mL for THCCOOH.

Results: After oral THC, OF THC decreased over time from baseline concentrations ≤20.5ng/mL; concentrations were not significantly different from those after placebo, reflecting residual THC excretion from previously self-administered smoked cannabis. CBD and CBN were only detected in three specimens with concentrations ≤1.1ng/mL. After Sativex®, THC, CBD and CBN increased greatly with peak concentrations of 266 – 11,424, 196 – 12,120, and 9.5 – 560ng/mL (low dose, respectively); 1,323 – 18,216, 1,552 – 18636, and 74 – 22,32ng/mL (high dose, respectively) occurring at 0.25 – 1 hr, except one CBD at 4.5 hr. After low- and high-dose Sativex®, all specimens were positive for THC and CBD until 10.5 hr post-dose with concentrations 1.0 – 92.0 and 0.5 – 131ng/mL, respectively. After low- and high-dose Sativex®, 43% and 79% of specimens, respectively, were CBN-positive for 10.5 hr with concentrations ≤6.9ng/mL. Median (range) CBD/THC and CBN/THC ratios were 0.82 – 1.34 (0.27-2.26) and 0.04 – 0.06 (0.01-0.52), respectively, over 0.25 – 10.5 hr. In comparison, median (range) CBD/THC and CBN/THC ratios after smoking a single 6.8% THC cigarette were 0.04 – 0.05 (0.03-0.09) and 0.07 – 0.08 (0.04 –0.15), respectively, within 0.25 – 6 hr post dose. OF THCCOOH concentration changes over time were less evident and significantly masked by baseline concentrations in all dosing sessions. THCCOOH/THC ratios were <4pg/ng for 4.5 and 1 hr post Sativex® and smoked cannabis, respectively, while ratios were never below 4pg/ng after oral THC and placebo. THCCOOH/THC ratios increased over time in each dosing session.

Conclusions: Oral THC and Sativex™ administered in low and high dosages produced OF cannabinoid disposition different from those after smoked cannabis; THC, CBD, and CBN were rarely detected after oral THC while Sativex® generated high CBD/THC ratios. Low THCCOOH/THC ratios suggest recent Sativex® and smoked cannabis exposure. Study results indicate that relapse to smoked cannabis during oral THC pharmacotherapy for cannabis dependence should be evident with OF cannabinoid monitoring. In contrast, compliance with Sativex® pharmacotherapy should be clearly apparent by the high OF CBD/THC ratio as compared to that following cannabis smoking; however, additional research is needed to determine if relapse to cannabis smoking can be identified during Sativex® pharmacotherapy, as the high OF CBD/THC ratio after Sativex® may not be altered sufficiently to identify single smoked cannabis episodes. Interpretation of OF cannabinoid tests will be improved by these data, the first defining OF cannabinoid disposition after single-dose medicinal cannabinoid products. These data also

are valuable for formulating policy and legislation for OF testing, and for effectively managing patients undergoing cannabinoid pharmacotherapy.

Oral Fluid, Cannabinoids, Cannabis

K50 Current Research Initiatives in Toxicology at the National Institute on Drug Abuse

Marilyn A. Huestis, PhD, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Blvd, Rm 05A721, Baltimore, MD 21224; Ariane Wohlfarth, PhD, and Rebecca L. Hartman, BA, National Institute on Drug Abuse, 251 Bayview Blvd, Baltimore, MD 21224; and Nathalie A. Desrosiers, MSc, 251 Bayview Blvd, Ste 200, Rm 05A721, Baltimore, MD 21224*

After attending this presentation, attendees will be able to describe new research from Chemistry and Drug Metabolism (CDM), detailing National Institute on Drug Abuse (NIDA) findings on urinary cannabinoid excretion, oral fluid cannabinoid stability, Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) confirmation of urinary synthetic cannabinoids, and performance impairment and blood THC concentrations in driving cases.

This presentation will impact the forensic science community by revealing CDM investigations of illicit drug agonists, antagonists, and drug dependence treatment pharmacotherapies. Controlled drug administration studies in drug users were conducted under Institutional Review Board-approved protocols and Investigational New Drug applications from the Food and Drug Administration.

CDM investigates the pharmacodynamics and pharmacokinetics of illicit drug agonists and drug dependence pharmacotherapies. Phase I controlled drug administration studies are conducted in drug users under Institutional Review Board-approved protocols and Investigational New Drug applications from the U.S. FDA. Recently, this study focused on mechanisms of action of cannabinoid agonists, development of evidence-based drug policy, and legislation for oral fluid testing and emerging designer drugs. In this presentation, new research findings are shared on urinary cannabinoid excretion, oral fluid cannabinoid stability, LC/MS/MS confirmation of urinary synthetic cannabinoids, and performance impairment and blood THC concentrations in driving cases.

Twelve chronic frequent and nine occasional cannabis users smoked one 6.8% Δ^9-tetrahydrocannabinol (THC) cigarette. Cognitive, subjective, psychomotor and physiological responses, and urinary cannabinoid pharmacokinetics were characterized. THC, cannabidiol (CBD), cannabinol (CBN), 11-hydroxy-THC (11-OH-THC), 11-nor-9-carboxy-THC (THCCOOH), THC-glucuronide, and THCCOOH-glucuronide concentrations were simultaneously quantified by LC/MS/MS and normalized to urine creatinine. THCCOOH (frequent N=12; occasional N=6), THC-glucuronide (frequent N=12; occasional N=9), and THCCOOH-glucuronide (frequent N=12; occasional N=9) were identified; THC, 11-OH-THC, CBD, and CBN were not detected. Highest concentrations (ng/mg creatinine) in frequent and occasional cannabis smokers, respectively, were: THC-glucuronide 3.5-60.7 and 3.0-35.1; THCCOOH 2.7-17.2 and 0-7.2; and THCCOOH-glucuronide 146-548 and 20.8-298. Concentration-time curves for the excretion of urinary cannabinoids and the presence of potential markers for recent cannabis smoking will be presented.

Analyte stability is critical for interpreting drug concentrations, although there are few data on cannabinoid stability in oral fluid, an important new drug testing matrix. Cannabinoid stability in authentic oral fluid collected with the StatSure® and Oral-Eze® collection devices after controlled smoking of one 6.8% THC cigarette was evaluated. Stability pools were prepared for each participant (n=16) by combining oral fluid collected in the first 13.5 hr. Pools were aliquoted into polypropylene cryotubes and stored at room temperature (RT), 4°C, or -20°C. Baseline specimens were quantified within 24 hr, and the remaining aliquots analyzed after one week at RT and 4°C, and four weeks at 4°C and -20°C. Specimens were considered stable if concentrations were within ± 20% of baseline. Specimens collected with the Oral-Eze® and StatSure® devices were stable for THC and THCCOOH at 4°C for one week and one month, while after longer frozen storage a small number of specimen concentrations increased or decreased more than ± 20%. Mean THC and THCCOOH oral fluid concentrations were 93.0 – 96.7% of target after refrigeration for one or four weeks, and 89 – 117% (THC) and 81 – 110% (THCCOOH) for one month frozen. Elution and stabilizing buffers in oral fluid collection devices help maintain cannabinoid concentrations in oral fluid, as well as improving cannabinoid recovery from the collection pad.

Synthetic cannabinoids are an important new designer drug class. Assays are needed to identify these drugs in human urine. An LC/MS/MS method was developed for the qualitative confirmation of ten synthetic cannabinoids (JWH-018, JWH-073, JWH-081, JWH-122, JWH-200, JWH-210, JWH-250, AM 2201, and RCS-4) and their hydroxyalkyl, hydroxyindole, and carboxy metabolites in human urine. Specimen preparation includes hydrolysis and protein precipitation, followed by monitoring of a single MRM transition in a survey scan that triggers an enhanced product ion (EPI) scan at three different collision energies. This information-dependent acquisition experiment is conducted on an ABSciex 5500 QTrap. Qualitative results from several hundred authentic urine specimens will show prevalence of parent and metabolites and metabolite patterns.

Finally, this latest investigation on cannabis effects on driving is presented. In collaboration with other toxicologists, driving under the influence of drugs (DUID) cannabis cases were compiled and analyzed and police reports on apprehended drivers under the influence of cannabis and blood THC concentrations were evaluated. Representative individual case reports with varying THC concentrations are presented, as well as aggregate/summary statistics. The case reports focus on cannabis-only cases, to avoid complications imposed by polypharmacy.

Urine Cannabinoids, Oral Fluid Stability, Designer Drugs

K51 Detection and Quantification of Antidepressants in Aqueous Matrices

Kenton J. Chodara, BS, 710 S Atherton, Apt 203, State College, PA 16801; and Dan G. Sykes, PhD, and Melissa M. Gettle, 330 Whitmore Laboratory, University Park, PA 16802*

The goal of this presentation is to delineate the process of developing a detection method capable of simultaneously identifying and quantifying antidepressant compounds in aqueous matrices using a Liquid Chromatograph/Tandem Mass Spectrometer (LC/MS/MS), the determination of quantitative differences between detection methods, the effect of stationary phase composition on the separation of analytes, and applications to wastewater samples pursuant to a relevant EPA method.

This presentation will impact the forensic science community by showing how the methodologies and results presented will provide widely applicable LC/MS/MS method for the detection of small molecules in a variety of aqueous matrices, including wastewater, blood, and urine. The development process can be adapted to produce a quantitative screening method for any compounds of interest suitable for LC/MS/MS identification.

Antidepressants are psychiatric medications that are taken with the intent to alleviate mood disorders. These drugs and their metabolites enter the environment as a byproduct of use, and may pose a danger to the health of humans and the environment. In the U.S., there are few regulations concerning the discharge, fate, and transport of such pharmaceuticals, many of which remain biochemically active after passing through current treatment processes. An important first step toward developing proper regulation is the creation of a selective and sensitive detection method in relevant matrices.

This presentation will discuss the methodology developed for the detection and identification of a variety of commonly used antidepressant drugs and their metabolites. High Pressure Liquid Chromatography (HPLC) on fused core silica phases is used for the separation of analytes, and a triple-quadrupole mass spectrometer is employed using both Scheduled Multiple Reaction Monitoring (s-MRM) and Information Dependent Acquisition (IDA) detection methods with Electrospray Ionization (ESI). Sample preparation is performed in accord with EPA method 1694, using solid-phase extraction with an Oasis® HLB cartridge suitable for retention of acidic, basic, and neutral compounds.

A library containing reference spectra was created using direct syringe pump infusion of standards of each antidepressant in methanol. Generalized parameters capable of ionizing and fragmenting each compound were optimized and compiled. The composite method was used to create and assess the efficacy of identifying and quantifying components of a mixture using both SMRM and IDA.

Preliminary testing was performed on a C18 column, the currently most-used column for analysis of antidepressants. The variance of s-MRM, which scans for analytes at specified expected retention times, was determined to be within acceptable limits to provide reproducible results. Information Dependent Acquisition, a method that scans using s-MRM and produces additional library matching spectra for analytes with intensities over a certain threshold, supposedly at a cost of quantitative reproducibility. The difference in quantification between the two methods was determined using labeled analogues of each compound as internal standards.

The optimized detection method was then applied to chromatographic separations using different stationary phase compositions including C8, C18, phenyl-hexyl, and amide. The goal was to determine how chemical interactions between analytes and the column influence separation and analysis. Parameters such as efficiency, reproducibility, and selectivity were considered in method optimization. Retention times, elution order, and peak shapes were compared when possible.

Antidepressant, LC/MS, Wastewater

K52 ∆9-Tetrahydrocannabinol, 11-Nor-9-Carboxy-Tetrahydrocannabinol, Cannabidiol, Cannabinol, and 11-Hydroxy-Tetrahydrocannabinol in Oral Fluid Following Controlled, Smoked Cannabis in Frequent and Occasional Smokers

Sebastien Anizan, PhD, National Institute on Drug Abuse, 251 Bayview Blvd, Baltimore, MD 21224; Garry Milman, PhD, National Institute on Drug Abuse, 251 Bayview Blvd, Ste 05A.505.16, Baltimore, MD 21224; Nathalie A. Desrosiers, MSc*, NIDA Intramural Research Program, 251 Bayview Blvd, Rm 05A721, Ste 200, Baltimore, MD 21224; Allan J. Barnes, BS, NIDA Intramural Research Program, 5500 Nathan Shock Dr, Rm 373, Baltimore, MD 21224; David A. Gorelick, MD, PhD, National Institute on Drug Abuse, 5500 Nathan Shock Dr, Baltimore, MD 21224; and Marilyn A. Huestis, PhD*, Chemistry & Drug Metabolism Section, Intramural Research, NIDA, NIH, 251 Bayview Blvd, Rm 05A721, Baltimore, MD 21224*

After attending this presentation, attendees will understand pharmacokinetic differences in Oral Fluid (OF) concentrations between chronic frequent and occasional cannabis smokers.

This presentation will impact the forensic science community by improving interpretation of oral fluid test results for different populations of cannabis smokers and may suggest recent cannabis use by selecting different analytes and cutoff concentrations.

In a previous study, additional cannabinoid analytes and cutoff concentrations were proposed to reduce the possibility of a positive cannabinoid OF test from environmental cannabis smoke contamination; however, the data only included chronic frequent cannabis smokers.[1] The objectives of the present study were to compare pharmacokinetic data from chronic frequent and occasional cannabis smokers, and to evaluate different cannabinoid analytes and cutoff concentrations to distinguish recent smoking from residual excretion in these populations.

This study consisted of healthy, 18 – 45-year-old cannabis smokers, who used cannabis at least four times per week (frequent smokers) or a maximum of two times per week (occasional smokers), provided written informed consent for this Institutional Review Board-approved study, and resided on the secure research unit for two days. OF specimens were collected with the Statsure™ device, 14 hr and 1 hr before and up to 30 hr after *ad libitum* smoking of a 6.8% ∆9-Tetrahydrocannabinol (THC) cigarette. Specimens were analyzed within 24 hr following collection. THC, 11-nor-9-carboxy-THC (THCCOOH), cannabidiol (CBD), cannabinol (CBN), and 11-hydroxy-THC (11-OH-THC) were quantified by 2D-GC/MS. Limits of quantification (LOQ) were 0.5 ng/mL for THC, CBD, CBN, and 11-OH-THC, and 15pg/mL for THCCOOH.

Eighteen subjects (eleven chronic frequent and seven occasional cannabis smokers) provided 306 OF specimens. Fourteen hours before smoking, all chronic frequent smokers' OF tested positive for THC (range 6-396.5ng/mL) and THCCOOH (23-124pg/mL), whereas all occasional smokers' OF specimens were negative for both analytes. One hour prior to dosing, nine chronic frequent smokers' OF specimens were still positive for THC (range 0.9 to 7ng/mL), while THCCOOH was always measurable in this population (range 2.0 – 13.6pg/mL).

No significant differences ($p>0.05$) in THC concentrations were observed 2h after cannabis smoking between chronic frequent and occasional smokers. OF THC concentrations were highly elevated for 2h with medians (range) of 517.3ng/mL (113.8 – 6,508), at 0.5 hr, 238.5ng/mL (28.4 – 6,362) at 1 hr and 72.5ng/mL (7.5 – 350.5) at 2 hr for the chronic frequent smokers. Medians (range) in occasional smokers were 481.8ng/mL (84.5 – 1471.3) 0.5 hr after smoking, 82.8ng/mL (48.4 – 561.5) at 1 hr, and 69.3ng/mL (23.4 – 213.7) at 2 hr. Eight of eleven chronic frequent smokers' OF specimens were still THC-positive at 30h (0.6 – 2.2ng/mL), whereas only one of seven occasional smokers was positive (0.5ng/mL). OF THCCOOH concentrations showed large differences between chronic frequent and occasional smokers at all time points: Results showed 83% of all specimens from occasional smokers were negative (all medians equal to 0) and 95% of OF specimens from chronic frequent smokers were positive. For both groups, CBD and CBN concentrations were maximal 0.5 hr after smoking, decreasing rapidly over time. The last positive OF CBD occurred 10.5 hr after smoking in two chronic frequent smokers (0.5 – 0.6ng/mL) and at 6 hr for one occasional smoker. For CBN, four chronic frequent and one occasional smokers' OF were still positive at 13.5 hr (0.6 – 1 and 0.6ng/mL, respectively). 11-OH-THC was not present in OF except when THC concentrations were greater than 1,000ng/mL.

At a cutoff concentration of 2ng/mL THC, proposed by the Substance Abuse and Mental Health Services Administration, 72% and 71% of chronic frequent and occasional smokers were positive for 21 hr and 10.5 hr, respectively.

These findings improve interpretation of cannabinoid OF concentrations in the workplace, cannabis dependence treatment, motor vehicle accidents, and doping in sports cases.

Oral Fluid, Tetrahydrocannabinol, Cannabinoids

K53 Laboratory Based Evaluation of Commercially Available Oral Fluid Testing Devices

Amanda L. Arntson, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Ave, Willow Grove, PA 19090; and Bill Ofsa, MS, Matthew M. McMullin, MS, and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to assess sensitivity and specificity, and detection thresholds of several commercially available oral fluid testing devices designed for use in the field, as well as issues with respect to their readability, robustness, and ease of use.

This presentation will impact the forensic science community by highlighting factors to be considered when selecting field-based testing devices for the presence of drugs in oral fluid.

Oral fluid is increasing in popularity as a biological matrix for drug testing in the workplace, probations and parole, and traffic law enforcement.

Three devices were selected for comparison with the Drager® DT5000 7-panel, based on their price, general availability, and advertised ease of use. The devices evaluated were the Oral Fluid 6 Drug Test (Oral Q®), Alere iScreen®, and Xalex™. Nine blind controls containing a total of 12 drugs representing the classes of amphetamines, MDMA, opiates, benzodiazepines, PCP, cocaine, THC, methadone, oxycodone, and dextromethorphan were prepared in synthetic oral fluid. An open positive (100ng/mL) and drug-free oral fluid negative control were also used.

The concentrations of the target analyte were selected so evaluations could be made below the listed cutoff concentration, near the cutoff concentration, and significantly above the advertised cutoff of the device.

Each device was evaluated in triplicate for each control group with the results being independently verified by two different individuals. The testing protocol used was specific to the device, following a protocol based on the device instructions. In devices with a sorbent sponge, the sponge was saturated with the oral fluid control mixture and subsequently tested as directed. After the verification of the results, the performance of each device was evaluated by drug class and how the device performed around its stated cutoff concentration. For each device, the sensitivity, specificity, and accuracy were assessed.

Positive results were scored as true positives if the analyte was present in the control, irrespective of its concentration. With all negative results, the concentration in the control was compared to the manufacturer's cutoff concentrations and determined if the result was a true positive or true negative relative to that cutoff.

The Drager® DT5000 was an instrumented test with an electronic analyzer generating a printed result. The remaining devices were visually read. These three had cannabinoid tests that were targeted to carboxyTHC which is known to be excreted at very low concentrations in oral fluid. The Xalex™ and Alere iScreen6 did not give a positive cannabinoid result at 100ng/mL of THC. The OralQ gave false positive results for cannabinoids in every negative control. The Drager® DT5000 did not detect the presence of THC at the positive control concentration of 7ng/mL, in spite of its published cutoff of 5ng/mL. Controls at 15ng/mL all tested positive.

The Drager® DT5000 had lower cutoffs for benzodiazepines, methamphetamine, and opiates. The OralQ® had an elevated cutoff for benzodiazepines at 50ng/mL. The Xalex™ and Alere iScreen6® devices did not include a benzodiazepine test. The Drager® DT5000 gave positive results for benzodiazepines at its advertised cutoff of 15ng/mL.

The sensitivity and specificity results for the Xalex™ and iScreen6® did not include scoring from the THC panel because the target analytes were THC metabolites, which would not be expected at the advertised cutoff in oral fluid. Absent this consideration, the Xalex™ device had sensitivity, specificity, and accuracy of 100%, and the Alere iScreen6® had 95% sensitivity, 93% sensitivity, and 94% accuracy. The OralQ® had the lowest sensitivity at 65%, specificity of 86%, and accuracy of 75%. It generated 16 false negative results relative to its advertised cutoffs across several drug classes. The Drager® DT5000 had 97% sensitivity, 100% specificity, and 98% accuracy.

Based on this initial evaluation, it was concluded that the Drager DT5000 gave the best overall performance and lacked the issue of subjectivity in reading the test strips. This laboratory-based assessment, however, indicated it had higher sensitivity for THC than advertised. Additional devices are in the process of being evaluated.

DUID, Oral Fluid, Field Test

K54 Simultaneous Analysis of Opiates and Acetaminophen With Noscapine Monitoring

Jeffrey P. Walterscheid, PhD, HCIFS, 1885 Old Spanish Tr, Houston, TX 77054; Ashraf Mozayani, PhD, PharmD, Texas Southern Univ, 3100 Cleburne Ave, Houston, TX 77004; and Michael Chen, PhD, HCIFS, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will learn about a novel liquid extraction solvent and acquisition cycle for determining opiates in forensic toxicology specimens. This extract is suitable for analysis by Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) to measure various common opiates, along with acetaminophen as a co-compound and monitoring of noscapine as an alkaloid contaminant from illicit morphine preparations. The procedure is a robust and sensitive method for routinely evaluating blood, stomach, urine, and vitreous humor for evidence of opiate use and abuse. The audience will also learn about the opiate levels commonly found in postmortem death investigations, DUI suspects, and sexual assault victims. In addition, heroin deaths involving related concentrations of 6-monoacetylmorphine, codeine, and morphine will be reconciled with the presence of noscapine.

This presentation impacts the forensic science community by distinguishing a new way to analyze opiates with advantages on enhanced recovery, preparation economy, time savings, and signal stability. Since implementing this procedure over the last year, not one analytical run failed to meet acceptance criteria. Sample volumes have been reduced by half, turnaround times have been decreased, and more information is obtained without a separate extraction for acetaminophen analysis. These benefits raise services for clients in the community and help to achieve goals for laboratory accreditation.

Opiates are an important category in forensic toxicology for their prevalence in impaired drivers and overdose deaths. Another factor often overlooked is that acetaminophen is a toxicologically significant drug frequently compounded with hydrocodone tablet preparations. Although Solid Phase Extraction (SPE) purifications are a useful way of obtaining clean drug extracts for instrumental analysis, acetaminophen recovery suffers greatly. A multiple-targeted analysis of opiates consisting of morphine, hydromorphone, oxymorphone, codeine, oxycodone, 6-monoacetylmorphine, acetaminophen, and hydrocodone combined with noscapine monitoring using a modified Liquid-Liquid Extraction (LLE) has been developed. The simple LLE method utilizes a mixture of organic solvents consisting of isopropyl alcohol, isoamyl alcohol, and 1-chlorobutane for extraction to yield enhanced recovery that saves money and time.

In the LC/MS/MS acquisition method, two separate mass spectroscopy segments were utilized to improve the detection sensitivity, while short dwell times were used for acetaminophen transitions to lower sensitivity in adjusting for its relatively high concentration scale. The opiates follow a linear curve fit from 10ng/mL to 2,000ng/mL with a corresponding curve range of 1mg/L to 200mg/L for acetaminophen. The 15-minute chromatography gradient cycle allows for clean separation of all analytes, especially morphine and hydromorphone as well as codeine and hydrocodone, which are isobaric pairs that can interfere with each other in qualitative and quantitative confirmations.

This method has many benefits for the toxicology laboratory at many levels. Extraction analysts find the process to be faster and easier than SPE protocols. Instrument data processors report stronger responses with sharp peaks, linear curve fits, and quality controls in good agreement with expected outcomes. Laboratory managers realize successful sequential analytical runs decrease turnaround time, which reduces the burden on consumable budget, and provides more data using less specimen. Overall, this method has been validated as a superior process for routine forensic toxicology opiate analysis.

Opiates, LC/MS/MS, Toxicology

K55 Method Development and Validation for the Analysis of Cannabinoids in Meconium Samples

Marykathryn Tynon, BS, 2901 Burlington Ave, Delanco, NJ 08075; and Marcellino Porto, MSFS, and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to compare different solid-phase extraction methods for the cleanup of meconium samples prior to Three-Dimensional/Gas Chromatography/Mass Spectrometry (3D/GC/MS) analysis.

This presentation will impact the forensic science community by providing perspectives on how to assess and improve methods for extracting, isolating, and measuring cannabinoids and their metabolites from meconium.

The purpose of this project was to develop an extraction method and instrumental parameters for GC/MS and 3D/GC/MS methods for the analysis of tetrahydrocannabinol (THC), 11-OH-THC, and THC Carboxylic Acid (THCC) that meet laboratory requirements for accuracy and precision and is cost and time efficient. The project resulted in development of an improved screening for the presence of drugs in meconium samples in aid of diagnosing and detecting marijuana use by the mother during gestation.

Collectively, the components of the marijuana plant, *Cannabis sativa*, are known as cannabinoids, and have a variety of pharmacological effects in humans including, but not limited to, analgesia, appetite suppression, hypertension, euphoria, and suppression of nausea. The main active component, THC, is broken down by the liver into a variety of oxidized metabolites. The major route of metabolism is hydrolysis of THC at carbon-11 to form 11-OH-THC which is further oxidized to form 11-Nor-carboxy-THC (THCC). These three components are the major focus of most marijuana testing in human bodily fluids. Prenatal exposure of THC is thought to possibly have detrimental effects, including effects on the systems involved in emotions and maturation. Animal studies have shown that rat pups prenatally exposed to THC could have long-lasting neurological effects. Many drug court and monitoring programs require the mother to abstain from marijuana use while pregnant to avoid exposure of the developing fetus to cannabinoids, and methods are needed to monitor their compliance with those orders.

Comparisons of several variables for the isolation of cannabinoids from meconium were performed, including the comparison of two different brands of THCC-specific Solid Phase Extraction (SPE) columns, Agilent™ and Strata X™, the length of incubation while hydrolyzing the samples, the effect of homogenizing the meconium sample before extraction, the wash solvents used, and the effects of the polarity of the GC/MS columns on which the samples were run.

The significance of these variables was evaluated by performing the same extraction with only the variable in question being altered. The general extraction method includes adding 0.25g of samples to phosphate buffer pH 7.0 and adding 25µL of 12M potassium hydroxide to hydrolyze the samples. After hydrolysis, the samples were neutralized using hydrochloric acid. The neutralized samples were then treated with acetonitrile precipitation and centrifugation before pouring the supernatant onto the SPE columns. The columns were the washed, eluted, and the extract dried down before derivatization with BSTFA.

From the comparison between the two SPE columns, it was determined that the Strata X™ columns had a better recovery of THCC with the extraction method used while the Agilent™ columns had a better 11-OH-THC recovery. The percent recovery of THCC and 11-OH-THC while using the Agilent™ columns was determined to be 91% and 66.5%, respectively. The Strata X™ columns resulted in a 95% and 56% recovery for THCC and 11-OH-THC, respectively. The incubation-time evaluation led to the conclusion that while there was little change in recovery from commercially available control samples (ElSohly Labs), an authentic THC-positive meconium control sample showed significantly increased abundance of free THCC at 30 min incubation at 60°C.

Applying the optimized extraction method using deuterated internal standards for all three analytes generated calibration curves with R^2 values greater than 0.998.

The study concluded that SPE analysis of meconium samples gave cleaner extracts than liquid/liquid extraction, that hydrolysis improved recovery of the drug from the sample, and that combined with GC/MS, SPE produced calibration curves that met laboratory requirements.

Cannabinoids, Meconium, GC/MS

K56 Effect of Ethanol on Succinyl Semialdehyde Dehydrogenase—Implications for Exacerbation of GHB Toxicity

Robert H. Powers, PhD, CT Dept of Public Safety, Controlled Substances/Tox Lab, 278 Colony St, Meriden, CT 06451; Robert M. Lockwood, MSFS, Univ of New Haven, Forensic Science Dept, 300 Boston Post Rd, West Haven, CT 06516; and Sophia M. Panaccione, Kings Coll Dept of Neuroscience, 133 N River St, Wilkes-Barre, PA 18711*

After attending this presentation, attendees will gain a greater understanding of the central nervous system, its endogenous inhibitory neurotransmitters and their metabolism, and the effects of ethanol on part of that metabolic process.

This presentation will impact the forensic science community by offering a mechanistic explanation for one aspect of the combined effects of ethanol/GHB co-ingestion. This knowledge will help forensic pathologists and toxicologists evaluate and interpret drug results in DFSA cases where both ethanol and GHB are determined to have been present.

Drug Facilitated Sexual Assault (DFSA) cases routinely involve the use of central nervous system (CNS) depressant agents such as benzodiazepines, barbiturates, and more recently, γ-hydroxybutyrate (GHB). A common mechanistic basis for the actions of these agents is an effect on GABA-nergic inhibitory neurotransmission. GABA (γ-amino butyric acid) is the primary inhibitory neurotransmitter in the CNS, functioning as a post-synaptic ligand-gated chloride channel agonist (GABA receptor agonist). Activation of the GABA receptor by either endogenous GABA, or by xenobiotics, results in the influx of chloride ion into the post-synaptic neuron, resulting in a hyperpolarization (inhibition) of that neuronal membrane. Removal of GABA from the synaptic space following the neurotransmission event is a function of uptake and catabolism of GABA by astrocytic cells in proximity to the synapse rather than re-uptake directly into the pre-synaptic neuron. Succinyl Semialdehyde Dehydrogenase (SSADH) is a central enzyme in the oxidative degradation of GABA and GHB, converting their common oxidative metabolite, succinyl semialdehyde (SSA), to succinate as an end product. SSA is produced directly from GABA by an enzyme-catalysed transamination (with alpha-keto glutarate, (αKG)), and from GHB by a GHB-dehydrogenase (GHBDH)-catalysed oxidation. GHB dehydrogenase is a cytosolic

enzyme reducing NAD^+ as a cofactor, while SSADH and the transaminase are mitochondrial enzymes, with SSADH reducing $NADP^+$ as a cofactor.

Ethanol is commonly found in DFSA cases, either alone or in combination with other CNS depressants, including GHB, and its presence may have an impact on the interpretation of drug findings in such cases. Ethanol has been shown to exacerbate the effects of GHB; however, a mechanistic basis for that effect has not been demonstrated. It has been hypothesized that one consequence of alcohol ingestion in the body is an inhibition of SSADH by both ethanol and its oxidative metabolite, acetaldehyde, because of the structural homology between ethanol, acetaldehyde, and carbons 3 and 4 of SSA. Inhibition of SSADH would be expected to increase the effective half-life of GABA in the body, with the consequential increase in background GABA concentration, and GABA-mediated CNS depressant activity. Initial experiments with a combined enzyme system consisting of GABA-αKG transaminase/SSADH indicated that ethanol inhibited enzyme activity at a concentration equivalent to 0.4 g/dL, but did not do so appreciably at a concentration equivalent to 0.1g/dL, suggesting that any such effect of ethanol on SSADH would only be a factor in significant alcohol ingestions. Kinetic evaluation of initial reaction rates by UV spectrophotometry (monitoring generation of NADPH) indicated that ethanol affected SSADH rather than the GABA-αKG transaminase. Substrate-velocity experiments indicated that SSADH in the preparation had a Michaelis constant (K_m) for SSA of 49 μM in the absence of ethanol, and 61 μM in the presence of 0.4g/dL ethanol, as determined by Lineweaver-Burke plot. Maximal velocity (V_{max}) of the enzyme was unaffected by the inclusion of ethanol, a pattern consistent with competitive inhibition.

Based on the effect of ethanol on SSADH, it is suggested that the ingestion of alcohol in the body would, in a concentration-dependent manner, inhibit SSADH, thereby decreasing the rate of GABA- and/or GHB-derived SSA oxidation, and potentially increasing both the half-life of endogenous GABA and exogenous GHB. This effect may play a contributory role to the CNS depressant consequences of significant ethanol ingestions and combined ethanol-GHB exposures, such as could be seen in some DFSA cases.

Ethanol, GHB, GABA

K57 Incomplete Recovery of Codeine in Urine Using Common Enzymatic Hydrolysis Procedures

Sumandeep Rana, MS, Tara Brunson, BS, and Wayne B. Ross, MCLS, Redwood Toxicology Laboratory, 3650 Westwind Blvd, Santa Rosa, CA 95403*

The goal of this presentation is to inform attendees about the effectiveness of various commonly used hydrolysis techniques and conditions for the hydrolysis of opiates, stressing the incomplete hydrolysis of codeine following common enzymatic hydrolysis procedures.

This presentation will impact the forensic science community by demonstrating that choosing the right combination of hydrolyzing agent and hydrolysis conditions is critical to accurate results and leads to significant improvement in recovery of opiates from urine samples.

Methods: Opiates included in this method are: morphine, hydromorphone, codeine, and hydrocodone. Deuterated analogues of all four analytes are used as the internal standards.

Extraction: Authentic urine samples were hydrolyzed using β-glucuronidase from *Escherichia coli and Helix-Pomatia* for 3 hr and 16 hr each. Samples were spiked with internal standard, centrifuged and supernatant was diluted with mobile phase before injecting on the column. In separate experiments, the amount of enzyme added was doubled to evaluate optimal concentration of the enzyme for efficient hydrolysis. In addition, one set of samples was hydrolyzed using acid hydrolysis with 0.1N HCl and the results were used as the reference (100% recovery) to evaluate recovery from different enzymatic procedures.

Analysis: Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) analysis was performed in Electronic Spray Ionization (ESI) mode by Multiple Reaction Monitoring (MRM) using a 3200 triple quadrupole mass spectrometer connected to a Shimadzu prominence HPLC system. Separation was achieved on an ultra II biphenyl 5µ column (50 X 2.1mm). Mobile phases were 0.1% formic acid and 0.2% ammonium formate in de-ionized water (A) and in acetonitrile with 2% water (B). All analytes were eluted within four minutes. Two ion transitions for each analyte; morphine (286/152, 286/128), hydromorphone (286/185, 286/157), codeine (300/152, 300/115), hydrocodone (300/199, 300/128), and one ion transition for each internal standard; morphine-D6 (292/152), hydromorphone-D3 (289/185), codeine-D6 (306/165), and hydrocodone-D6 (306/202) were monitored.

Results: The procedure was applied to 50 authentic urine specimens previously tested positive for two or more analytes using acid hydrolysis and GC/MS. Results showed that efficient hydrolysis is essential to the optimum recovery of all analytes. β-glucuronidase from both *H. Pomatia* and *E. Coli* were not able to cleave codeine glucuronides efficiently and recovered only 25% and 50% of the free drug after 3 hr and 16 hr hydrolysis time, respectively. On the contrary, 100% recovery was achieved for hydrocodone after 3 hr with both *H. Pomatia* and *E.Coli*. Average morphine recovery was 84% with *H. Pomatia* at 3 hr and 100% after 16 hr of incubation. *E. Coli* recovered 77% and 89% morphine at 3 hr and 16 hr, respectively. Average hydromorphone recovery with *H. Pomatia* was 80% after 3 hr and 95% after 16 hr. *E. Coli* recovered only 41% hydromorphone at the end of 3 hr and 58% after 16 hr of incubation. Doubling the amount of enzyme did not improve the recovery for any of the opiates.

Conclusion: Acid hydrolysis for opiates has been commonly used with GC/MS analysis in the past. With the advancement of instrumentation, LC/MS/MS is gaining popularity in the clinical and forensic labs and enzymatic hydrolysis is the preferred method for releasing the free drugs. Post-enzymatic hydrolysis specimens can simply be diluted and injected on the column, eliminating the need for time-consuming extractions. It is essential, however, to optimize the hydrolysis conditions for the opiate glucuronides specific to each source of β-glucuronidase. Codeine glucuronide is the most difficult to cleave and only 50% of the drug was recovered in free form after 16 hr of hydrolysis with β-glucuronidase from *H. Pomatia.* In general, the enzyme from *H. Pomatia* performed better than the one obtained from *E. Coli*, under the conditions tested. Although *H. Pomatia* was able to release 100% of the free drug form morphine, hydrocodone, and hydromorphone conjugates in the urine samples at the end of 16 hr (3 hr in case of hydrocodone), it was found to be ineffective in cleaving codeine glucuronide. Further investigation is necessary to find the optimal conditions for enzymatic hydrolysis of codeine. The labs must carefully evaluate the hydrolysis efficiency of various enzymes for opiates and specifically for codeine.

Opiates, Hydrolysis, LC/MS/MS

K58 Sweat as Alternative Matrix to Monitor Buprenorphine Compliance, Opioids, Cocaine, and Tobacco Use in Opioid-Dependent Pregnant Women

Marta Concheiro-Guisan, PhD, Intramural Research, NIDA, NIH, 251 Bayview Blvd, Rm 05A729, Baltimore, MD 21224; Hendree E. Jones, PhD, Johns Hopkins Bayview Medical Center, 4940 Eastern Ave D 3 E, Baltimore, MD 21224; Rolley E. Johnson, PharmD, 10710 Midlothian Turnpike, Richmond, VA 23235; Robin Choo, PhD, National Inst on Drug Abuse, Chemistry and Drug Metabolism, 5500 Nathan Shock Dr, Baltimore, MD 21224; and Marilyn A. Huestis, PhD*, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Blvd, Rm 05A721, Baltimore, MD 21224*

The goal of this presentation is to describe Buprenorphine (BUP), opioids, cocaine, and tobacco prevalence and concentrations in sweat patches from opioid-dependent pregnant women, and to compare their detection in sweat patches, Oral Fluid (OF), and urine.

This presentation will impact the forensic science community by showing how sweat is a good alternative matrix for monitoring drug use in clinical settings.

Introduction: Sweat is an alternative matrix for detecting drug consumption over about seven days, depending upon the time the patch is worn. Sample collection is easy, gender-neutral, and less invasive than for urine collection. However, limited sweat disposition data are available, especially for BUP and for opioid-dependent women.

Objective: To describe BUP, opioids, cocaine, and tobacco prevalence and concentrations in sweat patches from opioid-dependent pregnant women, and to compare detection in sweat patches, OF, and urine specimens over the same period.

Methods: Sweat patches were collected once weekly (n = 121), and OF and urine twice or three times weekly (n = 283) from seven opioid-dependent pregnant women during the 2nd and, primarily, the 3rd trimester, and up to one month postpartum. Sweat was collected with PharmCheck™ sweat patches worn for 6 ± 2.3 days, and OF with the Salivette® collection device. Sweat and OF specimens were analyzed by Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) for BUP, norbuprenorphine (NBUP), methadone, 2-ethylidene-1,5-dimethyl-3-diphenylpyrrolidine (EDDP), cocaine, benzoylecgonine (BE), ecgonine methyl ester (EME), morphine, codeine, 6-acetylmorphine (6AM), heroin, 6-acetylcodeine (6AC), cotinine, and trans-3′-hydroxycotinine (OH-cotinine) (LOQ 1-5ng/patch, 0.5-1ng/mL, respectively). Urine specimens were assayed for cocaine and opiates by immunoassay (cutoff 300ng/mL). Women received 8 – 24mg BUP daily.

Results: BUP was detected in 88% of sweat patch specimens (median 2ng/patch; range 1 – 15.3ng/patch) and NBUP in 37.2% (range 1 – 24.7ng/patch). BUP alone was dectected in 51.2%, along with NBUP in 37.2%. Cotinine was detected in 89.3% (median 159ng/patch; range 8.9 – 1,390ng/patch) and OH-cotinine in 86% (median 52.5ng/patch; range 3.1 – 377ng/patch). Most OF specimens contained both analytes (86%). Methadone from non-prescribed sources was detected in 47.9% specimens (range 1 – 661ng/patch); and EDDP in 14.9% (range 1 – 18.4ng/patch). In 24% of specimens, 6AM was identified (range 1.2 – 180ng/patch), morphine in 23.1% (range 2.3 – 51.3ng/patch), heroin in 14% (range 1.1 – 526 ng/patch), codeine in 9.1% (range 4.5 – 25.1ng/patch), and 6AC in 8.3% (range 1.4 – 17.8ng/patch). Morphine and 6AM were detected alone (5% and 3.3%, respectively), together (5.8%), or in combination with the other analytes (6.6%). For identifying illicit cocaine exposure, cocaine was identified in 88.4% of specimens (median 14ng/patch; range 1 – 5,660ng/patch), BE in 47.9% (range 1.4 – 850ng/patch), and EME in 18.2% (range 8.7 – 567ng/patch). Cocaine was detected alone in 39.7% of cases, cocaine and BE in 30.6%, and the three analytes in 17.4%. Comparing sweat patches and urine, there was an 85.1% concordance for opioids, while for cocaine, only 35.9% agreement was achieved. Sweat patches and OF concordance was 93% for tobacco, 88.6% for BUP, 81.6% for opioids, 61.5% for methadone, and 56.1% for cocaine.

Conclusions: These results offer new information about drug and metabolite concentrations and prevalence in sweat from opioid-dependent pregnant women. Sweat is a good alternative matrix for monitoring drug use in clinical settings.

Sweat, Pregnant Women, Drug Testing

K59 Discovery-Based Analyses of Wastewater Samples for Characterization of Drug Usage

Adrienne W. Brockman, BS, 107 Whitmore Labs, University Park, PA 16802; Jack Cochran, BS, 110 Benner Cir, Bellefonte, PA 16823; Michelle Misselwitz, BS, 110 Benner Cir, Bellefonte, PA 16823; and Frank Dorman, PhD, 107 Whitmore Labs, University Park, PA 16802*

After attending this presentation, attendees will understand the principles and design of Wastewater Treatment Facilities (WWTFs) and how these locations and wastewater systems in general may be used to determine temporal and spatial trends in the usage of a wide variety of compounds. Monitoring human usage of several categories of controlled substances can yield the information to allow for either targeted enforcement or targeted education. Additionally, the location of possible synthetic operations may be determined through the monitoring of wastewater. This may aid law enforcement in focusing their efforts in a certain region. Additionally, attendees will have a better understanding of appropriate extraction methods used to recover specific analytes from wastewater and also know what steps can be taken to identify and quantify the analytes of interest.

This presentation will impact the forensic science community by providing a mechanism to inform law enforcement and community leaders on community drug habits by the development of a method for monitoring wastewater. Questions such as the following can be answered using this approach: In what areas/neighborhoods are drugs being consumed? What drugs are being consumed? In what volumes are drugs being consumed and in what usage patterns? This could help pinpoint at-risk populations for drug abuse, which may help tailor the drug education curriculum in specified school districts. This could also help facilitate law enforcement in combating areas with identified drug usage.

The information obtained through the monitoring of WWTFs may be used for a variety of purposes. The objective of this research is to determine compounds present in wastewater samples specifically obtained from the Pennsylvania State University wastewater treatment plant, which is being used as a control facility to refine analytical methodology. Rather than beginning with a target compound approach, a discovery analysis approach was chosen to attempt to determine as many compounds as possible prior to any compound list restriction. The difficulty in this approach can be the resulting complexity of the analysis. For this reason, utilization of both Comprehensive Gas Chromatography coupled with Time-Of-Flight/Mass Spectrometry (GC x GC/TOF/MS) analysis and also High Performance Liquid Chromatography coupled with Time-Of-Flight/Mass Spectrometry (HPLC/TOF/MS) analysis were chosen for their inherent ability to characterize these potentially complex samples more successfully compared to other possible techniques. Several categories of compounds were found using this approach in the initial discovery experiments. Specifically, a number of antidepressants (SSRI's and MAOI's), synthetic opioids, and steroids, were found in addition to a number of endocrine disrupting compounds. Additionally, a series of chlorophenyl cyanates were found, which may indicate a chemical synthesis operation, though likely not an illicit drug facility. The determination, through spatially-resolved sampling, of the source will serve as a model for how other synthesis operations could be uncovered and located through the use of this procedure. An example of the complexity of the analysis is revealed through inspection.

Once the discovered compounds are identified and quantified, the ultimate goal is to determine when and where these compounds were introduced into the wastewater system. Employing time-resolved sampling at locations upstream from the WWTF, both the location and the usage patterns were narrowed down. Although a large array of compounds could be identified in the wastewater, this research project will focus particularly on drugs and drug metabolites.

For the discovery phase, samples of wastewater were gathered by "grab" sampling from the Penn State WWTF. Multiple four-liter samples were gathered from each of the following: influent flow, effluent flow, three intermediate stages, and final spray effluent. Following USEPA method 3510, a liquid-liquid extraction process was performed to demonstrate a "baseline" to compare with other extraction methods. A separatory funnel was used for extraction purposes, with methylene chloride as the solvent. Immediately following, the Kuderna-Danish technique was used to concentrate the samples to 1mL. Once the samples had undergone the clean-up process, they were introduced to the analytical systems to identify and quantify the compounds.

The presentation will discuss the methods used to extract, identify, and quantify the analytes of interest. Also, in the discussion, Pharmaceuticals And Personal Care Products (PPCPs) will be brought to the forefront for conversation, as this research project's focus also covers PPCPs as well as emphasizing drugs and drug metabolites.

Analysis, Wastewater, Drugs

K60 Analysis of the Cocaine Metabolite Benzoylecgonine in Wastewater

Juliet Kinyua, MSc, and Todd Anderson, PhD, The Institute of Environmental and Human Health, Texas Tech University, 1207 Gilbert Dr, Lubbock, TX 79416*

After attending this presentation, attendees will gain insight on the utility of sewage epidemiology as a tool in forensic toxicology and the multiple applications of this methodology beyond the forensic science discipline, particularly in regard to toxicological investigations within law enforcement. The presentation will delineate the long-term benefits of this approach to society and law enforcement.

This presentation will impact the forensic science community by contributing an optimized method to forensic toxicology. Sewage epidemiology will reveal comprehensive information on the concentrations of illicit drugs in raw sewage that enables a more precise estimation of their illegal usage, and a relatively quick alternative to gain insight into the toxicological map of a given area. The presentation is geared toward generating interest in developing robust techniques for continuous data generation that can be used to make correlations with crime statistics and create sturdy monitoring tools.

Abuse of illicit drugs is a major problem in society and leads to high morbidity, mortality, and is responsible for many socio-economic problems. Estimates of cocaine consumption are currently obtained from crime statistics, population surveys, and consumer interviews; these estimation methods may not reflect the real extent of cocaine abuse. Another approach that has been used successfully in Europe is sewage epidemiology—a technique based on analysis of urinary biomarkers in sewage. This approach is based on analysis of a stable cocaine metabolite, Benzoylecgonine (BE) in waste water. In humans, cocaine is extensively metabolized to BE by chemical hydrolysis and Ecgonine Methyl Ester (EME) by enzymatic hydrolysis. BE is the major metabolite of cocaine; its presence in urine confirms cocaine abuse. In urine, cocaine can be detected up to 8 hr after use, while BE and EME can be identified for more than 96 hr after cocaine use.

Sewage epidemiology offers an adaptable, alternative method to consistently measure and monitor community drug use. Furthermore, the results from the study can be used to establish a framework for drug use monitoring. The goal of this study was to test the utility of sewage epidemiology in monitoring cocaine metabolite BE in waste water. Influent to the Lubbock (TX) Water Reclamation Plant (LWRP) was tested twice a week to assess weekly variations in cocaine consumption over a five-month period (February 2010 – June 2010). BE was extracted from influent wastewater samples using solid phase extraction and analyzed using Gas Chromatography/Mass Spectrometry (GC/MS). Filtered 500ml influent waste water samples were spiked with deuterated internal standard (BE-d_3) and extracted using Oasis® MCX 60mg SPE cartridges. To determine BE and BE-d_3 in sample extracts using GC/MS, the extracts were first derivitized using N-Methyl-N-(trimethylsilyl)trifluoroacetamide (MSTFA) to enhance volatility forming the Trimethylsilyl (TMS) derivative of BE or BE-d3. GC/MS analyses was performed using a DB-5MS column for separation and the Mass Selective Detector (MSD) was set to operate under selected ion monitoring mode targeting ion masses of 82, 240, and 361 for BE and 243 and 364 for BE-d_3.

The concentrations of BE derived from the analysis were used to calculate cocaine equivalents deposited in the sewer system through excretion by users. The cocaine equivalents and wastewater daily volumes and flow rates were used to estimate cocaine use by the population. The average daily consumption of cocaine during the study period was estimated at 1,152 ± 147g. Higher cocaine consumption was observed on weekends compared to weekdays. The present study showed that sewage epidemiology is a useful tool to detect BE and subsequently estimate cocaine consumption. The method described is an efficient tool for investigating temporal variations (daily, weekly, and seasonal) at a local level. In addition, this method, along with the ability to sample wastewater at the neighborhood level, could provide a valuable forensic tool for law enforcement.

Cocaine, Sewage-Epidemiology, Toxicological Map

K61 Weeding Analytes Out of Marijuana: The Identification and Quantification of Pesticides in Cannabis Utilizing Comprehensive Gas Chromatography

Emily Ly, and Frank Dorman, PhD, 107 Whitmore Labs, University Park, PA 16802; and Jack Cochran, BS, and Julie Kowalski, BS, 110 Benner Cir, Bellefonte, PA*

After attending this presentation, attendees will understand the principles of analyzing and quantifying cannabis for specific cannabinoids such as Cannabinol (CBN), Cannabidiol (CBD), Cannabichromene (CBC), cannbigerol (CBG), and Delta-9-Tetrahydrocannabinol (THC) using Gas Chromatography with Flame Ionization Detection (GC/FID). They will also understand the concepts and reasons for testing for pesticides contained on cannabis utilizing Gas Chromatography/Mass Spectrometry (GC/MS) and Gas Chromatography/Electron-Capture Detectors (GC/ECD) as well as the practical applications for such analyses. Finally, attendees will understand how Comprehensive Gas Chromatography (GCxGC) can be utilized to potentially determine both potency as well as trace organics characterization in a single analysis.

This presentation will impact the forensic science community in a variety of different ways, but loosely falls into two classes: characterization of cannabis as a potential pharmaceutical; and, potentially fingerprinting the trace compounds in cannabis to determine the point of origin. Testing for potency can help determine the identity and abundance of target cannabinoids that have therapeutic qualities. These qualities have been confirmed to relieve pain, control nausea, stimulate appetite, and decrease ocular pressure.[1] With this knowledge, medical marijuana can be grown more effectively by lessening the main psychoactive component, THC, which may cause discomfort in patients, and increasing the target therapeutic cannabinoids.[2] The abundance of THC and other

cannabinoids is affected by a variety of factors including environmental conditions, harvesting periods, and the sex of the plant.[3] Furthermore, many pesticides, fungicides, and insecticides are used to treat the cannabis plant. This is of concern for any person that consumes the material due to the residual toxins that are potentially harmful. Moreover, a study was conducted in 1992 for the United States Drug Enforcement Administration (DEA) which determined that chemical profiles of cannabis samples could be used to locate the geographical origin.[4] However, the system could only eliminate possible sources of origin and therefore had low specificity due to the fact that only cannabinoid constituents were analyzed.[4] By identifying and quantifying the pesticides on the cannabis plant, it may be possible to develop a "chemical fingerprint" relating to compounds used by growers to increase the crop yield. This information may allow law enforcement agencies determine and/or link the source location of the confiscated illicit drug.

One hundred and six different samples of illicit marijuana were analyzed. These were obtained directly from local law enforcement personnel. Samples were initially homogenized, and the finely ground marijuana, weighing approximately 0.2 to 2g, was mixed with 10mL of acetonitrile and 10mL of water in 50mL centrifuge tubes, similar to the QuEChERS extraction procedure developed at the USDA.[5] Water was added to increase the extraction efficiency of more polar pesticides.[6] This solution was spiked with internal standards and pesticides for recovery purposes before soaking for an hour. The solution was shaken for 30 min with a vortex mixer. QuEChERS EN salts were added and the solution was shaken for 1 min.[5] This was followed by a 5 min phase separation utilizing centrifugation.[5] The supernatant was removed and refrigerated.[6] QuEChERS extraction is an efficient method that minimizes organic solvent waste and increases laboratory throughput as compared to more conventional solvent extraction techniques. SPE clean-up followed the extraction step to remove high levels of chlorophyll and organic acids that may interfere with the resulting chromatographic analysis.[6] Sample extract clean-up was performed by cartridge SPE procedures utilizing a 500mg graphitized carbon black/500mg Primary Secondary Amine cartridge, to which MgSO4 was added to the top of the SPE cartridge at approximately half the height of the GCB/PSA bed. The cartridge was rinsed with 20mL of acetone. Then 0.5mL of the sample extract was added, 2.5uL of anthracene (recovery surrogate) was spiked onto the cartridge and carefully mixed by syringe. The solution was eluted with a 3:1 acetone:toluene mixture. The solution was then evaporated with nitrogen at 108°C until it was reduced to approximately 0.3mL. Toluene was added to adjust the final volume to 0.5mL. The samples were analyzed using various GC methods, which will be discussed in detail during the presentation, allowing for the potency analysis and the pesticide fingerprint to be determined in a single GCxGC separation.

K62 Forensic Toxicology Findings in 150 Alleged Cases of Drug-Facilitated Sexual Assault (DFSA) in San Francisco

Nikolas P. Lemos, PhD, Eric A. Ingle, BA, Cecilia O. Medina, BS, Glenda M. Easterling, BS, Pavlos Karamanidis, BS, Chinyere M. Williams, BS, Jonas E. Knight, BS, Jonas E. Knight, BS, and Justin A. Volk, OCME, Forensic Lab Division, Hall of Justice, N Ter, 850 Bryant St, San Francisco, CA 94103*

After attending this presentation, attendees will understand the wide variety of drugs commonly encountered in DFSA cases and value the usefulness of toxicology testing in such cases.

This presentation will impact the forensic science community by providing valuable information on drug incidence in victims of DFSA and will offer blood reference concentrations of drugs commonly detected in such cases.

Between July 1, 2010, and June 30, 2011, the Laboratory Division of the San Francisco OCME performed toxicologic evaluations in 150 cases of suspected Drug Facilitated Sexual Assault (DFSA). The age of the subjects ranged from 12 to 57 years (mean: 30). The 150 cases were comprised of 129 females, 18 males, and three transgender females. Healthcare providers attending to DFSA victims are trained to collect urine specimens in these types of cases and only collect blood specimens if the alleged crime took place within hours of their examination. Specimens are typically evaluated for ethanol and related volatiles using Gas Chromatography equipped with Flame Ionization Detection (GC/FID), then screened by Enzyme-Linked Immunosorbent Assay (ELISA) for amphetamines, benzodiazepines, cannabinoids, cocaine, methadone, phencyclidine (PCP), ketamine, and opiates/opioids and by Gas Chromatography/Mass Spectrometry (GC/MS) for over 100 other drugs and metabolites including, but not limited to, diphenhydramine, carisoprodol, meprobamate, and γ-hydroxybutyrate (GHB).

Of the 150 cases, 101 had urine only, 17 had blood only, one had plasma only, and 31 had both blood and urine specimens. The 101 cases with only urine pertained to 93 females, five males and three transgender females. Of them, 33 cases had no drugs detected, but 28 were positive for ethanol with a mean ethanol concentration of 0.22% (w/v) and a range of 0.04 to 0.44 % (w/v). It is noteworthy that ethanol is only quantified in urine if the Division is provided with a forensic urine specimen (i.e., a urine specimen obtained about 20 min after the voiding of the urinary bladder; a collection protocol believed to produce urine that is a recent kidney filtrate and which better approximates blood ethanol concentrations). Besides ethanol, the most frequently reported substances in these urine specimens were cocaine/benzoylecgonine (15/18 cases), THC-COOH (14 cases), levamisole (11 cases), diphenhydramine (10 cases), and methamphetamine/amphetamine (8/8 cases). Many other psychoactive compounds were also detected as listed in Table 1.

Table 1: Drugs in Urine-Only Cases

Compound	Frequency
Benzoylecgonine	18
Cocaine	15
THC-COOH	14
Levamisole	11
Diphenhydramine	10
Methamphetamine	8
Amphetamine	8
Cocaethylene	5
Methadone	4
Oxycodone	3
Morphine	2
Codeine	2
MDMA	2
MDA	2
Citalopram	2
Pseudoephedrine	2
Dextromethorphan	2
Sertraline	2
7-Aminoclonazepam	2
Alprazolam	1
Diazepam	1
Nordiazepam	1
Lorazepam	1
6-Monoacetylmorphine	1
Diacetylmorphine	1
Hydrocodone	1
Hydromorphone	1
Bupropion	1
Promethazine	1
Venlafaxine	1
Trazodone	1
Mirtazepine	1
Phencyclidine	1
THC	1
Carbamazepine	1

The 18 cases which had blood products (17 whole blood specimens and one plasma specimen) pertained to 10 females and 8 males. These alleged victims' age averaged 27 years (range: 12 – 41 years). The plasma case was found to be negative. Ethanol was reported in five cases with a mean concentration of 0.11% (w/v) and a range from 0.01 – 0.15% (w/v). Methamphetamine was the most commonly encountered substance in these blood cases as it was found in four cases with a mean concentration of 0.35mg/L (range: 0.16 – 0.66mg/L). Amphetamine was detected in two blood specimens (0.01 and 0.04mg/L) as was THC-COOH (6 and 86ng/mL). Finally, THC was found in one of these blood specimens at a concentration of 8ng/mL.

The 31 cases that had both blood and urine specimens associated with them pertained to 26 females and five males whose average age was 29 years (range: 17 – 57 years). Of these 31 cases, seven had no drugs detected in either blood or urine. Ten blood specimens were positive for ethanol at a mean concentration of 0.11% (w/v) with a range of 0.02 – 0.37% (w/v). THC and THC-COOH were the most commonly encountered substances in these blood specimens found in six and four cases, respectively. THC mean concentration was 2ng/mL with a range of 1 – 4ng/mL while THC-COOH mean concentration was 20ng/mL with a range of 6 – 59 ng/mL. Other psychoactive compounds were also detected in these blood specimens as presented in Table 2. Of the corresponding 31 urine specimens, nine were positive for ethanol at a mean concentration of 0.17% (w/v) with a range of 0.02 – 0.38% (w/v). Methamphetamine, amphetamine, diphenhydramine, THC-COOH, and cocaine were among the most frequently detected drugs in this set of urine specimens (Table 2).

Table 2: Drugs in Cases with both Blood and Urine Specimens

Compound	Frequency in Blood	Frequency in Urine
Benzoylecgonine	3	4
Methamphetamine	3	6
Amphetamine	2	6
Cocaethylene	2	4
Methadone	2	3
Diphenhydramine	2	5
Cocaine	1	4
Citalopram	1	0
Chlordiazepoxide	1	0
Nordiazepam	1	0
Oxycodone	1	3
Trazodone	1	1
Venlafaxine	1	1
Levamisole	0	3
THC-COOH	0	4
Paroxetine	0	1
Hydroxyzine	0	1
Dextromethorphan	0	1

This study demonstrates the variety of substances that are commonly encountered in alleged DFSA victims' toxicology specimens. Ethanol, cocaine, methamphetamine, cannabis, and diphenhydramine are among the most frequently encountered drugs in DFSA case investigations. Interestingly, 44% of the cases reported early enough for a blood collection to take place pertained to male victims, suggesting males are more likely to report early on to the authorities that they may be victims of DFSA but females often delay the reporting, thus rendering blood collection useless. This study will improve the ability of forensic toxicologists and law enforcement personnel to better participate in the investigation of such crimes in their own jurisdictions.

DFSA, Toxicology, San Francisco

K63 Epidemiology of Rodenticide Poisoning in Manipal, South India

Shankar M. Bakkannavar, MD, Dept of Forensic Medicine, Kasturba Medical Coll, Manipal, 576104, INDIA; Pradeep K. Gouda, MD, Kasturba Medical Coll, Manipal Univ, Manipal, 576104, INDIA; and Vinod C. Nayak, MD, Dept of Forensic Medicine, Kasturba Medical Coll, Manipal, 576104, INDIA*

After attending this presentation, attendees will gain knowledge about the incidence and prevalence of rodenticide poisoning cases in South India. The toxicoepidemiology of the rodenticide poisoning, will be presented. Attendees will better understand how the hemorrhagic manifestations appear on the body, and the proper diagnosis can be better understood.

This presentation will impact the forensic science community by providing information about hemorrhagic manifestations occurring in rodenticide poisoning and the duration of their occurrence. This research provides more information in an area with little previous research. This presentation will add to research being carried out in forensic medicine by broadening the understanding of how hemorrhagic manifestations occur in rodenticide poisoning cases, enabling a better appreciation of these manifestations in humans.

Human Poisonings due to chemicals like insecticides, rodenticides, etc. commonly occur because of easy accessibility. Poisoning due to rodenticides, even though rare, are not uncommon. The mortality and morbidity due to rodenticides is increasing worldwide. Hence, knowledge about the epidemiology and clinical manifestations of rodenticide poisoning is not only essential for the treating doctor, but also to the forensic pathologist. The hemorrhagic manifestations of rodenticide poisoning can sometimes mimic contusions, posing problems while interpreting the injuries.

In this retrospective research, the toxic epidemiology of fatal poisoning due to rodenticides in this part of the world is described.

The hemorrhagic manifestations and altered laboratory findings in the victims will also be discussed.

In the present study, fatal rodenticide cases constituted 13.89% of the total poisoning cases, with the majority of the victims being male. The age of the victims ranged from 2 to 82 years. External hemorrhages were present in only five cases, although hemorrhage in Gastrointestinal Tract (GIT) was seen in a maximum number of victims. The prothrombin time (PT) was increased in 21 cases. The enzymes such as Aspartate Aminotransferase (AST) and Alanine Aminotransferase (ALT) were raised in 20 cases and total bilirubin was raised in 13 cases.

Rodenticides belong to a category of pest control chemicals intended to kill rodents. The chemicals which act as rodenticides are anticoagulants like warfarins, superwarfarines, thallium, phosphorous, metal phosphides, barium carbonate, red squill, strychnine, etc. Though the mechanism of action of various rodenticides is different, all lead to coagulopathy. Various studies done in the past have suggested the hemorrhagic manifestations due to altered coagulation profiles were induced by these rodenticides.[1-3] Substantial ingestion produces epistaxis, gingival bleeding, widespread bruising, hematomas, aematuria with flank pain, menorrhagia, gastrointestinal bleeding, rectal bleeding, and hemorrhage into any internal organ. Spontaneous hemoperitoneum has been described. Severe blood loss may result in hypovolaemic shock, coma, and death.[1] Hematoma and hemarthrosis as reported by Greeff, M.C., *et al*. were observed in children who accidentally consumed redenticide.[4] Cutaneous hemorrhage and hematemesis were also observed by Dolin E *et al*. in their study.[5] Similar observations were made in this study also.

In conclusion, hemorrhagic manifestations as a result of rodenticide poisoning can be misinterpreted as being due to assault. The differential diagnosis is quite broad and includes all causes of vitamin K deficiency, Disseminated Intravascular Coagulation (DIC), and liver disease. Perusal of hospital records is highly recommended for coagulation profile and is of paramount importance while concluding mode, manner, and cause of death. Rodenticide poisoning as a probable cause should be considered in nontraumatic bruises associated with suspected poisoning cases encountered at autopsy.

K64 Stability of Seven Benzodiazepines Together With Zolpidem, Methodone, and Propoxyphene in Bloodstains

Carole Jamey, Antoine Tracqui, MD, PhD, Bertrand Ludes, MD, PhD, and Jean-Sébastien Raul, MD, PhD, Institut de Medecine Legale, 11 Rue Humann, Strasbourg, 67085, FRANCE*

After attending this presentation, attendees will learn about another aspect of bloodstain analysis. The goal of this presentation is to emphasize the potential interest in toxicological analysis of bloodstains.

This presentation will impact the forensic science community by highlighting another aspect of bloodstain analysis that should be valued in forensic practice.

Blood ranks among the most usual kind of physical evidence encountered on a crime scene. Individualization of human blood has been performed for decades by using the ABO system and, more recently, DNA typing granted the forensic scientist a high-performance tool for this purpose. Forensic toxicology, however, also followed a continuous progress, currently providing the possibility to detect various drugs in very small blood samples. This purportedly offers the opportunity to assay bloodstains for toxicological analysis, which could be of interest in some situations, e.g., determination of the victim's toxicological status even if no corpse is found at the crime scene, or of the perpetrator's status if he/she bled in the surroundings of the crime scene. Moreover, when DNA typing cannot be compared to a reference (the victim and/or any biological element for DNA comparison was not found), detecting drugs in bloodstains could contribute to the victim's identification. Until now, only a few works have dealt with the detection of drugs in such samples, and the stability of drugs in bloodstains under different storage conditions have never been studied before. The stability of seven benzodiazepines (diazepam, bromazepam, clonazepam, alprazolam, clobazam, tetrazepam, and triazolam) were investigated, together with zolpidem, methadone, and propoxyphene over periods ranging from 24 hr to one month under various environmental conditions (drugs were chosen because of their frequent prescription in France).

Drug-free 50µL blood samples were spiked with an amount of 10ng/ml of each analyte (500pg per blood sample) and deposited on a glass slide. After storage at -20°C, +4°C, and +35°C away from light, at +20°C in daylight, away from light, and in "extreme" conditions (outside the laboratory exposed to daylight, wind, and variable temperature), bloodstains were collected after 24hr, 48hr, 72hr, one week, and one month by scratching and by swabbing. When scratched, the bloodstain was weighed and rehydrated for 45 min in 0.5mL ammonium buffer (pH 9.5). Swabbing was performed with swabs previously moistened with saline. Swabs were placed in 0.5mL ammonium buffer, sonicated 15 min, and stored away from light for 45 min before swabs were removed. Liquid/liquid extraction was performed using methylenechloride, N-Heptane, isopropanol (65:25:10, v/v) with Prazepam as an internal standard. Then toxicological analyses were carried out by Ultra Performance Liquid Chromatography/Liquid Chromatography with Tandem Mass Spectrometry (UPLC/MS/MS) under previously reported conditions.

The validation of the method was performed on dried bloodstains stored away from light at room temperature for six hours spiked with the different analytes. Under these analytical conditions, the method appeared sensitive (0.0005<LOQ<0.005ng/mg), linear (LOQ-10ng/mg), and accurate (CV<20%).

Results showed a good stability of all drugs tested even after one month of storage in each condition, except for clonazepam at -20°C (sometimes undetected), and for all drugs tested at +35°C and in "extreme" condition with sometimes up to 50% loss after one month. By scratching or swabbing, each analyte could be detected, except for clonazepam at -20°C. This study shows an acceptable stability of most benzodiazepines, zolpidem, methadone, and dextropropoxyphene in dried bloodstains. It opens the way to a new analytical approach which may enhance the bloodstain pattern analysis of a crime scene.

Bloodstain, Drugs, Stability

K65 Determining Zolpidem Compliance: Urinary Metabolite Detection and Prevalence in Chronic Pain Patients

David M. Schwope, PhD, Aegis Sciences Corporation, 515 Great Circle Rd, Nashville, TN 37228; Anne DePriest, PharmD, 515 Great Circle Rd, Nashville, TN 37228; David L. Black, PhD, Aegis Sciences Corporation, 515 Great Circle Rd, Nashville, TN 37228; Edward J. Cone, PhD, Cone Chem Research, LLC, 441 Fairtree Dr, Severna Park, MD 21146; Yale H. Caplan, PhD, National Scientific Services, 3411 Philips Dr, Baltimore, MD 21208-1827; and Rebecca Heltsley, PhD, Aegis Sciences Corporation, 515 Great Circle Rd, Nashville, TN 37228*

After attending this presentation, attendees will be able to describe a Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) method for the simultaneous identification and quantification of zolpidem (Ambien®) and its primary urinary metabolite, zolpidem 4-phenyl carboxylic acid (ZCA), in human urine.

This presentation will impact the forensic science community by offering a novel analytical method for sensitive and specific simultaneous quantification of zolpidem parent and metabolite in a single urine extract, as well as providing useful data detailing zolpidem metabolite prevalence in a chronic pain patient population.

Introduction: Zolpidem is the most prescribed insomnia treatment in the United States; however, little is known about zolpidem metabolite excretion in chronic pain patients. As zolpidem is extensively metabolized *in vivo*, metabolite detection may provide improved accuracy for compliance determinations, thereby improving clinical decisions and treatment courses. It is believed that no reported method simultaneously quantifies both parent zolpidem and ZCA in urine.

Method: This study was IRB-approved. Zolpidem and ZCA were extracted from 1mL human urine by mixed-mode solid-phase extraction following buffering with 0.1M acetic acid. Samples were eluted, evaporated to dryness, and reconstituted in 200µL aqueous mobile phase. Samples were injected onto an LC/MS/MS instrument comprised of a Shimadzu Prominence HPLC and ABSciex™ API 3200 tandem mass spectrometer. Ionization was by electrospray (positive mode) with Multiple Reaction Monitoring (MRM) mode employed for detection and quantification. Gradient chromatographic separation starting at 20% B (0.1% formic acid in acetonitrile) was achieved using a C_{18} column (100 x 2.1mm, 3µm particle). Flow rate was 0.7mL/min with an overall run time of 1.8 min.

Results: Conservative Limits Of Quantification (LOQ) were 4ng/mL for both analytes. The assay was validated for linearity from 4 – 1,000ng/mL for zolpidem and 4 – 5,000ng/mL for ZCA (r^2>0.990 and concentrations within ±15% of target). Inter-day recovery (bias) and imprecision (n=20) were 100% – 107% of target and 2.4% – 3.7% relative standard deviation, respectively. Extraction efficiencies were 78% – 90%. Freeze-thaw, processed sample, and autosampler stability were examined (n=6 each), with concentration changes <6.0% observed in all cases. No quantifiable carryover was observed at the method Upper Limit Of Quantification (ULOQ).

A total of 3,264 urine samples were obtained from chronic pain patients over five months and analyzed, with 3,142 (96.3%) meeting qualitative acceptance criteria. Results were de-identified and examined for zolpidem and ZCA prevalence, with concentrations normalized to urine-specific gravity. Zolpidem was detected > LOQ in 720 specimens (22.9%) while ZCA was detected in 1,579 specimens (50.3%). Two specimens (0.06%) contained zolpidem > ULOQ and 45 specimens (1.43%) contained ZCA > ULOQ. Of specimens within the dynamic linear range, median (range) zolpidem and ZCA concentrations were 28.3 (4.08 – 805) ng/mL and 2,038 (4.53 – 23,000) ng/mL, respectively. Only five specimens (0.16%) contained zolpidem alone (median concentration 488ng/mL). As ZCA was observed without parent zolpidem in 864 samples, addition of this metabolite to the assay increased detection rates by 27.5% in this cohort.

Conclusions: An LC/MS/MS method for simultaneous detection and quantification of zolpidem and ZCA in human urine is presented. Addition of zolpidem metabolite to compliance determinations resulted in substantially more positive samples compared to zolpidem alone at the same LOQ. This method is rapid and conducive to a high-throughput environment. Improved detection windows for zolpidem intake should prove useful in both clinical and forensic settings.

Zolpidem Metabolite, Compliance, LC/MS/MS

K66 Detection of Volatiles in Postmortem Samples by Headspace Gas Chromatography With Mass Spectrometry

Charlotte A. Baker, PhD, 2212 Pearl Bay Ct, Pearland, TX 77584; Fessessework Guale, DVM, HCIFS, 1885 Old Spanish Tr, Houston, TX 77054; Ashraf Mozayani, PhD, PharmD, Texas Southern Univ, 3100 Cleburne Ave, Houston, TX 77004; and Jeffrey P. Walterscheid, PhD, HCIFS, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will become knowledgeable about the detection of toxic volatiles in postmortem specimens such as blood, lung, and brain using Headspace/Gas Chromatography with Mass Spectrometry (HS/GC/MS). Four cases of death caused by toluene, difluoroethane, difluorochloromethane, and nitromethane abuse will be discussed.

This presentation will impact the forensic science community by providing a more reliable method for the detection of volatiles in postmortem specimens.

Volatile inhalants have become a common and dangerous substance of abuse. These inhalants include a broad range of chemicals such as volatile organic solvents, aerosol propellants, and other gases which are readily available, easily purchased, and can be used without supervision or accessories. The mechanism of acute intoxication and death due to inhalant abuse is through fatal ventricular arrhythmia, asphyxiation, and pulmonary edema.

Undoubtedly, the ability to confirm these gases in autopsy specimens presents unique challenges to the forensic toxicologist. Headspace/Gas Chromatograph/Flame Ionization Detector (HS/GC/FID) is currently the most widely applied technique in determining the presence of volatile compounds. However, this method does not provide sufficient data for identifying poorly combustible gases. In these cases, HS/GC/MS is more advantageous because it provides spectral data specific to the volatile compound that can be matched with data stored in the NIST library for identification and confirmation. Postmortem samples such as blood, brain, and lung are collected by the medical examiners in a headspace vial and analyzed by HS/GC/MS. The analysis of these cases was performed using an Agilent 7890 GC equipped with Agilent 5975 inert, triple axis Mass Selective Detector (MSD) utilizing a split injection of 100:1. The column was DB-VRX (40m x 0.180mm x 0.100µm) and helium was used as the carrier gas. The oven was programmed for an initial temperature of 55°C that ramped to a final 80°C at a rate of 20°C/min and the entire run time was 11.25 min.

Case 1: Presents a 58-year-old White male found dead with evidence of spray paint on the fingers and face; spray paint cans were located at scene. Upon analysis, toluene was found in his blood sample. Toluene, or methylbenzene, is used in the production of benzene, solvent-based cleaning agents, household aerosols, nail polish, paints and paint thinners, lacquers, adhesives, and as a gasoline additive.

Case 2: Presents a 50-year-old female found with a spray can of Dust Off™ in her hand. Dust Off™, the main ingredient being difluoroethane, is becoming increasing favorable to inhale.

Case 3: Presents a 39-year-old White male found dead, lying prone beside an air conditioning unit, with his mouth against a pipe connected to the unit. Diflurochloromethane, also known as Freon, is growing in popularity because of its ease in being inhaled from outdoor units.

Case 4: Presents a 56-year-old White male that involves nitromethane, which is a component of airplane fluid. In this unique case, the decedent died as a result of consuming airplane fluid in an attempt to get drunk.

Volatiles, Headspace Gas Chromatography, Postmortem

K67 Fatal Intravenous Injection of Oral Therapeutic Drugs in an Elderly Patient

Silvia Tambuscio, MD, Piazza De Gasperi 12 35131, Via Ospedale Civile 6 35121, Padova, ITALY; Luca Massaro, MD, Via degli Artigiani n 4, Este (PD), 35042, ITALY; and Giampietro Frison, PhD, Piazzale Giustiniani 11e/2, Mestre Venezia, ITALY*

After attending this presentation, attendees will be more conscious of the potential lethal effects following adverse reactions due to erroneous intravenous administration of oral therapeutic drugs.

This presentation will impact the forensic science community by promoting awareness of rare lethal therapeutic errors.

A 77-year-old male resident in a retirement home, suffering cardiac failure, severe neurological diseases, and dysphagia, died immediately after intravenous administration of a mixed compound, obtained by manual fragmentation of one tablet Respicur® 200mg (theophylline), one tablet of Dintoina® 100mg (phenytoin sodium salt), one tablet Luminale® 100mg (phenobarbital sodium), and a few milliliters of water. The nurse, educated in an Eastern European country and recently employed in Italy, intentionally injected the compound into a jugular catheter to bypass daily difficulties in oral administration, since the patient's parents had refused gastrostomy. A few minutes after the drug-blend injection, the patient showed convulsions, loss of consciousness with cardiac arrest.

Autopsy showed myocardiosclerosis and previous myocardial infarction, pulmonary emphysema, exogenous lipid pneumonia, interstitial fibrosis due to previous repeated gastric aspirations, remarkable congestion in the residual alveolar septa, and no emboli in the pulmonary vessels.

Toxicological analyses on the jugular catheter and syringe revealed extremely high concentrations of all three drugs, as expected from the unusual administration procedure. Toxicological analyses on biological specimens showed drug levels below the maximum therapeutic concentration (left ventricular blood: phenobarbital 15.33mcg/mL; theophylline 1.97mcg/mL; phenytoin 3.70mcg/mL; right succlavian artery blood: phenobarbital, 18.60mcg/mL; theophylline, 2.92mcg/mL; phenytoin, 5.26mcg/mL; left jugular cath residual blood: phenobarbital, 492.3mcg/mL; theophylline, 1395mcg/mL; phenytoin, 463.3mcg/mL). In fact, some degree of postmortem redistribution is expected to have occurred, considering the autopsy was performed three days after death.

Death was caused in this elderly patient by acute phenobarbital, phenytoin, and theophylline toxicity, following erroneous intravenous administration of oral therapeutic doses.

Severe theophylline-related arrhythmias happened very quickly after inoculation of the drug-blend, since the immediate and complete bioavailability produced extremely high concentrations, incomparable to any model of toxic overdose. The total lack of drug metabolism due to first hepatic passage was also responsible for this huge concentration. Moreover, intravenous injection at the left jugular site realized an exceptional condition inoculating theophylline very close to the heart, target of toxicity, and obtaining a sort of topic toxic effect at dramatically high concentrations.

The unusual way of administration also suggests phenytoin-related arrhythmias, as discussed for theophilline. Phenytoin is an anticonvulsant drug usually administered in tablets for chronic therapy, and intravenously at higher dosages for the treatment of acute epileptic seizures. In these cases, rapid parenteral injection can induce cardiac arrhythmias, while oral overdoses usually produce only neurological toxic effects.

Theophylline dose-related toxicity on the central nervous system should also be considered in the mechanism of lethality. On the contrary, the role of phenobarbital neurotoxicity is ruled out, since death rapidly took place and this barbiturate needs a longer time span to cross the hematoencephalic barrier.

Other possible lethal effects related to chemico-physical properties of excipients contained in the micro-fragments of injected tablet-mixture have been considered, but no relevant toxicological or hystopathological findings were noted.

In conclusion, this is the first case in the forensic literature reporting fatality by erroneous parenteral administration of oral therapeutic drugs. This study also points out that in similar occurrences postmortem analytical data have limited value. For this reason, the forensic scientist takes advantage in the diagnosis by the application of uses an appropriate methodology evaluating a complex of elements (circumstantial data; pathology; analytical data), but mainly inquiring/discussing evaluating the pharmacodynamic of each drug in relation to this bizarre irregular method of administration.

Teophylline Toxicity, Phenytoin Toxicity, Therapeutic Error

K68 Postmortem Redistribution and Necrokinetics of Amphetamine, Cocaine, Morphine, and Oxycodone During Post-Embalming Decomposition

Murray K. Marks, PhD, Univ of Tennessee, Dept of Pathology, 1924 Alcoa Highway, Box 108, Knoxville, TN 37920*

WITHDRAWN

K69 Cannabinoids in 105 Postmortem Forensic Toxicology Cases

Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Ter, 850 Bryant St, San Francisco, CA 94103*

After attending this presentation, attendees will understand the usefulness and value of postmortem cannabinoid analysis and will have a better understanding of the potential cardiotoxic effects of these compounds in humans.

This presentation will impact the forensic science community by providing postmortem cannabinoid incidence data among different types of deaths and by offering postmortem cannabinoid blood reference concentrations.

Between July 1, 2010, and June 30, 2011, the laboratory performed 1,338 postmortem toxicologic evaluations. Cannabinoids were confirmed/quantified in 105 cases (7.8%) comprising of 31 naturals, 31 homicides, 30 accidents, 12 suicides, and one undetermined. Decedents averaged 40 years (range: 16 – 71) and were predominantly male (72%).

Of the 31 naturals, one had antemortem whole blood (AMB) where only THC-COOH was found (11ng/mL). Twenty-eight had peripheral blood (BLP) where THC (n=25; mean: 8; range 1 – 48ng/mL), THC-COOH (n=22; mean: 75; range 5 – 640ng/mL), and THC-OH (n-=4; mean: 77; range: 17 – 210ng/mL) were found. One natural had central/cardiac blood (BLC) and only THC-COOH was detected (69ng/nL). The final natural case involved a decomposed decedent with no blood but THC-COOH was measured in her liver (2.6mg/kg).

In the 31 homicides, four cases had AMB and THC (n=3; mean: 2; range 1 – 5ng/mL), THC-COOH (n=4; mean: 31; range 10 – 78ng/mL), and THC-OH (n=1; 6ng/mL) were detected. Seventeen had BLP and THC (n=15; mean: 21; range 1 – 120ng/mL), THC-

COOH (n=15; mean: 39; range: 1 – 170ng/mL), and THC-OH (n=2; 6 and 14ng/mL) were detected. Nine of the homicides had BLC and THC (n=5; mean: 7; range: 1 – 21ng/nL), THC-COOH (n=9; mean: 24; range: 7 – 96ng/mL), and THC-OH (n=1; 6ng/mL) were detected. The final homicide involved a decomposed decedent with no blood but THC-COOH was measured in her liver at a concentration of 1.4mg/kg.

In the 30 accidents, BLP and BLC existed in 27 and 3 cases, respectively. THC (n=20; mean: 6; range: 1 – 27ng/mL), THC-COOH (n=25; mean: 35; range: 5 – 330ng/mL), and THC-OH (n=1; 5ng/mL) were detected. In cases with BLC, THC (n=1; 3ng/mL) and THC-COOH (n=3; mean: 39; range: 5 – 89ng/mL) were found.

In the 12 suicides, only THC (n=8; mean: 7; range 2 – 24ng/mL) and THC-COOH (n=9; mean: 23; range 6 – 51ng/mL) were detected. Finally, in the one undetermined case, THC and THC-COOH were measured in BLP at 6 and 13ng/mL, respectively.

Comparison of postmortem BLP cannabinoid concentrations among types of cases suggest that THC-COOH averages the highest in natural deaths (75ng/mL, which is more than double its concentration in any other manner of death) whereas THC concentrations run on average three times higher in homicides (21ng/mL) than in any other manner of death. THC-OH, most often found when cannabis-containing products are eaten, averaged 77ng/mL in natural deaths as compared to only 10 and 5ng/mL in homicides and accidents, respectively.

Cannabinoids were not listed in the Cause of Death (COD) in any of the 31 homicides or in any of the 31 natural deaths, but featured as a Significant Other Condition (SOC) in 12 of the homicides (39%) and in 23 of the naturals (74%). Cannabinoids were listed in the COD in 8 of the 30 accidents (27%) and listed as an SOC in an additional 12 of these cases (40%). Cannabinoids were listed in the COD in one of the 12 suicides (8%) and were listed as an SOC in five more suicides (42%). Finally, the one undetermined death listed cannabinoids in the COD together with morphine.

Closer examination of the 31 natural deaths suggests that 84% of these (n=26) showed significant cardiac pathology such as hypertensive heart disease, atherosclerotic cardiovascular disease, and cardiomegaly. In three of these cases, the medical examiner was of the opinion that the decedent had suffered probable lethal cardiac arrhythmia which has previously been reported in the clinical literature as a possible toxic manifestation of cannabis overdose.

This study is the first of its kind and demonstrates the usefulness of cannabinoid analyses as part of every death investigation and provides postmortem concentration reference data that will improve the ability of toxicologists, medical examiners, coroners, and others to evaluate cannabinoid concentrations in human postmortem specimens as well as their possible contribution to death.

Cannabinoids, Forensic Toxicology, Cardiotoxicity

K70 Tapentadol in Postmortem Casework

Ruth E. Winecker, PhD, and Justin O. Brower, PhD, OCME, Box 7580, Chapel Hill, NC 27312; and Laura W. Friederich, BS, 613A Pleasant Dr, Durham, NC 27703*

After attending this presentation, attendees will be able to detail the types of postmortem casework associated with tapentadol at various concentrations.

This presentation will impact the forensic science community by providing information regarding tapentadol as it relates to cause and manner of death determinations.

Tapentadol (Nucynta®, Palexia®, Zyntap®) is a mu-opioid receptor agonist and norepinephrine reuptake inhibitor. Approved by the Food and Drug Administration in 2009, tapentadol is available as immediate-release tablets of 50, 75, and 100mg and is indicated for acute moderate to severe pain. Adverse reactions associated with tapentadol are generally related to CNS depression including drowsiness, dizziness, headaches, as well as nausea and vomiting. Limited information has been published on tapentadol toxicity. A literature review indicates there are presently only four reported deaths in which the causative agent(s) included tapentadol.

At the North Carolina Office of the Chief Medical Examiner, cases suspicious for toxicological cause or with essentially negative autopsy findings are routinely screened for common over-the-counter, prescription, and illegal drugs via various laboratory techniques. This presentation will detail a group of 12 cases were tapentadol was detected during routine postmortem drug screening in support of cause and manner of death determination. Tapentadol is easily detected by the laboratory's basic organics screen which utilizes both Gas Chromatography with Nitrogen Phosphorus Detection (GC/NPD) and Gas Chromatography Mass Spectrometry (GC/MS). The extraction procedure has been previously described.[1]

Quantification of tapentadol is accomplished using GC-NPD with a calibration curve (blood matrix) and matrix matched positive/negative controls using the extraction procedure referenced above. Linearity, LOD, and LOQ are 0.2-2, 0.025 and 0.2mg/L, respectively. Accuracy and precision in blood (liver) are 99.4 (106) and 4.5 (12)%, respectively. Decedents were divided into groups according to manner of death for the purposes of studying tapentadol concentrations in overdose and non-overdose situations. The accidental and suicidal overdoses were subsequently divided into subgroups for further study: those where tapentadol was determined to contribute to the cause of death (attributed) and those where it was not (unattributed). The deaths in which tapentadol was determined to contribute to the cause of death were further divided into those where tapentadol additively combined with other drugs to cause the death and those where the drug was present in sufficient amounts to have caused the death regardless of other drugs and their concentrations.

Discussion: In all, since December 2010, there have been 12 cases where tapentadol was detected during routine drug screening. Eight cases had paired central and peripheral blood specimens and central/peripheral ratios averaged 1.65 and ranged from 0.54 – 3.3. The mean (median) concentration of tapentadol in central blood was 3.8 (3.3) and concentrations ranged from to <0.2 – 10mg/L. Likewise, for peripheral blood the mean (median) are 2 (2.5) and range is <0.2 – 3.1. For liver, the mean (median) and range are 10 (7.1) and <1 – 25mg/Kg, respectively. Co-intoxicants included antidepressants, antipsychotics, antihistamines, ethanol, cocaine, and miscellaneous CNS depressants.

In conclusion, of the 12 cases studied: 2 (16%) tapentadol were ruled not contributory to death, 7 (58%) were ruled accidental multiple drug intoxication, and 3 (25%) were ruled suicidal multiple drug intoxication. Concentrations of tapentadol in these groups were <0.2, 0.58 – 3.1, and 2.5 – 5.2mg/L, respectively.

Tapentadol, Death Investigation, Toxicology

K71 I'll Huff and I'll Puff: Dust Off™ Canister Abuse

Theresa M. Hippolyte, MS, Miami-Dade Medical Examiner, Number One on Bob Hope Rd, Miami, FL 33136-1133; Diane Boland, PhD, Miami-Dade Medical Exam Dept, Toxicology Laboratory, Number One on Bob Hope Rd, Miami, FL 33136; and Wilmo Andollo, BS, Dade County, Medical Examiner's Office, Number One on Bob Hope Rd, Miami, FL 33136*

After attending this presentation, attendees will be aware of the potential for abuse of Dust Off™ in combination with other drugs and the challenges of potentially misleading crime scene evidence.

This presentation will impact the forensic science community by illustrating how simple household products can be abused in conjunction with other drugs.

This presentation discusses a number of inhalant deaths that have occurred in Miami-Dade and Collier County, Florida, since 2010.

The Medical Examiner's Department has investigated six cases during this time period in which the decedents were engaged in inhaling, or "huffing," 1,1-difluoroethane found in commercial products.

In addition to 1, 1-difluoroethane, the cases presented included other drugs such as benzodiazepines, opiates, anti-depressants, diphenhydramine, or synthetic cathinones and tryptamines.

The decedents were mostly Caucasian, three males and three females, ranging in age from 26 – 37 years. In all cases, the decedents were declared dead at the scene with no resuscitative efforts employed. All decedents were surrounded by multiple canisters of products containing 1,1-difluoroethane. The propellant, 1, 1-difluoroethane, typically found in products such as Dust Off™, is readily absorbed by the lungs when inhaled, and causes alcohol-like intoxication including drowsiness, lightheadedness, and loss of inhibition. At toxic levels, effects can include asphyxiation and cardiac arrhythmias. Typical users engage in the inhaling of these vapors by expelling the aerosol into a bag that is held over the head or mouth. Death can occur from either an acute episode or chronic abuse of these inhalants. The manufacturer now includes a bitterant agent in their products to deter or discourage huffing practices.

Blood samples collected during the autopsy that were used for the analysis of 1, 1-difluoroethane were stored in glass screw-top tubes. Initial volatile screening for ethanol, methanol, acetone, and isopropanol by headspace gas chromatography indicated an unknown peak on the chromatograms later identified as 1,1-difluoroethane. Follow-up confirmation was performed using solid phase micro-extraction followed by Gas Chromatography Mass Spectrometry (GC/MS). A commercial Dust Off™ product was used as reference standard for the identification of 1,1-difluoroethane. A working stock solution was prepared by spraying the aerosol into a headspace vial and capping immediately. A working control was prepared by taking a 100µL aliquot of the headspace with a gas-tight syringe from the working stock solution and infusing it into a sealed headspace vial containing internal standard (n-propanol, 15mg/L in de-ionized water). Samples were prepared by adding 1mL of blood to a vial containing 1mL of internal standard. All samples and controls were heated at 65°C for a period of 15 min prior to analysis. The analysis was performed by solid phase micro-extraction using a 75µm Carboxen-PDMS fiber (Supelco, Inc). The fiber was exposed to the samples and controls for 5 min prior to injection into the GC/MS. A 60m x 0.25mm I.D. x 1.4µm Rtx-VMS column (Restek, Inc.) was employed. Analysis was performed in the full scan electron ionization mode, with identification based on spectral library matching. The primary ions used for identification are m/z 51 (base peak), m/z 65 (major ion), and m/z 47 (major ion).

Despite the presence of multiple canisters at each scene, the cause of death is still in question. Toxicology findings in these cases indicated the decedents were abusing more than just Dust Off™. Initial interpretations based on the scene alone could be misleading without extensive toxicology follow-up. In only one of the presented cases was the cause of death solely attributed to 1,1-difluoroethane toxicity. The remaining cases are still pending the pathologist's findings due to the presence of other drugs.

Case	1, 1-difluoroethane	Other Drugs Present	Date
1	Detected	Buprenorphine, Norbuprenorphine, Diazepam, Nordiazepam, Temazepam	July 2010
2	Detected	Diphenhydramine, Clomipramine, Norclomipramine	October 2010
3	Detected	Alprazolam, Citalopram, Norcitalopram, Diphenhydramine	May 2011
4	Detected	MDPV, MDMA, BZP, TFMPP, 5-MeO-DiPT, Dextromethorphan	November 2011
5	Detected	Diphenhydramine	September 2011
6	Detected	Alprazolam, Oxycodone, Tramadol	February 2012

K72 Scientific Method for Controlled Substance Analog Determination

Lindsay Reinhold, MFS, 1150 Woods Rd, Southampton, PA 18966; Heather L. Harris, MFS, JD*, 2401 Lombard St, Ste 1, Philadelphia, PA 19146; Dale E. Forrester, PhD*, USPS, National Forensic Laboratory, 22433 Randolph Dr, Dulles, VA 20104-1000; Kevin P.C. Minbiole, PhD*, Villanova Univ, 800 E Lancaster Ave, Villanova, PA 19085; Kevin G. Shanks, MS*, 2265 Executive Dr, Indianapolis, IN 46241; Jason R. Stenzel, PhD*, 580 W 7th St, Cheney, WA 99004; and J. Graham Rankin, PhD*, Marshall Univ, Forensic Science Program, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will understand relevant scientific concepts needed to comprehensively evaluate non-controlled substances as potential analogs of controlled substances, acceptance criteria associated with those concepts, the ability to establish laboratory practices to present scientific data regarding analog determination in court, and assist in the scientific prosecution or defense of analog drug cases.

This presentation will impact the forensic science community by providing laboratories with objective, science-based criteria to evaluate compounds and a means to establish consistency in analog determinations made in laboratories across the country. This presentation will introduce toxicological, chemical, and synthetic concepts surrounding the evaluation of potential controlled substance analogs and offer a scientific method for this evaluation.

The Advisory Committee for the Evaluation of Controlled Substance Analogs (ACECSA) was established by scientists from federal, state and private forensic laboratories, academia, and law to develop a scientifically valid and peer-reviewed means of evaluating the analog status of non-controlled substances and serve as a resource to law enforcement, legal counsel, laboratories, and government agencies in the scientific categorization of non-controlled substances. The Committee was gathered intentionally to maintain an independent, un-biased, and un-weighted stance in the scientific and legal communities. The main goal of constructing this group was to address a lack within the forensic chemistry field regarding the evaluation of analogs. To date, there are no guidelines, recommendations, or methods that exist in our field and no consensus or consistency in the determination of these compounds. Scientifically-sound guidelines or recommendations for analog determination are needed in the forensic arena in response to the overwhelming "designer drug" explosion and the difficult task of legislating potentially harmful new drugs.

The members of the ACECSA, in collaboration with national and international subject-matter experts, developed five aspects of a compound that should be included in evaluating analog status: Chemical Structure; Physicochemical Properties; QSAR/Computational Chemistry; Synthetic Pathway; and, Toxicology/Pharmacology will present applicable concepts and associated acceptance criteria to demonstrate the comprehensive approach to analog determination.

The Chemical Structure subcommittee aims to develop a process by which potential controlled substance analogs are evaluated and compared on the basis of their structural similarity. This structure evaluation process focuses on both 2D and 3D aspects of a chemical's structure. Initial investigations look at core structures and functional groups.

The use of physicochemical properties in proposing potential new drug candidates has its basis primarily in the bioavailability of the compound *in vivo*. For example, solubility, partition coefficient, and pKa/pKb provide preliminary *in vitro* guidance as to the potential bioavailability.

Solubility primarily affects the dosage form and route of administration. Partition coefficient is used to predict membrane permeability. The compound's acidity or basicity determines where an orally-administered drug might be absorbed in the body. These properties will be retrieved from scientific literature (if available) or

may be calculated by modern computer programs designed and used for this purpose.

The Quantitative Structure-Activity Relationship/Computational Chemistry subcommittee will utilize available predicted activities for new chemicals. It will also evaluate the utility of similarity co-efficient models such as Tanimoto.

The goal of the Synthetic Pathway subcommittee is to analyze the structure of potential controlled substance analogs by the pathway in which they were created, i.e., deducing their chemical construction. The pathway of chemical synthesis of any organic compound can be modified by employing different building blocks; this serves as a rapid means to generate analogs of beneficial, or controlled, chemical compounds.

The Toxicology subcommittee will evaluate available pharmacological and toxicological data regarding novel compounds and compare their properties to existing controlled or scheduled drugs. This will include receptor binding and functional assay data, human and animal dosing studies, case reports, behavioral studies, adverse event reporting, and epidemiological data with clinical indicators, provided in the latter two cases that they are accompanied by analytical confirmation of the substance identity.

Analog, Controlled Substance, Method of Evaluation

K73 Cross-Reactivity of Cathinone Derivatives and Other Designer Drugs in Commercial Enzyme-Linked Immunosorbent Assays

Madeleine J. Swortwood, BA, Fla Int'l Univ, 11200 SW 8th St, Miami, FL 33199; W. Lee Hearn, PhD, 425 SW Balfour Ave, Port Saint Lucie, FL 34953; and Anthony P. DeCaprio, PhD, Florida Int'l Univ, International Forensic Research Institute, 11200 SW 8th St, Miami, FL 33199*

After attending this presentation, attendees will gain an understanding of designer drugs, particularly "bath salts" or cathinone derivatives, and their prevalence in our society. In addition, the audience will also learn about the immunoassay techniques involved in screening for these substances and how the compounds cross-react in such commercial assays.

This presentation will impact the forensic science community by serving as a resource for cross-reactivity data of designer drugs in commercial Enzyme-Linked Immunosorbent Assays (ELISAs), an important factor to consider when screening biological specimens for drugs of abuse.

Designer drugs have been no stranger to the drug market in the United States over the past few decades. Recently, "legal highs" in the form of "bath salts" or "research chemicals" have dominated the drug scene as substances that are labeled "not for human consumption" in order to bypass recent regulations. While a number of bans have been put in place regarding such compounds, the abuse of these designer drugs has been on the rise while manufacturers have been staying one step ahead of the law with constantly evolving modifications to structures. When an intoxication or fatality occurs, presumptive techniques, such as immunoassays, are employed to quickly screen biological specimens for common drugs of abuse. However, since cathinone derivatives are fairly new, few assays have been created for the detection of such compounds. It is hypothesized that during routine drug screens by ELISA, the cathinone derivatives and other designer drugs may be missed. In a toxicology lab, a negative screen would not be further investigated and the substances may never be detected. For this reason, it is important to investigate the cross-reactivity of such designer drugs by analyzing across several commercial immunoassays.

In this large-scale experiment, ELISA reagents from Immunalysis, Neogen®, OraSure®, and Randox® were evaluated to determine the cross-reactivity of 30 designer drugs, including 24 phenylethylamines (including MDPV and eight cathinone derivatives), 3 piperazines, and 3 tryptamines. The study determined the percent cross-reactivity for the compounds in 16 commercial immunoassays, targeting amphetamine, methamphetamine/MDMA, benzylpiperazine, mephentermine, methylphenidate, ketamine, MDPV, mephedrone/methcathinone, PCP, and cotinine.

Cross-reactivity towards the "bath salts" was 0.5% – 4% in the assays targeting other phenylethylamines such as amphetamine or methamphetamine/MDMA. Compounds such as MDA, MDMA, ethylamphetamine, and α-methyltryptamine (AMT) demonstrated cross-reactivities in the range of 30% – 250%, but were consistent with both the manufacturer's inserts and published literature. Some assays, such as BZP, cotinine, PCP, mephentermine, methylphenidate, ketamine, and MDPV demonstrated almost no cross-reactivity toward any of the analytes evaluated. The mephedrone/methcathinone kit from Randox® demonstrated cross-reactivity toward cathinone derivatives—with false positives occurring at concentrations as low as 150ng/mL. The mephedrone/methcathinone kit was not a suitable assay for detecting other more traditional amphetamine-derived compounds but may be more fitting for screening postmortem specimens for "bath salts" when putrefactive amines may be present.

This comprehensive study determined the cross-reactivity for 30 designer drugs in biological specimens across 16 commercial immunoassay reagents. Very few "false positives" were observed in this study, which indicates the selectivity of the immunoassays and the antibodies that are employed. However, the fact that very few additional compounds were detected demonstrates a need for more broad-range screening techniques to be applied when analyzing biological specimens by immunoassays for drugs of abuse, specifically the more recent designer drugs.

Immunoassay, Designer Drugs, Cross-Reactivity

K74 Analysis of Synthetic Cannabinoids Using Disposable Micropipette Extraction Tips and LC/MS

Apisri Leamniramit, BS, 1850 Park Ave, Bensalem, PA 19020; Warren Korn, BS, Center for Forensic Science Research, 2300 Stratford Ave, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to evaluate the effectiveness of disposable micropipette tips for the extraction of synthetic cannabinoids from biological samples, relative to traditional liquid/liquid extraction.

This presentation will impact the forensic science community by describing a rapid drug screening technique for a class of drugs that is becoming increasingly popular. This technique can aid in the regulation of these "legal high" products and identify their role in criminal activity or death investigations.

This project was designed to evaluate the applicability of the use of solid phase micropipette extraction tips for the isolation of synthetic cannabinoids from biological samples.

Synthetic cannabinoids are a rapidly growing class of drugs that have similar effects to those of marijuana. The scope of this class of drugs is fast-growing because their structures are easily manipulated, but can still produce cannabis-like effects. The chemical constituents of these synthetic marijuana products change frequently as attempts to regulate them evolve. Being able to detect these various drugs in biological samples has significant forensic toxicology applications. Previously, liquid/liquid extraction procedures have been performed to isolate the drugs prior to analysis by Liquid Chromatography Tandem Mass Spectrometric (LC/MS/MS) analysis; however, liquid/liquid extractions can be very time consuming, generate large amounts of waste, and involve multiple manipulations, resulting in reduced recovery.

This study describes the development of a rapid method to screen for the model synthetic cannabinoids AM-1248, AM-2201,

JWH-122, JWH-210, and XLR-11using disposable micropipette extraction tips. Disposable micropipette extraction is a novel technique based on solid phase extraction. The pipette tips contain a sorbent material that binds to the sample as the solution is aspirated and expelled through the frit in the tip. These tips are advantageous over traditional liquid/liquid extraction because they are more efficient, rapid, and require lower solvent volume. Reduced solvent waste is an environmental benefit of this approach. Once extractions are performed, samples are analyzed LC/MS/MS.

Variables such as time for extraction, total solvent volume, and sample volume were evaluated as part of this assessment. A previously reported liquid/liquid extraction method was evaluated for comparison to the proposed extractions with disposable micropipette tips. The liquid/liquid extraction is performed using 1mL of sample which is acidified and extracted with chloroform/isopropanol/n-heptane, 50/17/33. Liquid/liquid extractions from serum demonstrated R^2 values above 0.98 with a linear range of 0.1 – 15 ng/mL.

Preliminary results show that the individual 10 ng/mL standards can be extracted from the micropipette tips with a significant increase in abundance when compared to liquid/liquid extractions of the 10ng/mL standards. Abundances for the micropipette tips were almost five times greater than that of liquid/liquid extractions of samples of the same concentration. Extractions with the tips also proved to be less time consuming. To prepare calibrators and perform extractions with the tips takes 2 hr as compared to 4 hr with liquid/liquid extractions. Solvent and sample volume are also decreased when utilizing the tips. The micropipette tips use 2.25mL of solvent and 0.50mL of sample volume while liquid/liquid extractions use 4.20mL of solvent and 1 – 2mL of sample volume.

Based on the work described above, disposable micropipette tips successfully extract standards of AM-1248, AM-2201, JWH-122, JWH-210, and XLR-11. The micropipette tip extraction thus far proves to have higher extraction efficiency while utilizing less sample and solvent volume.

Cannabinoids, Pipette Tip Extracts, Designer Drugs

K75 Cross-Reactivity of Designer Phenethylamines With the Emit® II Plus Amphetamine/Methamphetamine Assay in Urine

Wendy R. Adams, PhD, Bill Ofsa, MS, Linay Williams, BS, and Edward J. Barbieri, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

The goal of this presentation is to provide attendees with cross-reactivity information for 4-methylethcathinone and other psychoactive phenethylamines that may aid with screening for designer drugs in postmortem and police cases. The discussion will include the parameters of the analysis as well as some specific case examples.

This presentation will impact the forensic science community by providing a fast means of screening for phenethylamine designer drugs in urine.

4-methylethcathinone (4-MEC) is a designer stimulant that has been a popular drug of abuse in New Zealand. It has been sold in the United States in bath salts products and as a research chemical. It is reportedly abused for psychoactive effects, including euphoria and alertness. 4-MEC was recently indicated in the suicide death of a New Zealand teenager and is an important compound to include in forensic toxicology testing.

NMS Labs recently reported two positive results for 4-MEC in blood that also had positive amphetamine immunoassay results in urine. None of the usual amphetamines, including amphetamine and methamphetamine, were detected in the blood using Liquid Chromatography With Tandem Mass Spectrometry (LC/MS/MS). Since the structure of 4-MEC and other phenethylamines appears similar to amphetamine, it may be possible to use existing immunoassay kits to screen for this class of designer drugs.

There have been several recent reports of designer drugs producing similar positive screening results. Mephedrone was found to cross react with a methamphetamine ELISA in postmortem blood.[1] In addition, Methylenedioxypyrovalerone (MDPV) was found to cross react with PCP.[2]

In order to further characterize these potential false positive results, the cross-reactivities for several popular phenethylamines were determined by spiking standards into blank human urine. Analysis was performed using the Emit® II Plus Monoclonal Amphetamine/Methamphetamine Assay (Syva). Amphetamine, methamphetamine, cathinone, methacathinone, mephedrone, methylone, MDPV, alpha-pyrrolidinovalerophenone (alpha-PVP), 4-MEC, pentedrone, buphedrone, and naphyrone were evaluated between 500 and 10,000 ng/mL. The final concentrations in urine were verified by LC/MS/MS for those compounds with a quantitative method available. The results of this cross-reactivity testing will be presented along with some case examples.

The landscape of the designer drug market has been changing rapidly, making it difficult to develop sensitive methods for detection. Structural similarities may be used as a guide to select existing screening methods that may be sensitive to emerging designer drugs. These findings also indicate that unconfirmed methamphetamine screens could potentially contain phenethylamines. While there may be many explanations for false positive screens, the possibility of bath salt ingestion should be added to the list for consideration by medical and laboratory professionals.

This is especially important considering that one of the most attractive attributes of designer drugs is their invisibility on standard drug tests. Many analytical laboratories have been developing quantitative methods that can confirm designer phenethylamines in a variety of matrices, but targeted screening with these methods is often cost-prohibitive. The Emit® II Plus and other immunoassay tests are readily available and inexpensive tools that can potentially be validated as designer drug screens.

Immunoassay, Designer Drug, 4-MEC

K76 Validation of Enzyme Linked Immunosorbent Assay (ELISA) for Detection of Synthetic Cannabinoids Metabolites in Urine

Denise N. Lancaster, MS, 906 Spring St, Bristol, PA 19007; John R. Simon, PhD, Tulip Biolabs Incorporated, PO Box 334, West Point, PA 19486; and Bill Ofsa, MS, Matthew M. McMullin, MS, and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to evaluate the use of immunoassay tests for the detection of synthetic cannabinoid metabolites in urine.

This presentation will impact the forensic science community by outlining an approach to method validation for immunoassay, and by providing an assessment of the merits of an immunoassay approach to the detection of these emerging compounds.

The prevalence and popularity of synthetic cannabinoid drugs has created the need for a low-cost option for screening for the presence of these drug metabolites in biological fluids. Liquid Chromatography/Mass Spectrometry (LC/MS/MS), which is in limited

use as a method for screening for these compounds, requires sample extraction, lengthy run times, and is an expensive approach for high-volume screening. It also requires additional development for every new analyte or new metabolite discovered. Enzyme Linked Immunosorbent Assay (ELISA) is in widespread use for screening for many classes of drugs, and the development and evaluation of two ELISA tests to detect synthetic cannabinoids is described. ELISA is a rapid procedure that uses low-cost reagents and can be readily automated, making it an optimal technique for this process.

Following the production of antibodies in a rabbit model, antisera was harvested and antibodies isolated. After evaluating the performance of antibodies from several animals, the optimum antibody was used in a homogeneous ELISA plate immunoassay on a 96-well plate.

Two ELISA assays were developed, targeted to JWH-018 (1-naphthyl-(1-pentylindol-3-yl)methanone) and JWH-250 (2-(2-methoxyphenyl)-1-(1-pentylindol-3-yl)ethanone), respectively. At the time of development, JWH-018 and JWH-250 were the most prevalent compounds on the illicit drug market.

The assays were validated to determine their performance at the defined cut-off of 5ng/mL. The 5ng/mL cut-off was selected based on analysis of incurred authentic positive urine samples and LC/MS/MS analysis of JWH-018 and JWH-250 metabolite concentrations in authentic samples. Intraday and interday precision were evaluated by analyzing calibrators and controls over 10 days with 2 runs per day. Cut-off calibrators were run in duplicate and the mean OD used to establish the cut-off. A negative control, positive control (20ng/mL), and near cut-off concentration control (10ng/mL) were evaluated and performed acceptably for both assays under these conditions.

The assays showed significant cross reactivity with other synthetic cannabinoid standards, and metabolites. Several compounds including JWH-018 4-OH pentyl, JWH-018-5OH pentyl, JWH-081, JWH-081 4-OH pentyl, JWH-081 5-OH pentyl, JWH-122, JWH-122 5-OH pentyl, AM-2201, AM-2201 4-OH pentyl, and others generated positives on the JWH-018 assay at concentrations of less than 20ng/mL. Fewer compounds including JWH-250, JWH-250 4-OH pentyl, JWH-250 5-OH pentyl, and others generated positives on the JWH-250 assay at the same threshold. Common drugs of abuse and therapeutic drugs did not react at elevated concentrations (>10,000ng/mL).

Validation controls (positives and negatives) as determined by LC/MS/MS were presented to the ELISA methods. Subject samples testing positive for JWH-018 (5-hydroxypentyl) metabolite using LC/MS/MS with a cutoff concentration of 0.1ng/mL were assessed using the JWH-018 Direct ELISA kit. There were 61 of 63 LC/MS/MS positive samples which tested positive by ELISA, while all 51 pedigreed negative samples tested negative by ELISA. Thus, the sensitivity, specificity, and accuracy for the JWH-018 Direct ELISA kit were 96%, 100%, and 98%, respectively.

Subject samples testing positive for JWH-250 (4-hydroxypentyl) metabolite using LC/MS/MS with a cutoff concentration of 0.5ng/mL were assessed using the JWH-250 Direct ELISA kit. There were 32 of 33 LC/MS/MS positive samples which tested positive by ELISA, while all 51 pedigreed negative samples tested negative by ELISA. Thus, the sensitivity, specificity, and accuracy for the JWH-250 Direct ELISA kit were 97%, 100%, and 99%, respectively.

These ELISA assays have proven effective, sensitive, and specific for the purposes of screening for many of the currently popular synthetic cannabinoid compounds. Continued vigilance is needed to ensure that the assays will cross react with newly emerging drugs in this class.

ELISA, Cannabinoids, Designer Drugs

K77 Qualitative Analysis of Designer Stimulants and Bath Salts Chemicals in Blood, Serum/Plasma, and Urine by LCTOF

Joseph Corvo, BS, Ian McGarvey, BS, and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to discuss the use of Liquid Chromatography Time-Of-Flight Mass Spectrometry (LC/TOF/MS) for the screening of designer stimulants and hallucinogens in biological samples and identify considerations that reduce the risk of false positive findings.

This presentation will impact the forensic science community by increasing forensic toxicologists' understanding of the strengths and limitations of LC/TOF analysis and the need for confirmatory testing by independent methods.

LC/TOF is becoming an increasingly popular technique for drug screening in forensic and clinical toxicology laboratories. The technique is based on high-efficiency liquid chromatographic separations, coupled with a detection system that confirms the identity of the analyte by assessing its retention time and accurate mass relative to an analytical standard and its accurate mass. A panel was developed and validated for the detection of 40 analytes, including popular designer drugs such as MDPV, mephedrone, methylone, ethylone, naphyrone, 5-MeODALT, 5-MeO-DIPT, 2C-D, 2C-E, 2C-H, 2C-I, 2C-T-2, 2C-T-7,and others. The compounds were selected based on the fact that they are scheduled either at the state or federal level and are increasingly being found in "Bath Salts" type of products for purposes of abuse.

Samples (0.5mL) were buffered with 0.1M borax buffer followed by liquid-liquid extraction using 70:30 n-butylchloride:ethyl acetate. The acquisition method used a run time of 10 min with a flow of 0.700mL/min. The method used six representative deuterated internal standards to monitor analyte recovery. A target cut-off of 10ng/mL was selected for most compounds in blood and urine. Criteria used to evaluate positivity were retention time, mass accuracy, and percent concentration compared to the cutoff.

Validation of the assay consisted of assessment of precision around the cut-off, stored sample stability (room temperature (light and dark), refrigerated and frozen), carryover, autosampler stability, interference, sensitivity, and specificity.

The validation of this panel yielded an overall sensitivity of 99.7% with a range of 72% to 100% and selectivity of 99.0% with a range of 79% to 100%. Generally, analyte stability was shown to be sufficient in refrigerated and frozen samples and insufficient otherwise, whether light protected or not. Naphyrone in serum was an exception, which was shown to be unstable after one day. No carryover was detected following a sample spiked at 100 times the cutoff. Potential interferences were investigated by testing various mixed analyte pools, and did not yield any false positive findings.

The method's reproducibility was demonstrated by observing internal standard area, performance of the positive and negative controls, and the limited number of false positives. False positives only appeared to be an issue with isobaric pairs of analytes, such as 3-FMC and flephedrone, and MDMA and mephedrone. For this reason, when either member in the pair is present, confirmation testing will be done for both.

LC/TOF is a useful tool for forensic toxicology screening; however, the limitations of the technique must be acknowledged. Recognizing isobaric compounds is key to using LC/TOF as a screening tool, since the molecular mass of the analytes is the main identifying criteria. The success of the technique is highly demanding of high resolution chromatography and chromatographic quality and stability during the assay. Mass accuracy is one parameter that can help in determining the positivity of an analyte. Ion suppression due to sample matrix is another issue that must be addressed. Using

representative deuterated internal standards is one way of determining the likelihood of ion suppression in a given sample.

LC/TOF, Designer Drugs, Stimulants

K78 Stability of Synthetic Cathinones (Bath Salts) in Toxicology Specimens

Jeffrey P. Walterscheid, PhD, Afshin Nejabat, MS, and Michael Chen, PhD, HCIFS, 1885 Old Spanish Tr, Houston, TX 77054; and Ashraf Mozayani, PhD, PharmD, HCIFS, Texas Southern Univ, 3100 Cleburne Ave, Houston, TX 77004*

After attending this presentation, attendees will learn about the *in vitro* degradation of synthetic cathinones, often referred to as bath salts. Based on the hypothesis that beta-keto amphetamines are inherently unstable in biological matrices, a preliminary study using several cathinones spiked in blood and urine samples stored at ambient and refrigerated temperatures was evaluated by Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) and Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS) over a five-week time period. This model system revealed temperature-dependent and compound-specific decay rates among the commonly known cathinones.

This presentation will impact the forensic science community by emphasizing the effects of storage conditions and type of biological sample used to perform analysis. Data reflected a rapid signal degradation, which was accelerated in ambient storage conditions and urine specimens. The values extrapolated from each experiment yielded putative rate constants, which were compared to previous actual cases with confirmed cathinones. The limited data analyzed from the five-week trial with sampling each week produced a broad generalization that could aid interpretation of results, especially when intoxication was observed yet there is an absence of confirmatory signal.

The most stable cathinone in this study was methylenedioxypyrovalerone (MDPV), which retained as much as 29% in blood stored at room temperature. In distinction, naphyrone and mephedrone showed a complete loss of response. Compared to room temperature, refrigerated blood had an overall average increase in stability by 34%. Urine samples at room temperature demonstrated the most dramatic effect between sample and temperature. All cathinones, excluding MDPV, fell sharply at day 8, followed by an even greater drop below 5% or complete loss of signal by day 29. In comparison, refrigerated urine had an overall average increase in stability by 45%. The differences show that biological specimen and temperature significantly affect synthetic cathinone stability. Both specimens produced more stability in refrigerated temperature (4°C) compared to ambient temperature (21°C). The complete or significant loss in signal occurred earliest in urine samples at ambient temperatures.

The lessons learned from this pilot study were applied to actual postmortem and DUI forensic toxicology cases. For postmortem samples collected at autopsy, the urine specimens were stored frozen at -20°C without preservative, while decomposition fluid was stored at 4°C in grey top blood tubes preserved with sodium fluoride. For DUI samples collected, the urine contained no preservative and was refrigerated at 4°C. These specimens were re-analyzed and the rate constant and half-life calculated from the stability experiment were applied and compared to previous cases. The degradation of each cathinone followed a first order rate of decay. MDPV was the compound confirmed in all cases. The rate constant determined from the pilot study agreed fairly well with actual case results.

This study indicates that it is possible for a specimen to generate a false negative result if the specimen was stored at room temperature or analyzed after a significant time delay. Refrigeration proved to lengthen stability for both types of specimens, with refrigerated urine producing the greatest stability. The stability of cathinones in biological samples is extremely important due to its increasing use among drug abusers and lack of experience in toxicology laboratories. Factors that may influence drug stability in stored samples include: storage temperature, storage time, addition of preservatives, and initial condition of the collected sample. Furthermore, LC/TOF/MS analysis revealed that as cathinone levels diminished, their corresponding "reduced" forms became more prevalent. This development may signal the need for reduced derivatives of cathinone standards for use in forensic toxicology confirmations.

Bath Salts, Stability, Toxicology

K79 Forensic Investigation of PSU Herbal Incense Products Using GC/MS and LC/MS/MS

Sharyn E. Miller, BS, 1051 Teaberry Ln, Apt E109, State College, PA 16803; and Julie C. McIntosh, and Dan G. Sykes, PhD, 330 Whitmore Lab, Univeristy Park, PA 16802*

After attending this presentation, attendees will gain knowledge on herbal incense products as an emerging designer drug, applications of method development for Gas Chromatography-Mass Spectrometry (GC/MS) and Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS), in addition to the detection, identification, and quantification of synthetic cannabinoids in two commercially available products, Down2Earth Climax and Wet. In order to aid law enforcement's efforts to contain and prevent the use of these emerging designer drugs by youth, it is essential that the forensic science community develop rapid screening methods for detection that will enable rapid designer drug screening. This research will also provide significant chemical information regarding the unknown compounds in these street samples, and assist with drug awareness in a college town, a prevalent drug-consuming community, by presenting the findings at local high schools and colleges in the area.

This presentation will impact the forensic science community by developing methods for detection that will facilitate rapid designer drug screening, aiding law enforcement's efforts to contain and prevent the use of these emerging drugs.

Legal herbal products, found readily available through the internet and local gift shops, are increasingly being used for recreational drug use by youth. Marketed as herbal incense and specifically labeled "not for human consumption," these products are plant materials sprayed with cannabinoid-related chemicals that users vaporize and inhale.[1,2] Two commercial herbal samples, Wet and Down2Earth Climax, purchased in downtown State College, PA, are investigated and analyzed to determine synthetic cannabinoid presence and quantity. JWH-018, JWH-073, JWH-200, CP-47, 497, and cannabicyclohexanol are analyzed, as these represent five chemicals currently placed on Schedule I classification by the U.S Drug Enforcement Administration (DEA).[2] Scheduling was in response to an increase in the frequency of hospitalizations involving incense inhalation in the United States.[3] In addition to the five Schedule I chemicals listed above, 30 other synthetic cannabinoid related chemicals are being investigated in order to construct a library for instrumental drug screening.

To accomplish synthetic cannabinoid chemical screening, multiple extraction techniques were compared and the QuEChERS (Quick, Easy, Cheap, Rugged, and Safe) extraction method proved to be most suitable.[4] QuEChERS provides a time-effective option by combining the herbal sample with magnesium sulfate and calcium chloride buffering salts and methanol solvent in a 50mL centrifuge tube. After shaking the sample for 5 min, sample centrifuging ultimately allows for removal of the organic phase. Extracts are characterized using a GC/MS and an triple quadrupole LC/MS/MS. Optimized methods, coupled with library construction of synthetic cannabinoid standards, enable simultaneous screening of cannabinoid species, and permit a comparison of the two instrumental setups for drug screening and quantification of street herbal products.

Currently, employee drug testing does not incorporate these compounds, but as more analogs become illegal and available, screening will be forced to expand to include such chemicals. Thus, it is important to develop and validate instrumental methodology for such screening. Traditional crime laboratory drug analyses focus on GC/MS instrumentation, but semi-volatile and thermally unstable compounds may not be suitable. LC/MS/MS methods may prove more suitable for such chemicals. Preliminary results indicate a rapid, effective method for the separation and identification of synthetic cannabinoid standards and commercial herbal samples for GC/MS and LC/MS/MS. Using the method of internal calibration, deuterated analogs are utilized to quantify the synthetic cannabinoids in the samples. Products from the same brand allow for determination of inner-batch variability. Future analyses will expand to incorporate other street samples from the area, and to evaluate sample heterogeneity. Pending method optimization, the research project can be expanded to include other emerging cannabinoid-based drugs that come into vogue.

Synthetic, Cannabinoids, Screening

K80 Development of an LC/MS/MS Method for 30 Synthetic Cannabinoids and Metabolites

Erica A. Guice, MS, Matt Pentis, BS, Brad T. Holden, BS, and Mounira Ozoor, 1197 Rochester Rd, Suite K, Troy, MI 48083*

After attending this presentation, attendees will: (1) understand the challenges of testing for synthetic cannabinoids; (2) obtain knowledge on the effects of matrix on synthetic cannabinoid testing; and, (3) understand the differences in platform for synthetic cannabinoid testing

This presentation will impact the forensic science community by providing needed information for the detection of several synthetic cannabinoids that are currently being missed by laboratories.

Synthetic cannabinoids have been a topic of much discussion since their popularity as a legal high started in 2004 in Europe. To date, several states have moved to ban the use and sell of synthetic cannabinoids. However, most state and federal law makers have banned specific compounds, not structural moieties, allowing for similar compounds to come onto the market. As such, the detection of synthetic cannabinoids has always been mostly reactive.

Laboratories who generally rely on a screen-confirm methodology for their testing were further hampered until immunoassays for these compounds were developed. And, to date, most of the immunoassays developed are limited and some are already outdated. In order to remain current with the compounds on the market, based on seizures and blogs, Western Slope Laboratory developed a drug-monitoring method using liquid chromatography-online sample extraction-tandem mass spectrometry with full scan orbitrap. This method allows for targeted analysis as well as unknown compound elucidation.

With this methodology, testing is available for 30 synthetic cannabinoid compounds including metabolites. Included in the method are markers for JWH-018, JWH-073, JWH-200, JWH-019, AM-2201, JWH-122, JWH-398, JWH-022, JWH-210, JWH-015, JWH-081, JWH-020, JWH-250, HU-210, AM-694, STS-135, and XLR-11. The method tests for synthetic cannabinoids in urine and saliva.

The method is validated in concentration range of 100pg/mL – 1,000ng/mL with a Lower Limit of Detection (LLOD) below 100pg/mL and a Lower Limit of Quantification (LLOQ) at 100pg/mL. The method is linear in the aforementioned quantification range. The method was tested for matrix suppression and enhancement and none was seen in the quantification window as defined as ±25%. Imprecision has a specification limit of ±20% for all compounds; however, repeated injections (n=10) were under ±10%. Similarly, inaccuracy has a specification limit of ±20%. The method was tested to be accurate at three concentrations (low=250pg/mL, medium=50ng/mL, and high=650ng/mL) for repeated injections (n=10).

Urine samples are hydrolyzed, spiked with internal standards, and injected on the turbulent flow column. Saliva samples are spiked with internal standards, filtered, and injected onto the turbulent flow column. Standards are purchased from Cayman Chemical and Cerilliant. Mobile phase was water and methanol with ammonium formate and ammonium acetate additives. All samples were run on a Transcend TLX-2 (Thermo Scientific) coupled to a Exactive Orbitrap (Thermo Scientific). Run time for the method was under 8 min.

This method is comparable to the quantitative method previously developed at Western Slope Laboratory for synthetic cannabinoid confirmatory services. The drug-monitoring method was able to compare to the confirmatory method for the eight compounds in the confirmatory method; those compounds are JWH-200, JWH-018, JWH-018 N-pentanoic acid, JWH-073, JWH-073 N-Butanoic Acid, AM-2201, AM-694, and HU-210. The quantifiable results were similar (±10%).

In conclusion, a drug-monitoring method was developed to allow for detection of 30 synthetic cannabinoid compounds and metabolites to help in the fight against the use of these compounds. This method allows for both confirmatory testing as well as unknown identification. With this type of methodology, laboratories can now be more proactive.

Synthetic Cannabis, LC/MS/MS, Urine and Saliva

K81 Designer Stimulants and Hallucinogens in Routine Casework

Sherri L. Kacinko, PhD, Wendy R. Adams, PhD, and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to discuss the type and frequency of synthetic stimulants and hallucinogens seen in routine casework at a large reference laboratory.

This presentation will impact the forensic science community by providing a comprehensive review of designer drugs being seen in routine postmortem and human performance casework.

Over the past several years, the forensic toxicology community has been challenged with the emergence of large numbers of designer stimulants and hallucinogens in products commonly referred to as "Bath Salts." The speed at which the drug-using community is able to adjust to new legislation and find compounds that are not specifically scheduled has mandated a mechanism to quickly add new compounds to the scope of routine testing. A protocol was developed to rapidly expand the Deconvolution Reporting Software (DRS) library for the Gas Chromatography/Mass Spectrometric (GC/MS) screen used in the laboratory.

Data was extracted from the laboratory information management system for all GC/MS screening analyses from January 1, 2012, to July 26, 2012. All cases in which the presence of at least one

designer drug was indicated were included in the data analysis. A total of 178 such cases were identified. Pentedrone was the most prevalent compound identified (42 cases), followed by alpha-pyrrolidinopentiophenone (Alpha-PVP, 41 cases), dimethylamylamine (DMAA, 36 cases), and methylenedioxypyrovalerone (MDPV, 26 cases). Other drugs identified were methylone (16), 4-methylethcathinone (10), methylbenzylpiperazine (7), pentylone (5), butylone (5), ethylone (4), dimethylamphetamine (4), 3,4-dimethylmethcathinone (3), 1,4-dibenzylpiperazine (3), buphedrone (3), methoxetamine (2), 2C-I (2), and 1 case each of paramethoxymethamphetamine, 2C-H, 5-MeO-DALT, and paramethoxyamphetamine. Twenty-eight cases included multiple compounds. Nine of these contained didesmethylsibutramine, a metabolite of the diet drug sibutramine, but no sibutramine.

The compounds commonly found in "Bath Salts" generally fall into one of several classes of compounds, substituted phenethylamines, beta-keto cathinones, tryptamines, or piperazines. They are abused for their stimulant and/or hallucinogenic properties. The mechanism of action has not been elucidated for each compound. They generally elicit their effects by acting on serotonergic and dopaminergic receptors or by stimulating the production of related neurotransmitters. DMAA has been detected in "Bath Salts" products, specifically "PumpIt Powders," but is not structurally similar to other common bath salt compounds. It is widely available as a supplement and used by body builders and is believed to stimulate the release of catecholamine. It does not work directly at adrenergic receptors. While 92% of cases which had a positive screen for DMAA did not appear to contain any other "Bath Salt," three cases contained DMAA in combination with other compounds. One also contained Alpha-PVP and didesmethylsibutramine, one contained only Alpha-PVP, and one contained methylone.

The review of seven month's worth of routine GC/MS screening data confirms the necessity of establishing a method able to detect designer stimulants and hallucinogens. These compounds are relevant to both postmortem investigations and as substances which can potentially impair driving.

Designer Drugs, Bath Salts, Postmortem

K82 Postmortem Pediatric Toxicology

Robert A. Middleberg, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090; Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Ter, 850 Bryant St, San Francisco, CA 94103; Daniel S. Isenschmid, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090; Margaret Greenwald, MD*, 37 State House Station, Augusta, ME 04333; and Lucas Zarwell, MFS*, OCME, 1910 Massachusetts Ave, SE Bldg. 27, Washington, DC 20003*

After attending this presentation, attendees will gain an appreciation of the challenges unique to toxicological findings in postmortem pediatric cases. Attendees will learn interpretive guidelines for pediatric cases involving forensic toxicology in both a general and case-specific sense.

This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in the pediatric population.

In this 14th Annual Special Session within the Toxicology section, pediatric cases involving toxicological findings are discussed. As a relative dearth of interpretive information exists involving toxicological findings in the pediatric population, this session is a forum to help elucidate and clarify such issues. The format is a short case presentation including pharmaco-toxicokinetic data and other relevant ancillary information followed by audience participation to provide interpretive clarity around the case-specific impact of the toxicological findings. This session, attended by various sections of the Academy, allows for various perspectives of case issues that lead to integrative consensus, or differing opinions, as to cause-of-death in children.

Dan Isenschmid, PhD, will be presenting a case where a 2-month infant was characterized as being "colicky." The teenage mother, an illegal alien from Mexico, may have seen a doctor in Mexico and received medications for the infant. The infant died after administration of the obtained substances. Specimens obtained at autopsy were analyzed and determined to contain acetaminophen, metoclopramide, and chlorpheniramine, at concentrations potentially adversely affecting the health of the child. The pharmacology of these agents as well as potential toxicity to the infant will be discussed.

Peggy Greenwald, MD, will be speaking to a case involving α-PVP and pentylone in a 1-month-old infant. These relatively new compounds to the drug scene belong to the class of substances more commonly referred to as "bath salts." Case studies involving the presence of such compounds in infants are indeed rare today. This case study will reflect on the pharmacology and toxicology of these compounds and strive to ascertain expected effects in infants.

Lucas Zarwell, MS, will discuss two cases of uncommon toxicological findings in children. The first case involves a 2-year-old that complained of "hotness." This finding was accompanied by shaking, sweating, and gasping for air. The child became non-responsive and, despite resuscitative efforts, died. Toxicological findings demonstrated a fatal concentration of chloroquine and metabolite. Chloroquine is used in children for the treatment of malaria. As little as 1g is potentially fatal in a child. The second case involves a 6-year-old who was found in seizure. She died 2 hr later and had a negative autopsy. Toxicological analyses demonstrated a fatal concentration of the atypical antidepressant bupropion. Bupropion is used in children for such conditions as ADHD. Seizures are a minor side effect of bupropion administration in children, but have been reported.

The case studies presented reflect current-day findings in medicolegal investigations of childhood deaths. In years past, discussions of these types of cases have been educational and demonstrative of the issues in this special population. Only through these continued case studies and audience participation can there be shared perspectives on the meaning of the toxicological findings.

Pediatric, Toxicology, Postmortem

LW1 Martin Frobisher's Gold: Forensic Inquiry of a 16th-Century Explorer's Findings

Robert N. Anderson, PhD, RNA Consulting, Inc, 27820 Saddle Ct, Los Altos Hills, CA 94022*

After attending this presentation, attendees will have an understanding of the early exploration of the search for a Northwest Passage from England to China, and of the life of an English sea captain. In addition, they will learn of the mystery of the iron blooms.

This presentation will impact the forensic science community by providing an understanding of the investigative procedures akin to the type of forensic inquiry used in the 1981 Smithsonian expedition to this area.

Martin Frobisher (1535–1594) was an English sea Captain, an Admiral in the sea battle with the Spanish Armada, and a privateer.[1] With the funding help from an English merchant consortium company, he commenced a search for the Northwest Passage to China. He sailed June 7, 1576 with three ships and 35 men. He reached Baffin Island in Northeastern Canada on August 18, 1576. He was prevented from searching further for the Northwest Passage because of heavy ice. During his time ashore, he collected a few specimens of black rocks.

Isobel, Martin Frobisher's indignant spouse of 17 years, spurned a gift of a black rock on his return from his four-month voyage and tossed it into the fireplace. When the rock was later retrieved, it sparkled "with a bright marquesset of golde," causing the start of both the largest Arctic exploration ever organized and gold fever.

A frenzy of investing groups formed, new financial paradigms were developed, and a second voyage of 145 men including miners and soldiers, arrived at the mouth of Frobisher Bay July 17, 1577. The voyagers returned on September 23, 1577 with about 200 tons of "black ore."

A third voyage started with 240 men on June 3, 1578, with 15 ships and ended October 6, during which 1,360 tons of "black ore" were collected. The "black ore" was taken to a specially built smelting plant in England and proved to be valueless. The black rock was principally Hornblende and the gold content was less than one ppb. The "marquesset of golde" was not iron pyrite, as previously thought, but was biotite.

Despite the failure to find gold, Martin Frobisher was determined to be an innocent participant and exonerated as a swindler. The guilty parties appear to be the metallurgists who performed the fire assays. The "black ore" was found to be useful for filling potholes in roads.

The interest in the Martin Frobisher voyages was reawakened by Charles Francis Hall, an American explorer who in 1861 visited Kodlunarn, or "white man's island," in Frobisher Bay. Among other items, Hall collected lumps of iron. These iron blooms were later Carbon-14 dated to 1100 A.D., centuries before Frobisher landed. For this reason, a Smithsonian expedition set out to explore Kodlunarn in August of 1981.[2] The source of these pre-Frobisher items is still a mystery.

The three voyages of Martin Frobisher failed to discover the Northwest Passage to China and India. Scholars believe this caused a loss of interest in Arctic exploration and turned British interest to colonization and exploitation of the more southern regions of the New World. Although, after the unsuccessful Arctic voyages, Martin Frobisher went on to command the largest of the Queen's ships, the Triumph, in the sea battles against the Spanish Armada.

Martin Frobisher died from a gunshot wound received while leading his marines in the attack of a Spanish garrison.

This presentation will describe the lure of gold that drove the 16th-century exploration of the Northwest area and the mystery that surrounds the artifacts left by Frobisher's adventures.

Frobisher, Northwest Passage, Kodlunarn

LW2 The Continuing Journey of the Mortal Remains of St. Damien: The "Leper Priest of Molokai"

Vincent J. Sava, MA, JPAC, Central Identification Lab, 310 Worchester Ave, Bldg 45, Hickam AFB, HI 96853*

After attending this presentation, attendees will appreciate St. Damien of Molokai as a historical figure and the role forensic science played in the preservation of his remains.

This presentation will impact the forensic science community by showing applications of forensic anthropology to a case involving the remains of a historical figure.

Health and disease influence the histories and cultures of any region. The legacy of leprosy in Hawaii is one of horrific and heartbreaking suffering, unimaginable hardships, as well as inspirational and heroic sacrifice, all leading to the sainthood of two individuals. One of these saints, Father Damien of Molokai, is the subject of this presentation which is also an update of a 2003 Last Word Society presentation on this topic.

A hundred years after Western contact, introduced diseases had scythed the Native Hawaiian population from 300,000 down to 50,000 people. Leprosy afflicted up to five percent of Native Hawaiians by the 1870's. To halt its spread, the Hawaiian authorities segregated patients. In 1866, several hundred patients were exiled to a "colony" on the isolated Kalaupapa peninsula on the island of Molokai. Geography makes the peninsula a natural prison. Ravaged patients were unable to climb the 2,000-foot cliffs comprising the colony's southern border or swim the rough shark-infested seas ringing its other three sides.

The early days of the colony were grim. Law and order were absent, there was inadequate shelter, little food, filthy water, scant medical care, and no hope. Half of the 800 patients arriving between 1866 and 1873 died within two years. Father Damien DeVeuster, a Belgian priest, arrived in 1873 and worked tirelessly to establish a quality of life for his patients. Father Damien died of leprosy in April 1889 at the age of 49 and was buried on Kalaupapa.

As in life, Father Damien did not rest too long in one place. In 1936, at the request of the Belgian government, Father Damien's remains were returned to his homeland. Father Damien's travels would have ended there if not for a 37-year-old French nun. Sister Simplicia Hue fell ill in February of 1895 with an acute and severely painful gastrointestinal condition—possibly ulcerative colitis, cancer, or diverticulitis. Near death, Sister Simplicia prayed for intercession by Father Damien, whose picture hung next to her deathbed. On September 11, Sister Simplicia became comatose. Early in the morning of September 12; however, she awoke pain free and ate a hearty breakfast. Sister Simplicia lived for another 32 years without any recurrence of her illness.

A sainthood cause began for Father Damien in 1938. In 1956, Belgian pathologists examined his remains as a requirement for

sainthood. In 1991, Sister Simplicia's cure was declared miraculous. Consequently, Father Damien was declared a Christian hero in 1995, resulting in another journey. Father Damien's right hand was reinterred in its original grave on Molokai.

In 1998, after praying at Father Damien's grave, Audrey Toguchi, from Hawaii, was cured of terminal cancer of the fat cells that had metastasized to her lungs. This miracle led to Father Damien's canonization as a saint on October 11, 2009 in Rome. Hundreds of Hawaiian islanders attended the ceremony. St. Damien would undertake another journey.

The Bishop of Honolulu requested from the Church in Belgium a relic of St. Damien for enshrinement in Hawaii. Rather than re-open St. Damien's crypt, officials instead selected a relic that was inexplicably left out of the crypt during the 1956 examination. The relic was a poorly preserved partial talus, side undetermined.

The relic had significantly deteriorated during its trip from Belgium to Rome and Hawaii. The Bishop requested assistance from the author regarding its conservation. The Central Identification Laboratory, Hawaii received the relic as an unofficial case on October 19, 2009. Time was donated to the conservation effort. Further deterioration was halted by treating the bone with a polymer. The relic was confirmed as a left talus.

The relic is currently enshrined in the Cathedral of Our Lady of Peace in Honolulu, thus completing, for now, the travels of the mortal remains of St. Damien.

Leprosy, Human Remains, Religious Relics

LW3 Slavery in Illinois: John Hart Crenshaw and the Old Slave House

Darlene Shelton, PhD, 3 Taliar Ridge Rd, Guilford, CT 06437*

After attending this presentation, attendees will become familiar with an elaborate interstate criminal enterprise for kidnapping, enslaving, trafficking, and breeding free African-Americans that operated in Southern Illinois and neighboring states from 1840 to 1860.

This presentation will impact the forensic science community by providing information to those who are involved with missing persons, kidnapping, human trafficking, slavery, and torture.

From 1840 to 1860, while Abraham Lincoln was establishing his reputation as a talented orator, attorney, and politician in Southern Illinois, another individual, John Hart Crenshaw was creating an interstate crime organization fueled by greed, cruelty, corrupt politics, and callous disregard for the law. Based in the town of Equality, Illinois, the criminal operation preyed on freedmen and their families drawn to Southern Illinois by fertile farmland and large communities founded by former slaves—Locust Grove in Williamson County and Miller's Grove in Pope County. Crenshaw's Gallatin County adjoined these settlements and his crime ring was dedicated to kidnapping, enslaving, and breeding his African American neighbors, including children as young as seven-years-old.

John Hart Crenshaw employed an elaborate criminal network of family and friends, using hideouts and holding stations in Western Kentucky, Southern Illinois, and an area of Missouri that stretched from St. Louis to the southern tip of the state's boot heel. He successfully laundered his criminal profits through legitimate businesses, while his occasional brushes with the law were inconsequential. Crenshaw and his wife, the former Sina Elizabeth Taylor, enjoyed a prominent place in local society. Crenshaw's wealth and land grew exponentially as he exploited the slave labor of his kidnapped victims to mine salt from the natural mineral-rich springs of present day Saline County.

As Crenshaw's interests grew, he sought to expand his political influence. He was one of the few Illinois Democrats to support a system of internal improvements, and probably conferred with one of the system's staunchest proponents, the Whig minority leader, Illinois Representative Abraham Lincoln. Local tradition says that Crenshaw held a dance in Lincoln's honor and hosted him overnight in his home, the Hickory Hill Plantation House. Built in 1838, the Hickory Hill Plantation House, known today as "The Old Slave House," still stands and is the only remaining structure of its type. The house was specifically designed to hold kidnapped African-American men, women, and children. The captives were held on the third floor, which includes a series of small wooden cells, a whipping post, and markings on the floors and walls from chains and leg irons which restrained the victims.

Crenshaw's kidnapping and slavery operation was one of the longest operating slavery rings in U.S. history. His cruelty and sexual depravity became legendary and still persist in the oral tradition of Southern Illinois.

Kidnapping, Slavery, Racketeering

LW4 Finding Amelia Earhart With Forensic Science

Richard Gillespie, BA, TIGHAR, 2812 Fawkes Dr, Wilmington, DE 19808*

The goal of this presentation is to review what The International Group for Historic Aircraft Recovery (TIGHAR) has learned in applying forensic techniques to evidence uncovered during our investigation of the Earhart disappearance. Contrary to the general public's misconception that forensic science is only of use in confirming or disproving "smoking gun" evidence, TIGHAR uses forensic analysis whenever possible to quantify aspects of the investigation that would otherwise be left to subjective judgment. In that sense, forensic findings serve as stepping stones in a sea of speculation; but, because they often direct the course of the investigation and the budgeting of scarce resources, it is important to have crucial findings verified and lab results replicated by independent, disinterested sources. It has also been learned that in some rapidly-evolving forensic disciplines such as DNA research, there are misconceptions – even among professionals – about what is and is not possible. Unrealistic optimism can burden field work with time-consuming and expensive procedures while fostering high expectations that result in unnecessary disappointment.

This presentation will impact the forensic science community by providing an example of how a nonprofit institute that is not directly affiliated with government, academia, or law enforcement is using forensic analysis to solve an iconic historical mystery.

In its ongoing investigation of the 1937 disappearance of famed female aviator Amelia Earhart, The International Group for Historic Aircraft Recovery (TIGHAR), a nonprofit aviation history institute, has drawn upon a variety of forensic disciplines in assessing evidence gathered during twenty-four years of research and ten archaeological expeditions to the uninhabited South Pacific atoll where Earhart and her navigator appear to have met their fate.

Most of TIGHAR's forensic work is done on a volunteer basis by scientists who are members of the organization. When outside expertise is needed, TIGHAR often receives assistance from government agencies and, when necessary, contracts with specialists and laboratories. Examples include:

- Forensic anthropologist and TIGHAR member, Karen Ramey Burns PhD, University of Georgia and forensic anthropologist Cecil Lewis PhD, Molecular Anthropology Laboratories, University of Oklahoma have performed forensic examination of bones and bone fragments suspected of being Earhart's. Some specimens have been eliminated. Others await further study.
- Small broken bottles recovered from a site on the island where a castaway's remains were discovered in 1940 have been identified by a variety of forensic techniques as having contained products of American manufacture marketed to women in the 1930s.

- Forensic analysis of historical photos has been key to TIGHAR's Earhart investigation, enabling TIGHAR field teams to locate important archaeological sites on the island and, most recently, evaluating a photo that may show debris from the Earhart aircraft on the island's fringing reef three months after the disappearance. Forensic imaging specialist and TIGHAR member Jeff Glickman determined that an anomalous object in the photo is consistent with the landing gear of Earhart's aircraft. The U.S. State Department Bureau of Intelligence & Research Photo Imaging Section replicated his findings.

The riddle of Amelia Earhart is being solved through the application of rigorous historical research, sound archaeological field work, and meticulous forensic examination.

Earhart, History, Aviation

LW5 Losing Your Hair in Missouri — The Centralia Massacre and Scalping by Missouri Guerillas in the American Civil War

Thomas P. Quinn, JD, 355 S Teller St, Ste 200, Lakewood, CO 80226*

WITHDRAWN

LW6 DNA and Forensic Anthropology in Trial of a Cold Case

J. Christopher Anderson, JD, 700 Adams St, Ste 250, Toledo, OH 43624*

After attending this presentation, attendees will understand the practical difficulties of a multi-jurisdiction cold case investigation, the forensic tools used in the investigation, and the evidentiary issues in a trial of a murder that occurred more than 40 years earlier.

The presentation will impact the forensic science community by providing information from a case study from the discovery of a 14-year-old girl's body until the trial and conviction of her murderer, some 44 years later.

On December 18, 1967, 14-year-old Eileen Adams left school on a public bus in Toledo, Ohio. She was expected to arrive at her sister's house at 3:30 p.m. A friend saw her on the bus but Eileen never made it to her sister's house. Forty-four days later, a hunter found her body in Monroe County, Michigan. Her body was dressed in clothing she wore to school the day she disappeared. She was hog-tied and a tenpenny nail protruded from her skull. The Monroe County coroner concluded that the homicide was caused by probable strangulation, without any mention of a hyoid bone. The investigation turned up no suspects and the case went cold.

Five years after Eileen disappeared, Margie Bowman reported to Toledo Police that in December 1967, she was living with Robert Bowman in Toledo and had recently given birth to their daughter, Brenda. She opened a door in the basement to investigate a noise and saw a young girl, naked, tied to the wall, "like Jesus." Robert threatened to kill both Margie and Brenda, and he made Margie go with him when he drove the girl's body into Michigan. Margie and Robert moved soon after, and Margie left Bowman while they were living in Miami, Florida.

After Margie's report, detectives located Bowman living in a burned out Miami restaurant. A Spiderman doll with a needle pushed between its eyes hung upside down on one wall, and a tenpenny nail was stuck in the back of the head of a Mattel® Ken doll. Interviews of Bowman failed to provide evidence sufficient to support charges and the case went cold again.

In September 2006, the Toledo Cold Case Unit reopened the case. A partial DNA profile was obtained from semen in Eileen's underwear, but Bowman's profile was not in CODIS. However, a reverse paternity test compared Brenda's profile to the sample obtained from Eileen's underwear. The test results indicated that Bowman could not be excluded as the source of the DNA and a warrant was issued for his arrest. In 2008, he was located in Riverside, California where he was homeless. He waived extradition and was returned to Ohio.

Before trial, Eileen's remains were exhumed. The hyoid bone was not found in the exhumation. Three forensic anthropologists concurred that Eileen had at least five blunt force injuries to her head. The injury to her forehead was the most severe, causing a linear fracture that ran the entire circumference of her skull. The anthropologists concluded that she died of blunt force trauma.

The trial was held in August 2011 but resulted in a hung jury. Bowman was convicted when he was retried and at the age of 76 was sentenced to life in prison.

DNA, Forensic Anthropology, Cold Case

LW7 A Producer's Wife, One Cliff in Malibu, and a Decapitated Head — Two Cases Utilizing Forensic Art

Sandra R. Enslow, BA, 4700 Ramona Blvd, Rm LL40, Monterey Park, CA 91754*

After attending this presentation, attendees will understand some of the various aspects of the forensic art discipline and its function in a criminal investigation.

This presentation will impact the forensic science community by raising awareness of the forensic art discipline. Two very different cases will illustrate the use of forensic art, both under difficult circumstances. The first case presented is a composite that corroborated identification of the suspect; and the second case, a postmortem drawing that assisted in the identification of the victim of decapitation. Though it is ideal for a forensic composite to elicit an outright identification, they do not need to identify a suspect directly to be successful. Many forensic composite artists work in the field, in the media, in the public, and in the courtroom for the jury.

The first case involves the victim of an attempted rape. Out for an early morning jog along the cliffs, a woman, a mother and wife of a TV producer, stopped to sit and meditate with the rising sun, when she was attacked. After a lengthy struggle with her attacker, she was able to get near the cliff. Rather than face what the attacker was offering, she made the decision to take the plunge off the cliff (100') in Malibu, California – leaving her car keys behind. She survived the fall but gave up her car to her assailant. DNA found on a tequila bottle at the crime scene would ultimately identify the suspect. The conditions under which the drawing was created were not ideal, yet the victim was willing and eager to describe the assailant, despite her injuries. The final composite had similarities to the booking photo and played a supporting role in the courtroom as jurors considered all of the evidence before them. The forensic drawing did not elicit a direct identification but supported the other disciplines in the investigational process. The victim, the local media, and ultimately the jury saw the likeness and agreed.

The second case presents a 1995 homicide in the Santa Clarita Valley region of Southern California. The investigation required a postmortem forensic drawing, not a composite, to be created. The forensic image, created from the views of the victim's decapitated head, ultimately allowed a sister to recognize and subsequently identify her missing and troubled younger brother. This is the case of Frederick Walker, who was beaten, beheaded, and dismembered by two of his associates for $635.00. The course of this very convoluted case includes U.S. Forest Service undercover agents and a fifteen-year-old girl and her mother. The Los Angeles County Sheriff's

Department forensic artist testified to her work in each defendant's trial. After both trials were over, the victim's sister met with the detective and forensic artist. Since she didn't have a picture of her brother as an adult, and felt the forensic drawing was an accurate reflection of him, she asked if the family could have it.

This presentation will examine the interesting turns in each of these cases. How forensic art supported the investigations, in the field and in the courtroom, will be highlighted.

Forensic Composite, Postmortem Drawing, Homicide

LW8 The Titanic Identification Project: Lessons Learned

J.E. Molto, PhD, Univ of Western Ontario, London, ON N6A 5C2, CANADA; Scott I. Fairgrieve, PhD, Laurentian Univ, Dept of Forensic Science, 935 Ramsey Lake Rd, Sudbury, ON P3E 2C6, CANADA; and Ryan Parr, PhD, Mitomics, Inc, 209 Munroe St, Thunder Bay, ON P7A 7P1, CANADA*

The goal of this presentation is to illustrate the multifaceted nature of historic investigations highlighting the importance and problems of mitochondrial DNA (mtDNA) testing in such cases.

This presentation will impact the forensic science community by showing how mtDNA testing holds the key to final identification of unknown human remains when there is sufficient verifiable DNA and compliant known mitochondrially related relatives.

Hypothesis: mtDNA testing holds the key to final identification of unknown human remains when there is sufficient verifiable DNA and compliant known mitochondrially related relatives.

Methods: Pedestalling excavation techniques, dental aging, and amplification and sequencing of mtDNA in both the coding and non-coding regions of the mitochondrial genome.

All forensic cases, including those of historic interest, begin at the scene. In May of 2001, permission was obtained to exhume and identify three bodies from the Titanic disaster buried in the Fairview cemetery in Halifax, Nova Scotia, using mtDNA. As part of this research living relatives of the targeted individuals were identified and permission to secure their mtDNA was also obtained. The genealogical sleuthing was carried out long before the excavation. After failing to obtain any biological material from two adult skeletons where a backhoe was used directly over the bodies, the potential of DNA recovery from a child burial (#4) seemed remote. The decision to pedestal the child burial was made despite time restrictions. The change in excavation strategy was rewarded by the recovery of a long bone fragment and several tooth buds. The fact that the organic remains were submerged in water did not auger well for the preservation of mtDNA despite the fact that the remains had been interred for less than a century (April of 1912). Historically, "burial 4" had always been assumed to be Gösta Pålsson a 28-months-old Swedish boy. Immediately, the examination of the tooth buds for damage clearly indicated a much younger individual, approximately 1 year $\pm$3 months of age using Caucasian dental standards, and verified in blind by three experts. This information was withheld (blind design) from the DNA part of the investigation. Surprisingly, DNA was amplified both from the bone and dentin with the HV1 and HV2 regions of the mitochondrial genome being targeted. Of six children who could potentially be identified as "burial 4", two individuals, Eino Panula a Finish child aged 13 month and a British child Sidney Goodwin aged 19 months, were clearly the closest fit with the dental and non-biological (shoe) evidence. Both had the same and common HV1 and HV2 Caucasian haplotypes. In a PBS documentary, the Titanic Identification Project's final puzzle was aired with the Panula family placing a reef of flowers around the grave of the now known child. However, several aliquots from the dentin of "burial 4" were saved and continued DNA testing for SNPs from the non-coding region by the Armed Forces DNA Identification Laboratory resulted in Goodwin being identified as the unknown child via a rare SNP (T9923C?). Many lessons were learned through this collaborative research program:

- Despite time restrictions using a proper recovery method was fundamental for the whole project – no sample, no testing!
- Assume nothing – water destroys DNA but in this case even with fragmentary from a sub-adult verifiable mtDNA was obtained by several labs.
- Dental standards have to be population specific, and with single samples, the standard deviations are just a guideline. The Goodwin child was outside two standard deviations.
- All research, where possible, should be done in blind, an obvious but often overlooked aspect of forensic research.
- With common mtDNA HV1 and HV2 haplotypes the use of variation in the non-coding regions is fundamental and should possibly be mandated for all forensic testing.

Conclusions: This project shows the problems associated with making assumptions based on previous research (e.g., can't get DNA from waterlogged samples) and the importance of continued DNA testing especially when dealing with common mtDNA haplotypes.

mtDNA, Excavation, Aging

Program Committee Disclosure

As a sponsor of continuing education, the American Academy of Forensic Sciences must insure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty participating in a sponsoring activity are expected to disclose any significant financial interest or other relationship: (1) with the manufacturer(s) of any commercial product(s) and/or provider(s) of commercial services discussed in an educational presentation; and, (2) with any commercial supporters of the activity. (Significant financial interest or other relationship can include such things as grants or research support, employee, consultant, major stockholder, member of speaker's bureaus, etc.) AAFS has an established policy regarding conflicts of interest that includes decisions the Program Committee members may make in selecting content for the Annual Scientific Meeting Program. By serving on the committee, regardless of role, each member has agreed to comply with Section 1.4.7. of the *AAFS Policy and Procedure Manual*.

To serve on the 2012-13 Program Committees, it is required that relevant AAFS staff members, program committee members, and/or reviewers complete a Financial Disclosure form before they are provided access to review submissions for the program. For continuing education accreditation purposes, the disclosed relationships are published below so that learners are aware of the nature of any relationships that may impact the selection of presentations for the program. If a committee member failed to provide complete disclosure of a relevant financial interest or relationship, the committee member or reviewer was not allowed to serve. The executed Faculty Disclosure Forms are on file in the AAFS Office.

Faculty Disclosure

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have related to the content of their presentation(s). The existence of commercial or financial interest of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s); however, disclosure should help participants form their own judgments. AAFS and the Program Committee review the submissions to ensure that the content is educational and not a commercial presentation for companies and their products. Participants may notify AAFS by email (abstracts@aafs.org) should any presentation be considered solely a commercial endorsement presentation. Notification should include presentation number/ID (e.g., BS10, E100, W30) and speaker name.

If an author failed to provide complete disclosure of the discussion of commercial products, a relationship with the manufacturer including employee/employer relationship, sources of support for the research project, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted. Authors are required to disclose at the beginning of each presentation any information disclosed and listed below. Copies of the executed disclosure forms are kept on file in the AAFS Office.

65th Anniversary PRESENTING AUTHOR INDEX 1948 - 2013

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2013 AAFS Anniversary Meeting. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Criminalistics	J	Questioned Documents
B	Digital & Multimedia Sciences	K	Toxicology
C	Engineering Sciences	LW	Last Word Society
D	General	BS	Breakfast Seminar
E	Jurisprudence	ES	Evening Session
F	Odontology	L	Luncheon
G	Pathology/Biology	S	Special Session
H	Physical Anthropology	W	Workshop
I	Psychiatry & Behavioral Science
