S1 A National Forensic Sciences Enterprise and Transparency in Forensic Science: Legal and Practitioner Views on our Path Forward

Kenneth E. Melson, JD, George Washington University School of Law, 2000 H St NW, Washington, DC 20052; Dean M. Gialamas, MS*, Los Angeles County Sheriff's Office, Scientific Services Bureau, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032; Michael T. Ambrosino, JD*, U.S. Attorney's Office, 555 4th St NW, Washington, DC 20001; Steven D. Benjamin, JD*, Benjamin & DesPortes, PC, PO Box 2464, Richmond, VA 23218-2464; Barbara Parker Hervey, JD*, Texas Court of Criminal Appeal, PO Box 12308, Capitol Station, Austin, TX 78711; Reggie B. Walton, JD*, U.S. District Court, 333 Constitution Ave NW, Rm 2428, Washington, DC 20001; Joe S. Cecil, PhD, JD*, Federal Judicial Center, Director of the Scientific Evidence Project, Washington, DC; Laura L. Liptai, PhD*, BioMedical Forensics HQ CA/FL, 1660 School St, No 103, Moraga, CA 94556; Carla M. Noziglia, MS*, ICITAP, 305 Ascot Dr, Aiken, SC 29803-7833; Robin W. Jones, BS*, U.S. Dept of Justice, 99 New York Ave, NE, Washington, DC 2002; and Robert E. Barsley, DDS, JD*, LSU School of Dentistry, Oral Health Resources, Rm 5345, New Orleans, LA 70119*

Educational Objective: The goal of this session is to take part in hearing the points of view from several diverse perspectives.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by developing awareness and hopefully consensus on the roadmap for our forensic science future.

An effective justice system is the cornerstone of freedom in the United States and abroad. Forensic science plays a critical role for which there is shared responsibility among the stakeholders in the criminal justice arena. The National Academy of Sciences recognized this important role and has articulated the critical need for strengthening forensic science in the United States. Efforts have been underway in the four years since the NAS Report to create our path forward to further strengthen forensic science. This is an opportunity to provide input and to help create our forensic science path forward.

Presenters from the Subcommittee on Forensic Science, along with representatives from the crime laboratory, judiciary, defense, and prosecution communities, will thoughtfully consider, discuss, and refine the future opportunities and challenges for forensic science. With a critical eye toward implementation, the infrastructure to support enhancing quality in forensic science, including standards and competency, will be paramount. The goal for this session is embodied in President Robert Barsley's theme for the Annual Meeting "*The Forensic Sciences: Founded on Observation and Experience, Improved by Education and Research,*" as well as the objectives of the American Academy of Forensic Sciences: *To promote professionalism, integrity, competency, education, foster research, improve practice, and encourage collaboration in the forensic sciences.*

Subcommittee on Forensic Science — Kenneth Melson, Professorial Lecturer in Law at the George Washington University Law School will discuss the forensic science issues studied by the NSTC Subcommittee on Forensic Science. These issues provide a foundation to meet the needs of the criminal justice system through a uniform, national forensic science enterprise. Kenneth Melson comes to us with a background in law and forensic science as a state and federal prosecutor, Past President of the AAFS, a former and long-time member of the ASCLD/LAB board of directors. He also served as the co-chair of the Subcommittee. Robin Jones will discuss the need for robust standards development processes and their use by Scientific Working Groups. Robin Jones is the principal of RWJ Consulting Services and has served as the Executive Secretary for the Subcommittee on Forensic Science, the Executive Assistant for the National Commission on the Future of DNA Evidence established by Attorney General Reno, and developed and executed Attorney General Ashcroft's Initiative on DNA Laboratory Backlogs. She has also contributed to the development of many publications and training tools for the National Institute of Justice in the area of forensic science.

Crime Laboratory Perspective — Consensus and cooperation from the entire range of forensic science service providers, from full-service crime laboratories to law enforcement identity units, are essential to advancing the quality of forensic science. Dean Gialamas is the Director of the Los Angeles County Sheriff's Department Scientific Services Bureau and has over twenty-two years of experience in forensic science. He is an accomplished author and instructor, and has been a leading-edge innovator in forensic science laboratory management. His insights will reveal the impact that forensic science reform will have on the quality and efficiency of the crime laboratory's work and whether the proposed reforms have gone too far, or not far enough.

Prosecution and Defense Perspectives — Advocates representing the defense and the state have important perspectives helpful to the creation of a fair and balanced system of adjudication. Steve Benjamin, President of the National Association of Criminal Defense Lawyers and a Richmond, VA, defense lawyer will explicate the needs of the defense community and the impact of the recommendations for improving forensic science. As Special Counsel to the Virginia Senate Courts of Justice Committee, a member of the Virginia Board of Forensic Science, the Virginia Indigent Defense Commission, and a Past President of the Virginia Association of Criminal Defense Lawyers, Mr. Benjamin is a 2003 recipient of the Virginia State Bar's Lewis F. Powell Pro Bono Award. He was also counsel in the landmark Virginia Supreme Court decision recognizing a constitutional right to forensic expert assistance at state expense for indigent defendants.

Michael Ambrosino is Special Counsel for DNA and Forensic Litigation in the United States Attorney's Office for the District of Columbia. Since 1989, he has been a federal trial attorney and prosecutor in the civil, fraud, homicide, and appellate divisions of the office. In 2010, Mr. Ambrosino was designated by the United States Attorney as Special Counsel to represent the United States in cases involving DNA and other forensic science disciplines. His duties include handling *Frye* and *Daubert* hearings, training assistant prosecutors, coordinating their work with crime laboratories, and overseeing post-conviction DNA testing. His perspective will reflect the challenges prosecutors have in using forensic science in investigations and in court proceedings as well as the ways laboratories can help ensure admissibility of their evidence and just verdicts.

Judicial Perspective — Judge Barbara Parker Hervey was elected to the Texas Court of Criminal Appeals in November 2000. Prior to her election, she was Assistant Criminal District Attorney in the Bexar County District Attorney's Office, Appellate Section for 16 years. In 2008, Judge Hervey formed the Texas Criminal Justice Integrity Unit to review the strengths and weaknesses of the Texas criminal justice system. She served on the Governor's Ad Hoc Committee to Rewrite the Texas Code of Criminal Procedure and received the Appellate Advocacy Award, Regional Awards, Region VI, Association of Government Attorneys in Capital Litigation. She was honored with a Certificate of Appreciation from the San Antonio Police Officers Association, for work on Jonathan Moore vs. State of Texas (Capital Murder of SAPD Officer Fabian Dominguez).

Judge Reggie Walton, United States District Judge for the District of Columbia, was appointed to Judge of the United States Foreign Intelligence Surveillance Court as well as served as the Chairperson of the National Prison Rape Reduction Commission and on the federal judiciary's Criminal Law Committee. While serving on the Superior Court, Judge Walton was the court's Presiding Judge of the Family Division, Presiding Judge of the Domestic Violence Unit and Deputy Presiding Judge of the Criminal Division. Judge Walton also served as President George H.W. Bush's Associate Director of the Office of National Drug Control Policy and as President Bush's Senior White House Advisor for Crime.

Forensic Science, NAS Report, Forensic Standards

S2 Applications of Education and Research to the Diverse Field of Forensic Science

Lindsey E. Saunders, BS, West Virginia Univ, 208 Oglebay Hall, Box 6217, 1600 University Ave, Morgantown, WV 26506; Taryn M. Mead, BS, and Jennifer L. Newton, BS, OME, 850 Bryant St, Bldg 606, San Francisco, CA 94103; Lauren R. Pharr, MA, Louisiana State Univ, Dept Geography and Anthropology, 227 Howe-Russell Geoscience Co, Baton Rouge, LA 70803; Lauren Bryan, PhD, 1115 Brooks St, Shreveport, LA 71101; Jennifer L. Malone, PhD, Wyoming State Crime Laboratory, 208 S College Dr, Cheyenne, WY 82002; Ashley E. Moulton, BS, 84 Howe St, Apt 502, New Haven, CT 06511; Alison P. Mostrom, MSFS, 536 S Clark St, Ste 800, Chicago, IL 60605; Lindsay Saylors, BS, 8703 W 123 St, Palos Park, IL 60464; Amber R. Neitzel, BS, 909 E Camelback Rd, Unit 3016, Phoenix, AZ 85014; Jacquelyn M. Jenkins, PhD, Alabama Dept Forensic Sciences, 2026 Valleydale Rd, Birmingham, AL 35244; Lara Frame, MA, 400 E Jackson St, Richmond, VA 23219; Katherine E. Knurek, 3020 Holly Ln, Westlake, OH 44145; Robert E. Barsley, DDS, JD, LSU School of Dentistry, Oral Health Resources, Rm 5345, New Orleans, LA 70119; Cheryl D. Hunter*, AAFS, 410 N 21st St, Colorado Springs, CO 80904; Carla M. Noziglia, MS*, ICITAP, 305 Ascot Dr, Aiken, SC 29803-7833; Katherine Ramsland, PhD*, DeSales University, 2755 Station Ave, Center Valley, PA 18034; Thomas J. David, DDS*, 1000 Johnson Ferry Rd, Bldg H, Marietta, GA 30068; Christopher W. Rainwater, MS*, OCME, 520 1st Ave, New York, NY 10016; Carolyn Bayer-Broring, MFS*, Immigration and Customs Enforce, 8000 Westpark Dr, Ste 325, OI FDL Stop 5116, McLean, VA 20598-5116; Dan T. Anderson, MS*, Los Angeles County, Dept of Coroner, 1104 N Mission Rd, Los Angeles, CA 90033; Ellen Moffatt, MD*, OME, City & County of San Francisco, 850 Bryant St, Bldg 606, San Francisco, CA 94103; Peter J. Diaczuk, BS*, 445 W 59th St, New York, NY 10019-2925; Josh E. Hanshaft, JD*, 100 United Nations Plaza, Apt 19E, New York, NY 10017; Patricia M. McNeill, JD*, 350 Jay St, Brooklyn, NY 11201; Christine E. Hay, BS*, 3012 Trappers Cove Trl, Apt 2D, Lansing, MI 48910; Angelique Corthals, PhD*, John Jay College of Criminal Justice, Dept. of Forensic Sciences, 899 Tenth Ave, New York, NY 10019; Anjali A. Ranadive, JD*, SciLawForensics, Ltd, 2345 Corinna Ct, State College, PA 16803; Sandra Koch, MFS*, FBI Laboratory, Trace Evidence Unit, 2501 Investigation Pkwy, Quantico, VA 22135; and Roderick T. Kennedy, JD*, New Mexico Court of Appeals, PO Box 25306, Albuquerque, NM 87125-0306*

Educational Objectives: The goals of this special session are to provide forensic science students and professionals with five years or fewer experience an opportunity to learn about the various applications of education and research in forensic science at a day-long session, to present their own work/research at a Bring Your Own Slides session and in a poster session, to learn the skills required to be a successful expert witness at a Breakfast session, and to have an opportunity to network with fellow students, professionals, and AAFS members.

Impact on the Forensic Science Community: This session will impact the forensic science community by demonstrating the vast career paths available in forensic science, how education and research apply to the field, and by providing young professionals with the tools needed to successfully contribute to the forensic science field.

For more than a decade, the Young Forensic Scientist Forum (YFSF) has provided a program for a group of students in both undergraduate and graduate programs, and forensic scientists with less than five years of professional experience. The goal of YFSF and the Special Session is to provide the participants the tools required to be a success in the field of forensic science. The session allows participants to interact with their peers as well as the professional speakers and to build professional relationships that can span a career. Special Session topics provide attendees with a broad outlook at the many opportunities in the field of forensic science. In addition to the special session, YFSF offers two opportunities for young forensic scientists to present their own work or research, the first being the YFSF Bring Your Own Slides (BYOS) session and the second, the YFSF Bring Your Own Posters (BYOP) session. In addition, the Forensic Sciences Foundation's Emerging Forensic Scientist Award Winner is always invited to present their award winning paper.

For the AAFS 65th Anniversary Meeting in Washington, DC, the YFSF Special Session will present: "Applications of Education and Research to the Diverse Field of Forensic Science." The special session will be held on Tuesday, February 19, and include speakers who will discuss the various applications of education and research and the vast career paths within the field of forensic science by presenting their unique casework experiences and career choices. Through the presentations, speakers will demonstrate the different paths a forensic student or scientist can choose to take. The session will include speakers from many of the AAFS sections, highlighting the many opportunities the field may offer. Lunch is provided to both attendees and speakers who are registered for the special session.

Following the Tuesday session, the YFSF BYOP session will be presented in the evening, giving young professionals the opportunity to showcase current cases and research conducted in a poster format.

The annual YFSF BYOS session takes place the evening of Wednesday, February 20, and will include presentations from students and new forensic scientists. YFSF does not require presenters of YFSF BYOS and BYOP to be members of AAFS and does not require they attend the special session but it is encouraged that they do so. The program will conclude Thursday, February 21, with the annual YFSF breakfast session which includes a resume review panel. The breakfast session, which traditionally focuses on professional development, will continue with that theme by presenting "The Role of a Forensic Scientist as an Expert Witness" and will focus on the requirements of expert testimony as a forensic scientist and what it means to be an expert. Following the speaker presentations, professionals throughout the Academy will be available to review resumes, answer questions, and give advice on how to best highlight education and career achievements. As in the past, the Special Session allows students, young professionals, and AAFS members a comfortable setting to foster a career-long relationship throughout the weeklong events. Participants will be encouraged to apply for membership to AAFS and will be given guidance on the many opportunities available to aid in career enrichment.

YFSF, Special Session, Diverse

ES1 150 Years — Does Time Bring Agreement? The H.L. Hunley, the R.M.S. Titanic, and the Assassination of John F. Kennedy

Michael M. Baden, MD, 15 W 53rd St, #18B-C, New York, NY 10019; J.C. Upshaw Downs, MD*, GBI Medical Examiner's Office, 925 A Mohawk Dr, Savannah, GA 31419; Timothy Foecke, PhD*, NIST, 100 Bureau Drive, M/S 8300, Gaithersburg, MD 20899-8300; Maria Jacobsen*, and Paul Mardikian*, Warren Lasch Conservation Center, Clemson Univ Restoration Institute, 1250 Supply St, North Charleston, SC 29405; Cyril H. Wecht, MD, JD*, 1119 Penn Ave, No 404, Pittsburgh, PA 15222-4205; and Robert E. Barsley, DDS, JD*, LSU School of Dentistry, Oral Health Resources, Rm 5345, New Orleans, LA 70119*

Educational Objective: After attending this presentation, attendees will: (1) have a greater understanding of the facts surrounding these events; (2) better understand the uncertainty surrounding them; and, (3) be able to draw conclusions about these events and the uncertainty surrounding them.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by highlighting known and unknown facts and areas for discovery in these three events—headline news in their day—still retaining great interest today.

The loss of the H.L. Hunley, the assassination of President John F. Kennedy, and the loss of the R.M.S. Titanic were newsworthy and were investigated to the extent possible at the time of their occurrence. However, even modern science cannot answer all of the questions raised. This presentation will highlight new discoveries and continuing questions.

H.L. Hunley: In 1864, a Confederate crew boarded the Hunley near Charleston, SC, to launch an attack on the Federal fleet blockading the harbor. A spar-mounted mine filled with black powder was targeted for the USS Housatonic stationed four miles off-shore. Even though spotted by sentries, the surprise submarine attack was so swift that the seamen onboard the Housatonic had no time to train the ship's guns on the Hunley. Handheld weapons fired a barrage of bullets that could not stop the attack. The submariners detonated the mine beneath the ship which sank in moments, becoming the first known submariners to successfully destroy an enemy ship in battle. After the attack, the submarine and its crew mysteriously vanished until 1995, when the Hunley was found buried on the seabed near the wrecked Housatonic. In 2000, the submarine was recovered and brought to the Warren Lasch Conservation Center in North Charleston where an interdisciplinary team performed the excavation, study, and conservation of the Hunley and the remains of its eight-man crew. A primary question the team hoped to answer was what happened to the crew and the submarine on that fateful night. Multidisciplinary collaborations have resulted in the development of a series of new methods and techniques for forensic site reconstruction, documentation, and interpretation which may be useful in modern crime scene investigations.

R.M.S. Titanic: The loss of the "nearly unsinkable" R.M.S. Titanic probably was considered the first mass fatality incident in modern times. Could the chain of events that led to the catastrophe and massive loss of life have been avoided? In the aftermath of the disaster, beginning with the discovery of the sunken ship by Robert Ballard in 1985, much has been explored and documented. Fifteen years of research and numerous expeditions to the wreck site detail how the ship was damaged and sank. Laboratory analysis, computer modeling, and a review of historical documents provide the evidence leading to a conclusion that a combination of management decisions, engineering design, sub-standard materials, combined with a one-in-a-million encounter with an iceberg led to this famous maritime disaster. Details on artifact recovery, conservation, and exhibition will be presented.

John F. Kennedy: It is astonishing that the interest and fascination with the assassination of President John F. Kennedy almost 50 years ago remains so intense and widespread. Few events have generated as much independent research, enthusiastic discussion, and passionate controversy. The event—originally witnessed by several hundred people, and over the past five decades, viewed by tens of millions (via the Zapruder film)—has remained the subject of doubt and outright rejection of the conclusions and official explanation of the responsible investigative governmental entity, the Warren Commission Report (WCR). Polls reveal 70-80% of the American public disbelieve the report. What reasons exist for this negative response? Numerous mistakes were made during the autopsy, performed by a pathologist not trained or certified to conduct autopsies on gunshot victims. In 1977, the U.S. House Select Committee on Assassinations appointed a nine-member autopsy panel of forensic pathologists—all Fellows of the American Academy of Forensic Sciences—to independently re-evaluate the autopsy findings. It concluded that two, and only two, bullets struck the President from behind and that their trajectories showed that they were fired from the Texas Book Depository Building where three discharged casings were found. Yet, many reject the "single bullet theory" that one bullet produced seven wounds in President Kennedy and Governor John Connally. Should this investigation be re-opened?

Titanic, Hunley, John F Kennedy

BS1 Grant Funding Opportunities in the Forensic Sciences for Academic Programs

Heather E. Mazzanti, MSFS, 450 S Easton Road, Glenside, PA 19038; Gerald M. LaPorte, MSFS*, National Institute of Justice, Office of Inv & Forensic Sci, 810 Seventh Street, NW, Washington, DC 20531; Melissa K. Taylor, BA*, 100 Bureau Drive, Gaithersburg, MD 20899; and Jeri D. Ropero-Miller, PhD*, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

Educational Objectives: After attending this presentation, attendees will be able to: (1) identify grant funding providers; (2) locate grant funding opportunities on the Internet; and, (3) describe the current and planned activities of the Council of Forensic Science Educators (COFSE).

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing awareness of grant funding opportunities in forensic science for academic programs.

Most public crime laboratories primarily focus on performance of casework and providing testimony in support of that mission. Laboratories typically also have limited resources for basic research and continuing professional education. Many suffer from lack of instrumental resources that can be dedicated to research and lack of personnel to dedicate to method development, evaluation, validation of new technologies, and technology transfer.

Partnerships between academic programs in forensic science and laboratories performing casework offer opportunities that benefit both parties, and these relationships are encouraged by the Forensic Science Education Programs Accreditation Commission (FEPAC) and the National Academies of Science (NAS) report from 2009. Forensic science as a field is highly applied and while forensic science practitioners rely on basic research in support of their methods and opinions, very little of that primary research is performed in public crime laboratories. Academic programs have well-established infrastructure to facilitate funded research and to assist with the transfer of technology from the research environment to its application in casework.

The Council of Forensic Science Educators (COFSE) is a group of program directors and faculty from forensic science programs that promotes accreditation and strong academic standards in forensic science programs. The group seeks to share resources and best practices to improve the quality of forensic science research and education. It also aims to help members identify funding opportunities and partnerships to support their programs. COFSE meets during the annual AAFS meeting and all forensic science educators are encouraged to attend.

COFSE has invited representatives of the National Institute of Justice (NIJ), the National Institute for Standards and Technology (NIST), and the Forensic Science Center of Excellence at Research Triangle Institute (RTI) to describe their granting philosophy, programs, and grants that may offer opportunities for academic programs.

Grants specifically for the forensic sciences are available through the NIJ, NIST, and RTI, among other groups. In 2011, more than $200 million were allocated to the forensic sciences for research in forensic labs and educational institutions, travel for training, training of law enforcement personnel, laboratory improvements, backlog projects, instrumentation, and other needs. There is funding available to students and educators that some may not know about and is within reach. This presentation will include speakers from various organizations that award grants to the forensic science community. With better awareness of opportunities that exist for funding, academic programs have the opportunity to contribute to the overall improvement and development of forensic science.

Grants, Education, Forensic Science

BS2 Quincy vs. Ducky II: The Rematch — An American Forensic Pathologist and a British Home Office Pathologist Face Off Again

Stuart J. Hamilton, FRCPath, East Midlands Forensic Pathology Unit, Level 3 Robert Kilpatrick Bldg, Leicester Royal Infirmary, Leicester, UNITED KINGDOM; and Wendy M. Gunther, MD*, OCME, Tidewater Dist, 830 Southampton Ave, Ste 100, Norfolk, VA 23510-1046*

Educational Objectives: The goal of this presentation is to provide an entertaining breakfast session of verbal sparring between two pathologists. More importantly, this presentation will provide an insight into the differences between how expert evidence (and indeed experts themselves) are treated in the United States and Great Britain, as well as providing the relative requirements in the two jurisdictions to be considered an expert and the different ways that expert witnesses interact with legal representatives of the different parties in the case.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by showing how, despite the substantial differences between the two systems, the education, experience, and up-to-date knowledge of relevant research of the pathologists can be applied to the criminal justice system in a manner that serves the ultimate goal of each system, the appropriate administration of justice.

In Chicago in 2011, the might of the United States and the majesty of the United Kingdom went toe-to-toe in a contest to decide once and for all which country had the best medicolegal system. On the side of the Stars and Stripes was Dr. Wendy Gunther, the experienced and highly regarded Medical Examiner. Representing the Union Flag was the young Tyro and Home Office Pathologist, Dr. Stuart Hamilton. After a bruising (but strangely hilarious) contest over hot coffee and croissants, Dr. Gunther claimed victory as the result of a technical knockout (Hamilton's inability to stand still near a microphone) while the British challenger claimed a points victory based on the fact that he had more letters and titles after his name. The conflict remained unresolved and the rivalry festered. It was unfinished business.

Until now.

In Washington, DC, these two intellectual pugilists will bring their knowledge and experience together again, honed by research and training to answer once and for all one of the great questions of our era, "Who has the finest approach to expert testimony between these two great nations?" On the one side, Dr. Gunther has the well-defined gatekeeper role enshrined in case law. On the other side, Dr. Hamilton has a two paragraph "expert witness self-certification" clause to put into his reports. In her corner, Dr. Gunther has *Daubert*, *Joiner,* and *Kumho*. In his corner, Dr. Hamilton has a week of expert witness training and a well-developed sense of his own superiority.

There is no doubt that the medicolegal investigation of death has diverged between England and the United States, but also the way that the legal systems has diverged seems even greater. Therefore, the role of the expert and the way evidence is presented in court is now substantially different. English pathologists are permitted to comment upon injuries in non-fatal cases and many Home Office pathologists provide expert reports to both the prosecution and defense (but not in the same case—that would be weird). Do these differences make one

system more likely to produce an outcome that best serves the interests of justice, or are the two approaches equally valid? Only a deep exploration of the issues (punctuated by sarcastic observations regarding "colonials" and "losing the war of independence") can answer this question.

Expert Evidence, Forensic Pathology, Jurisprudence

BS3 Working With Law Enforcement and Prosecutors: A Conversation With Two Former Feds

Timothy P. Ryan, MS, and Alan E. Brill, MBA, Kroll Advisory Services, 300 Harmon Meadow Blvd, Ste 305, Secaucus, NJ 07094; and Michael DuBose, JD*, Kroll Advisory Solutions, 2101 L St NW, Washington, DC 20037*

Educational Objective: After attending this presentation, attendees will understand how both law enforcement and prosecutors view cases involving digital and multimedia forensic evidence, having had the unique opportunity to discuss with two former Department of Justice officials how to understand the needs of law enforcement departments and prosecutors.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing private sector personnel with the opportunity to understand how best to work with law enforcement and prosecutors to pursue a criminal case and how to most effectively provide information to them.

Private sector computer and media forensic specialists who find themselves working for their employers or clients on what could reasonably be a criminal matter ultimately have to work with law enforcement and prosecutors. After all, while a U.S. private sector individual or company can directly use the civil courts and file a lawsuit; they just can't throw someone into prison.

Even where private-sector specialists have backgrounds in law enforcement, keeping up with the evolution of investigative technology and how the investigative and prosecutorial processes change in response to new laws, new court decisions and both domestic and international standards is vital. This session will provide an up-to-the-minute update.

Working with law enforcement effectively involves gaining an understanding of what information they need in today's legal environment and how their work can be presented to law enforcement and prosecutors. What are alternatives that officials think of in terms of evidence collection (digital forensic data, log files, interview notes, affidavits, etc.), and what can you expect them to ask of you?

In this session, Michael DuBose, former Chief of the Computer Crime and Intellectual Property Section of the United States Department of Justice, and Tim Ryan, former supervisor of the largest FBI Cyber Squad in the U.S. and former Acting Director of the New Jersey Regional Computer Forensic Laboratory (RCFL), will hold an open discussion with the audience that presents a unique opportunity to learn how best to work with federal investigators and prosecutors.

Attendees will learn how the two aspects of law enforcement work together and where the private sector's investigators and forensic specialists fit in. The discussion will cover how cases are brought to the attention of law enforcement or prosecutors, the kind of information that should be provided, how cases are evaluated, and what helps—and doesn't help—in seeking government assistance. Attendees will understand why government investigators may re-visit some of the work already performed to make sure that the underlying source data was properly collected and documented. Small mistakes at the start can lead to disastrous consequences later in the process.

The role of the private sector specialists as the criminal investigation proceeds, as prosecution decisions are made, and as the prosecution prepares its case, will be reviewed, along with issues like claims of bias by defense counsel and attempts to blame the victim's company. This presentation will also discuss who in a company may be the best witness. It may or may not be the IT specialist. This presentation will discuss how they evaluate impartiality, forensic/investigative experience, and litigation experience.

With ample opportunity to interact and ask questions, this session represents the opportunity to learn from leaders in the field and improve your ability to determine what is likely to be an acceptable case, what evidence to collect, how to document it, when to contact the authorities, and how to work with authorities throughout the investigative and trial process.

While both speakers are former government officials, they are not speaking as representatives of any government agency, and their views are strictly their own.

Law Enforcement, Prosecution, Cooperation

BS4 They Really Are Out to Kill You: The Inconvenience of Lawyer Involvement When Presenting Forensic Testimony

Roderick T. Kennedy, JD, Court of Appeals, PO Box 25306, Albuquerque, NM 87125-0306*

Educational Objectives: After attending this presentation, attendees will be presented with the concepts of trial examination, direct examination, cross-examination and re-direct examination and their relationship to the needs of legal adversaries. Expert testimony is seldom either complete or direct evidence of what a trial is about, but is critical to the fact-finder's understanding of the evidentiary picture. Attendees should take away from this presentation an appreciation for the need of expert and technical witnesses to understand trial preparation and procedure from the lawyer's standpoint, as well as the roles of adverse parties' representatives. This understanding should improve witnesses' work flow, documentation, and preparation for trial.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing an understanding of the goals behind lawyers' examinations of witnesses and the purposes for which their testimony is offered, while also offering tools with which witnesses can increase the effectiveness of their preparation for trial and work on the witness stand.

It seems that every time a lawyer speaks at the AAFS meeting, a forensic scientist rises from the audience to complain of mis- or maltreatment at the hands of some member of the bar. Scientists are sternly ordered to answer "yes-or-no" questions or abused by an attorney who was not held in check. Lawyers are ignorant of the principles underlying science, do not read reports, and frequently either follow a prepared script or seek testimony of a final result without any regard for the process of how it was obtained. The fear of cross-examination is universal. This presentation will discuss two propositions of value to young forensic scientists: the attorney who calls you as a witness is likely your worst enemy, *not* the one on the other side; and witnesses who are beaten up on cross-examination likely had it coming, though not necessarily because of anything they did.

Being largely a product of the legal system's need to explain or clarify other evidence at trial, the forensic sciences occupy an interesting place in the trial court. Depending on the adversary process for their living, scientists who testify must maintain a degree of objectivity, independence, and honesty that may seldom be apparent in the legal milieu. The temptations to pick sides or to act in concert with the side that employs the expert—usually the government in a criminal case—can be overwhelming, but must be avoided at all costs. The result of the work in the lab is what counts, not the result of others' work in the courtroom.

Witnesses cannot delude themselves to think they know more about trials than the lawyers do. The process of questioning a witness is designed to present a finite amount of useful information, provide some perspective as to its context or limitations, and finish. Direct examination that does not provide the proverbial "whole truth" subjects the witness to brutal cross-examination. Cross-examination by definition

consists of leading questions largely answered "yes or no," and is designed to expose any limitations or flaws in a witness's testimony. The lawyer who was not prepared to do a complete and thorough direct examination commits two sins: leaving the witness exposed to what the witness will doubtlessly feel is abuse on cross-examination, and being powerless to rehabilitate that beat-up witness on re-direct examination, which is designed to present the final evidentiary picture provided by the testimony and clear up any misconceptions about it.

The witness who is evasive, leaves out contextual information, or who is combative (whether by instruction or disposition) will likely suffer terribly on the witness stand. Some attorneys prefer witnesses to be less than forthright, but the expert has an ethical responsibility to science that includes acknowledging its limitations and uncertainties, as much as a responsibility to the witness oath "to tell the whole truth." The ethical expert should not allow an attorney to present an inaccurate or unfairly incomplete picture, but in any instance where it happens, should expect vigorous and perhaps nasty cross-examination where opposing counsel is better prepared than the witness's own side.

Trial Practice, Cross-Examination, Professionalism

BS5 How to Write Bestselling Novels and Screenplays in Your Spare Time: Tips From the Pros

Melissa Mourges, JD, and Martha Bashford, JD, New York County, District Attorney's Office, One Hogan Place, New York, NY 10013; Linda Fairstein, JD, 211 E 70th St, No 25A, New York, NY 10021; Jonathan Hayes, MD*, OCME, 520 1st Ave, New York, NY 10016; Kathleen J. Reichs, PhD*, Univ of North Carolina-Charlotte, Dept of Anthropology, Charlotte, NC 28223; Karen Bergreen, JD*, 420 E 51st St, New York, NY 10022; and Jan Burke, BA*, 11278 Los Alamitos Blvd, No 351, Los Alamitos, CA 90720*

Educational Objectives: The goal of this presentation is to give forensic scientists the background to lend accuracy and authenticity to the efforts of movie marquees, TV lineups, and best-seller lists that are filled with depictions of grisly crime scenes, futuristic crime solving techniques, and gripping courtroom encounters where drama and forensic science meet head on in the entertainment and publishing worlds. After attending this presentation, attendees will be able to: (1) give advice about how to write novels and screenplays; (2) understand how to attract agents and publishers; and, (3) understand how to market oneself using social media.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by enabling members to learn from five published authors how to turn their experience and insight into books, TV, and movie scripts and more, while also learning how to contact agents, submit manuscripts, and self-promote on social media.

Do you ever feel you are only one crime scene away from a *New York Times* bestseller? Do your friends constantly say, "You have the *coolest* job! You should write a book!" Do you find yourself muttering, "Objection!" during the courtroom scenes in *The Good Wife*? This is your chance to learn from five published authors on how to make that leap.

Linda Fairstein spent 25 years as head of the Manhattan DA's sex crimes unit, and is America's foremost legal expert on sexual assault and domestic violence. Linda's 14th novel starring prosecutor Alexandra Cooper (a thinner, blonder, and younger version of Ms. Fairstein) was released in July 2012. *New York Times* bestseller *Night Watch* is a knowing take on a rape scandal involving a hotel maid and a certain international financier known by his initials—with a surprising twist.

Jonathan Hayes is a veteran New York City forensic pathologist and author of the Jenner series of forensic thrillers, *Precious Blood, A Hard Death,* and the upcoming *Monster Park*. As a freelance writer, he's written for the *New York Times*, *GQ*, *New York Magazine*, *Food & Wine*, *Gourmet,* and *Martha Stewart Living* where he was contributing food editor. His Facebook, Twitter and Tumblr streams are renowned for their inappropriateness.

Karen Bergreen graduated from Harvard, became a lawyer, worked in a big firm, and clerked for a federal judge. None of that was as much fun as her current career as stand-up comic and author. Karen has two published novels: *Following Polly* and the recently released *Perfect is Overrated*. Karen is skilled in the art of self-promotion as publicity budgets for lesser-known authors have dried up. In between gigs on Comedy Central and NYC's Gotham and Comic Strip comedy clubs, Karen is a TV actor, but notes her range is limited: "I can't do anything that involves crying or porn."

Kathleen Reichs is a forensic anthropologist and bestselling author of the fabulous *Bones* novels about crime solver Temperance "Bones" Brennan who is, coincidentally, a forensic anthropologist. The TV show *Bones*, based on that series, is now in its eighth season. As show producer, Dr. Reichs is a stickler for scientific truth in those scripts. Her latest novel, *Bones Are Forever*, was released in August 2012.

Jan Burke has won every award there is for mystery writing, including the coveted Edgar from the Mystery Writers of America. Starting with *Goodnight, Irene*, she has crafted the 14 Irene Kelly mysteries, starring SoCal investigative reporter Irene Kelly and her husband, homicide detective Frank Harriman. Jan also heads the Crime Lab Project to raise awareness of problems facing crime labs and to fund forensic sciences.

Bestsellers, Novels, Screenplays

BS6 The Ballistic Evidence in the Assassination of John Fitzgerald Kennedy

Lucien C. Haag, BS, Forensic Science Services, Inc, PO Box 5347, Carefree, AZ 85377; and Larry Sturdivan, 1512 Lark Bunting Place, Longmont, CO 80504*

Educational Objectives: After attending this presentation, attendees will gain a complete understanding of the firearms evidence, the exterior and wound ballistic properties of the Model 91/38 6.5mm Carcano rifle and Winchester 6.5x52mm ammunition responsible for the assassination of John F. Kennedy (JFK) and the wounding of Texas Governor John Connally in Dealey Plaza on November 22, 1963. Such an understanding should dispel the many bizarre, fanciful, and even absurd claims and notions propounded by the numerous naive, uninformed, self-proclaimed experts, and agenda-driven individuals who know little or nothing about the exterior and wound ballistic behavior of this rifle/ammunition combination.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing attendees with new insight into the connections between Lee Harvey Oswald, the fatal rifle recovered at the sixth floor window of the Texas School Book Depository building, and the exterior and wound ballistics of this rifle and its ammunition.

With the possible exception of the 9/11 attacks on the United States, the November 22, 1963, assassination of President John F. Kennedy was the most horrific event in the last half-century of America's history. It was also one of the most documented events of that time, largely as a result of three amateur 8mm movie-makers capturing our 35th president's murder from three locations. Without question it was, and is to this day, the ultimate shooting reconstruction case.

The trail of documents, physical evidence, eyewitness accounts, and matters of motive and opportunity all led to Lee Harvey Oswald as the sole assassin.

Yet hundreds, perhaps thousands of articles, editorials, television specials, movies, and claims by would-be and self-proclaimed experts continue to offer bizarre, even absurd accounts and explanations of the November 1963 events in Dealey Plaza. Their origins are largely due to the fact that few people, even many forensic practitioners, knew very little regarding the exterior and terminal ballistics of full metal-jacketed rifle bullets. This is still the situation today and it is especially true insofar as the unusual and uncommon 6.5mm Carcano rifle and special ammunition identified as being responsible for the assassination of JFK and the wounding of Texas Governor John Connally.

This presentation will provide a detailed review of the ballistics evidence recovered at the scene and from the two victims. This will be followed by a thorough description and demonstration of the exterior and terminal ballistics of the 6.5mm Carcano rifle and ammunition found near the sixth floor window of the Texas School Book Depository building. A trace of the Model 38, 6.5mm Italian Carcano rifle, serial number C 2766 quickly revealed its mail order purchase by Oswald from Klein's Sporting Goods in Chicago, Illinois. A palm print subsequently matched to Oswald was found on the underside of the barrel in an area under the forward portion of the stock. Later investigation would reveal that Oswald had brought the disassembled rifle into the Texas School Book Depository building, where he was employed, by wrapping it in brown paper and claiming it contained curtain rods for his residence.

Techniques not available at the time or even in the three to four decades following the assassination will be employed to further explain the events in Dealey Plaza and to address those few issues and questions that have some merit, such as the shot that missed President Kennedy and Governor Connally. These techniques include computer enhancement of the Zapruder, Bell, and Nix films, 3D laser scanning and reconstruction of the entire scene, Doppler radar tracking of 6.5mm Carcano bullets over the distances involved as well as through various tissue stimulants at selected ranges, wound ballistic properties and ricochet behavior of these bullets, and the acoustics of the gunshots from such a rifle and its supersonic bullets.

JFK Assassination, Exterior Ballistics, Wound Ballistics

BS7 The Washing Away of Wrongs: Forensic Medicine in 13th-Century China

Brian McKnight, PhD, 2340 E 4th St, Tucson, AZ 85719; and Jeffrey M. Jentzen, MD*, Univ of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109*

Educational Objective: After attending this presentation, attendees will obtain an understanding of the sophistication and complexity of death investigations in 13th-century China by the author and translator of the ancient Chinese medicolegal text, *The Washing Away of Wrongs*.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by instilling an appreciation of ancient Chinese death investigation practices and bridging cross-cultural comparisons on the similarities between Chinese and European medicolegal practices.

The *Xiyuan Ji Lu* or *The Washing Away of Wrongs* was written by Song Ci (1186-1249), a jurist in 1247 C.E. during the Northern Song dynasty as a handbook for governmental officials who were assigned the task of holding inquests on homicides and other unnatural deaths. In China, state-ordered forensic investigations date back to 222-207 B.C.E. in the Ch'in dynasty. *The Washing Away of Wrongs* is earliest extant systemic treatise on forensic medicine produced in the world. Drawn from several older texts, it served as a template for subsequent Chinese works on the subject through the end of the 19th-century. In ancient times, Chinese investigators understood the importance of forensic examinations and the problems of distinguishing accidental from intentional deaths, suicide from murder, differentiating premortem from postmortem wounds, and discerning natural from unnatural death.

The most recent translation of the work was performed by Brian E. McKnight, PhD, while at the University of Michigan's Department of East Asian Studies. McKnight's masterful translation brings to life the 13th-century Chinese death investigation process. The book was "always carried to the scene of the inquest by the high territorial official." *The Washing Away of Wrongs* illuminates not only the general Chinese administrative patterns, but also the style of traditional legal practice. Song's book provides the clearest picture of the traditional Chinese detective processes. The ridged Chinese penal system required a systematic guide for death investigation. The elaborate Chinese bureaucratic system stands in contrast to the primitive system in use in Europe at the time. *The Washing Away of Wrongs* was reprinted and updated for centuries and was still in use at the time of Republican period in 1912 after some 25 editions. It was exceptional if physicians were involved in death investigation as McKnight himself observed, "the Western marriage of professional medical knowledge and forensic practice was lacking in China."[1]

Magistrates conducted inquests in China as early as 995 C.E. The actual examination of the body was carried out in the inquest by the wu-tso or "coroner," who were lowly figures, most often undertakers who might be more accurately called "coroner's assistants." Also present at the inquest was the accused, clerks, and the victim's family. There was a rule that a body could not to be moved and that the magistrate had to go to the autopsy site, accompanied by a clerk from the Bureau of Punishments. Documents used to validate the inquest were very sophisticated. By 1204, printed sketches showing the front and back of the body were used. With the exception of cutting flesh to examine bones, Chinese forensic examinations concentrated on the external examination of victims.[2]

Song's guidebook described methods to look for in hanging deaths, gave examples of different forms of strangulation, as well as the observation of bruises, self-inflicted wounds, and discussions of internal injury. As a type of casebook, *The Washing Away of Wrongs* provided cases for the magistrate and clerks to learn from in their own practice. The text discusses the use of bones and their color in the diagnosis of poisoning. Experimental manipulations were also a part of the text. The presence of ashes in the mouth of a pig used to ascertain whether an individual was alive or dead prior to being consumed with fire. Red cloth was used to evaluate bruises not visible to the naked eye. *The Washing Away of Wrongs* provides an ancient landmark from which to measure our own progress in medicolegal death investigation.

China, Legal Medicine, History

BS8 Thomas Krauss Memorial Bitemark Breakfast — Lessons From Eyewitness Identification Research for Forensic Scientists

Barry C. Scheck, JD, and Karen A. Newirth, JD, The Innocence Project, 40 Worth St, Ste 701, New York, NY 10013*

Educational Objective: After attending this presentation, attendees will understand how research into the causes of eyewitness misidentification can improve the collection and evaluation of forensic evidence.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by explaining aspects of social science research on eyewitness identification that relate to the work of forensic scientists. Attendees will be able to consider research on relative judgment and suggestive feedback and how this research can improve the work of forensic scientists.

Eyewitness misidentification is the most common contributing cause of wrongful convictions, occurring in nearly 75% of the 297 DNA-based exonerations nationwide. For more than 30 years, psychological scientists have studied perception and memory as applied to eyewitness identification and have produced a robust body of peer-reviewed scientific research that the New Jersey Supreme Court recently declared to be the "gold standard in terms of the applicability of social science research to the law."[1] The scientific research has resulted in clear recommendations for police procedures that will result in more reliable and accurate identifications and will reduce the likelihood of eyewitness

misidentification. The underlying research and the recommendations are useful when contemplating how to improve the evaluation of forensic evidence.

In formulating recommendations for police practices, scientists studying eyewitness identification have considered the relationship between relative judgment and misidentification and have concluded that when witnesses rely upon relative judgment (comparing members of a lineup and choosing the member who looks most like the memory of the perpetrator), they are more likely to make errors than when they rely upon absolute judgment (making a decision about each lineup member independent of the other lineup members). Scientists have theorized that the use of relative judgment results in more errors because some members of the lineup will always look more like the perpetrator than the others, whether or not that lineup member is actually the perpetrator. Using procedures that force witnesses to make absolute judgments about each lineup member prevents them from comparing lineup members so that they don't select the "best match" among the group. Instead, it asks that witnesses make an independent evaluation of each lineup member against the memory of the perpetrator.

Scientists studying eyewitness identification have also focused on the effects of confirming feedback by administrators on eyewitnesses and have discovered that confirming feedback of eyewitness identifications can dramatically affect eyewitness reports on a variety of measures, including eyewitness's reports of the original viewing experience, of the lineup viewing experience, and of their confidence and certainty in their identifications. In all cases, confirming feedback dramatically increased the positive reports of witnesses on all measures.

Eyewitness identification research on relative judgment and confirming feedback have important implications for forensic analysts who can be equally affected by relative judgment and the influence of external information. The problem of relative judgment in the context of fingerprint analysis was addressed in the Office of the Inspector General Report on the Brandon Mayfield Case, which recommended practices to protect against relative judgment, including linear analysis.[2] Researchers, including Itiel Dror and his colleagues are working to understand the potential influence of external information on forensic analysts.[3] Dror *et al.* have performed several groundbreaking studies that examine how external information affects the behavior of experienced fingerprint analysts.[4]

Eyewitness, Identification, Bias

L1 Ensuring Continuing Access to Our Nation's Heritage: The National Archives' John F. Kennedy Assassination Records Collection

Martha W. Murphy, MA, and Steven D. Tilley, BA, National Archives and Records Administration, Special Access and FOIA Branch, 8601 Adelphi Rd, College Park, MD 20740; and Margaret Ann T. Kelly, MS*, DHS, ICE-HSI Forensic Laboratory, 8000 Westpark Dr, Ste 325, McLean, VA 20598-5116*

Educational Objectives: After attending this presentation, attendees will understand the National Archives and Records Administrations' historic and ongoing role in accessioning, organizing, preserving, documenting, and making accessible the records and artifacts contained in the John F. Kennedy Assassination Records Collection.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by providing a practical foundation for the ongoing discussion of current and proposed further scientific research into the JFK assassination as the 50th anniversary of the tragedy approaches.

John F. Kennedy was killed on November 22, 1963. Almost 30 years later, hoping to allay lingering doubts about the circumstances surrounding that event, Congress enacted the President John F. Kennedy Assassination Records Collection Act (Public Law 102-526, signed on October 26, 1992, by President George H.W. Bush). One provision of the law mandated that all assassination-related material be housed in a single collection in the National Archives and Records Administration (NARA). The clear intent of the law was to open most of the records for research. On December 28, 1992, NARA established the John F. Kennedy Assassination Records Collection, which now contains more than five million pages of assassination-related records, photographs, motion pictures, sound recordings, and artifacts.

The John F. Kennedy Assassination Records Collection includes federal government records of presidential commissions, such as the Warren Commission; congressional committees, such as the House Select Committee on Assassinations; executive branch agencies, such as the Federal Bureau of Investigation and the Central Intelligence Agency; and judicial branch courts, as well as a variety of donated historical materials.

The President John F. Kennedy Assassination Records Collection Act defined narrow categories of information whose release could be postponed and established the Assassination Records Review Board (ARRB) to consider all individual agency decisions to postpone the release of records. The Act requires that all assassination-related records be opened by 2017, with the exception of documents certified for continued postponement by the President. Additions to the John F. Kennedy Assassination Records Collection holdings are made as agencies continue to review records identified as relevant and transfer newly opened records to the National Archives.

This presentation will provide an overview of the John F. Kennedy Assassination Records Collection holdings at the National Archives and Records Administration and a review of current search-and-access information and procedures for potential researchers. The presentation will also illustrate the ongoing preservation and documentation efforts undertaken by the National Archives since enactment of the President John F. Kennedy Assassination Records Collection Act, during and after the Assassination Records Review Board tenure. These efforts include the development of preservation strategies for the Zapruder film and for the Dallas Police Department dictation belts; further scientific examinations brokered for one of the bullet fragments and its associated trace evidence, including the microscopic identification and characterization of trace fibers and human tissue; the design and fabrication by the NARA conservation laboratory of custom-built housings for the long-term preservation of assassination-related artifacts and associated samples; and, the currently proposed high-resolution imaging of bullets and bullet fragments from the Warren Commission exhibits.

JFK, Assassination, Records

L2 Does Your Family Have the Munchies? It Might Be By Proxy

Janean M. Fossum, BSN, PO Box 11053, Eugene, OR 97440; and Melodie Brooks, MSN*, 3091 Widdock St, Erie, MI 48133*

Educational Objectives: After attending this presentation, attendees will: (1) understand the principles of medical child abuse, including a brief historical review, distinguish Munchausen By Proxy (MBP) from Munchausen Syndrome; and, (2) recognize victim and offender characteristics, and comprehend the importance of a Multidisciplinary Team (MDT) approach for successful investigation and prosecution. The use of case studies will provide examples of the multiple populations affected and often a diagnosis of exclusion is needed as evidence to validate this form of child maltreatment.

Impact on the Forensic Science Community: This presentation will impact the forensic science community by explaining the principles of medical child abuse, concluding with a clear understanding of the implications to health care providers, law enforcement, and protective services. A review of victim and offender characteristics, and the importance of the multidisciplinary team will also be discussed. This presentation will provide an overall view of the magnitude and covert nature of MPB. Moreover identifying how coordinated forensic investigations can impact children's lives and the communities in which they live.

The term Munchausen was coined after an 18th-century German dignitary Karl Friedrich Hieronymus Freiherr von Munchausen. The Baron was well known for his eccentric tales that many times proved to be fictitious. Moreover, the Munchausen term was first used in 1951 by Dr. Richard Asher who described self-induced illnesses in his patients.[1]

Today, many terms have come to symbolize Munchausen Syndrome, including fabricated illness and hospital-addiction syndrome. Additionally, this disorder is classified as a psychiatric illness, mainly noted in men and believed to bring individuals gratification from the sympathy and attention given to the individual by medical personnel; however, another form of this attention seeking behavior is known as MBP.[1]

MBP or factitious disorder, unlike Munchausen's, is defined as a form of medical child abuse hallmarked by a parent, mainly mothers, over reporting illness or creating a venue where children have unnecessary medical procedures performed.[2] This term was first identified in 1977 by R. Meadow, MD. He noted that Munchausen Syndrome was present in two of his patients' mothers who had projected fabricated illnesses onto their children. The literature describes two roles played by perpetrators of this abuse, inducers and fabricators. Inducers directly cause illness with the child and fabricators exaggerate their child's symptoms to receive attention.[1]

The incidence of MBP is as elusive as the perpetrators of this form of child maltreatment. The literature suggests that a minimum of 600 new cases a year are noted from suffocation and non-accidental poisoning in children. Two main contributing factors for the unknown incidence is a

lack of a standard definition for MBP and a central repository for data related to this phenomenon. Moreover, a collective approach is required to investigate and expose this form of child abuse.[3]

The coordination of multiple disciplines is required across agencies in order to be successful with investigation and prosecutorial efforts with MBP. Each discipline must focus on its own specialty but communicate openly with other team members. Step one includes awareness of the disorder which may include unexplained medical illnesses after testing or a history of multiple visits to different hospitals and physicians. Step two involves a complex organized MDT with a goal of complete removal of the child from the offending caregiver. A planned hospitalization is recommended with hospital video surveillance as an element required to produce evidence of deliberate harm to the child. Additionally, a thorough and complete medical record review should be conducted.[3]

Medical Child Abuse, Forensic Nurse, MDT

W1 Practice, Procedures, and Protocols: How SWGDE, SWGIT, and FISWG Can Help You Navigate the Complex World of Digital and Multimedia Evidence

Richard Vorder Bruegge, PhD, FBI, OTD-DES, Bldg 27958A, Pod E, Quantico, VA 22135; Mary F. Horvath, MFS*, 6786 N Stuart Rd, King George, VA 22485; and Melody A. Buba, BS*, FBI, Engineering Research Facility, Bldg 27958A, Quantico, VA 22135*

After attending this workshop, attendees will: (1) become familiar with forensic guidelines for the proper recovery, processing, storage and authentication of digital and multimedia evidence (DME); (2) understand strategies regarding admissibility of DME in court; and, (3) learn information regarding current research and educational requirements in DME.

This workshop will impact the forensic science community by increasing awareness regarding digital and multimedia evidence and the proper procedures associated with it. With this, attendees will be able to utilize this type of evidence, and to ensure to the greatest extent possible that the justice system and the public benefits from it.

With today's technology more DME evidence may find its way into the courtroom. Analyses conducted on computer files, electronic devices, images, videos, and audio recordings may be crucial to an investigation. The increased use of DME has led some to raise criticisms in an attempt to exclude such evidence. It is critical that agencies and investigators take measures to ensure that the technologies, practices, and procedures used can be defended in the court room. Recognizing this challenge, multiple Scientific Working Groups have been formed over the years, starting with the Scientific Working Group on Imaging Technology (SWGIT) in 1997 and the Scientific Working Group on Digital Evidence (SWGDE) in 1998. In 2009 the Facial Identification Scientific Working Group (FISWG) was formed. Together these Scientific Working Groups ("SWGs") address the myriad of issues that can arise related to the science and technology of digital and multimedia evidence.

As of June 2012, SWGDE, SWGIT, and FISWG have published over fifty documents that address issues ranging from chain of custody and the proper preservation of digital and multimedia evidence, to procedures for video and image processing, best practices for mobile phone examination, image authentication, maintaining the integrity of DME, guidance on procurement and deployment of face recognition systems, and recommendations for training in DME procedures.

This workshop will familiarize investigative, forensic, and courtroom personnel with these documents and the guidance contained therein, so that the attendees can incorporate them into the procedures within their own practices. Attendees will learn about chain of custody issues as they relate to recovery of DME at crime scenes, including proper recovery of computers as well as crime scene photographs and surveillance video recordings from both analog and digital systems. Attendees will also receive guidance regarding proper procedures for preserving such data and ensuring its integrity, as well as learn where they can go to find out more about it.

Once evidence has been acquired in an investigation, it must be processed and analyzed to produce meaningful results. SWGDE, SWGIT and FISWG have all developed guidelines regarding what sort of processing steps or approaches may be most useful in a forensic setting and often provide guidance on how to document those steps. Included in such best practices are those to ensure the integrity of the evidence, as well as demonstrate the validity of the analytical procedures used. Workshop attendees will learn about the options available to them for ensuring such integrity, the difference between integrity and authentication, and preserving their data over the long run.

Likewise, many in forensic science remain concerned regarding the admissibility of DME within the courtroom. This workshop will provide attendees with a reference list of case law, as well as describe some myths and misconceptions associated with DME. These documents should help them ensure that their evidence is admitted in court.

Finally, in keeping with the theme of this year's meeting, "*The Forensic Sciences: Founded on Observation and Experience, Improved by Education and Research*," attendees will receive an overview of many of the most recent research publications related to DME. This will demonstrate the active research being performed in the discipline and should help attendees identify future avenues of research.

Digital Evidence, Audio/Video/Image, Face Recognition

W2 Electrocution, Electrical Injury, and Lightning Death Investigations

Ronald K. Wright, MD, JD, 1000 Ducks Nest Rd, Turtletown, TN 37391; and Helmut G. Brosz, PEng, BASc*, Institute of Electro-Pathology, Inc., 64 Bullock Dr, Markham, ON L3P 3P2, CANADA*

After attending this presentation, attendees will be able to: (1) identify both common and uncommon electrical low and high voltage circuits having the potential to produce electrical shock, injury or death; (2) properly document (photograph and draw) electrical injury defects; (3) properly document the scene of an electrical injury accident; and, (4) differentiate between lightning and non-lightning electrical injury.

This workshop will impact the forensic science community by equipping attendees with theoretical and practical knowledge to effectively investigate electrical injuries and deaths. The workshop will examine the concept of Ohm's Law and its application to case investigation. Included in this discussion will be the use of Ohm's law to estimate the current flow when the voltage is known.

Direct and alternating current and the differences in lethality and injury will be discussed along with the history of the dispute between George Westinghouse and Thomas Edison over the distribution of electrical current. As a corollary, an explanation of the electric chair will be explored, which was a spinoff of their dispute. Professor Dalziel's work on perception thresholds and no let-go thresholds in humans will be explored. Included in the presentation will be a chart showing the effects of current flow on humans at varying current amounts.

The stereotypic automatic response to current flows at or above let-go threshold will be examined, with case examples presented, including the differences between upper and lower extremities to the flow of electricity. The delay between repolarization and muscle action will be investigated and the effects of these phenomena upon case work explored. The amount of time required to lose consciousness following the onset of ventricular fibrillation will be elucidated and the reasons for this explored. The effect of this time lag upon civil litigation will be discussed and the varying interpretations of different state courts will be explained.

Examination of the effects of both high and low voltage exposure in humans will be presented. The biphasic response to current flows below and above one ampere will be explained, including the length of time required to initiate ventricular fibrillation. The concept of cellular poration, which is seen in high voltage electrical injury, will be discussed including the effects of poration upon the human body and the devastating tissue destruction which ensues.

Special consideration of lightning and other extremely high voltages will be shown, including the effects of explosive expansion of gases and

the explosive effects upon ear drums and clothing. In the case of both lightning and distribution lines around 250,000 volts, if a person is near or in the circuit, the person's clothing is explosively torn and the ear drums ruptured from the explosion. The magnetization of ferrous metal objects in or near a lightning strike will be examined. The importance of lightning in explained death or injury has significance in the civil litigation arena, as generally lightning, as an "act of God," is not compensable.

Case examples from the experiences of Professor Brosz and Dr. Wright will be examined and utilized to illuminate the approaches to all deaths and injuries which may be from electrical current whether manmade or natural. Special consideration of the possibility of both over diagnosis and under diagnosis will be examined.

Electrocution, Electrical Injury, Lightning Deaths

W3 Analysis and Interpretation of Chemical Unknowns

Vincent J. Desiderio, MS, and Andrew M. Bowen, MS*, U.S. Postal Inspection Service, National Forensic Laboratory, 22433 Randolph Dr, Dulles, VA 20104-1000; and William L. Chapin, BA*, McCrone Associates, Inc, 850 Pasquinelli Dr, Westmont, IL 60559*

After attending this workshop, attendees will better understand the analysis of various types of chemical unknowns that frequently are encountered in the forensic laboratory.

This workshop will impact the forensic science community by providing much-needed education in a discipline that currently is lacking in substantial formal training.

Chemical unknowns present a unique challenge to forensic laboratories. As the name suggests, these are materials of an unknown origin and composition that may be found in connection with a virtually limitless number of scenarios of forensic significance. In the best case scenarios, they are common single component materials that have benign uses. At worst, they are complex mixtures of rare, dangerous compounds that have the potential to cause great harm.

Chemical unknowns are submitted to forensic laboratories for a variety of reasons, including: (1) outright identification of a material, commonly, either a suspicious powder or liquid in a public space or a white powder included in a threatening letter; (2) analysis of an item to determine if any tampering may have occurred, commonly in the form of an allegedly adulterated foodstuff; or, (3) comparison of an unknown material found on or in the possession of a suspect to a similar material recovered from a crime scene. An example of the latter might be a white powder observed on the body of a homicide victim being compared with lime from the garage of a suspect. The information obtained from the analysis and characterization of these unknown substances can be used to help associate suspects with scenes and victims as well as to provide information for investigative purposes.

A wide variety of unknown materials are routinely encountered as chemical unknown evidence, to include solids, liquids, gases, and both homogeneous and heterogeneous mixtures of these various phases in any combination. The specific phases present may be organic, inorganic, or mixtures thereof, and may come from either natural or man-made sources. Samples that occur in different physical states will be amenable to different analytical approaches, and examiners should ideally have access to a wide variety of instrumentation and be intimately familiar with the strengths and limitations of each piece of equipment.

Considering the broad range of scenarios and materials that could be encountered, the analysis and characterization of chemical unknowns can pose some serious challenges to the forensic scientist. With this in mind, the primary goal of this workshop is to educate practitioners, educators, and other interested members of the forensic community about the types of approaches that have proven successful for the presenters. The presentations will provide some guidance on a logical approach for handling such cases. The presenters will include individuals with diverse backgrounds and experience in the identification of chemical unknowns. This workshop will outline the techniques that are commonly used for the characterization, identification, and comparison of chemical unknowns. Specific attention will be paid to sample preparation techniques, microscopical examinations, and various forms of instrumental analysis, to include Fourier Transform-infrared spectroscopy, Raman spectroscopy, scanning electron microscopy, energy dispersive spectroscopy, X-ray fluorescence, X-ray diffraction, chromatographic techniques, and mass spectrometry. During the course of the workshop, presentations covering safety, sample handling, interpretation of results, and reporting strategies will be provided. In addition, the attendees will be given handouts listing a wide variety of published literature, online resources, training opportunities, and more that cover instrumental theory, application, and interpretation. Several of these resources have proved invaluable to the presenters for the purposes of determining whether the identified materials in a chemical unknown are consistent with a specific household product, for example.

In order to better appreciate many of the points made during the lecture portion of the workshop, the attendees will have the opportunity to perform hands-on exercises designed to familiarize them with some of the techniques that have been discussed. These hands-on activities will include actual examination of chemical unknowns, with an opportunity to perform sample preparation and microscopical examination of the samples, with instrumental results provided by the presenters to assist in their interpretation of the samples.

Chemical Unknowns, Trace Evidence, Microscopy

W4 Signature Examination of Healthy and Impaired Writers

John L. Sang, MS, 1 Harbor Ln, Glen Head, NY 11545; Linton Mohammed, PhD, Forensic Science Consultants, Inc, 851 Cherry Ave, Ste 27-110, San Bruno, CA 94066; and Michael Caligiuri, PhD*, Univ of California San Diego, Dept of Psychiatry, 9500 Gilman Dr, San Diego, CA 92093*

After attending this presentation, attendees will: (1) become more aware of the kinematic values of strokes in static signatures; and, (2) be exposed to features of signatures that are impacted by the effects of age, illness, and substance abuse.

This presentation will impact the forensic science community by increasing the knowledge base of forensic document examiners in the area of kinematic analysis of the signatures of healthy writers and those affected by age, illness, or substance abuse.

The examination of signatures is the most prevalent type of casework for many Forensic Document Examiners (FDEs). In many cases, a person's signature may change over time in subtle ways increasing the difficulty in estimating authenticity. Among several considerations, the FDE may take into account the age and health of the writer and changes in health status. Illness or impairment in a writer may cause that writer's signatures to exhibit a greater range of variation than that of a healthy writer. Since the FDE has to make determinations about whether features in a signature are the result of variation (authenticity) or a fundamental difference (non-authentic), the presence of an illness or impairment that affects handwriting can make that determination quite difficult.

In this workshop, participants will have an opportunity to examine genuine and simulated signatures of healthy and impaired writers in two hands-on sessions. Didactic sessions will provide participants with the necessary empirical and scientific bases to evaluate questioned signatures. Participants will evaluate signatures prior to and then after the didactic sessions.

The morning didactic lecture will introduce to participants principles of motor control and motor programming such as motor equivalency. This lecture will provide a framework for the first hands-on session where participants will assess the authenticity of questioned signatures of healthy writers written under various conditions. A second lecture will be given on the topic of stroke kinematics. Kinematic analyses provide descriptions of how strokes are produced in space and time. Size, velocity, and acceleration are important in kinematics and are often

parameters which are inferred by FDEs in the examination of static images of handwriting. The kinematics involved in the production of a signature may be different depending on whether the signature is authentic or forged. Additional variation may result due to differing conditions in which the signature was executed. For example, writing when standing may produce different kinematic results than writing when sitting.

This lecture will be followed by a hands-on session to develop skills for detecting invariant features in signatures written under various spatial constraints. Participants will be tasked with examining specific features in static signatures and evaluating their kinematic values. The results will be correlated with the actual kinematic values. From this feedback, the attendees will get an idea of their individual ability to estimate kinematic values from static signatures. Additionally, participants will be asked to examine pairs of signatures and determine whether specific kinematic parameters are useful in distinguishing one signature from another. A general discussion will follow about the pros and cons of the current and kinematic approaches in detecting forged or disguised signatures.

In the afternoon sessions, participants will assess more challenging questioned signatures based on knowledge of how advanced age, dementia, and substance abuse impact handwriting. The session will begin with an overview of signature and handwriting formation in young and aged healthy adults, individuals with known histories of illegal substance use, and individuals with dementia. Data will be presented on cross-sectional age-related changes in signature kinematics demonstrating nonlinear changes in stroke amplitude, duration, stroke velocity and smoothness to address questions pertaining to the presence of Parkinsonian handwriting features in the elderly writer. The lecture will include recent findings on the relationship between signature formation and cognitive status in patients with Alzheimer's disease. Participants will examine challenging signatures from writers with dementia and assess authenticity in the afternoon hands-on session. Participants will be debriefed on the results of their judgments of authenticity in relation to kinematic findings that distinguished known from questioned signatures.

The workshop will conclude with a discussion of the extent to which empirical findings increase the objectivity of the examinations. At the end of the workshop, attendees should have an increased knowledge of the neuroscientific bases of healthy and impaired writing. Additionally they will be exposed to techniques that may increase the objectivity of forensic signature examinations.

Healthy Writing, Impaired Writing, Signature Exam

W5 Science in the Courtroom: A Matter of Perspective?

Ted W. Vosk, JD, 8105 NE 140th Pl, Kirkland, WA 98034; Sandra E. Rodriguez-Cruz, PhD*, Drug Enforcement Admin, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081; Roderick T. Kennedy, JD*, New Mexico Court of Appeals, PO Box 25306, Albuquerque, NM 87125-0306; Michael J. Nichols, JD*, 3452 E Lake Lansing Rd, East Lansing, MI 48823; and Christopher G. Boscia, JD*, 70 West Hedding St, West Wing, San Jose, CA 95110*

After attending this workshop, attendees will be able to: (1) understand the role, objective, and meaning of scientific evidence in the criminal justice system; (2) learn common difficulties experienced in the use and application of scientific evidence in the courtroom; (3) foster understanding between legal participants; (4) facilitate better communication, increased trust, and more productive working relationships; (5) demonstrate how this can lead to improved forensic and courtroom practice; and, (6) explain why and how this can lead to more just and reliable outcomes.

This workshop will impact the forensic science community by improving forensic and courtroom practices to achieve more just and reliable outcomes.

The need for reforms in the forensic sciences became manifested in the wake of the 2009 Report issued by the National Academy of Sciences, *Strengthening Forensic Science in the United States: A Path Forward*. One of the areas of concern touched upon was the effect of contextual bias due to the fact that most forensic labs and practitioners are either part of law enforcement or prosecutorial offices or closely aligned therewith. However, contextual issues impacting the performance, use and presentation of forensic evidence are not limited to forensic scientists. Prosecuting and defense attorney, as well as judges, also utilize and consider scientific evidence from unique perspectives that may determine what and how scientific evidence is generated and presented as well the conclusions that may be drawn from it. If forensic science is to live up its promise as a tool for the determination of truth in the courtroom, then the roles of each of the participants in a criminal case must be properly understood so that contextual issues don't undermine it. This workshop addresses forensic science, its role, objective, meaning and actual use/practice in the criminal justice system from the perspective of the system's primary participants in this endeavor, the forensic scientist, judge, and prosecuting and defense attorney. The intended audience includes judges, criminal defense and prosecuting attorneys, and forensic scientists.

The workshop consists of three sessions. The workshop's first session will consist of each a forensic scientist, judge, prosecuting and defense attorney discussing the proper role, objective, and meaning of scientific evidence in the criminal justice system and point out how this is often different from how these are commonly viewed. Each will also discuss the difficulties encountered in trying to adhere to proper practices, in particular, those caused by the other participants in either properly or improperly trying to perform their role.

The workshop's second session will consist of live examination and cross-examination of a forensic witness in front of a judge in order to illustrate some of the issues discussed in session one. These will be accompanied by commentary pointing out issues as they arise, how the performance either does or does not conform to the properly defined practices, where difficulties arise and how they might be addressed.

The workshop's third and final session will consist of a panel discussion tying everything together for the audience. The discussion will address the unique perspectives of each of the participants, whether there are aspects of the adversarial approach that make it inherently difficult to adhere to proper practices and why and how appreciating how each role is viewed by its protagonist can facilitate better forensic and professional practices by each leading to more just and reliable outcomes. Audience participation in the discussion will be facilitated by a moderator who will keep the discussion directed towards the goals of the workshop.

Science, Courtroom, Perspective

W6 Beyond the Numbers: An Objective Approach to Forensic Toxicological Interpretation

Dwain C. Fuller, BS, Vet Adm North Texas Health Care System, Toxicology-B113, 4500 S Lancaster Rd, Dallas, TX 75216; Laura J. Liddicoat, BS*, Wisconsin State Lab of Hygiene, Forensic Toxicology Section, 2601 Agriculture Dr, Madison, WI 53707-7996; Kathryn H. Haden-Pinneri, MD*, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trl, Houston, TX 77054; Steven H. Wong, PhD*, Wake Forest Univ, School of Medicine, Dept of Pathology, 1 Medical Center Blvd, Winston-Salem, NC 27157; and George S. Behonick, PhD*, AIT Laboratories, 2265 Executive Dr; Indianapolis, IN 46241*

After attending this presentation, attendees will understand: (1) interpretative differences between antemortem and postmortem toxicological results; (2) how death scene investigation, basic forensic pathological findings, and postmortem artifacts can aid in toxicological interpretation; (3) how anecdotal observations, standard field sobriety tests (SFST), and drug recognition examinations (DRE) can enhance proper interpretation; (4) pharmacological tolerance and potential impact on interpretation; (5) how genetic differences can affect drug

metabolism; and, (6) how to objectively explore and apply literature references to case data.

This presentation will impact the forensic science community by equipping forensic toxicologists, pathologists, and other persons charged with toxicological interpretation in understanding and evaluating evidence beyond the drug concentrations alone. Additionally, this presentation will equip attendees with the knowledge and tools to objectively assess all the evidence in its full context when interpreting a toxicological result.

Forensic toxicologists, forensic pathologists, and other investigators are often tasked with the interpretation of drug, alcohol, or other xenobiotic concentrations in bodily fluids and tissues. Such requests are often made without providing the investigator with a complete contextual reference or suitable history of the case under consideration. Due to the many factors that must be considered, the interpretation of a toxicological result is most appropriately performed while considering the complete context of the result and the circumstances and history of the case. A primary context for consideration is whether the analyzed specimen is an antemortem or postmortem specimen.

In antemortem interpretation, important considerations are: the specimen analyzed (i.e., serum, plasma, or whole blood); the type of laboratory performing the analysis; the method in which the specimen was analyzed (i.e., enzymatic alcohol vs. headspace alcohol); potential pharmacological tolerance of the subject; duration and amount of drug use; clinical history; elapsed time between observed behavior and specimen collection; the results of standardized field sobriety tests and drug recognition examinations; observations of driving or other behavior, statements made at the scene; prescription information; and, potential idiosyncratic anomalies in metabolism, among others.

In postmortem interpretation, important considerations are: potential for postmortem redistribution; site and method of specimen collection; potential pharmacological tolerance; clinical history; observed pathology and postmortem artifacts (i.e., track marks, visceral congestion, pulmonary edema, skin coloration, chemical odors, etc.); notes left at the scene; missing medications; prescription history; circumstances surrounding the death (i.e., trauma, drowning, fire, etc.), the state of decomposition, postmortem interval; and, pharmacogenomic considerations, among others. Furthermore, an investigator should consider whether the collection and analysis of alternate or additional specimens such as liver, bile, vitreous humor, or gastric contents may clarify interpretative issues.

Additionally, forensic toxicologists, pathologists, and others often misuse or misinterpret published drug and xenobiotic concentrations by not considering or even recognizing the difference in postmortem and antemortem concentrations, the difference between whole blood and serum/plasma drug concentrations, the way in which therapeutic drug concentrations are determined, and failing to recognize the limitations of published data. Among the limitations of published data are potential selection biases in epidemiological studies of drugs and driving, such as those derived from drivers stopped for aberrant driving behavior, and the potential statistical biases of published "lethal" drug concentrations brought about by mathematical skewing.

Toxicology, Interpretation, Context

W7 Practical Homicide and Medicolegal Death Investigation: Practical and Clinical Perspectives Regarding the Homicide Investigation and the Medical Examiner's Determination in Various Modalities of Death Including Child Deaths and Suicide

Vernon J. Geberth, MS, PO Box 197, Garnerville, NY 10923; Barbara C. Wolf, MD*, District 5 MEO, 809 Pine St, Leesburg, FL 34748; and Anny Sauvageau, MD*, OCME, 7007 116 St, Edmonton, AB T6H 5R8, CANADA*

After attending this presentation, attendees will be able to: (1) understand the role of fantasy in sex-related death; (2) collect and preserve physical and psychological evidence in sex-related incidents; (3) determine the *modus operandi* and signature characteristics in crime scenes; and, (4) understand investigative and behavioral analysis in criminal profiling.

This presentation will impact the forensic science community by informing the audience of the dynamics and proper procedures in the investigation of sex-related homicides and death investigations.

The professional investigation of homicides and sudden violent deaths require the practitioner to employ revolutionary forensic techniques as well as the modern investigative procedures found in the "Best Practice" model of Practical Homicide Investigation®, which has become the recognized protocol for professional death investigation. In addition, straightforward and candid communication between investigators and the various forensic specialists is vital. Specifically, the medical examiner and how the determination of the cause, manner, and mechanism of death are the basis of a thorough medicolegal investigation

This workshop will familiarize forensic scientists and investigators in the art and science of homicide and death investigation. The workshop will focus on the elements of detective work and the dynamics of sudden and violent death, and provide the most practical and conventional information available to detectives and practitioners responsible for conducting intelligent investigations of violent and sudden death.

Upon completion of this workshop, participants will have gained an understanding of the practice and theory of professional homicide and medicolegal investigation. Participants will have the most current information and knowledge on various modalities of death and some of the myths of asphyxiation will be dispelled. Based on the extensive experience and education of the three presenters the forensic community will benefit and be better informed of the dynamics and proper procedures employed in the investigation of homicides and death investigations.

In the morning segment, comprehensive discussion will be provided of the practice and theories of professional homicide investigation and the preliminary duties of the death investigator at the homicide scene. In order to conduct an efficient and effective investigation, the detective first concentrates on the mechanical aspects of the death, i.e., motives and methods, wound structures, crime scene reconstruction, bloodstain pattern analysis, the cause, manner and time of death, as well as other factors that provide clues to the dynamics of the event. The detective then accesses various sources, which can be applied to his or her investigation.

The medical examiner/coroner's office is primarily concerned with the investigation of violent, sudden, unexpected, and suspicious deaths. The procedures used in the official medicolegal investigation of death fall under the supervision of the chief medical examiner or coroner, who is responsible for the evaluation and interpretation of the results of this inquiry. Medicolegal investigation of unnatural deaths, emphasizing the importance of the multidisciplinary investigation of homicides as well as suspicious and equivocal deaths will be discussed. Specifics include medicolegal death investigative systems, time of death and firearm injuries to include a discussion of gunshot wounds and the classification of gunshot wound structure.

In the afternoon segment the investigation of asphyxial deaths based on the research studies of the Working Group on Human Asphyxia will be presented. Several myths on asphyxial deaths are deeply rooted in the forensic community these myths as well as others will be discussed and eradicated. In addition there will be a discussion on blunt and sharp force trauma with a presentation of some research data on criteria to distinguish falls from blows in the challenging cases of blunt head trauma where there are no witnesses to the injury. This segment will be followed by a discussion on the investigation of suspected child homicides and child abuse-related injuries are presented as well as information on the medicolegal investigation. The workshop will conclude with a discussion on the investigation of suicide and equivocal death.

Each of the presenters bring years of practical experience and research into various aspects of homicide and medicolegal death investigation and will share their expertise with the attendees. The overall goal will be to provide comprehensive and practical information

which will serve an investigative guide in the investigation of sudden and violent death inquiries.

Homicide Investigation, Medicolegal Death, Asphyxia-Suicide

W8 Multidisciplinary Approaches to Effective Communication and Report Writing

Jenna L. Oakes-Smith, MFS, St. Louis Metro Police Dept, 1200 Clark Ave, St. Louis, MO 63103; Tanisha V. Henson, MFS, 400 E Jackson St, Richmond, VA 23219; Julie A. Howe, MBA, Saint Louis Univ, College of Health Sciences, Allied Health Professions, 3084, St. Louis, MO 63104-1028; Donna C. Boyd, PhD*, Radford Univ, Forensic Science Institute, PO Box 6939, Radford, VA 24142; Ryan M. Rezzelle, MFS*, Johnson Co Sherriff's Office, Criminalistics Laboratory, 11890 S Sunset Dr, Olathe, KS 66061; Kim A. Collins, MD*, 1333 Martins Point Rd, Wadmalaw Island, SC 29487; Ted R. Hunt, JD*, Jackson County Courthouse, 415 E 12th St, Fl 7M, Kansas City, MO 64106; Pamela A.W. King, JD*, 400 S Broadway, Ste 15, Rochester, MN 55904; Jill L. Spriggs, MBA*, California Dept of Justice, Sacramento Lab, 4949 Broadway, Rm F104, Sacramento, CA 95820; and Jayne E. Thatcher, PhD*, Dept of Forensic Science, 700 N Fifth St, Richmond, VA 23219*

The goal of this workshop is to discuss the importance of communication among the various agencies involved in an investigation and the essentials of effective report writing.

This workshop will impact the forensic science community by providing encouragement, tools, resources, and support needed to give forensic professionals the ability to positively contribute to the forensic science field through effective, thorough, and clear communication.

With continual advancements in technology, various evidence collection methods, and the wide range of forensic disciplines, the importance of effective and efficient communication and the significance of accurate report writing have increased. Practitioners must communicate with individuals assigned to a case to ensure that accurate information is relayed and that evidence handling is coordinated between forensic disciplines. Analysts must keep abreast of new techniques; all the while contemplating how those findings should be presented to outside agencies and the judicial system. All of this work and coordination must then be summarized into a clear and concise report that can be used in court. The investigation of a criminal case is a constant give and take of information and this workshop will help illustrate the fact that no discipline is an island and without teamwork justice cannot and will not prevail.

Collaboration is most apparent in disciplines which require coordination with outside agencies in order to issue findings, including determining manner of death. This workshop will allow those who speak for the dead to share how to speak with them. Tanisha V. Henson will make a case that the information from law enforcement agencies can not only impact a ruling on manner of death, but can also determine if the medical examiner's office should be involved at all. Forensic Pathologist Kim Collins will discuss the pertinent information that is needed when she is working "alone in the basement" to determine cause of death.

The need for effective communication of course is not limited to the medical examiner's office. Members of the crime lab require the same exchange of information, often times with people in the same building. Ryan Rezzelle will discuss the various issues that arise as evidence moves through a crime lab and Jayne Thatcher will share the best way to communicate with the local toxicologist. Providing a managerial perspective, Jill Spriggs, lab director and current ASCLD-LAB president, will help workshop attendees define successful communication.

Of course the end result of most analyses is a report and tailoring reports to particular audiences can sometimes be difficult, as Donna Boyd will discuss from a forensic anthropology perspective. All of the speakers, however, will discuss what is included in standard reports and how they determine what goes into their report. Ted Hunt and Pam King will then discuss how these reports are used in the jurisprudence system from the perspective of the prosecution and defense, respectively.

Because true communication cannot occur without a certain amount of discourse, the end of the workshop will consist of a panel discussion with the speakers. The panel will be presented with topics important to the forensic community as well as points that arise during their presentations. Attendees will also be given the opportunity to pose questions, which will allow for a direct exchange of information.

This workshop will demonstrate that forensic analysis does not occur in a vacuum, but rather requires the work of multiple disciplines to form a complete and accurate picture of an event. This picture is painted with clear and concise reports, but only after an exchange of accurate information provides a rough sketch from which to begin. Only through open and effective communication, can a case, and ultimately a forensic discipline, progress, and move forward.

Forensics, Communications, Report Writing

W9 The Predator Next Door: Everything You Always Wanted to Know About Sex Offenders and Had No One to Ask!

Vivian Shnaidman, MD, 812 State Rd, Ste 220, Princeton, NJ 08540; Cinzia Gimelli, PsyD, PhD*, Viale Montegrappa, 29/C, Reggio Emilia, ITALY; Luciano Garofano, PhD*, Via G. D'Annunzio n.9, Parma, ITALY; Roberto Testi, MD, PhD*, Via Lessona 54/12, Torino, ITALY; Melania Lugli, PhD*, Viale Montegrappa, 29/C, Reggio Emilia, ITALY; Marina Genis, MA*, 21 Sunset Ave, Unit 149, Johannesburg, SOUTH AFRICA; Eleanor B. Vo, MD*, 285 Durham Ave, Bldg 6, Ste 2A, South Plainfield, NJ 07080-2546; and Michael Shnaidman, PhD*, 6 York Dr, Princeton, NJ 08540*

After attending this presentation, participants will: (1) understand the different types of rapists, pedophiles, and sexual psychopaths; (2) obtain a basic understanding of risk assessment; and, (3) have a clear picture of the warning signs when an individual they encounter might have a history of sexual offenses.

This presentation will impact the forensic science community by: (1) describing and differentiating the various types of sexual offenders; (2) explaining risk factors so practitioners will be able to appropriately identify and assess sexual predators; and, (3) providing information on determining risk factors in predators in order to make predictions about repeat activity.

Forensic evaluators will be able to utilize statistical and actuarial information appropriately, as well as understand the difference between a true clinical evaluation and clinical evaluations that the literature derides. Many individuals who work in the mental health field obtain the majority of their understanding about sex offenders from the popular media. This presentation will teach evaluators how to distinguish between fact and fiction. The "abuse excuse" and the politically incorrect topics of mentally ill and mentally retarded offenders will be presented and explored.

This workshop will present the following topics in as much detail as time permits:

- What might qualify as a sex offense can be surprising. Some of the theoretical underpinnings from the psychoanalytic literature will be touched upon, but in a very understandable and accessible manner.
- What is a sexually violent predator? Legal and colloquial understanding of this term differs greatly and in order to do this work, the evaluator must know the difference, which also depends on jurisdiction.
- Pedophiles—subtypes and morphologies—including the most likely culprits, how they operate, and "Stranger Danger."
- Internet Porn and the "victimless crime"—are they sex offenders, predators, or something else—and how does the use of internet porn predict offending against real live victims?
- Rapists and serial killers—can a serial killer not be a sexual predator?
- Rapist Morphology—because jargon is important.
- Sex offender risk assessment instruments—how they work

and how they do not—the theory behind using these instruments and how to use them with the appropriate caution.
- Sadists versus non-sadists—and what is sadism?
- Mentally ill and mentally retarded offenders—the "politically incorrect offender."

All topics—What is a sexual offense? In order to understand sex offenders their offenses must be identified—and will include case presentations and discussion. This workshop is intended to be an overview of all the types of sexual predators, how to identify them, how to perform risk assessments, and what clues to look for in their evaluations.

Sex Offenders, Rapists, Pedophiles

W10 Quality Assurance in Human Identification

John E. Byrd, PhD, 95-033 Hokuiwa St, No 51, Mililani, HI 96853-5530; and Thomas D. Holland, PhD*, Vincent J. Sava, MA*, Bradford Byrnes, LLM* and Stephanie R. Ah Sam, MS*, Hickam AFB, Central ID Lab, 310 Worchester Ave, HI 96853*

After attending this workshop, attendees will: (1) understand the basic quality assurance principles and measures applicable to human identification; (2) learn the unique challenges faced by professionals involved in human identification when striving to have their facilities, procedures, and casework meet the standards demanded by the criminal justice and medical-legal systems; and, (3) utilize the material presented to formulate a quality assurance program for their organization.

This presentation will impact the forensic science community by demonstrating how quality assurance in forensic laboratories and forensic programs has led to objective and measurable standards of performance that ultimately strengthen and elevate the forensic profession as a whole.

Quality Assurance Programs (QAP) and activities in forensic laboratories have been a growing trend over the past decade. The publication of the National Academy of Sciences Report: *Strengthening Forensic Science in the United States: A Path Forward* and its recommendations have made quality assurance programs and accreditation an increasing priority for forensic human identification laboratories. Since 1999, the Joint POW/MIA Accounting Command (JPAC), Central Identification Laboratory (CIL) has implemented a stringent QAP to ensure the scientific integrity of its casework. The CIL's QAP ultimately led to its accreditation by the American Society of Crime Laboratory Directors Laboratory Accreditation Board (ASCLD-LAB) in 2003—the first forensic skeletal identification laboratory so credentialed. In 2008, the CIL was re-accredited under the ASCLD-LAB *International Program* using ISO 17025 Criteria.

The goals and objectives of this workshop are to introduce the attendee to the CIL's QAP and to convey the lessons learned resulting from its implementation and growth. The workshop begins with an overview of the CIL, its mission, and QAP. A video of the CIL's mission and operations is presented. In the latter, the concept of the scientific integrity of the CIL is discussed followed by a summary of the "Surety" model of quality assurance.

The participants become familiar with each measure that comprises the surety model of quality assurance. The importance of integrating and synchronizing all of the surety measures discussed during the workshop is continually stressed.

Issues that are currently at the forefront of forensic quality management are presented. These include:
- Professional qualifications and development
- Ethics
- Research and development
- Validation of technical procedures
- Uncertainty of measure
- Data management and information release

Infrastructure and support considerations necessary for a successful QAP are also presented. Surety measures addressed include, but are not limited to:
- Desired qualities of a laboratory manual and other vital documentation and their control
- Adequacy and safety of laboratory facilities
- Purchasing and contracting for laboratory services and supplies
- Policies and procedures conducive to a positive work environment
- Customer service programs and complaint procedures
- Evidence management and security
- Training and professional development

Gathering and interpreting evidence discusses quality assurance measures directly related to field operations and trace evidence casework. These surety measures include:
- Peer review process
- Preparation of analytical notes, test reports and other case documentation
- Photography and other imaging
- Maintenance, calibration, and performance checking of equipment
- Taphonomic effects and evidence conservation considerations
- Writing and editing standard operating procedures (SOPs)

Quality assurance procedures and programs are ineffective unless they are monitored, enforced, and subjected to corrective action when non-compliances are discovered. Monitoring and corrective actions outline how these are accomplished in the CIL. Discussed are a myriad of surety measures including:
- Proficiency testing
- Review of court testimony
- Internal and external audits
- Annual reports to, and management reviews with, top management
- Corrective action policies and procedures regarding personnel, technical procedures, facilities, etc.

In closing, the workshop discusses problems that hindered, and the processes that led to, the accreditations of the CIL. Surety assistance programs offered by the CIL are discussed in the event an attendee's organization desires assistance with their QAP or accreditation efforts. Additionally, the contributions, to date, of the Scientific Working Group in Forensic Anthropology (SWGANTH) to the human identification profession are briefly discussed.

Quality Assurance, Human Identification, Forensic Anthropology

W11 Bones and Children: An Interdisciplinary Approach to Forensic Issues

Andrew M. Baker, MD, OCME, 530 Chicago Ave, Minneapolis, MN 55415; Kathryn H. Haden-Pinneri, MD*, and Jennifer C. Love, PhD*, Harris Co Institute of Forensic Sciences, 1885 Old Spanish Trl, Houston, TX 77054; B.G. Brogdon, MD*, Univ of South Alabama, Medical Center, Dept of Radiology, 2451 Fillingim St, Mobile, AL 36617; Christian Crowder, PhD*, OCME, 520 1st Ave, New York, NY 10016; and Christopher S. Greeley, MD*, UT Health Science Center, Dept of Pediatrics, 6431 Fannin St, Houston, TX 77030*

After attending this workshop, attendees will be able to: (1) understand strengths and weaknesses of the various disciplines (pathology, anthropology, pediatrics, and radiology) that can evaluate fractures in children; (2) describe medical conditions that can mimic fractures or predispose pediatric populations to fractures; (3) recognize that the collaboration of various medical and forensic specialists is the most productive way to find and evaluate fractures; (4) understand the strengths and limitations of various techniques for constructing the biological profile (age, sex, ancestry, and stature) of the dead, and how various factors impact these determinations; and, (5) understand the techniques used in evaluating pediatric remains that may be decomposed, unidentified, and/or skeletonized.

This workshop will impact the forensic community by assisting in the evaluation and interpretation of fractures in children. The finding of

fractures in children, particularly the very young, can have profound medicolegal implications if the fractures are suggestive of inflicted injury. The clinical, radiological, histological, and anthropological aspects of the fracture may provide useful information as to the mechanism and/or age of the injury. Correlation with published studies and the experience of the pediatric and radiological communities may prove vital in assessing whether a fracture might be accidental, or whether the child may have a medical condition predisposing to—or mimicking—fractures. By bringing a variety of medical and forensic specialists together to examine all aspects of fractures—including accidental fractures, conditions that might mimic fractures, and conditions that can predispose to fractures in the pediatric population—this workshop will help attendees increase knowledge of fracture evaluation within their own disciplines, and develop a deeper appreciation for the understanding of fractures that other medical and forensic specialists can bring to the table. This workshop also will impact the forensic science community by going beyond fractures to examine skeletal features of children and techniques which can be used that may prove useful in estimating or establishing age, verifying identity, estimating time since death, and confirming the presence of antemortem trauma.

The complex intersection of skeletal trauma analysis, bone pathology, clinical pediatrics, and radiology is centered on children, and often necessitates a multidisciplinary approach. The presence of unexplained fractures in living and deceased children—particularly infants and the very young—may have profound implications for how injuries are assessed and deaths investigated. Pediatricians, radiologists, pathologists, and anthropologists all have much to offer in the assessment of the pediatric skeleton, but may be unaware of other disciplines' skills that can be brought to bear on questions of considerable legal and forensic significance. Furthermore, some diseases may mimic fractures, or predispose to fractures, and these conditions must be recognized to ensure proper treatment and/or avoid miscarriages of justice. Just as the finding and interpreting of fractures in children is different than in adults, so too is the recovery and identification of pediatric remains. Thermal injury, decomposition, postmortem changes, and a variety of other factors present significant challenges in recovery and identification.

This workshop will utilize multiple medical and forensic disciplines (anthropology, pathology, radiology, and pediatrics) to examine features of children's bones that have forensic and legal implications: the recognition and interpretation of fractures; and, aspects of recovering, identifying, and evaluating skeletonized or decomposed pediatric remains. A significant portion of the workshop will be dedicated to explaining and demonstrating how various disciplines, working together, can provide more and better information and stronger conclusions than any one discipline alone. Specific examples of the multidisciplinary approach to the pediatric skeleton will include the complementary expertise of the pathologist and anthropologist in finding and interpreting fractures, the radiological and pathological correlation of fractures, clinical and radiological consultation with regard to pediatric development and likely fracture mechanisms, clinical and radiological features of diseases that mimic or predispose to fractures, and the multidisciplinary approach to the recovery and interpretation of pediatric skeletal remains. Historical and technical aspects of the various disciplines: anthropology (fracture identification, tissue maceration, fracture photography, assessment of healing, skeletal recovery, techniques for aging); pathology (fracture identification, specimen handling, bone development, normal and abnormal bone histology); radiology (the historical development of the recognition of abuse, techniques in radiological evaluation); and, pediatrics (examination of the patient, the differential diagnosis of skeletal findings) will be addressed.

Bones, Children, Fractures

W12 Principles and Applications of Liquid Chromatography Mass Spectrometry (LC/MS) for the Forensic Toxicologist

Peter R. Stout, PhD, and Megan Grabenauer, PhD*, RTI International, Center for Forensic Science, 3040 Cornwallis Rd, Research Triangle Park, NC 27709; and Michael Chen, PhD*, and Jeffrey P. Walterscheid, PhD*, Harris Co Inst of Forensic Sci, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will understand the fundamentals of LC/MS for screening and confirmation of drugs and the advanced applications for forensic toxicology and insights into how results are reported. Attendees will benefit from and have the opportunity to discuss challenges at the end of the session.

This workshop will impact the forensic science community by raising awareness of the capabilities of LC/MS in detection strategies by accurate mass measurements and confirmation techniques by tandem mass spectrometry. This workshop will also explore cutting-edge analytical methods for evaluating routine and emerging drug compounds involved in impairment or death investigations.

The use of liquid chromatography time-of-flight mass spectrometry (LC/TOF-MS) for screening purposes has gained popularity in recent years. Different laboratories have developed screening methods for drugs of abuse, pesticides, veterinary drugs, doping agents, and other poisons in different matrices such as blood, urine, vitreous humor, hair, and even food. The original fame of accurate mass for confirming theoretical molecular formulas for synthetic compounds has grown to include its use in identification of unknowns and searching for target compounds in complex matrices. Mass measurements that are accurate to several decimal places coupled with creation of target drug compound list with retention time data allows for rapid, selective, and specific screening of target compounds.

The first session will address the basics of liquid chromatography based mass spectrometry. The commercialization of LC/MS permits the use of gentle electrospray ionization, while providing accurate mass and retention time data to identify analytes. Instrumental variants that use time-of-flight analysis provides an expansive technique for screening a large number of known and unknown analyte possibilities, while tandem-mass hardware is ideal for confirmation and quantitative analyses. A wide array of drugs, metabolites, adulterants, and other exotic compounds can be monitored by these techniques.

There are extensive classes of known synthetic cannabinoids and cathinone derivatives yet limited panels of available reference standards. These groups have quickly become an emerging threat to public safety due to their accessibility and lack of detection by routine screens. Furthermore, these drugs continue to evolve as manufacturers creatively modify side chains to complicate identification of new drugs and alter drug potency. The second presentation will address this problem by applying a technique of identifying compounds by accurate mass defect filtering. This approach allows the analyst to distinguish unique signals from matrix elements and other components that may obscure significant findings in unknown samples.

Once scans have revealed the presence of compounds of interest, it is necessary to authenticate the identity by establishing the concentration in comparison to a standard. However, there are many pitfalls that can obfuscate true proof of the analyte in question. Isobaric compounds are isomers that share the same molecular formula, mass, and possibly the same fragmentation ions or retention time. Techniques for extraction, chromatography, and mass spectrometry confirmations will be outlined. Choices of solvents, gradient profiles, specification of daughter ions, and, collision energies to enhance sensitivity and specificity in unambiguously defining the compound by liquid chromatography tandem mass spectrometry (LC/MS/MS) will be discussed.

From screening to confirmation, the data is assembled for reporting a result in the final analysis. The interpretation of data for toxicology reports requires knowledge of anticipated mass, retention time, and relative abundance of daughter ion ratios. Lastly, attendees will be

shown how to discern supportive data from suspect outcomes, and evaluate the veracity of the declared determination.

LC/MS/MS, LC/TOF-MS, Toxicology

W13 Calculating Likelihood Ratios Incorporating a Probability of Drop-Out: Introducing Lab Retriever — A Free and User-Friendly Software Program

Keith Inman, MCrim, Dept of Criminal Justice Adm, 4069 Meiklejohn Hall, 25800 Carlos Bee Blvd, Hayward, CA 94542; Norah Rudin, PhD*, 650 Castro St, Ste 120-404, Mountain View, CA 94041; Kirk Lohmueller, PhD*, Dept of Integrative Biology, 3060 Valley Life Sciences, Bldg 3140, Berkeley, CA 94720; and Daniel J. Gregonis, MS, California Dept of Justice, 7425 Mission Blvd, Riverside, CA 92509*

After attending this workshop, attendees will: (1) gain an understanding of how to solve challenges encountered by analysts in interpreting and weighting difficult DNA profiles; and, (2) learn the basics and mechanics of a free user-friendly software program to calculate statistics based on maximum profile information.

This presentation will impact the forensic science community by addressing one of the most difficult and prevalent challenges that forensic DNA laboratories face today—the interpretation and statistical weighting of complex DNA samples.

One of the most difficult and prevalent challenges that forensic DNA laboratories face today is the interpretation and statistical weighting of complex DNA samples. The forensic DNA community has struggled to provide reliable statistics for these ambiguous profiles. In a well-intentioned attempt to be "conservative," much of the information in the profile often is simply ignored. Far from being safe, this approach is dangerous in that it can lead to incorrect or grossly mis-weighted conclusions.

It is believed that the most reliable scientific interpretation and weighting of forensic DNA profiles should use as much information as possible. While general agreement exists that a likelihood ratio (LR) incorporating a probability of drop-out ($P(D_O)$) is the gold standard, implementation has been difficult for a number of reasons. First, although several automated tools to perform LRs in general have been proffered, they have been opaque, expensive, and not particularly user friendly. Second, in order to maximize the utility of LRs for challenging samples, it is necessary to incorporate a $P(D_O)$. Although a vast repository of data is available from the validation studies of forensic DNA laboratories, this information has not yet been mined for its value in empirically estimating drop-out probabilities. Third, it is critical to use a scientifically-determined analytical threshold to maximize the data used to generate a statistical weight.

The elements required to perform a LR with a $P(D_O)$, in particular the empirical determination of an analytical threshold and the empirical determination of the $P(D_O)$ will be discussed. A software tool that includes an easily-accessible user interface will be introduced. The Lab Retriever software, including the back-end computer code will be freely available without charge.

Approaches to assessing the weight of challenging samples — The advantages and limitations of several different approaches to assessing the weight of forensic DNA evidence will be discussed. These include the use of a stochastic threshold, the "2p rule," and a likelihood ratio (LR) that explicitly models the possibility of drop-out. Using current research results, Incorporation of drop-out leads to accurate estimates of the LR will be demonstrated. Similarly, data that the stochastic threshold approach often heavily underestimates the strength of the evidence and can lead to false exclusions will be presented. Further, results demonstrating that the "2p rule" performs similarly to the LR approach for some of the same situations will be shown.

Empirical determination of an analytical threshold — How thresholds currently employed by DNA labs are frequently too high and true DNA peaks left undetected, resulting in the abandonment of valuable information from difficult samples will be explained. We will show how an empirically derived analytical threshold assists in properly calculating an LR with a $P(D_O)$. How to determine an appropriate analytical threshold as the first step in preparing data for input into the "Lab Retriever" computer program will be demonstrated.

Empirical determination of $P(D_O)$ — A major impediment to implementing LR with $P(D_O)$ has been the lack of an empirically determined $P(D_O)$. How to determine an appropriate range of $P(D_O)$ for use with Lab Retriever, from data that every DNA laboratory has produced during validation will be demonstrated. The resulting algorithm is used to estimate the $P(D_O)$ for evidence samples.

Introduction to Lab Retriever — Lab Retriever, (Buckleton and Balding 2009, modified by Lohmueller) a program to calculate LRs with drop-out will be introduced. How data from an ambiguous profile is prepared for LR analysis will be demonstrated. Workshop attendees will participate in a practical exercise to reinforce their understanding of selection and preparation of data for use in Lab Retriever. Participants will be instructed on using the software, and will be provided with materials with which to practice their newly acquired knowledge and skills at home.

Low Template DNA, Likelihood Ratio, Dropout Probability

W14 *Melendez-Diaz*, *Bullcoming*, and *Williams*: Scientific Evidence and the Right to Confrontation

Justin J. McShane, JD, 4807 Jonestown Rd, Ste 148, Harrisburg, PA 17109; Marc A. LeBeau, PhD*, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135; David Kaye, JD*, Penn State Univ, Dickinson School of Law, Lewis Katz Building, University Park, PA 16802; Boris Moczula, JD*, Office of The Attorney General, PO Box 080, Trenton, NJ 08625-0080; and Robert A. Middleberg, PhD*, and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this workshop, attendees will be able to: (1) discuss the courts' interpretation of the Sixth Amendment on right to confrontation; (2) assess the impact of the rulings on forensic laboratory operations; and, (3) consider aspects of these rulings from perspectives other than their own.

This presentation will impact the forensic science community by educating forensic laboratory management and personnel about the requirements courts place on forensic science testimony, while educating attorneys about the impact of these rulings on laboratory operations and encouraging dialog between scientists and lawyers on meeting constitutional obligations while practically allocating resources within laboratories.

This workshop will examine the impact of three recent Supreme Court rulings on the right of defendants to confront expert witnesses at trial. The program will consider the issue from the perspectives of an academic constitutional law, prosecution, defense, and forensic laboratory director perspective, and will include an update on new appellate cases.

The Sixth Amendment to the United States Constitution guarantees that a defendant will have the right to confront their accuser. Becoming effective in 1791 as part of the Bill of Rights, this amendment was designed to help ensure fairness in criminal prosecutions and goes back to earlier European law. But in the age of electronic communications, video conferencing, automated testing, increasingly complex scientific evidence, and constrained forensic laboratory resources, how is that to be interpreted in 2012?

This workshop considers three important rulings issued by the U.S. Supreme Court in the last four years concerning the admissibility of laboratory results in criminal cases: *Melendez-Diaz vs. Massachusetts*, *Bullcoming vs. New Mexico*, and most recently *Williams vs. Illinois*.

These cases address, in part, the issue of what constitutes testimonial evidence, and who is permitted to testify to what aspects of scientific evidence under some case specific conditions. The Court, however, leaves many questions unanswered, including who is the "analyst" for purposes of confrontation, and can a scientist testify about their opinion on scientific evidence not admitted?

Courts interpretations of these cases has a significant impact on the presentation of scientific evidence in court, management of forensic laboratory resources, and the outcomes of trials in major crime cases.

This workshop will present four perspectives on the issue, beginning with a consideration of the language of the sixth amendment, its context in the time it was adopted, and subsequent interpretation in United States case law. This is followed by presentations between appellate attorneys on the state and defense side both with extensive experience in the presentation of scientific evidence. Perspectives on legal and practical aspects of litigating cases with forensic evidence will be presented and followed by the perspective of a forensic laboratory director responsible for planning laboratory operations, assigning job duties, and ensuring scientist availability for court in a laboratory environment where typically many people are involved in the analysis of a single piece of evidence.

The session concludes with a moderated discussion by the panel of presenters and a question and answer session with the participants.

***Melendez-Diaz*, Sixth Amendment, Testimony**

W15 Improving the Effectiveness of Forensic Service: Using the Foresight Project as a Platform for Quality

Max M. Houck, PhD, PO Box 6250, Arlington, VA 22206; Jay W. Henry, BS*, Utah State Crime Laboratory, 4501 S 2700 W, Salt Lake City, UT 84119; and Paul J. Speaker, PhD*, West Virginia Univ, Coll of Business and Economics, PO Box 6025, Morgantown, WV 26506-6025*

After attending this workshop, attendees will be: (1) able to use basic metrics to evaluate the effectiveness and costs of their forensic services; and, (2) provided a platform for bench-marking with other forensic providers.

The workshop will impact the forensic science community by providing tools that will help improve operations of sections, units, or laboratories, while keeping in mind the importance of effectiveness and efficiency to ensure accuracy, quality, and timely provision of forensic services.

Forensic service providers are—in essence—non-profit, production-oriented organizations staffed largely by knowledge workers. Forensic scientists as knowledge workers take evidence and data and convert them into knowledge in the form of reports and testimony. They specialize in these transactions and, therefore, simplify them for the benefit of the criminal justice system; the investigators or attorneys do not need to find numerous individuals to conduct the specific examinations required for a case. As long as the costs of providing these services externally do not exceed the costs of their internal provision, for example, by a government forensic laboratory, then the organization can prosper. If the government laboratory costs are greater than the cost of finding private laboratories to provide services, then the organization may be re-evaluated. Comparatively, non-profit and for-profit organizations are similar in some ways (money is an input for both) yet different (money, in the form of profits, is an output only for the private sector). Non-profits must therefore measure success in other ways, such as "low cost" or "cost effective." Forensic service providers and their parent organizations use terms such as "cost-effective" vaguely without reference to other disciplines which use these as well-defined technical terms in evaluative phrases or formulae. Despite the great concern and administrative angst over forensic service providers' "performance" and "capacity," these metrics go undefined as industry standards.

Managers of scientific laboratories see themselves as scientists first and managers second; consequently, they tend to devalue the managerial aspects of their jobs. Despite—or perhaps because of—this lack of explicit understanding, forensic service providers are held accountable by one or more agencies for their performance based on non-standard, ill-defined, or non-existent criteria. Successes and improvements go unrecognized and opportunities for advancing the mission and goals of the organization are squandered. The stakes for forensic laboratories are high given the importance of quality science to the criminal justice system. The need for training and support in forensic laboratory management has been recognized for many years but little has been done to transition the tools of business to the forensic laboratory environment.

This workshop will provide an overview on how to use simple business metrics to evaluate your forensic services, improve effectiveness and quality, and provide the supporting information to request or justify additional resources. The workshop uses tools and data from the FORESIGHT Project, a business-guided self-evaluation of forensic science laboratories across North America. The process involves standardizing definitions for functional areas of the laboratory and metrics to evaluate work processes, linking financial information to work tasks and functions. Laboratory managers can then assess resource allocations, efficiencies, and value of services—the mission is to measure, preserve what works, and change what does not.

As an exercise to highlight the relevancy of the process, attendees are encouraged to develop the following data from their agencies for DNA, fingerprints, or toxicology (antemortem or postmortem): total financial expenditure in that area; number of full-time employees, including clerical; total compensation including benefits; number of cases submitted; and number of tests conducted. For this data, attendees are encouraged to use the standard definitions of the FORESIGHT Project as listed on the Laboratory Reporting and Analysis Tool (LabRAT).

Effectiveness, Efficiency, Foresight

W16 Forensic Entomological Aspects of Abuse and Neglect

Ralph E. Williams, PhD, Purdue Univ, Dept of Entomology, 901 W State St, West Lafayette, IN 47907; Neal H. Haskell, PhD*, 425 Kannal Ave, Rensselaer, IN 47978; Sharon L. Plotkin, MS*, 700 NE 124 St, North Miami, FL 33161; Laura La Cagnina, RN, MSN*, 1980 Kramer Way, Marietta, GA 30062; and Natalie M. Borgan, MS*, 22249 Summit Vue Ln, Woodland Hills, CA 91367*

After attending this workshop, attendees will: (1) review the different scenarios in which insects are involved in abuse and neglect; (2) be shown how entomological investigations in such cases are carried out and how insect evidence can be of importance in the investigation; (3) be presented with the legal aspects of such cases; and, (4) be presented with criminal activity associated with using insects to make false accusations of abuse and neglect.

This presentation will impact the forensic science community by showing how abuse and neglect cases, in which insect evidence is present, are assessed and dealt with in the forensic investigation. Attendees will also become familiar with recognizing how insect evidence can be useful in addressing abuse and neglect cases in the criminal justice system.

Forensic entomology is often thought of as being involved with death investigation; however, insects can be of real concern in various aspects of abuse and neglect. Human insect infestations can sometimes become an issue with abuse and neglect of nursing home patients when bedding, clothing and hygiene of patients is at issue, with babies whose personal hygiene is not properly cared for, with the improper handling of wound cleansing, and various other situations in the medical profession. Some of the same insects (especially various fly species) associated with death investigations can also be involved in abuse and neglect cases. Many of these cases end up in the court system either as lawsuits or as criminal cases. This workshop will present the various situations in which insects can become involved in abuse and neglect with specific case studies presented. The criminal aspect of planting insects to appear as abuse and neglect will also be discussed.

Insect evidence can be found on contaminated clothing, bedding material, urine and fecal deposits, diapers, open sores and wounds, soiled wound dressings and bandages, among others. Entomological procedures will be presented to provide guidance in recognizing insect evidence associated with abuse and neglect along with collection and preservation techniques of insect evidence. Insects that are often seen in abuse and neglect cases are various species of flies, including blow flies, flesh flies, house flies, and others. Other insects and related arthropods that may be of issue include ants, beetles, bedbugs, mites and ticks, and spiders. Specific case studies will be presented to include abuse and neglect of elderly in care centers and nursing homes; infant abuse and neglect where insect invasion of clothing and feeding has occurred, and situations involving insect contaminated wounds from patients of outpatient caregivers. Also, cases of insect and related arthropod invasion and attack in which people claim to have been bitten will be presented. In addition to real cases of neglect and abuse, the criminal aspect of the planting of insects to appear as abuse and neglect and falsifying insect evidence will be discussed. Related to non-real cases is the area of delusory parasitosis, or entomophobia (a fear of insects). This will be presented to distinguish it from real cases of abuse and neglect. Discussion will be presented including the involvement roles of the entomologist, crime scene investigator, forensic nurse, and legal counsel.

The workshop will be concluded with discussion on the legal system's role in dealing with abuse and neglect cases from the aspect of lawsuits to criminal cases. How to determine the difference between lawsuits and criminal involvement will be discussed since this is often a point of contention. The role of the attorney and expert witness (entomologist, CSI, medical personnel, etc.) will be reviewed from both the plaintiff and defendant viewpoint.

Abuse and Neglect, Insect Evidence, Forensic Entomology

W17 Image Analysis — 3D Imaging and Virtopsies: Developments, Methods, and Reasoning About Images

William R. Oliver, MD, East Carolina Univ, Brody School of Medicine, Brody Medical Sciences Bldg, Greenville, NC 27834; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, NETHERLANDS; Michael Thali, MD*, Univ of Zurich, IRM/Forensic Institute, Winterthurstrasse 190/52, SWITZERLAND; David R. Fowler, MD*, OCME, 900 W Baltimore St, Baltimore, MD 21223; and Jurrien Bijhold, PhD*, Laan van Ypenburg 6, Den Haag, NETHERLANDS*

After attending this workshop, attendees will understand: (1) the issues with interpretation of images; (2) how virtopsies can help with interpretation; and, (3) what methods for validation exist.

This workshop will impact the forensic science community by: (1) explaining the different methods in imaging; (2) giving a relation between general image interpretation and interpretation of images in virtopsies and crime scene imaging; and, (3) briefing attendees on pitfalls, possibilities, and future expectations of image analysis.

The field of forensic imaging is expanding rapidly. There is a wide variation of images that can be used in forensic science, ranging from CT/MRI scans to photographs, video, three-dimensional acquisition of images with laser, or light to spectral and thermal imaging of crime scenes. The integration of these new technologies into working offices can be a challenge.

This workshop will discuss some of the issues related to this type of integration. Some of these technologies will be discussed and examples of how they are being used in offices today will be demonstrated. The use of 3D scanning provides better measurement and visualization as well as the ability to estimate error. The development of image databases allows exploitation of imagery over time and among different activities. Automated methods of image comparison and data mining allow exploitation of imagery that is transforming investigations. The use of computed tomography (CT) and magnetic resonance imaging (MRI) provides new and important information in the investigation of death, including better measurement of three-dimensional features and even, in the case of MR spectroscopy, biochemical analysis of tissues.

While these new technologies provide important benefits, they also present significant challenges. New technologies require interdisciplinary cooperation and training. Integrating these new technologies into existing organizational structures requires new infrastructure and different workflows. Rapid changes in large organizations can be a challenge, and those who are considering them should be aware of common organizational pitfalls. Practical issues of funding, organization, operation, and acceptance can be as or more important than the technical issues commonly considered.

Quality assurance is important to have in place when implementing these systems, especially in handling large amounts of data. For validation, a reference database of images can also be used to have a statistical approach on conclusions that can be drawn from these. Development of algorithms for comparison in databases and using these for computing likelihood ratios are presented, as well as a Bayesian framework that can be used for combining conclusions of different independent features. Examples are shown for related to morphometric comparison of 3D shapes in fields such as cartridge cases, shoeprints, and tool marks in databases. New developments in forensic science such as thermal imaging for determining the time of death at the crime scene and spectral imaging provide a new solution; however, it should be validated before being used in actual casework and/or integrated in the standard quality assurance system. Lessons of implementation of fast developing technology, such as digital evidence, can learn from the best practices from each other.

Further, modern requirements for justification of scientific conclusions require that one look at how these images are analyzed. The analysis of imagery includes determination of image authenticity, image integrity and provenance, and image content. This involves both technical issues and issues about how we think about images. It is important to examine how we look at images and what our reasoning processes are. The workshop will cover a broad range of imaging techniques, their validation and the implementation on conclusions that can be drawn from these from a broader perspective in a multidisciplinary approach.

Image Analysis, 3D Imaging, Virtopsies

W18 Staged Crime Scenes: Crime Scene Clues to Suspect Misdirection of the Investigation

Grant D. Graham, MFS, Fayetteville Police Dept, 467 Hay St, Fayetteville, NC 28301; and Arthur S. Chancellor, MA*, 131 Wed Denning Rd, Angier, NC 27501*

After attending this workshop, attendees will: (1) be able to identify the three new categories of staged scenes with case examples of different types of crimes where staging is prevalent; and, (2) learn the "red flags" or common findings in staged scenes.

This presentation will impact the forensic science community by introducing distinct categories of staging based on the motive of the offender's scene alteration. Ultimately, applying these categories may help in the quick recognition of scene alterations or staging.

In the course of their career, most detectives and forensic practitioners will come into contact with a staged crime scene; a scene that has been altered by the offender to either mislead a police investigation as to the true facts of the crime or for other reasons understood only by the offender. Staged scenes and "staging" are possible in nearly every type of criminal offense raging from property crimes such as arson and burglary to violent crimes such as homicide, child abuse, or sexual assaults.

To better understand the dynamics and the general nature of "staging" this workshop will introduce distinct categories of staged crime scenes based on the motive of the offender's scene alteration. The thrust of this workshop is to understand that the offender's actions to stage a

scene can actually be identified through common findings or "red flags" that are often found when scenes are altered. Further, that these same red flags may help in the quick recognition of scene alterations or staging, and based on new criteria may be divided into three separate and distinct categories. These categories are herein referred to as, Primary, Secondary, and Tertiary staging.

The Primary staged scene is intentionally altered or changed by the offender with criminal intent to misdirect a subsequent police investigation and can be further sub-categorized into two types: ad hoc and premeditated. The ad hoc subtype is staged without forethought and planning, at the spur of the moment after the event has taken place, and is generally intended to deflect attention away from the offender and true facts of the crime. The scene is considered premeditated when the offender pre-plans the scene alterations in accordance with a preconceived scenario. Premeditated staging is often designed to focus attention onto the staging and false evidence. Ultimately, through Primary staging the offender in effect creates a false reality that in his/her mind will successfully and with criminal intent, misdirect the police investigation.

Secondary staging involves the intentional alteration or manipulation of the crime scene or victim by an offender that is unrelated to misdirecting or diverting subsequent investigations. This is really a new category of staged scenes and would include such examples as posing the victim's body into sexual provocative positions as found in sexual homicides or other elements of what is more commonly known as "staging" such as covering the face or body in what is generally often described as depersonalization. The perpetrator's purpose in Secondary staging is not to misdirect the investigation, rather it is often something that is psychologically part and parcel to the crime, such as demeaning the victim or demonstrating ultimate control over the victim.

Tertiary staging defined consists of noncriminal, accidental, or innocent alterations; i.e.. changes to the original crime scene, generally by witnesses or family members, who find the victim and alter the scene without any criminal intent. An example would be a family member finding a loved one in an embarrassing position from an autoerotic misadventure and changing the scene to prevent embarrassment to the family. These types of alterations are best regarded as scene artifacts.

Primary Staging, Secondary Staging, Tertiary Staging

W19 Developments in Emerging and Designer Drug Markets 2013

Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090; Jeri D. Ropero-Miller, PhD*, RTI International, 3040 Cornwallis Rd, Bldg 7, Rm 211, Research Triangle Park, NC 27709; DeMia Peters Pressley, MS*, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Dr, Springfield, VA 22152; Roumen Sedefov, MD*, EMCDDA, Cais do Sodré, 1249-289, Lisbon, PORTUGAL; Kabrena E. Rodda, PhD*, USAFA Prep School, 5220 Cedar Dr, Ste 117, Colorado Springs, CO 80840-3100; Marilyn A. Huestis, PhD*, Intramural Research, NIDA, NIH, Chemistry and Drug Metabolism, 251 Bayview Blvd, Rm 05A721, Baltimore, MD 21224; Jeffrey Moran, PhD*, Public Health Laboratory, Slot 47, 4815 West Markham, Little Rock, AR 72205; Peter R. Stout, PhD*, RTI International, Center for Forensic Science, 3040 Cornwallis Rd, Research Triangle Park, NC 27709; and Michael Baumann, PhD*, Intramural Research, NIDA, NIH, DHHS, Medicinal Chemistry Section, 333 Cassell Dr, Ste 4500, Baltimore, MD 21224*

After attending this workshop, attendees will be able to: (1) evaluate their laboratory's preparedness for meeting the demands for designer drug testing; (2) describe the major features of the current illicit designer drug market; and, (3) implement additional resources for testing and interpretation.

This workshop will impact the forensic science community by providing updates on the most dynamic and rapidly changing area of forensic chemistry and toxicology in recent years, as well as providing forensic scientists with practical resources to implement at their own laboratories.

This workshop will provide updates on the rapidly changing field of designer drugs and their analogs. The workshop will present epidemiological information, trends reports from forensic laboratories, novel testing methodologies, and new analytical resources for criminalistics and toxicology laboratories.

Starting in 2009, a variety of products containing psychoactive drugs not previously known in the United States began to appear in the recreational drug marketplace. To date, these substances have been principally synthetic cannabinoid agonists or stimulant/hallucinogenic cathinone derivatives. The market is further changing; however, with Fatty Acid Amide Hydrolase (FAAH) Inhibitors, ketamine analogs, psychedelic phenethylamines, tryptamines, and benzofurans are now emerging in products and blends of multiple drugs. In the United States, federal authorities have moved to update scheduling and analog laws to keep up with the changes, but clandestine drug manufactures are constantly adding new classes.

This workshop begins with a series of presentations that evaluate the latest trends in the drug marketplace and help guide laboratories as to what drugs they should prioritize for method development and inclusion in their databases. These presentations include data from toxicological tests and street drug samples from labs throughout the United States as recorded in the U.S. NFLIS data set. The U.S. Drug Enforcement Administration (DEA) will also discuss their approach to categorization of the synthetic cannabinoid structural classes. Furthermore, the presentations include data from European laboratories where many of these drugs appear before reaching the United States' market. The epidemiological session will end with a discussion of the designer drug movement as a threat to the United States' domestic security.

The latter presentations will review developments in large scale screening for designer drugs as part of urine drug screening programs, and the challenges faced in matching screening technologies with confirmatory methods to make sure they remain compatible with each other and with the drug market. The session continues with presentations on elucidation of metabolic pathways for the synthetic cannabinoid and cathinone families of designer drugs, including use of *in vitro* and *in vivo* studies, and the application of GC/MS, LC/MS/MS and LC/TOF technologies. Publicly funded online databases and analytical data libraries will be described and approaches to their use in the identification of unknowns will be reviewed. The final sessions of this workshop will address the pharmacology and toxicology of methylenedioxypyrovalerone (MDPV), which emerged in mid-2012 as one of the most prevalent synthetic stimulant drugs, including animal behavioral studies which identify similarities between its effects and those of cocaine, explaining its popularity and potency. Also, discussed will be a collection of case reports of adverse events in users of synthetic drugs which have led to deaths and intoxications with fatal consequences.

Designer Drugs, Bath Salts, Cannabinoids

W20 Mobile Devices Examination

Rhesa G. Gilliland, MS, U.S. Postal Inspection Service, National Forensic Laboratory, 22433 Randolph Dr, Dulles, VA 20104-1000; Jason L. Shadle, BME*, U.S. Postal Inspection Service, Cleveland Digital Evidence Unit, 2400 Orange Ave, 2nd Fl, Cleveland, OH 44101; and Samuel I. Brothers, BBA*, and Willilam J. Abaunza, MS*, U.S. Customs and Border Protection, 7501 Boston Blvd, Rm 113, Springfield, VA 20598*

After attending this workshop, attendees will be educated in the examination of mobile devices in a forensically sound manner through discussion of relevant topics:

Handling and Preservation of Mobile Devices – Attendees will understand proper procedures for collecting and handling mobile devices so as to preserve data for forensic examination.

Validation of Mobile Device Examination Methods – This discussion will present a proposed framework for validating mobile device examination methods and software tools in light of agency accreditation requirements. By learning to leverage available resources against their limitations, attendees will be able to relate the *Daubert* standards to the

challenges specific to codifying methodologies in an ever-evolving discipline.

Cell Phone and GPS Forensic Tool Classification System – Given the overwhelming prevalence that mobile devices have in our society, there is a need for a common framework to classify the plethora of tools released into the commercial marketplace. With the claims of software manufacturers often exaggerated, there is a specific need to understand not only how these tools work but when they should be used. Attendees will be provided with an overview of current commercial tools available for cell phone data extraction and will be able to effectively categorize any mobile device acquisition tool within a classification system.

GPS Forensics – Given the overwhelming prevalence that GPS devices have in our society there is a need to classify the plethora of tools released into the commercial marketplace. With the claims of software manufacturers often exaggerated, there is a specific need to comprehend in depth the way these GPS tools operate and the features they provide an analyst for data acquisition and analysis. Attendees will be provided with an overview of current commercial tools available for GPS data extraction/analysis and will be able to effectively categorize these tools within a classification system.

This presentation will impact the forensic science community by providing sound strategies and methodologies that can be directly applied to the examination of mobile devices and furthering the development of the digital forensic discipline.

Our world has become saturated with inexpensive digital devices. The ubiquitousness of these devices has changed the way we do everything, from staying in touch with friends on our "smartphone's" to finding the nearest gas station with our Global Positioning System (GPS). These devices are also frequently used by those engaged in criminal enterprise. Mobile devices themselves contain a wealth of information and intelligence for investigators; however the field of mobile digital device forensics is still in its infancy. In the forensic science community, mobile devices continue to be one of the most challenging areas for gaining and maintaining expertise. Mobile devices continue to evolve as new hardware/software combinations are updated several times a year. Trying to stay current with this evolving technology is a daunting task for any forensic analyst. This workshop will provide all knowledge levels the information to begin and/or maintain the ability to examine mobile devices. The process begins with the proper seizure of the device and how to ensure the device's data is maintained. Included will be a discussion of several different isolation methods that can be used to protect the mobile device from communicating while an examination is in progress. Isolation is necessary as any successful communication during the examination may result in a change in the data contained within the phone, or at worst, a complete forensic wipe of the device. There will be a discussion on the various isolation methods to protect the mobile device both on scene and in the laboratory. There will be a discussion on the need of verification to review the data located on the mobile device. This review correlates the information stored in the device with the data present in the data extraction report. The next step is the testing of the tools used for data extraction. Understanding what to expect from a given tool and then ensuring the information it provides matches what is stored in the mobile device is another critical step in the analysis process. An overview of validation as it pertains to the tools for mobile examination will be provided based upon ISO 17025.

A discussion of several of the commercially available GPS forensic tools will transpire. The workshop will conclude with a question and answer period. This workshop is designed to provide information and resources to computer forensic professionals regarding the examination of mobile devices from initial seizure to forensic analysis. Attendees will be provided with a rationale for the validation of mobile forensic examination methods. Additionally, detailed discussion will address classification of cell phone and GPS tools and extraction of deleted call history and text message records from the Apple® iPhone®.

Mobile Device, Computer Forensic, GPS

W21 Tracking John Wilkes Booth: An Interpretive Bus Tour

James E. Starrs, LLM, 8602 Clydesdale Rd, Springfield, VA 22151; Kenneth E. Melson, JD, George Washington Univ School of Law, 2000 H St NW, Washington, DC 20052; and Walter J. Knowles, MA*, 5593 Marshall House Ct, Burke, VA 22015*

After attending this workshop, attendees will understand the complexities in the tracking, the death, and the final burial of John Wilkes Booth, the assassin of President Lincoln, and the forensic science issues spawned by the assassination.

This presentation will impact the forensic science community by providing an interactive tour that will provide a fuller, real-world understanding of the escape route taken by John Wilkes Booth as well as the places and persons entwined with this place in American history.

This program will focus, through a moderated bus tour and site visitations, on the escape of John Wilkes Booth from Ford's Theatre to the homes of Mary Surratt and that of Dr. Samuel Mudd in Southern Maryland. Commentaries will be provided on the identification of the derringer as the murder weapon as well as the terminal medical care of Lincoln at the near-by Petersen House in Washington, DC and the identification of John Wilkes Booth.

The assassination of President Abraham Lincoln on Good Friday, April 14, 1865, and its aftermath put the spotlight on a number of historical matters of forensic significance. This one-day bus tour will highlight the places and events at the District of Columbia's Ford's Theatre, the site of the assassination, and at the Petersen House where Lincoln died and will follow the escape route of John Wilkes Booth to the Surratt Tavern and the home of Dr. Samuel A. Mudd in Southern Maryland where tours of the sites and discussions of the involvement of Mary Surratt and Dr. Mudd in the assassination conspiracy will be provided. Both Mary Surratt and Dr. Samuel A. Mudd were tried in a conspiracy trial by a military tribunal in Washington, DC with Mrs. Surratt being sentenced to be executed by hanging and Dr. Mudd being sentenced to a life term at Fort Jefferson, located in the Dry Tortugas ninety miles off the coast of Florida

During the tour, narrators will comment on various matters of historical and forensic significance in connection with the assassination of Abraham Lincoln including the unsuccessful medical attempt to save Lincoln's life and the killing, the identification, and the final burial of Booth at Baltimore's Green Mount Cemetery as well as the firearms identification of the gun used in the assassination that was left behind at Ford's Theater. Controversies are said to remain on a number of key matters in the history of the assassination, such as whether Booth was in fact killed at Garrett's Farm in Virginia and, if so, by whom among the tracking Union troops the deed was accomplished.

Assassination, John Wilkes Booth, Derringer

W22 Pediatric Pathology for Forensic Pathologists: What They Can Do for Us

Wendy M. Gunther, MD, OCME, Tidewater District, 830 Southampton Ave, Ste 100, Norfolk, VA 23510-1046; Kim A. Collins, MD*, 1333 Martins Point Rd, Wadmalaw Island, SC 29487; and Janice J. Ophoven, MD*, 6494 Crackleberry Trl, Woodbury, MN 55129*

After attending this workshop, attendees will: (1) be able to recognize rare and fascinating pediatric natural diseases; (2) become familiar with consequences of common pediatric problems, such as prematurity, birth asphyxia, and birth trauma; (3) review placental pathology that is useful; (4) have a better understanding of the significance of a single abnormal finding in a forensic autopsy; (5) be able to recognize a number of natural diseases that can mimic neglect; and, (6) better understand when the situation calls for consulting a pediatric pathologist to assist in a forensic autopsy.

This presentation will impact the forensic science community by illustrating when consultation with a pediatric pathologist may be helpful to a forensic pathologist faced with a challenging case.

Pediatric cases sometimes present with baffling gross and microscopic findings, ranging from natural diseases which show up once in a forensic pathologist's lifetime, to complications of common diseases that are uncommon in forensic practice. For forensic pathologists, these baffling findings may obligate us to invest significant time searching references and discussing the case with colleagues, perhaps without finding the right diagnosis. If we know the diagnosis, we may not know the significance of the diagnosis to the cause and manner of death, or its consequences to the decedent's family. We may not know whether consultation with a pediatric pathologist will solve the problem, assist with part of the problem, or be of no use. Pediatric pathology may be a daunting field for forensic pathologists because of its encyclopedic knowledge base. To "prune the thicket" of pediatric pathology for the forensic pathologist, this workshop is presented in a case-based format utilizing actual forensic cases in which pediatric pathology resolved the mystery, or assisted us with understanding the significance of a natural finding, or its meaning for the family.

Progressing in sequence from the youngest possible patients, fetuses, with a look at placental pathology that is of use to the forensic pathologist as well as the consequences of birth trauma, the workshop examines cases from each stage of childhood, with attention to birth asphyxia and complications of prematurity. Unsuspected tumors, infections, metabolic disorders, congenital malformations and syndromes, and a number of rare disorders which may be genetic and significant for the family, along with predisposing factors of family concern, will be covered as we go on to discuss deaths in younger and older children, and finally, deaths from unexpected natural disease in teenagers.

Inflicted child abuse will not be the topic under discussion in this workshop; pediatric pathology will take center stage. Abusive head injury, unsafe sleeping deaths, and other primary forensic topics, will not be presented; however, when there is a question of fatal neglect, pediatric pathology may offer invaluable assistance by identifying alternate natural explanations for death. Natural conditions that mimic neglect in infants and children will be a topic of special attention.

The workshop will also delve into what we might do after identifying a finding of uncertain significance. These cases will be presented under the rubric of "All I have is this: does it matter?" Along with these cases, to hone their decision-making skills, participants will be involved in self-directed learning activities. Case histories with gross and microscopic findings will be made available, to allow the participants to diagnose and judge for themselves whether pediatric pathology consultation would be of some help, great help, or no help at all.

By the end, participants will learn a case-based format presenting a range of common and uncommon problems in pediatric pathology as they present forensically. Detection of rare diseases has always formed part of the reward of practicing pediatric pathology, and the forensic pathologist may be in the best position to identify these diseases at autopsy and to share them with our pediatric pathology colleagues, who can help us in turn to help the family. Participants will better understand when forensic pathology and the families we serve can benefit from pediatric pathology, and perhaps, vice versa.

Pediatric, Forensic, Pathology

W23 DNA in Real Time: Amplifying Productivity in Today's Forensic Laboratory

Anthony J. Onorato, MS, Tamyra R. Moretti, PhD*, Jeffrey E. Monaghan, BA*, Nicole M. Nicklow, MSFS*, and Heather LaSalle, MS, FBI Laboratory, DNA Analysis Unit, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this workshop, attendees will gain the tools to be able: (1) to recognize opportunities for change within their own laboratories; and, (2) to prepare attendees to develop and implement their own strategies for improving DNA testing services.

This workshop will impact the forensic science community by providing a laboratory with information that enables it to recognize the potential for change within its casework operations, to define a roadmap for improvement, to recognize factors that mitigate the risks of change, and to achieve greater productivity and efficiency while maintaining quality.

Using the experiences of a forensic DNA laboratory, the goal of this workshop is to provide information that enables a DNA laboratory to recognize the potential for change within its casework operations, define a roadmap for improvement, recognize factors that mitigate the risks of change, and achieve greater productivity and efficiency while maintaining quality.

Today's forensic DNA testing laboratory is faced with unprecedented demands from the criminal justice and intelligence communities, and many laboratories are challenged to meet those needs given available resources. Failure to keep pace with case submissions results in a need to prioritize cases; which effectively decreases the utility of CODIS for cases with investigative needs such as missing persons and no-suspect cases. Furthermore, backlogs can drive the creation of case acceptance policies that limit testing for multiple-item submissions and thereby minimize the utility of DNA testing for law enforcement.

This workshop is not just about big laboratories doing big things but rather it stresses universal approaches to maximize production in DNA laboratories of any size. Topics of discussion will help a laboratory to evaluate and establish an infrastructure to eliminate existing case backlogs, to achieve targeted service times, to increase technical capacity and to improve typing success rates. In the long term, the strategies conveyed can prepare the laboratory for unanticipated trends in case submission and increased service requirements, and can enable the laboratory to implement new testing services and continually evolve with technology.

Using the re-engineered nuclear DNA laboratory at the FBI as a model, presentations will detail changes implemented from 2010 to the present, including: (1) progressive strategies to expand and enhance DNA testing services; (2) research and validation studies; (3) integration of information technology to manage and automate scientific processes and robotics; (4) workflow strategies; (5) workforce repurposing in response to changing needs; and, (6) maintenance of the quality system in the new laboratory environment. These changes have enabled the FBI to achieve an unprecedented level of casework productivity, including elimination of a backlog of some 2,700 cases and the typing of nearly 13,000 samples in 2011; to improve turnaround time from more than 600 days to 30 days on average; to increase the typing success in missing persons cases from approximately 10 to 80 percent, and to contribute more than 3,400 haplotypes to the US Y-STR Database.

Forensic DNA, Automation, STR Analysis

A1 Detecting Organic Gunshot Residue by Electrospray Ionization: Ion Mobility Spectrometry

Lee A. Greenawald, BS, 104 Royal Pl, McMurray, PA 15317; Suzanne Bell, PhD, West Virginia Univ, 1600 University Ave, Oglebay Hall, Rm 208, Morgantown, WV 26506-6121; and Monica Joshi, PhD, West Chester Univ, Dept of Chemistry, Schmucker Science South, 750 S Church St, West Chester, PA 19383*

The goal of this presentation is to raise awareness of the need to improve the current method of analyzing gunshot residue and learn of a novel technique that is promising to this application.

This research will impact the forensic science community by presenting a novel, fast, and reliable detection for gunshot residue by a swab of the hand of a suspected shooter.

A method was developed to characterize organic components of Gunshot Residue (GSR) using electrospray Ionization-Ion Mobility Spectrometry (ESI-IMS) as well as ^{63}Ni-ion mobility spectrometry. As a field test, IMS displays potential for providing probabilistic determinations of shooter vs. non-shooter based on statistical pattern matching of the combination of compounds common to GSR. There is a need for reliable, rapid field screening of hands because current gunshot residue analysis techniques are merely presumptive. Due to many factors such as high false positive rates and low informational content, traditional color-based presumptive testing is increasingly used for visualizing reagents for distance determinations. The Griess reagent, a color-based GSR test, detects the presence of nitrites, which are heavily and naturally present in the environment. Organic Gunshot Residue (OGSR) analysis may provide valuable information when inorganic gunshot residue cannot be detected, or there is a question as to whether the metals found on a hand are distinctive compounds of firing a handgun. The combination of organic and inorganic compounds unique to GSR increases the confidence of a shooter/non-shooter decision. OGSR come from energetics and propellant additives such as stabilizers, plasticizers, flash inhibitors, coolants, moderants, surface lubricants, and anti-wear additives. Recent analytical studies of OGSR have targeted diphenylamine, nitrocellulose, nitroglycerin, and 2,4-dinitrotoluene; this work has demonstrated that phthalates and nitroso-derivatives of diphenylamine are also detectable post-firing using ion mobility spectrometry. This study is unique in that the target compound list has been extended to include organic combustion by-products that are specific to firing a handgun. The combination of these unique compounds should decrease the rate of false positives that are detected on the hand of a suspected shooter. Additionally, detection of a combination of propellant ingredients and combustion products significantly increases the confidence of a field shooter/non-shooter decision. The combustion by-product compounds were identified after collection of the vapors associated with small arms discharge using an enclosed firing box. The analysis of the collected vapors was performed on ESI-IMS and confirmed using gas chromatography-mass spectrometry and standards when available. These standards were then analyzed using ^{63}Ni and ESI-IMS to determine figures of merit for the analytical methods. Additional experiments were undertaken with hand swabs taken from individuals after discharging a gun (as well as individuals who did not discharge a gun) and it was determined that combustion products are detectable from the hands of shooters using IMS. The results were also confirmed with ESI-IMS-MS. Development of swabbing and extraction parameters will be discussed. Mobility spectra collected from hand swabs were incorporated into multivariate statistical models that ultimately provide the foundation for probabilistic assessment of shooter/non-shooter. These results will be presented and discussed.

Gunshot Residue, ESI, IMS

A2 Kinetics of Ion Mobility Spectrometer Sampling With Gunpowder and Methamphetamine

Joshuah M. Usilton, 1331 Rising Sun Rd, Camden, DE 19934; Marriah C. Ellington, BS, 235 Dewey St, Morgantown, WV 26501; and Suzanne Bell, PhD, West Virginia Univ, 1600 University Ave, Oglebay Hall, Rm 208, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand that, across multiple forms of IMS sampling, whether positive or negative, results in an adjustment of the area of a spike following a set pattern of kinetics.

This presentation will impact the forensic science community by presenting groundwork, such as on a spectrum when it no longer becomes possible to extract the sample from the IMS swab and identify it in a GC/MS.

Ion Mobility Spectroscopy (IMS) is a commonly used instrument for field detection of drugs and explosives. A major disadvantage of IMS testing is its need to vaporize and therefore destroy part of the sample applied to the swab, limiting repetitive testing that may be required in a criminal case by both the defense and the prosecution. This research was undertaken to study the diminution of sample over repeated IMS samplings. A search of the literature revealed no previous studies of this kind.

The testing regime examined detection after continuous repetition using diphenylamine, methamphetamine, GSS, nitroglycerin, and ephedrine, starting with 1µl amounts to minimize the sample needed, and also to prevent overloading the device. A swab was inserted into the machine repeatedly with a spectrum taken of each run, until the sample could no longer be detected by the IMS due to the sample's peak blending into the small amount of background noise. The chemicals varied in length of retention from as short as three runs, to as long as 89 consecutive runs with clean cycles every 20 runs to assure that the signal being observed was not the result of carry-over. After data collection was complete, a Gaussian fit was taken of the average peak spectrum and cataloged in an excel spreadsheet, wherein it was found that every chemical tested seemed to follow a similar pattern. All chemicals decayed rapidly at first being diminished by half within the first two runs and then quickly declining until a nearly flat line is achieved. Upon further analysis, a distinct pattern was observed when plotting the natural log (ln) and inverse area of the peaks. The plot revealed a pattern pertaining to second order kinetics. This was confirmed by applying the form $1/kt+1/[A_0]$ to all peaks and running the numbers through the formula, with the same areas being concluded once k and A_0 were computed.

This study indicates that in both negative and positive mode of the particle analysis sampling in an IMS instrument, the major components of both gunpowder and methamphetamine follow a pattern of second order kinetics when repeatedly submitted to the spectrometer. It is hoped that continued research will determine at which point samples tested in the field are still suitable for subsequent testing in the laboratory by GC/MS.

Kinetics, IMS, Analysis

A3 Gunshot Residue Signal Decay and Back-Extraction Analysis Using Thermal Desorption Ion Mobility Spectrometry

Marriah C. Ellington, BS, 235 Dewey St, Morgantown, WV 26501; Joshuah M. Usilton, BS*, 1331 Rising Sun Rd, Camden, DE 19934; and Suzanne Bell, PhD*, West Virginia Univ, 1600 University Ave, Oglebay Hall, Rm 208, Morgantown, WV 26506-6121*

After attending this presentation, attendees will gain perception of the capabilities and functionality of the thermal desorption ion mobility spectrometer, focusing to illuminate the ability of the Thermal Desorption Ion Mobility Spectrometry (TD-IMS) to analyze, qualify, and quantify organic gunshot residue.

This presentation will impact the forensic science community by supplying a sturdy and portable preliminary testing device to analysts in the field, thus limiting the possibility of contaminating evidence en route to the lab. Evidence used in the TD-IMS can be recycled as well, allowing more to be done with less.

Current popular methods of gunshot residue analysis include Scanning Electron Microscopy (SEM) and Energy Dispersive X-ray Spectroscopy (EDS). SEM characterizes the morphology of particulates to determine if they are spherical, a sign that vaporized metallic Gunshot Residue (GSR) condensed upon cooling. EDS identifies whether these spheres consist of barium, antimony, and lead, the three most common metals in GSR. However, with lead-free bullets on the market and odd morphologies of particles possible, other methods of analysis would prove beneficial.

TD-IMS is primarily used as a field device for detecting narcotics and explosives. It has great potential for analysis of Organic Gunshot Residue (OGSR), an often-overlooked source of evidence from propellant combustion. The focus of this project was to develop a hand-swabbing method in which one swab could be interrogated using TD-IMS, back-extracted, then analyzed using Gas Chromatography-Mass Spectrometry (GC/MS). The ability to successfully extract after a thermal desorption cycle depends on the amount of organic material collected on the swab, the contact area of the desorber with the swab, and the efficiency of the thermal desorption process.

First, each thermal desorption cycle loss was evaluated using spiked swabs. Several different target analytes were studied including nitroglycerin and diphenylamine, both single-based gunshot surveillance standards. For each analysis, a swab was spiked with a known amount of the target analyte at the parts-per-million level in solvent. The swabs were allowed to dry and then repeatedly subjected to TD-IMS. In all cases, the decay of the peak of interest followed a second-order kinetics model. This suggests that the swabs could be analyzed first by TD-IMS and then extracted for further instrumental confirmation.

GSR field samples from a firing range were similarly analyzed and distinctive TD-IMS patterns were observed.

An isopropanol wiping method was developed to collect hand samples from a random population that also purposely included those who handle weapons and ammunition such as gun shop owners and police officers. This database was used to establish a range of typical background levels of compounds of interest and to develop TD-IMS signal-to-noise ratios. Results to date will be discussed, as will results from authentic post-firing samples.

This research displays the potential of TD-IMS as a screening method for detection of organic gunshot residue. A single swab collected post-firing can be used for both screening and confirmation, a luxury not afforded by older color testing methods and current SEM/EDS sample collection procedures. The work also further validates the potential of organic components of GSR as viable analytes in forensic GSR testing.

Gunshot Residue, TD-IMS, Field Instrument

A4 Substrate Interference and the Spectroscopic Identification of Body Fluids

Gregory McLaughlin, MS, 100 Manning Blvd, Albany, NY 12203; Vitali Sikirzhytski, MS; and Igor K. Lednev, PhD SUNY-Albany, 1400 Washington Ave, Albany, NY 12222*

After attending this presentation, attendees will better understand recent methodological advancements toward the non-destructive, on-field detection of body fluids using Raman spectroscopy. Specifically, the issue of substrate interference will be addressed. Attendees learn the research goal and will be presented with the data treatment and instrumental factors, which would be a benefit in this regard. This work has specific implications toward the development of a specialized, automatic instrument, which could be developed to identify body fluids at a crime scene.

This presentation will impact the forensic science community by noting the presence of Raman spectroscopy to have ample applications to forensic sciences, especially in the area of crime scene investigation.

Raman spectroscopy has been found to have ample applications to forensic sciences, especially in the area of crime scene investigation. The technique is based on the detection of scattered light by a sample upon irradiation by a laser light source. This approach is typically rapid, non-destructive, field applicable and confirmatory in the identification of unknowns. The identification of body fluids using this technique would represent a significant improvement over the current methodology, which encompasses a range of destructive chemical assays that provide only presumptive identification. However, the issue of substrate interference is a major hurdle inherent in this approach. With Raman spectroscopy, body fluids exhibit a weak-to-moderate signal while the signal from the material directly underneath can be quite strong. Eliminating the substrates' interference is a prerequisite to confident identification.

Although substrate interference is studied here in the scope of body fluid identification, it is an ubiquitous issue in rapid spectroscopic analysis methods. Until now, the solution to the problem of substrate interference has been to collect the sample for later analysis on a preferential, non-interfering surface. However, the requirements of the forensic community considerably favor analysis *in situ*.

Using blood and semen as model fluids, substrate interference is explored using common materials expected to be present at a crime scene (fabrics, glass, tile, skin, etc.). A Renishaw Raman microscope with variable laser excitation was used in conjunction with a motorized automatic stage. Matlab and WiRE software was used for data interpretation and analysis. A variety of experimental parameters were evaluated with simulated evidence to identify the best conditions to simplify identification. Such parameters evaluated were objective strength, laser excitation, simple spectral subtraction, advanced automatic subtraction, and statistical modeling.

The fluid in question and the nature of the substrate were found to be determinative of the most favorable experimental conditions. In the simplest example, the interference from glass beneath a bloodstain is negligible with careful selection of laser excitation. An example of a complex scenario would be detecting semen on a blended dyed fabric. For this type of evidence, statistical modeling was required to find areas of high fluid concentration before spectral subtraction. It was also discovered that blood could be easily identified from a cotton collection swab after mild data treatment. Identification is possible using auto correlation and previously developed Raman spectroscopic signatures, which provide a statistical measure of certainty.

Substrate interference is one of the final analytical obstacles impeding real-world Raman spectroscopic identification of body fluids. This work demonstrates that a non-specialized common Raman instrument and modest data treatment are capable of overcoming this challenge.

Spectroscopy, Serology, Biological Evidence

A5 Comparison of Six Latent Bloodstain Reagents for Sensitivity, Specificity, and Impact on DNA Yield and Quality

Sara E. Bitner, MSF, 1520 Penn Ave, Pittsburgh, PA 15222; Amanda Dargay, BS, 104 Cobblestone Dr, Pittsburgh, PA 15239; and Amanda Neis, BS, 321 S Maple Ave, Apt 6, Greensburg, PA 15601*

After attending this presentation, attendees will benefit from scientific observations on a variety of latent bloodstainenhancing reagents based on their sensitivity, specificity, longevity of reaction, ease of use, as well as impact on downstream DNA analysis.

This presentation will impact the forensic science community by providing aid in selecting latent bloodstaintesting methods that allows for high-quality results, while also aiding in efficiency of the laboratory. Because backlogs are a constant companion to the forensic science laboratory, efficiency is essential in proper casework management.

Due to the ease of use as well as the enhancements made by the manufacturers which allows for greater longevity in the reaction, the manufactured reagents will provide a suitable alternative to the traditional recipes many laboratories currently prepare in-house.

While blood is typically the most visually apparent physiological fluid present at a crime scene, or on items of evidence in a forensic laboratory, there are situations in which the blood is latent, or not visible to the naked eye. In these cases, some form of enhancement is required for the visualization and eventual collection of the bloodstains. The latency of the blood is often due to efforts to clean or remove the blood. As a result, any latent blood present at a crime scene has been thoroughly diluted. Additionally, there are often chemicals present in the area that is being tested that can potentially stymie future serological, chemical, or DNA testing. A latent blood test to aid the forensic scientist in locating the bloodstains must be sensitive, so that it can detect these low levels of blood, as well as specific, so that it properly identifies blood and not one of the many potential cleaning agents or other chemical and natural insults that could cause false positive or false negative results. A pitfall of latent bloodstain tests is the ephemeral quality of the reaction; the optimum reagent would present a reaction that could be easily viewed and potentially photographed without requiring further applications of reagent. Finally, the ideal reagent should not impact the downstream DNA testing that is required for identification of the source of the blood.

A wide variety of manufactured reagents, as well formulas for preparation of in-house reagents, are available to the forensic scientists. Six latent bloodstain reagents were selected for comparison. The reagents (luminol, fluorescein, fluorescein with thickener, Hemascein®, Tink's Starlight Bloodhound™, and BlueStar®) were applied to a variety of blood dilutions, substrates, and blood mixed with chemical and physiological fluid insults. The results of the testing, as well as observations on longevity of the results and ease of preparation, were noted. A selection of the blood dilutions was sampled for DNA analysis, to determine the impact on DNA yield and DNA quality. The selected samples were extracted on a variety of platforms, to monitor any variability that might result between an organic extraction method versus automated, silica-based extraction methods. Additionally, the impact on yield was measured through the quantitation of the DNA extractions. Finally, the quality of the DNA obtained from the tested samples was determined through the amplification and subsequent genetic analysis via capillary electrophoresis.

The manufactured reagents were observed to exhibit qualities commensurate or exceeding those of the in-house formulas. As a result, the manufactured reagents, while sometimes more expensive, provide an ease of use and quality of results that makes them a suitable, if not superior, alternative to the in-house reagents.

Latent Blood, Luminol, DNA

A6 Reliability and Reproducibility of Friction Ridge Edgeoscopy

Kimberly Hoffman, MS, 15100 W Cleveland Ave, Apt 279, New Berlin, WI 53151; Ismail M. Sebetan, MD, PhD*, National Univ, Forensic Sciences Program, 11255 N Torrey Pines Rd, La Jolla, CA 92037-1011; and Paul Stein, PhD*, 25757 Bellemore Dr, Ramona, CA 92065*

After attending this presentation, attendees will understand the problems involved in comparing exemplar prints to friction ridge prints recovered from crime scenes using edgeoscopy.

This presentation will impact the forensic science community by investigating the factors that affect ridge detail when fingerprints are deposited at crime scenes as compared to exemplar prints collected by the authorities.

In this study, the factors that affect ridge detail when fingerprints are deposited at crime scenes, and during the taking of exemplar prints, will be examined. These factors are: substrate, matrix, and pressurerelated deformations along with development media and anatomicalrelated distortions. Four of the most common methods of print development were used and evaluated for the level of detail in the recovered latent prints. These included: fingerprint powder, cyanoacrylate and iodine fuming, and development with ninhydrin. Each type of substrate, pressure, and development media combination will produce its own unique blend of distortions and deformations. Specific areas for edgeoscopy were selected and the exemplar prints were then compared to the developed latent prints to determine if these features could be distinguished and compared between both prints.

This study examined whether or not thirdlevel detail, namely edgeoscopy, could be distinguished among all of the distortions found in exemplars and latent prints. The first hypothesis tested was that variation in pressure and direction used to deposit fingerprints will create unpredictable deformation in edgeoscopy, even in exemplar prints. To do this, exemplars were deposited in five different directions onto photo paper to reduce ink bleed: roll to left, roll to right, roll down, roll up, and pressed vertically onto the paper. The second hypothesis tested whether prints lifted from surfaces typically found at crime scenes would produce the same level of detail as exemplars taken under ideal situations. Six edgeoscopy features were chosen at random for comparison across all latent and exemplar prints examined for hypotheses one and two. Analysis of these exemplar sets revealed that edgeoscopy features showed significant and inconsistent variation. Some features remained recognizable while others were distorted or obscured completely. The same areas of edgeoscopy were then evaluated on latent prints, deposited on a variety of surfaces and then developed using fingerprint powder, cyanoacrylate and iodine fuming, and ninhydrin. Some samples produced areas with excellent edgeoscopy reproduction. In the majority of the developed latent prints, however, the edgeoscopy details were unrecognizable. Ninhydrin in particular produced no observable edgeoscopy detail due to the fragmented appearance of the developed print.

Friction ridge prints play a vital part in criminal investigations. The public believes that latent prints are more reliable than they actually are in case investigations because of the CSI Effect. This study showed that edgeoscopy reproducibility is unpredictable. However, edgeoscopy could provide added supporting evidence in the rare occasions where this detail is recovered. This area of friction ridge print science warrants more research and evaluation. Methods for collection of exemplar prints that produce the highest level, and most reproducible amount, of third level detail have also yet to be determined. It is extremely important that everything possible be done to minimize distortion while taking exemplar prints. Without the detail present in an exemplar print to compare to, the detail recovered from a latent print will be useless to the investigator. Parallel research must also be done to determine the best methods for recovery of quality latent print ridge details. This is a large area of research due to the number of substrate and matrix combinations possible. Each will have a development method that is the most effective.

Friction Ridges, Latent Prints, Edgeoscopy

A7 Development of a Method for the Trace Analysis of Hexamethylenetriperoxide Diamine (HMTD) Using Liquid Chromatography/Atmospheric Pressure Chemical Ionization-Mass Spectrometry

Christine M. Lundblad, BS, 25 Cedar Ridge Dr, Apt 200, Stafford, VA 22554; Mark L. Miller, PhD, FBI, 2501 Investigation Pkwy, CFSRU, Quantico, VA 22135; Ronald L. Kelly, BS, FBI, 2501 Investigation Pkwy, Explosives Unit, Rm 4140, Quantico, VA 22135; and Robert Mothershead, MA, FBI, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will have a greater understanding for the prevalence of Hexamethylenetriperoxide Diamine (HMTD) in Improvised Explosive Devices (IEDs) and how to qualitatively detect trace/residue amounts of this peroxide explosive.

This presentation will impact the forensic science community by providing insight into the use Of Liquid Chromatography/Atmospheric Pressure Chemical Ionization-Mass Spectrometry (LC/APCI/MS) to analyze evidence related to IEDs suspected of containing HMTD.

Terrrorist groups are increasingly using peroxide explosives in IEDs. HMTD and Triactetone Triperoxide (TATP) are the most commonly used peroxide explosives and have similar explosive power to commercial and military high explosives. These compounds can be used as a main charge or an initiating explosive because they are extremely unstable, very sensitive to heat, friction, shock, and impact. Additionally, HMTD can be made from easily obtained retail materials, which results in it being a frequently identified component of IEDs. Consequently, with the increasing use of HMTD in terrorist explosive devices, it is imperative to be able to identify trace amounts of HMTD on items of evidence.

A qualitative method has been developed using LC/MS with an APCI ionization source in the full scan positive mode. Items suspected of containing trace amounts of HMTD are first extracted with deionized water for five minutes before filtering with 0.2µm syringe filters. Extracts are then injected into a separations module with a C18 column (150 x 2.1mm, 5µm particle size) and a solvent gradient of water: methanol, both containing 1.25mM ammonium nitrate. Lastly, an ion trap mass spectrometer is used for HMTD detection and identification.

Using the above method, HMTD elutes at approximately five minutes during an overall run time of 20 minutes. The observed mass spectrum contains m/z 207 and 224 that correspond to [HMTD-1]+ and [HMTD+NH4]+, respectively, in addition to 145, 177, and 209. Interference studies were performed by extracting different substrates to determine if anything present in commonly used materials will interfere with the assay. Results have shown that the following materials do not interfere with HMTD: cotton swabs, cotton balls, plastic scoops, wooden tongue depressors, rocky soil, and sandy soil. In addition, chemicals commonly used in HMTD synthesis were tested for interferences, and the following did not interfere with HMTD: hydrogen peroxide, reagent grade hexamine, reagent grade citric acid, sports tablet hexamine, and Gefen Sour Salt citric acid. TATP and HMTD were analyzed simultaneously, and results indicate that TATP is not an interference for the method.

An ion suppression/enhancement test was performed using a series of ten cotton swabs by fortifying the negative matrix extracts with HMTD before analysis, and the signal from the matrix samples was compared to the HMTD signal from a reference material at this same concentration. Also, matrix samples were processed and fortified with an HMTD standard and were analyzed every six hours following preparation for 72 hours to verify the processed sample stability. Lastly, the matrix limit of detection was determined by analyzing triplicates of matrix-matched reference materials fortified with HMTD reference material at 5, 10, and 15ppm levels.

This detection method yields sufficient peak resolution for the tested substrates and can qualitatively detect and identify HMTD at or above 10ppm.

Peroxide Explosives, HMTD, LC/MS

A8 Micro-FTIR-ATR Analysis and Statistical Validation of Dissimilar Inks on Paper

Gary H. Naisbitt, PhD, Andy V. Pham, and Bruce A. Jacoby, Utah Valley Univ, Criminal Justice Dept, MS 286, 800 W University Pkwy, Orem, UT 84058*

A9 Statistical Discrimination of Explosive Precursors Using Data Gathered From High Resolution Fourier Transform Infrared Spectroscopy

Felicity Carlysle, MSc, Centre for Forensic Science, Royal College Bldg, 204 George St, Glasgow, G1 1XW, SCOTLAND; Niamh Nic Daeid, PhD, Univ of Strathclyde, Centre for Forensic Science, 204 George St, Glasgow, G1 1XW, SCOTLAND; and Erwan Normand, PhD, and Michael McCulloch, PhD, Cascade Technologies, Castle Business Park, Glendevon House, Stirling, FK9 4TZ, UNITED KINGDOM*

The goal of this presentation is to give attendees an understanding of the statistical analysis used to discriminate between potential explosive precursor materials based upon spectra produced using high-resolution Fourier Transform Infrared (FTIR) spectroscopy.

This presentation will impact the forensic science community by demonstrating the use of readily available statistical software to discriminate between similar infrared spectra, initially applied to the analysis of explosive precursors, but with the potential for use in other areas of forensic analysis.

The characterization and discrimination of different explosive precursors is an integral part of the information gathering used in the development of explosives detection security systems. Detection of precursors facilitates the interception of such materials prior to the completion of an explosive device. The ability to discriminate between explosive precursors of different origins facilitates accurate detection, providing greater strength of evidence against suspected bomb-makers.

The increased use of the so-called “homemade explosives” has resulted in a range of potential explosive precursors. As the name suggests, these explosive materials can be produced without a specialist laboratory from precursor materials that are easily purchased in small amounts. However, the precursor materials are often not in a pure form depending on their commercial purpose. For example, acetone is the active ingredient in many nail polish removers and it is combined with emollients, conditioners, perfumes, and colorants to enhance the product. Different brands with different ingredients have the potential to produce different infrared spectra, thereby giving the potential for discrimination. Depending upon the concentration of the primary ingredient, its spectrum may be masked by the other ingredients. In addition, many explosive precursor materials in their “off the shelf” form contain a relatively large amount of water, which also affects the infrared spectrum. Through previous work, highresolution FTIR spectroscopy has been demonstrated to be suitable for the characterization of laboratorygrade explosive materials and their precursors, as the technique produces information-rich spectra. The production of information-rich spectra helps to overcome the issues of masking and water interference. Discrimination may be possible from visually examining spectra of different precursor brands; however, statistical techniques can be used to detect minute differences between spectra which on the surface appear visually very similar. Moreover even in cases where the spectra appear visually different, statistical analysis can aid the discrimination of different “off the shelf” brands.

Three main statistical techniques were used to explore the best data mapping system for the complex data emerging from the analysis: cluster analysis, principal component analysis, and, Pearson correlation. The data presented here detail the development of a protocol for the stepwise application of data processing, followed by statistical analysis

for the discrimination of explosive precursors and the initial results obtained from the application of the protocol.

Statistics, Cluster Analysis, Explosives

A10 Explosives Analysis Using Gas Chromatography/Mass Spectrometry

Randi S. George, BS, 705 S Gulph Rd, King of Prussia, PA 19406; Heather L. Harris, JD, 2401 Lombard St, Ste 1, Philadelphia, PA 19146; and Barry K. Logan, PhD, Center for Forensic Science Research and Education, 2300 Stratford Ave, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to assess their current laboratory techniques for analysis of problematic compounds and determine if the GC/MS method will improve trace explosives identification for a wider variety of compounds in relation to their current methods.

This presentation will benefit the forensic science community by showing laboratory personnel how to adjust their GC/MS equipment for the clearest mass spectra of high explosive compounds and their isomers.

This research will demonstrate those highexplosive compounds that do not survive typical GC/MS conditions. It also presents a new database of compounds for GC/MS, including common high explosives and related compounds. Such a complete database of these compounds is difficult to find, making this a useful tool for any laboratory.

More laboratories use GC/MS than any other technology for analytical purposes. Gas Chromatography (GC) is advantageous in trace analysis as it has a high resolving power, resulting in more efficient separations, which lead to better identifications. Mass Spectrometry (MS) is an accurate and reliable detector with the capability of examining a broad range of compounds and identifying them with specificity. The combination of GC with MS allows for improved separation of complex matrices and specific identification of trace analytes.

The greatest obstacle when analyzing highexplosive compounds by GC/MS is the high reactivity and propensity of the compounds to decompose rapidly at high temperatures. At high temperatures, the explosive compounds decompose and their mass spectra contain ions that can be found in a wide variety of molecular decompositions, making it difficult to produce and identify a unique explosive compound. In addition to the temperature challenges, active sites can be found throughout the chromatographic system attracting these explosive compounds and binding with them. The explosive compounds become lost in the system and never appear in the MS source to produce a spectrum.

This research includes method development for the following compounds: Trinitrotoluene (TNT), Cyclotrimethylenetrinitramine (RDX), Cyclotetramethylene-Tetranitramine (HMX), Pentaerythritol Tetranitrate (PETN), Dinitrotoluene (DNT), and Trinitrophenylmethylnitramine (tetryl). Optimum inlet temperatures for each of these compounds were determined in an attempt to decrease the effect of the most common decomposition location.

Three main inlet temperatures, 250˚C, 150˚C, and 80˚C, were tested with TNT, RDX, HMX, PETN, and Tetryl. Of these inlet temperatures, 250˚C was determined to be optimum for PETN, 150˚C for tetryl and RDX, and 80˚C for HMX. TNT was not affected by differing inlet temperatures. Furthermore, tetryl's mass spectrum matched N-methyl picramide, a product of tetryl hydrolysis, which was expected from reports in the literature. RDX showed breakdown resulting in a lower level of m/z 76 present in the spectrum. Similar data was collected from a total of 35 compounds including high explosives, their isomers, plasticizers, and others found in the presence of explosives.

This research will benefit the larger community of law enforcement, military, and even industry by providing more options to laboratories for explosive analysis. Forensic explosive analysis can identify compounds in improvised explosive devices (IEDs) and land mines in war zones to properly identify explosive components in pre- and postdetonation situations. Explosive manufacturers and research facilities would benefit from improved analytical techniques to determine the quality of their product and to evaluate changes that occur to bulk materials in storage.

The benefits go beyond these communities; however, extending into the environmental and medical fields. Improved analysis will help identify environmental soil and water samples contaminated by runoff and erosion from blasting and storage sites at lower levels, so the problem can be remedied before permanent damage occurs. Along with proper extraction techniques, GC/MS is capable of isolating and identifying each specific compound at the trace levels at which these compounds will most likely be detected. The challenges associated with this research project, the solutions to those challenges, and the resulting mass spectra for high explosives and related compounds for compilation into a user-searchable database will be presented.

Explosives, Gas Chromatography, Mass Spectrometry

A11 Electrophoretic Deposition of Nanoparticles and Nano-Structured Particles for Latent Fingerprints Detection on Different Surfaces

Roberto Rosa, PhD, Maria Cannio, PhD, Paolo Veronesi, PhD, and Cristina Leonelli, PhD, Dept Materials and Environmental Engineering, via Vignolese 905, Modena, 41125, ITALY*

After attending this presentation, attendees will be aware of the potential offered by Electrophoretic Deposition (EPD) of different kinds of nanoparticles and nano-structured particles in the development of latent fingerprints on a wide variety of porous and non-porous surfaces.

This presentation will impact the forensic science community by proposing for the first time the EPD technique in the development of latent fingermarks, and highlighting how nanotechnology and forensic sciences are becoming more and more intertwined.

Nanoparticles and nano-structured particles form the basis of several detection techniques for latent fingerprints and several reviews are yet available on this topic.[1,2]

Multimetal Deposition (MMD), for example, can be used for visualizing latent fingermarks on a wide range of porous as well as non-porous surfaces. MMD employs colloidal suspensions of gold nanoparticles, which preferentially deposit on fingerprint ridges, rather than in the valleys, through electrostatic and hydrophobic interactions.[3] Several works appeared later, aimed at enhancing the applicability of the MMD technique and trying to overcome its tedious experimental procedure, such as MMDII method, the use of functionalised and/or stabilised gold nanoparticles, and Single Metal Deposition (SMD).

Further nanoparticles and nanostructured particles employed for latent fingerprint detection include metal-oxides (such as TiO_2, ZnO, SiO_2, Fe_3O_4, and Eu_2O_3), sulfides, selenide, and tellurides, which were employed as pure powders or as fillers for nanocomposites in both Small Particle Reagent (SPR) techniques and dry powder dusting.

The goal of this presentation is to propose the use of electrophoretic deposition in place of or in combination with the aforementioned detection techniques based on the deposition of nanoparticles and nanostructured particles. EPD is a two-step electrochemical materials processing technique, usually carried out in a two electrode cell. In the first step, an electric field is applied between two electrodes and charged particles suspended in a liquid move toward the oppositely charged electrode (electrophoresis). In the second step, the particles accumulate at the deposition electrode and create a relatively compact and homogeneous film (deposition). EPD possesses several advantages over more conventional ceramic production strategies like short formation time, simplicity of the experimental apparatus, and almost no substrate shape restriction. Moreover, EPD can be applied to any solid that is available as a fine powder or as a colloidal suspension, including metals, polymers, ceramics, and glasses.

It is apparent that EPD techniques can be inserted into a latent fingerprint detection sequence. In this presentation, for example, it will be shown how aqueous EPD can play an innovative role after the first step of MMD. As known colloidal gold suspension creates a thin conductive layer perfectly reproducing the positive pattern of the

fingerprint ridges. EPD can exploit this newly formed fingerprint-electrode to deposit a wide range of different ceramic nanoparticles in order to improve the contrast by changing the substrate background coloration.

It will be shown that electrophoretic deposition alone can also be exploited for latent fingerprint detection on metallic and semi-conductive surfaces. Indeed, the presence of a fingerprint residue alters the electrical conductivity of the substrate underlying the ridges. Thus, the effectiveness of the deposit will reflect this electrical discontinuity. In this framework, EPD may also be considered a valid alternative to vacuum metal deposition (VMD).

Several examples will be presented including the use of different ceramic nanoparticle suspensions on different porous and non-porous substrates. Preliminary results regarding the role of nanoparticles' morphology on their adhesion to fingerprint ridges, under the application of an applied electric field, will be presented as well.

Latent Fingerprints, EPD, Nanoparticles

A12 Classification of Smokeless Powders by Cluster Analysis

Dana-Marie K. Dennis, BS, Michael E. Sigman, PhD, and Mary R. Williams, BS, Univ of Central Florida, NCFS, PO Box 162367, Orlando, FL 32816*

The goal of this presentation is to identify statistically valid sub-classifications of smokeless powders.

This presentation will impact the forensic community by providing a statistical basis for identification of smokeless powders beyond single- and double-base designations.

The purpose of this research is to determine if sub-classes (clusters) can be identified within two broad classes of smokeless powders, namely those that are single-based or double-based. Similarities between the total ion spectrum (TIS) were calculated and dendrograms of the similarity data were generated. Cophenetic correlation and inconsistency coefficients were calculated in order to determine the number of clusters which were present among the samples.

In 2009, the National Center for Forensic Science (NCFS) in collaboration with the Technical Working Group for Fire and Explosions (TWGFEX) developed a smokeless powders database, which consists of a compilation of analytical data for commercially available smokeless reloading powders. Methods utilized for analysis of these powders include stereomicroscopy, Fourier-Transform Infrared (FTIR) spectroscopy, and Gas Chromatography-Mass Spectrometry (GC/MS).

For this study, the GC/MS data for 87 smokeless powders analyzed in-house was exported as a condensed data file (CDF) format, and were used to generate the TIS. The TIS was generated by averaging the mass spectra across the entire chromatographic profile for each of the samples. The intensity values for m/z 43-400 were normalized to sum to one, and this data was used to calculate the similarities between the samples. Similarities that approach one indicate that the samples are more similar, while those that depart from one indicate that the samples are less similar.

Agglomerative hierarchical clustering was used to analyze the similarity data, and a study was done in order to determine the most appropriate distance (i.e., Euclidean, Manhattan, etc.) and linkage (i.e., Centroid, Complete, etc.) clustering method for further data analysis. The cophenetic correlation coefficient was calculated for each distance and linkage combination. Cophenetic correlation coefficients closer to one indicate that the clusters in the data, as defined by the dendrograms, closely reflect distances between objects in the original data. Agglomerative hierarchical clustering allows for the determination of natural divisions that may be present within data. This method initially assigns each object to its own cluster and continues by merging objects and/or clusters together until all samples are merged into one cluster. Natural divisions (i.e., optimal clusters) are determined based on the inconsistency coefficient. The inconsistency coefficient compares the link height in a given cluster hierarchy with the average of the link heights directly below it. A link that is approximately the same height as the links below it is said to be consistent, indicating that there are no natural divisions within the data. On the other hand, a link that has a significantly different height from that of the links below it is said to be inconsistent, which may indicate natural divisions within the data.

Preliminary results indicate that average linkage and correlation distance, as well as centroid linkage and correlation distance, methods are the most suitable for analysis of the smokeless powders data. The cophenetic correlation coefficient in both cases was 0.96, and the data clustered into two primary groups, namely single-based and double-based. In addition, there are a number of sub-clusters apparent within the two main groups. Some sub-clusters correspond primarily to a single manufacturer, while others are predominantly populated by powder kernels of a given shape. Additional investigations are underway to better understand the chemical nature of these sub-clusters.

Clusters, Similarity, Dendrograms

A13 Development of a Chemically Relevant Artificial Fingerprint Material

Edward Sisco, MS, 6819 Old Waterloo Rd, Apt 1035, Elkridge, MD 21075; Jessica L. Staymates, MFS, and Greg Gillen, PhD, NIST, 100 Bureau Dr, MS 8371, Gaithersburg, MD 20899*

After attending this presentation, attendees will be aware of the development of a novel artificial fingerprint material, comparing to both human fingerprints and other artificial fingerprint materials, and discussing the use of mass spectrometry techniques to qualitatively compare the composition of both natural and artificial fingerprints.

This presentation will impact the forensic science community by providing a potential method for developing a chemically relevant artificial fingerprint material and a number of different possible applications in which the use of artificial fingerprint material could be used.

The main focus of this work was development of an artificial fingerprint material to provide a reproducible sample for completing fingerprint aging studies as well as degradation studies; however, a comprehensive artificial fingerprint material could also be used in understanding the mechanism of development techniques, evaluating the efficiency of developing techniques, and understanding the interactions of fingerprint materials with various surfaces.

Human fingerprints are generally composed of two types of secretions – eccrine and sebaceous. The eccrine secretions, which are almost completely composed of water, also contain a number of other components including salts, amino acids, lactic acid, proteins, and vitamins. Sebaceous secretions contain chemicals such as free fatty acids, cholesterols, esters, and glycerides. While it would be extremely difficult to replicate the entire chemical composition of a human fingerprint, it is possible to develop an artificial fingerprint material containing a number of the most abundant and chemically relevant fingerprint components.

In this work, a series of mass spectrometry based techniques – including Secondary Ion Mass Spectrometry (SIMS), Direct Analysis in Real Time Mass Spectrometry (DART®-MS), and Desorption Electrospray Ionization Mass Spectrometry (DESI-MS) have been used to characterize real fingerprints and identify individual compounds typically found in fingerprints. These components were then compared

to those discussed in literature. From the results of these analyses, several iterations of artificial fingerprints, containing either or both sebum and eccrine secretions, were prepared. Every iteration was then compared, using multiple mass spectrometry techniques, to the collection of spectra from human fingerprints. Furthermore, the artificial fingerprint material was also compared to a number of other artificial fingerprint materials, both commercially available and reported in literature. Finally, once a chemically relevant artificial fingerprint material was developed, a way to reproducibly deposit the material was attempted. Initial studies are being completed to evaluate how piezoelectric inkjet printing can provide a way of accurately controlling the amount of material deposited on a surface of interest. The printing technique has the ability to print single spots or arrays of spots in a range of masses and possibly without the need of dissolving the fingerprint material in a solvent.

The ability to make a chemically relevant fingerprint material can have wideranging applications. It can allow for a reproducible sample set for any type of latent fingerprint research. The ability to deposit the fingerprint in spatially selected areas using inkjet printing could also be extremely useful for certain applications.

Fingerprints, Sebum, Mass Spectrometry

A14 Percutaneous Absorption of Organic Gunshot Residue Associated With Polymeric Membranes Using Ion Mobility Spectrometry

Jordan W. Moran, BS, Rt 1, Box 311, Grafton, WV 26354*

After attending this presentation, attendees will gain an understanding about dermal absorption principles and how the dermal absorption of organic gunshot residue (GSR) can be used in gunshot residue casework studies.

This presentation will impact the forensic science community by highlighing potential uses of Ion Mobility Spectrometry (IMS) for the detection of organic gunshot residue that has been transferred to human skin after the use of a firearm and has been percutaneously absorbed. IMS analyses are fast, inexpensive, and generate a minimum amount of waste. The data showed that the method could play a valuable role in the definitive analysis of gunshot residue in casework samples.

Smokeless powders are a class of propellants that were developed in the late 19th-century to replace black powder. Organic additives, such as diphenylamine (DPA), are used as stabilizers and are also present in gunpowder composition. DPA stabilizes the energetic composition by binding nitrous oxide gases that have originated from the decomposition of nitrocellulose and converts them into stable compounds. Identification of stabilizers like DPA has become of importance in forensic science because it can provide valuable evidence in firearm discharge cases. Additionally, DPA is frequently used in the construction of improvised explosive devices (IEDs) related to criminal and terrorist acts.

Previous work has demonstrated that DPA can be detected on the skin of persons who have fired a weapon for about four hours, after which the concentration of DPA and other organic residues drops below IMS detection limits. These loses are not due to secondary transfer, which suggests that at least some portion of the compounds are being absorbed into the skin. To test this hypothesis, preliminary dermal absorption studies in the laboratory using polymeric membranes have shown that DPA possesses penetrating properties. The cumulative amount of DPA that permeated through the membranes increased over the course of 24 hours, which correlated well with the aforementioned persistence study. The calculated values of three key dermal absorption parameters were as followes: steady-state flux (J_{SS}, $\mu g/cm^2/hr$) 5.6 ± 1.7, permeability coefficient (K_p, cm/hr) $2.9 \times 10^{-3} \pm 8.5 \times 10^{-4}$, and lag time ($\tau$, hr) 1.1 ± 0.7. These results are comparable with the calculated values using the Potts and Guy skin permeation equation calculator available on the National Institute for Occupation Safety and Health's (NIOSH) website. The goal of this study was to build upon the DPA results and expand into evaluating the dermal absorption of other organic compounds present in gunshot standards and gunshot residue samples. Ion mobility spectrometry (IMS) was used for the qualitative analysis of organic gunshot residue for *in vitro* transdermal Franz diffusion cell (FDC) experiments.

IMS analyses were performed using an IONSCAN-LS™. IM station software (version 5.389) was used for data acquisition and processing. For the analysis of organic gunshot residue samples, the sample introduction into the IMS was performed through thermal desorption on a Teflon membrane. Organic gunshot residue was analyzed in the positive ionization mode while nicotinamide served as the calibrant. To simulate human skin, polydimethylsiloxane (PDMS) membranes (0.006" thick), were used for *in vitro* release testing. The membranes were the appropriate size to fit the FDC diameter (1" o.d) and their surface areas were 0.64 cm^2. Organic gunshot standards and gunshot residue samples were applied to the surface of the PDMS membranes and sampling occurred at regular time intervals. The cumulative amount of DPA found in the receptor fluid (μg) was plotted against time (hr). Linear regression was performed on the steady-state part of the curve to calculate the steady-state flux, skin permeability, and lag time.

In conclusion, results to date indicate that organic compounds associated with GSR are absorbed dermally and as such could be developed into another avenue for making a shooter/non-shooter decision based on chemical evidence.

Ion Mobility Spectrometry, Diphenylamine (DPA), GSR

A15 The Development of Field Calibrants for Detection Canines

Katylynn Beltz, BS, Michelle Cerreta, BS, and Kenneth G. Furton, PhD, Florida Int'l Univ, 11200 SW 8th St, RM CP345, Miami, FL 33199*

After attending this presentation, attendees will learn the odors associated with illicit materials as well as the validation strategy of surrogate continuation aids that can be used to train biological detectors, such as canines.

This presentation will impact the forensic community by demonstrating how a detection canine can be as objective and reliable as a laboratory instrument.

The goal of this study was to aid in the standardization of detection canine training and handling through the use of field calibrants. Field calibrants, or surrogate continuation aids, are becoming more common in the field since obtaining and maintaining detection canine training aids can be problematic and require adherence to rules and regulations that may be beyond the capabilities of the agency maintaining the canine team. Ideal field calibrants overcome these commonly encountered challenges by having inert compositions not subject to the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) and Drug Enforcement Administration (DEA) terms and conditions. Field calibrants are also advantageous because they can be selected and manufactured in such a way that a known and controlled quantity of odor is released with minimized contamination concerns ensuring standardized training aids over their specified lifetime.

Biological detectors such as canines are valuable tools used for the rapid identification of illicit materials because they can be trained to reliably detect a wide variety of odors. However, recent increased scrutiny over the reliability of detection canines is currently being evaluated in the legal system as there are no formal regulations regarding detection canine maintenance and training. Best practices guidelines covering the various aspects of canine and orthogonal detectors for consistent and optimal practice among canine handlers have been established by the Scientific Working Group on Dog & Orthogonal Detector Guidelines (SWGDOG). SWGDOG has also outlined areas of needed research including the identification of odors associated with illicit materials and the validation of surrogate continuation aids, both of which are addressed in this study.

Previous studies have identified the dominant odor compounds of several illicit materials, which has led to the development of surrogate

continuation aids. Dominant odor compounds can be defined as the chemical compound or compounds identified in the headspace of the illicit material which, when exposed to the biological detector, induce an alert response. For example, methyl benzoate and 2,4-dinitrotoluene have been identified as the dominant odor compounds of cocaine and trinitrotoluene (TNT), respectively. This study deals directly with the steps taken for the validation of surrogate continuation aids and a Universal Detector Calibrant (UDC). Validation steps for these field calibrants include: the identification of the dominant odor compounds of the illicit material, the development of a surrogate continuation aid, field testing the surrogate continuation aid using trained and certified detection canines, substitution of the surrogate continuation aid into the initial training stages of the detection canines, and finally, the implementation of the surrogate continuation aid into daily training.

The development of a UDC provides one measure to evaluate the reliability of the biological and instrumental detectors. Currently there are no set practices to ensure that a biological detector is working at a reliable and suitable level on a daily basis. As instruments in a laboratory are calibrated to ensure that they are in proper working order, developing a UDC for which biological detectors can be calibrated would be useful. By training the canine to alert to the UDC before each working day, the handler can record if the biological detector is working to a suitable standard. The UDC has the potential to also be used in selecting future biological detectors by determining the time it takes to train the canine to alert to the compound and the sensitivity of detection that the canine can achieve. Standardization of detection canine training aids will ensure the optimal number of illicit material odors detectable in the most reliable manner. Implementation of field calibrants into daily detection canine training will improve the reliability of the canine by allowing for the direct comparison of other biological detectors as well as orthogonal detectors.

The Science and Technology Directorate of the U.S. Department of Homeland Security partially sponsored the production of this material under Interagency Agreement IAA # HSHQDC-10-X-00297 with the National Institute of Standards and Technology (NIST). Additionally, this research was supported in part through a Doctorial Evidence Acquisition Fellowship awarded by Florida International University.

Detection Canines, Training Aids, Calibration

A16 False Negatives and Decreased Sensitivity of Heme Tests on a Leather Substrate: Incidence and Causes

Alex J. Krotulski, BS, Kei A. Osawa, BS*, and Anna S. Duggar, MS, Loyola Univ, Dept of Chemistry, 6363 St Charles Ave, New Orleans, LA 70118*

After attending this presentation, attendees will be made aware of the potential for presumptive and confirmatory false-negative test results as produced by bloodstains on leather casework samples, and the possible chemical causes for the desensitized reaction.

This presentation will impact the forensic science community by showing how the possibility of substrate interference has significant implications. Although there are many publications devoted to the possibility of false positives when testing for blood (one of the most recent being a presentation at an AAFS meeting in 2011), comparatively little time has been spent investigating false negatives. Leather boots, jackets, and upholstery are encountered regularly as substrates during the investigation of violent crimes, and in this study, are identified as a possible source of false negative screening results. In turn, these results would mean lost opportunities for more discriminatory testing, such as DNA analysis. Field and serology analysts may be able to use the information generated during this study when deciding whether to include a "negative" sample for further DNA analysis.

Anecdotal reports from the New Orleans Police Department Crime Lab suggested that blood samples on Timberland® boot leather may produce false negative results when using phenolphthalein, a heme-catalyzed presumptive blood test. This claim was tested by acquiring boot leather samples and applying serially diluted human blood, using cotton cloth as a comparative standard. A general decrease in sensitivity over time, greater than that observed on control samples, was observed in the boot leather samples: in less than two weeks, blood dilutions of $1/10^3$ were still detectable on cotton cloth, but only 1/10 dilutions and whole blood were detectable on Timberland® boot leather. The result was then duplicated in upholstery leather samples when, after only two weeks, phenolphthalein sensitivity decreased from $1/10^3$ on cloth to 1/10 on two different types of upholstery leather. The common decrease indicates that the chemical inhibitor is most likely not specific to Timberland®-brand tanning processes, but is common to the leather industry as a whole.

A similar order-of-magnitude decrease in detection of blood on both boot leather and upholstery leather (as compared to cotton substrates) was observed with benzidine (another heme-catalyzed presumptive blood test); with Hematrace antibody/antigen test kits; and with traditional Takayama crystal testing. Heme-catalyzed color tests and Hematrace human hemoglobin detection tests showed a decrease in sensitivity in as little as two weeks; Takayama crystal tests showed a decrease in sensitivity in under a month.

The three tests utilize varying elements of the hemoglobin molecule. In heme-catalyzed color tests, the heme group central to the hemoglobin molecule behaves as a peroxidase, reducing hydrogen peroxide to water and, in turn, depleting the hemoglobin of electrons; these electrons are replaced from the test dye molecule, transforming the molecule from its colorless to a colored state. Although these tests are known to be pH-sensitive, phenolphthalein and benzidine have substantially different effective ranges (between 8 and 10 versus any pH above 4). The ABAcard Hematrace test uses anti-human-hemoglobin antibodies to produce a highly sensitive color-positive result. The Takayama crystal test relies on the formation of pyridine hemochromogen crystals when the reagent is reacted with hemoglobin and heated. As all three of these tests displayed reduced sensitivity and detection potential when performed on bloodstains exposed to a leather substrate, the question remains as to what chemical aspect of the leather substrate is affecting the tests, and whether the reaction can be easily reversed.

As the undesired effects appear not to be pH-dependent, and are common to multiple types of leather, the presence of residual tanning chemicals is the most likely source of the observed false negative effects. Further study on the effects of tanning chemicals on the iron atom at the center of the heme moiety is expected to reveal the source of the multi-test false negatives. Whether or not a simple counter-treatment can be identified, criminalists should be mindful of the age and environmental history of leather case samples submitted for serological screening, and make analytical decisions accordingly.

Blood Detection, Heme, Leather

A17 Advances in the Forensic Use of Human Scent

Lauren J. Colon-Crespo, BSc, Jessica S. Brown, BS, Norma I. Caraballo, BSc, and Kenneth G. Furton, PhD, Florida Int'l Univ, Dept of Chemistry and Biochemistry, 11200 SW 8th St, CP344, Miami, FL 33199*

After attending this presentation, attendees will increase their understanding of the sample collection procedures and analytical methods used to evaluate human scent from different biological specimens.

This presentation will impact the forensic science community by providing an overview of several recent research studies that have examined human scent, demonstrating its importance and application for the criminal justice system.

In 2010, Joshua Wade was sentenced to life in prison for the 2007 carjacking and murder of his neighbor Mindy Schloss. Human scent evidence played a crucial role in the resolution of this case after FBI-trained canines were able to identify both the victim's and Wade's scent on different items, as well as follow scent trails linking several locations and pieces of evidence to Wade. In *California vs. Benigo Salcido,*

challenges arose regarding canine evaluations of human scent, such as the durability of human scent, the ability of canines to discriminate accurately between scents, and the use of human scent to distinguish different individuals.[1] The courts found that human scent discrimination by a canine can be admitted into court as evidence whenever the training and experience of both the dog and the handler prove to be proficient, the handler's methods prove to be reliable, and the person performing the sample collection technique uses the correct scientific procedures. These court cases have highlighted the significance of human scent within the criminal justice system and in forensic investigations.

This presentation will summarize and discuss human scent research and its ability to be used as a form of associative evidence in forensic investigations. Presently, human scent-discriminating canines are often employed to discriminate individuals, crime scenes, and objects. This practice is based upon the theory that every individual possesses a distinct odor that is generated from a complex combination of the body's metabolism, gland secretions, hormonal control, and interactions with the residing bacterial populations.[2] Human scent is comprised of secretions and bacterial action that occurs on dead skin cells, commonly referred to as "rafts", which can easily be deposited into the environment allowing canines the opportunity to pick up a person's scent.[3] To obtain an understanding of what canines smell, human scent has been studied in the laboratory using a variety of specimens. A large portion of research has been conducted on hand odor since there is a high likelihood that a suspect's hands will come into contact with an object while committing a crime. Hand odor can be collected through two different methods: (1) direct contact of the collection material and the object/person; and, (2) non-contact sampling using a portable vacuum source that is designed to draw in volatile organic compounds (VOCs) from the object/person. Upon collection, scent samples are analyzed using solid-phase microextraction gas chromatography-mass spectrometry (SPME-GC-MS) and statistically evaluated to determine the distinguishability of the scent profiles obtained from different individuals.

Human scent research has advanced over the years to include other biological specimens of forensic interest, such as hair, nails, and saliva. Brown and Furton found that hair, nails, and saliva possessed VOCs that differed between specimens and between people, allowing for the discrimination of individuals. This was further evaluated using human scent-discriminating canines.[4] Field tests revealed these specially trained canines had the ability to discriminate an individual independent of the specimen being assessed.[5] In another study conducted by DeGreeff *et al*. in 2011, human scent profiles of living individuals were compared to those that were deceased.[6] It was found that human scent profiles of living subjects differed from one individual to the next; however, upon death, the scent profiles appeared similar from one person to the next, revealing a more general odor for deceased individuals. This presentation will highlight and explore the advances in human scent research, which demonstrates its significance, versatility, and application in forensic investigations and within the criminal justice system.

Human Scent, VOCs, Canines

A18 Testing a Combined Approach for DNA and Trace Evidence Recovery Using Tape Lifting on Forensically Important Substrates

Scott K. Watanabe, BS, 20064 Oakside Ct, Santa Clarita, CA 91390; Christopher Ehrhardt, PhD, 1015 Floyd Ave, Grace E. Harris Hall South, Rm 2014, Richmond, VA 23112; and Helen R. Griffin, BSc, and Shanin Barrios, BS, Ventura County Sheriff's Dept, Forensic Sciences Lab, 800 S Victoria Ave, Ventura, CA 93009*

After attending this presentation, attendees will have been introduced to a novel approach for recovering DNA and various types of trace evidence from forensic samples, specifically, a common technique called tape lifting, to collect both trace evidence and "touch" DNA across multiple substrates using modern, automated methods of forensic analysis.

This presentation will impact the forensic science community by promoting a comprehensive approach to technique evaluation, expanding awareness to other instances of discipline overlap, and exploring the effects of other methods on common trace practices. A single type of tape that is optimal for trace evidence and touch DNA collection would streamline training, further interdisciplinary cooperation, and promote synergy during evidence routing and analysis in the forensic science laboratory.

The goal of this study is to test differences in recovery efficiency for trace evidence touch DNA across six types of tape currently in use or being considered for use in the Ventura County Sheriff's Office Bureau of Forensic Services: Evercare™ Lint Pic-Up roller, 3M Scotch™ Lint Roller, HP-260 Duck™ Brand Packing Tape, Lyn-Peavey™ Fingerprinting Tape, Allene's® Tacky Double-Stick Sheets, and Staples® Stickies™ Adhesive Notes. All tapes were tested for the presence of (PCR) inhibitors based on the quality of their internal PCR controls after quantification and the appearance of their electropherograms after amplification. The inhibition study was performed with xylene-treated swabs, water-treated swabs, and with no swabbing of the tape. DNA was provided by spotting 10 µl of 1:200 diluted whole blood from a single source onto the tape to give 3ng of DNA. The ability to recover touch DNA was determined by comparing the average quantifiable DNA from each tape to the average DNA from three, co-extracted reference swabs after tape lifting dried saliva stains from tight weave, knit, and glass substrates. Saliva stains were produced by pipetting 15µl of a 1:30 dilution of whole saliva onto the substrate to give 15ng of DNA. Finally, trace evidence recovery for each tape sample was examined by comparing tape lifting efficiencies of glass fragments, four-layer house paint chips, 100% polyester clothing fibers, and 100% nylon carpet fibers, which had all been rendered to 0.5mm as well as whole pubic hairs and 100% nylon carpet fibers from the same three substrates. Quantitation of touch DNA was carried out using a sequence detection system with an amplification kit and amplified with an amplification kit and an genetic analyzer capillary electrophoresis instrument. Trace evidence identity was established with FT-IR using a single-bounce attenuated total reflectance accessory.

All tape samples produced fully amplified and interpretable profiles across all Combined DNA Index System (CODIS) loci with little to no PCR inhibition, regardless of the pre-extraction treatment. The Duck® Brand HP260 High Performance Packaging Tape recovered the highest amounts of trace evidence and touch DNA across all three examined substrates. While the packaging tape was transparent and easy to

analyze, it also picked up much of the background material present in or on the substrate and was somewhat difficult to use compared to the other tapes. The 3M Scotch™ Lint Roller was consistently the second best tape when recovering every type of trace evidence (except 0.5mm carpet fibers) and touch DNA while being easier to use on bedding and other large surfaces. In spite of its difficulty collecting small nylon carpet fibers, the 3M Scotch™ roller never lagged more than 10% recovery behind the packaging tape. All other tapes performed well in specific circumstances, but had inferior recovery efficiency compared to both the packaging tape and the lint roller across all three substrates. The Duck Brand® packaging tape was suggested as the optimal tape for the Ventura County Sheriff's Office Bureau of Forensic Services while the 3M Scotch™ was advised to be used for large areas or in case the packaging tape was not available.

Tape Lifting, Touch DNA, Trace Evidence

A19 Identification of Sildenafil and Other Male Potency Enhancers Found in Internet Products

Michael E. Lamb, MS, 265 Ribbon St, Franklin Square, NY 11010; and G. John DiGregorio, MD, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending the presentation, attendees will understand that erectile dysfunction pharmaceutical medication is being put into Internet products that are being marketed as all natural or herbal remedies. Attendees will be shown data from various analytical techniques such as Thin Layer Chromatography, Gas Chromatography/Mass Spectrometry, High performance Liquid Chromatography/Ultraviolet Detection and Liquid Chromatography/Mass Spectrometry. They will be made aware that this phenomenon is happening in the United States and around the world. Finally, they will be shown dangerous physical effects that can occur by taking these products without a prescription from a physician.

This presentation will impact the forensic science community by showing that the adulteration of Internet products with Viagra© and related compounds is actually occurring. This is significant because these medications have dangerous side effects and various contraindications, and should not be taken without a doctor's prescription. Many members of the forensic science community may not be aware this adulteration is happening; therefore, it is extremely important this information is made available to the community.

There has been an increase over the last decade in the sale of products marketed as male potency enhancers that can be purchased through the Internet. Erectile dysfunction drugs that are only available by a doctor's prescription such as sildenafil (Viagra©), tadalafil (Cialis©), and vardenafil (Levitra©), or their chemical analogs, are being added to various Internet products proposed to naturally enhance male potency, without regulation or medical approval. The danger in this manifests itself in the various side effects of these drugs that include stroke, loss of vision/hearing, and death. These drugs act as specific phosphodiesterase type 5 (PDE-5) inhibitors that block the degradation of an enzyme that allows for increased blood flow to the penis, thus maintaining an erection. The enzyme involved is cyclic GMP and has a variety of functions in the body, including being a carrier protein. This, in turn, causes significant vasodilation and can lower blood pressure drastically. Men with cardiovascular problems would normally not be prescribed this medication due to the inherent risks; however, now they have the possibility of obtaining it without a doctor's prescription by buying products on the Internet, in local shops, or in gas stations.

Various unregulated erectile dysfunction products were ordered over the Internet and analyzed by Thin Layer Chromatography, Gas Chromatography/Mass Spectrometry, High performance Liquid Chromatography/Ultraviolet Detection, and Liquid Chromatography/Mass Spectrometry. Ten of these products were examined. The matrices explored were pills, powders, and even a cream. They were all purchased over the Internet for a very low price and all were marketed as "all natural." Ingredient lists made no mention to the presence of sildenafil, tadalafil, or vardenafil. Results obtained indicate the presence of these compounds in various Internet products. Furthermore, other compounds such as caffeine were also found in these products without being listed on the ingredient list. This indicates that companies, both in the United States and overseas, are falsely marketing these products and selling them over the Internet, making them very accessible. This threatens the safety of individuals that may experience damaging side effects while consuming these products, believing them to be all natural.

Sildenafil, Internet Products, Adulteration

A20 Optimized Screening of Synthetic Cannabinoids With Phenyl Reversed-Phase Liquid Chromatography

Kaitlin Giovanni, BS, Mercurio Veltri, PharmD, William F. Nirode, PhD, and Ling Huang, PhD, Hofstra Univ, Chemistry Dept, 151 Hofstra University, Hempstead, NY 11549*

After attending this presentation, attendees will understand the fundamental principles of Reversed-Phase Liquid Chromatography (RPLC) with UV-Vis detection as pertaining to forensic chemistry, and the necessary elements for optimized separation and identification of illegal substances, specifically synthetic cannabinoids in herbal incenses. Through the comparison of several different phenyl-functionalized columns, the optimal screening technique for synthetic cannabinoids can be determined and used in a practical setting.

This presentation will impact the forensic science community by providing an optimized and simple chromatographic separation and quantification method for synthetic cannabinoids in herbal incenses in order to improve the accuracy and throughput of "spice" evidence processing.

The recently-passed S.3187 included five classes of synthetic cannabinoids into Schedule I controlled substance list. It creates great challenges for forensic scientists to rapidly separate, identify, and quantify these "cannabimimetic agents" in numerous herbal incenses due to the similarity of isomer or analog structures. Newer compounds are being synthesized promptly to circumvent the ban, which exacerbates the analytical difficulties for forensic labs, some of which are already experiencing backlogs. In this presentation, a novel yet simple RPLC separation method with phenyl functionalized column and Diode Array Detector (DAD) was dicovered to possess several advantages over conventional C-18 LC/MS methods. When the phenyl RPLC method is coupled with a simple liquid extraction method, the identification and quantification of synthetic cannabinoids in herbal incenses can be completed in less than 30 minutes.

All cannabinoids contain aromatic functional groups such as phenyl, naphthyl, indole, and pyrrole, which readily interact with phenyl stationary phases through pi-pi interactions. Compared to conventional C-18 or C-8 columns, these phenyl columns provide greater resolution in the separation of similar cannabinoids. Six different phenyl columns were compared to determine the ideal separation conditions for synthetic cannabinoids. The injection volume of the sample, composition of the mobile phase, and temperature are optimized to achieve ideal resolution and speed. A mixture of ten synthetic cannabinoids (6-16µg/mL methanol), including JWH-122, AM-2201, RCS-4, and various isomers and analogs, were prepared to evaluate the separation efficiency. For the herbal incense samples, a simple methanol extraction with paper filtration was employed as LC sample preparation. All separations were carried out isocratically on a HPLC system with pure acetonitrile and water as mobile phases flowing at 1-1.5mL/min. The detection wavelengths were set at 214nm and 280nm to capture all synthetic cannabinoids in 1-10µL injection volumes. Elevated temperatures (50-60˚C) increased separation speed.

After the optimization of separation conditions, all six columns can separate seven out of ten cannabinoids with satisfactory resolution in under 20 minutes. Phenylhexyl columns provide better separation compared to phenylpropyl or biphenyl columns, thanks to the diverse functional groups presented on the stationary phase surface and in the

analytes. Compact UPLC-type columns with porous shell provide more surface area in a shorter column, which increases speed without the sacrifice of resolution. Polymer reversed phase columns provide more uniform distribution of phenyl groups on the stationary phase, which performed better than silica-based phenyl columns. One polymer-based phenylhexyl column separated all 10 standards in under 14 minutes. With standard calibration, the synthetic cannabinoids in 30 samples were identified and quantified. Most herbal incense contain two to three cannabinoids with concentrations varying from 1-20mg/g of herb.

In conclusion, phenyl RPLC columns with DAD can be used to quickly separate, identify, and quantify synthetic cannabinoids in herbal incenses. When coupled with a simple methanol extraction method, the isocratic separation provides better resolution and rapid quantification compared to conventional C-18 LC/MS methods.

Cannabinoids, Chromatography, Drug Analysis

A21 Statistical Measures for Comparisons of Fiber Spectra: Forensic Database and Statistical Software

Edward G. Bartick, PhD, Suffolk Univ, Dept of Chemistry/Biochemistry, Beacon Hill, 41 Temple St, Boston, MA 02114-4280; John V. Goodpaster, PhD, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202; and Stephen L. Morgan, PhD, Univ of South Carolina, Dept of Chemistry & Biochem, 631 Sumter St., Columbia, SC 29208*

After attending this presentation, attendees will be acquainted with the utility, ease of use, and applicability of a forensic fiber database containing fiber characteristics and user-friendly software for visual and statistical comparison of fiber spectra. These combined tools offer support for objective data-based decisions regarding the similarity of questioned and known fiber data and the reliability of match exclusions.

This presentation will impact the forensic science community by describing a combined data archiving and statistical graphics and analysis system that offers both data management and decision-making support to the forensic fiber examiner. Trace fiber investigations, where the hypothesis of a common source for two fibers could not be rejected and evidence was found to have probative value.

Testimony of FBI examiner Paul Stombaugh before the Warren Commission concerned some fibers stuck on a jagged edge of Oswald's rifle stock stated, "There is no doubt in my mind that these fibers could have come from this shirt." However, the next statement, "There is no way; however, to eliminate the possibility of the fibers having come from another identical shirt," epitomizes the problem of class evidence. The goals of this research include: (1) assess error rate performance in trace fiber evidence examinations based on UV/visible microspectrophotometry and infrared spectroscopy; (2) create a database of fiber characteristics, including UV/visible or IR spectra, to establish a performance baseline relevant to discussions of fiber discrimination; and, (3) evaluate intra- and inter-laboratory consistency, and improvements in forensic laboratory practice.

Statistical evaluation of trace evidence data from UV/visible or IR spectroscopy has great utility for assessment of assessing similarity or dissimilarity of spectra when comparing questioned and known trace evidence samples. The use of statistical hypothesis testing with both univariate and multivariate data, coupled with good experimental design, permits the investigator to exercise control over errors in statistical decisions arising from measurement uncertainties. Both univariate and multivariate statistical methods to judge the significance of discrimination of UV-visible and infrared spectra from a wide variety of textile fibers were employed. Statistical methods, coupled with informative graphics for comparing grouped data distributions, can produce statistical support for inclusion and exclusion decisions in forensic fiber examinations. This presentation will show statistical analyses of fiber spectra from a user-friendly software package that has been developed for this purpose. The second tool presented here is a forensic fiber database that facilitates archiving fiber data such as polarized microscopy measurements (birefringence, sign of elongation), physical characteristics (diameter, shape), and spectral data. One immediate advantage is the ability to store data in a documented manner and access this information on demand from a relational database. XML, an extensible markup language that can be employed to define a flexible and self-documenting, but human-readable and standardized text format for forensic data was adopted. XML has experienced recent growth because of its adoption by a multinational software corporation as a file format for office application documents. NIST has long recognized the significance of XML and several ongoing interagency efforts involve data format standardization using XML (e.g., the NIST ITL American National Standards for Biometrics and efforts by ANSI, NIST, and the FBI). The web-based SQL/ASP database currently holds information on about 500 fibers, and facilitates queries for rapid retrieval of data and interactive visualization, export of existing raw data, and import of new fiber data sets. Although there is little likelihood of establishing a truly comprehensive fiber database because of fast-moving trends in manufacturing and globalization of production, a combined data archiving and statistical graphics and analysis system offers both data management and decision-making support to the forensic fiber examiner.

Research in this presentation was supported by Award No. 2010-DN-BX-K220 from the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

Fiber Spectra, Statistics, Database

A22 In-House Production of a Metrologically Sound Traceable Ethyl Centralite Reference Material for Smokeless Powder Analysis

Rodrigo B. Oliveira, PhD, and Regina Celia F. da Silva, Bsc, Ave N, S das Graças, 50 Xerém, Duque de Caxias, BRAZIL; and Erika Martins de Carvalho, PhD, Rua Sizenando Nabuco, Rio de Janeiro, BRAZIL*

After this presentation, attendees will be able to rationalize the in-house production of a metrologically sound, traceable, high purity Ethyl Centralite (EC) reference material for smokeless powder analysis and extend this knowledge to other compounds.

This presentation will impact the forensic science community by providing a method for analysts to make their own reference materials required in their routine analyses in a metrologically sound, traceable manner in order to compensate for the lack of available forensic reference materials. The chemical compound chosen to demonstrate this approach was EC, a common organic stabilizer of smokeless powders.

The analysis of organic compounds present in smokeless powder from ammunition and improvised explosive devices is important in crime elucidation, especially after the advent of "environmentally friendly" ammunition, free of barium, lead, and antimony. The most common organic additive in Brazilian ammunition is EC, in which its function is to stabilize the smokeless powder by delaying degradation of nitrocellulose. Both qualitative and quantitative analysis of additives and propellants in smokeless powder are important for forensic scientists. By qualitatively identifying and quantitatively determining the additives in smokeless powder it is possible to calculate a numerical propellant to stabilizer ratio which allows the association of handgun-fired organic gunshot residues with unfired powder. To perform quantitative analysis of most Brazilian ammunitions, the use of a smokeless powder certified reference material (CRM) containing EC is recommended for calibration, method validation, and quality control. Workers at the Brazilian National Institute of Metrology, Quality and Technology - INMETRO are working to produce a smokeless powder CRM containing EC as additive. However, to quantify EC in smokeless powder for the production of such a CRM, or even to quantify EC in common routine analysis, a high purity

EC CRM is required for calibration. Because such a commercial CRM is also not yet available worldwide, in-house production of a metrologically sound, traceable EC reference material for smokeless powder analysis is necessary. The objective of this research was to assess the purity of a commercial EC in a metrologically sound, traceable manner.

High purity EC was purchased and the identity of EC was confirmed by determination of melting point, Mass Spectrometry (MS), Fourier Transform Infrared spectroscopy (FTIR), and 1H and 13C Nuclear Magnetic Resonance (NMR). The purity was assessed by three independent methods: Differential Scanning Calorimetry (DSC), quantitative 1H NMR (using benzoic acid NIST 650b SRM as internal standard), and mass balance. The latter consisted of a broad investigation of the impurities, which included identification and quantification of non-volatile organic impurities (by gas chromatography coupled to flame ionization detector – GC-FID), volatile organic impurities (by headspace GC-FID), water content (by coulometric Karl Fischer titration), and inorganic impurities (by ashing).

EC melting point was 72.57 ± 0.03°C. Mass spectra of sample showed m/z = 268, 164, 148, 120, and 77, which is consistent with EC structure. FTIR and 1H and 13C NMR spectra were consistent with EC structure. All these data confirmed the identity of the commercial product as EC.

EC purity by DSC was 99.83 ± 0.05 mol % (average and standard deviation). EC purity (m/m) by quantitative 1H NMR was 99.89 ± 0.7% (average and measurement uncertainty – 95% CI; k = 1.98). EC purity (m/m) by mass balance was 99.86 ± 0.02% (average and measurement uncertainty – 95% CI; k = 2). The mass balance is also called 100% - impurities % method and the individual impurities found were (m/m): (1) non-volatile organic impurities: methyl-ethyl centralite (0.0762%); (2) volatile organic impurities: m/p-xylene (0.0263%), ethyl benzene (0.0079%) and dimethylchloramine (0.013%); (3) water content: 0.0083%; and, (4) inorganic impurities: 0.0025%.

EC purity results by three independent methods are in agreement with one another. It was decided to consider the mass balance result (99.86 ± 0.02% m/m) because of the reduced measurement uncertainty valor. Metrological traceability came by the use of a primary method (DSC), by the use of a certified reference material in quantitative NMR, and by a detailed investigation of impurities, which provided an indirect purity assessment (mass balance). This approach can be used for the production of in-house reference materials suitable for calibration, quality control (after spiking a blank matrix), and method validation involving forensic analysis.

Reference Material, Smokeless Powder, Ethyl Centralite

A23 Presumptive Color Test for Piperazine Designer Drugs

Tsunghsueh Wu, PhD, Chelsea Johnson, BS*, and Ethan Becker, BS, Univ of Wisconsin, 1 University Plaza, Platteville, WI 53818*

After attending this presentation, attendees will understand the development of a presumptive color test for piperazine designer drugs, the scientific principles underlying drug detection, and the results on detection of BZP and TMFPP using this technique.

This presentation will impact the forensic science community by introducing the new technique for law enforcement to effectively conduct the drug test in the field.

Presumptive color tests for drugs help investigators to narrow the possible identities of a substance. It is a quick and inexpensive chemical test, which is commonly performed by police officers on the street prior to the use of costly confirmative tests in the forensic science laboratory. This test is done to determine quickly on the scene if the police officer has probable cause for an arrest. Using this new technique, an investigator places the questioned substance in a disposable test tube containing ampules of chemical reagents necessary for the presumptive identification of piperazine drugs such as benzylpiperazine (BZP) and 3-trifluoromethylphenyl-piperazine (TFMPP).

Benzylpiperazine (BZP) and trifluoromethylphenylpiperazine (TFMPP) are synthetic phenylpiperazine analogues, which have stimulant and amphetamine-like properties.[1] As a result, they are commonly used as a recreational drug, and were legally available in a number of countries, particularly in New Zealand.[1] The drug was temporarily classified as a Schedule I controlled substance in the United States in 2002 because of its high abuse potential and lack of accepted medical use or safety.[2] On March 18, 2004, the DEA published a Final Rule in the Federal Register permanently placing BZP in schedule I. Several states have placed BZP in schedule I: Colorado, Idaho, Illinois, Indiana, Iowa, Kansas, Louisiana, Mississippi, Missouri, Oklahoma, Nebraska, Tennessee, and Wyoming.[2]

According to Office of Diversion Control, law enforcement officials submitted 48 drug items/exhibits to federal, state, and local forensic laboratories identified as BZP in 2004.[2] The number of BZP items/exhibits increased from 437 in 2007 to 6,088 in 2008. BZP items/exhibits submitted to forensic laboratories increased 127% from 6,088 in 2008 to 13,822 in 2009. BZP was smuggled internationally as powder by drug trafficking organizations. The bulk powder is loaded into capsules and pressed into tablets. BZP is encountered as pink, white, off-white, purple, orange, tan, and mottle orange-brown tablets. These tablets bear imprints commonly seen on MDMA tablets such as housefly, crown, heart, butterfly, smiley face, or bull's head logos and are often sold as "ecstasy." BZP has been found in powder or liquid form packaged in small sizes and sold on the Internet.[2] Because of the increasing trend in the distribution of these substances, the presumptive test for piperazine drugs is necessary to allow law enforcement to identify the controlled substances on the street within a minute.

Both BZP and TFMPP appear as a colorless solution when dissolved in deionized water. In this research, the BZP and TFMPP aqueous solution in the presence of our reagents will yield a yellow solution as a positive result. However, organic molecules containing primary amine functional group caused a severe interference. This presentation will discuss the principle behind the method and future plans to study this test method.

Presumptive Test, Party Drug, Benzylpiperazine

A24 Differentiation of South American and Domestic (U.S.) Crack Cocaine Through Headspace-Gas Chromatography/Mass Spectrometry (HS-GC-MS)

John F. Casale, BS, and Valerie L. Colley, BS, DEA, Special Testing Laboratory, 22624 Dulles Summit Ct, Dulles, VA 20166*

After attending this presentation, attendees will understand the methodology used to differentiate South American- and U.S.-produced crack cocaine.

This presentation will impact the forensic science community by providing a method by which South American- and U.S.-produced crack cocaine can be differentiated.

South American coca leaf-to-cocaine base processors have been making cocaine base in the form of "crack cocaine" for several years for distribution and consumption in South America. There had been no evidence of South American-produced crack cocaine being smuggled into the United States until recent U.S. interdiction efforts. This form of cocaine is typically produced by boiling crude cocaine base (obtained directly from coca leaf through traditional illicit processing methods), skimming off the water and impurities, and then allowing the cocaine base to solidify into the form of crack cocaine. In contrast, U.S. domestic

crack cocaine is typically made by the conversion of imported illicit cocaine hydrochloride into cocaine base by dissolving cocaine hydrochloride in hot water, converting it to cocaine base through the addition of sodium bicarbonate (or some other base), boiling the solution, allowing it to cool, and then removing the water after the cocaine base has solidified into crack cocaine. The presented research will show that, as a result of these production differences, South American crack cocaine can be distinguished from domestically produced crack cocaine. In addition, it will show that analysis of domestically produced crack cocaine can provide information on what solvents were used in the original cocaine hydrochloride processing in South America (i.e., prior to the cocaine base conversion process into cocaine hydrochloride).

Samples of cocaine base from South America (Colombia, Bolivia, and Peru) and the U.S. were analyzed by Headspace-Gas Chromatography/Mass Spectrometry (HS-GC/MS) to determine their solvent profiles. Analyses of the South American exhibits confirmed traces of low to high boiling hydrocarbons present in the crystal matrix. These residual solvents are due to the use of gasoline, kerosene, and diesel in the extraction process. In contrast, analyses of domestic crack cocaine exhibits show solvent profiles typically seen for cocaine hydrochloride exhibits, but at much reduced levels. The results demonstrate that South American crack cocaine is easily differentiated from U.S. domestic crack cocaine.

The correlation between cocaine hydrochloride solvent profiles and their corresponding domestic crack cocaine solvent profiles was also investigated. Samples of cocaine hydrochloride were analyzed by HS-GC/MS to determine what solvents were used in the clandestine cocaine base-to-cocaine hydrochloride conversion process. Each resulting cocaine hydrochloride sample was then converted to crack cocaine using the traditional domestic crack cocaine production method. Each crack cocaine sample was then analyzed by HS-GC/MS and its resulting solvent profile compared to its original cocaine hydrochloride solvent profile. In each case, the crack cocaine solvent profile contained essentially the same primary processing solvents found in the original cocaine hydrochloride, but at reduced levels. The levels of reduction varied by solvent but were typically one-half to one-tenth of the original levels. This data can provide valuable information on what solvents were used to produce the cocaine hydrochloride in South America prior to the production of domestic crack cocaine.

Currently, the DEA Special Testing and Research Laboratory routinely analyzes imported illicit cocaine hydrochloride samples to determine which solvents were used in the clandestine cocaine base-to-cocaine hydrochloride conversion by South American processors. This data provides the intelligence community with valuable information, which is used to monitor and, in some cases, control essential solvents used by clandestine laboratories. Analysis of domestic crack cocaine samples to determine which solvents were used in the clandestine cocaine base-to-cocaine hydrochloride conversion by South American processors will augment the strategic intelligence currently provided for solvent control and diversion efforts.

Forensic Science, Crack Cocaine, Occluded Solvents

A25 Comparative Study of Shotgun Spread Patterns

Keith B. Morris, PhD, West Virginia Univ, 208 Oglebay Hall, 1600 University Ave, PO Box 6121, Morgantown, WV 26506-6121; Justin N. Kirk, BS, 108 South Kanawha St., Buckhannon, WV 26201; James Tuckwiller*, HC 40 Box 11, Lewisburg, WV 24901; Eric Law, 306 Dux Landing, Cape Girardeau, MO 63701; Joshua Davis, 21710 Magnolia Ave, Matoaca, VA; and Roger Jefferys, 27 Dafonzo Hill Rd, Pursglove, WV 26546*

After attending this presentation, attendees will learn how to interpert statistical data, a shotgun spread pattern, and how the muzzle-to-target distance can be determined.

This presentation will impact the forensic science community by allowing examiners to refer to a statistical model to approximate the muzzle-to-target distance at a crime scene instead of performing test fires for each shotgun found at a crime scene.

When a shotgun is fired, the pellets exit the barrel in a tight packet. As the pellets get farther from the shotgun, they start to spread out and cover a larger area when they impact. The farther the target is from the shotgun, the wider the spread pattern becomes. Given that the same gauge, choke, and shot size is used, one should be able to predict the spread of the pellets over time. In 1983, Heaney and Rowe used a linear regression to model pellet dispersion from shotguns.[1] In their research; however, only one spread pattern at each distance was presented. This does not account for any variation in the spread pattern that could occur at that distance. In order to produce an accurate statistical model that accounts for variation, a larger sample size must be used. This research also only covered one degree of choke and pellet size. Arslan *et al*, completed a similar study in 2011.[2] A larger sample size at each distance was used in this study, which allows their statistical models to be more accurate. In this research, the effect of various gauges, choke types, and pellet sizes were also studied. The Arslan group concluded that each factor results in a new model to estimate shooting distances.

In this research, the effect of choke and pellet size was studied using a 500 series shotgun. Measures of dispersion such as maximum radius, a 95% confidence interval of the maximum radius, bounded rectangle, and fitted ellipse were used to measure the dispersion patterns. The position of each pellet in a spread pattern was calculated using the x and y coordinates of each pellet with the origin set in the center of the spread pattern. The 95% confidence interval at each distance was calculated by taking the average maximum radius plus/minus the standard deviation of the maximum radius multiplied by a t-value for that sample size. The bounded rectangle was calculated for each spread pattern by taking the maximum x value minus the minimum x value and the maximum y value minus the minimum y value. The x and y coordinates of each spread pattern were also used to calculate the width and height, a and b, of a fitted ellipse that represents the smallest ellipse that covers all of the pellets in the spread. Models were developed to estimate the firing distance and to associate an uncertainty in each particular test condition.

In the past when shotgun spread patterns were found at a crime scene, examiners would have to perform test fires with the suspect weapon to find the spread patterns of that gun at various distances. These test spread patterns would then be compared to the pattern found at the crime scene so the distance could be approximated. This research would instead allow examiners to refer to a known spread pattern at a given distance, pellet size, and gauge. The 95% confidence interval will allow examiners to say that they are 95% certain that the suspect spread pattern falls within the range presented in the model at that distance. Although the examiner may wish to confirm that these distances are correct with the suspect shotgun, this would allow the examiner to have a starting point, and save time when reconstructing the crime scene.

Distance, Spread Pattern, Mossberg 500

A26 Analysis of a New Synthetic Street Drug “Molly Plant Food” by Mass Spectrometry and Vibrational Spectroscopy

Nisha V. Patel, BS, 1514 Center Pointe Dr, Murfreesboro, TN 37130*

After attending this presentation, attendees will learn about the composition of the new synthetic drug “Molly Plant Food” as well as the

methods used for analyzing the synthetic drug. Interpretation of data acquired via pyrolysis-gas chromatography-mass spectrometry, liquid chromatography-mass spectrometry, and Raman spectroscopy will be presented. The analysis of this new synthetic drug will contribute to better understanding of this and other similar variations of this synthetic drug with different substituent groups among the cathinones. The methodologies and findings will contribute to future protocols for analyzing and assessing the toxicological effects of the banned synthetic stimulants substances.

This presentation will impact the forensic science community by providing an analysis of the the synthetic stimulant drug toxicology, the various kind of methcathinone commonly detected in these stimulant drugs, and the findings of methcathinone in the Molly Plant Food. This rapid, reliable method of analysis of synthetic stimulant substances will enable law enforcement authorities to easily identify the new drug and better understand the toxicological effects.

In recent years, the production of fake "Ecstasy" has grown quite popular. Many abuse this new synthetic drug as a substitute for the real Ecstasy, which is illegal to possess and expensive to purchase in the black market. Fake Ecstasy is commonly known as Molly Plant Food or Rave Bath Salts is sold in convenience stores as common household products like bath salts or plant food.[1] Molly Plant Food is said to provide the same euphoric feeling as Ecstasy. This synthetic drug is said to contain either methylone (3, 4-methylenedioxy-N-methylcathinone), MDPV, mephedrone (4-methylmethcathinone), or many other methcathinones derivatives.[2] Many users of this fake Ecstasy do not know that it closely resembles methamphetamine, lacking only two functional groups. The primary buyers of these drugs are teens that may not be aware of the dangers of this drug. In recent years, there have been many cases of hospitalization and even death resulting from the use these drugs. As previously mentioned, the effect of this drug resembles that of Ecstasy; however, other compounds are added to mask its intended use as a drug of abuse and to allow it to be advertised as a plant growth agent or muscle relaxant. Since not much is known of this drug, it has the capacity to be abused at high levels, which can lead to death.

The research used high performance liquid chromatography to retrieve the different kinds of chemical components present in the Molly Plant Food.[3] The results of the LC/MS showed the presence of mephedrone and MDPV in the Molly Plant Food. Mephedrone and MDPV are just two of the many methcathinones found in various illegal synthetic stimulant drugs. The use of Raman spectroscopy provided a spectrum of the chemical constituent. The Raman findings showed strong bands at 2950cm^{-1}, 1750 cm^{-1}, 1020 cm^{-1}, and 770cm^{-1}. These findings provide a general distinctive identifying characteristic for the illegal compound. The finding of exact transition ion intensities at 10V, 27V, 36V, and the existence of methcathinone were confirmed via LC/MS. Further, the pyrolysis-GC/MS conducted on Molly Plant Food showed a high concentration of analgesic chemicals of the naphthoylindole family. The use of high temperature nickel-cobalt foil at 590°C and 670°C showed the presence of JWH-018 and JWH-073 when Molly Plant Food was pyrolyzed. These compounds were recently used in many synthetic cannabis products to give the same "high" effects of those of THC.[4] Since the drug usually comes in capsule or powder form, the understanding of the chemical constituents of these drugs makes makes them easier to identify.

Toxicology, Stimulant Drug, Methcathinone

A27 Variability in a Mossberg Model 500 Shotgun's Firing Pin and Breech Face Impressions

Keith B. Morris, PhD, West Virginia Univ, 208 Oglebay Hall, 1600 University Ave, PO Box 6121, Morgantown, WV 26506-6121; Roger Jefferys, 27 Dafonzo Hill Rd, Pursglove, WV 26546; Joshua Davis*, 21710 Magnolia Ave, Matoaca, VA;23803; Eric Law*, 306 Dux Landing, Cape Girardeau, MO 63701; James Tuckwiller, HC 40 Box 11, Lewisburg, WV 24901; and Justin N. Kirk, BS, 108 South Kanawha St., Buckhannon, WV 26201*

After attending this presentation, attendees will understand how firing pin impressions correlate back to a specific shotgun, and how this information helps fill the gap between the uniqueness of shotgun evidence and its interpretation.

This presentation will impact the forensic science community by providing statistical data that helps support the reliability and use of the IBIS within the justice system.

The purpose of this study is to examine the precision (inter-day variability), repeatability (intra-day variability), reliability (consistency and stability of results), and correlations (degree to which variables are related as opposed to causality) between firing pin and breech face impressions in shotgun evidence.[5]

There is much controversy related to firearms evidence, specifically, in analyzing the relationship between crime scene evidence and evidence found in the possession of a suspect. Minimal research exists investigating the value of this evidence. Ogihara *et al*., (1983) and Shem & Striupait (1983) performed comparisons of 5001 and 501 consecutively fired bullets with .45 and .25 caliber semi-automatic handguns, respectively, by firing pin impressions.[1,2] Grove, Judd, & Horn (1972) also examined firing pin impressions using scanning electron microscopy.[3]

The research used the Integrated Ballistics Identification System and a Leica FS-C comparison macroscope. The IBIS system uses bullets and casings from case evidence from a crime scene and compares them to a database of known fired weapons. IBIS consists of a fully automated projectile and cartridge case comparison systems, BULLETPROOF® and BRASSCATCHER™, respectively.[4] These systems allow the IBIS examiner to compare across a known database within minutes. IBIS provides a relative score for each comparison, and a list of highest matching breech face and firing pin scores is generated that represents the highest matching comparisons in the database.[4]

The Leica FS-C comparison macroscope was used to test the reliability of the IBIS. The reliability was tested by using best known non-matches when present. The macroscope compared those to other casings that have been integrated into the IBIS and known to have been fired using the same firing pin. The FS-C was also used to compare the firing pins against corresponding firing pin impressions.

A Mossberg Model 500 twelve-gauge shotgun was used to perform all test firings. Remington ammunition (2¾ Express,) was used while varying the pellet size (00, #4, #6, and #8 (all lead). The firing pin in the shotgun had an unknown history. The firing pin scores generated with this firing pin were used as a baseline. All tests were repeated with four new firing pins.

The test fires were conducted at an outdoor shooting range and each shotshell was collected directly after firing. Upon logging the shotshells, they were then entered in the IBIS system and the correlation worksheets were generated.[4] The breech face and firing pin scores were analyzed using Microsoft Excel™. The effects of shot type on firing pin scores were evaluated. The intra-variability and inter-variability of firing pin scores relative to individual firing pins were contrasted. Receiver Operating Characteristic curves demonstrating the ability of using the firing pin score to effect identification was constructed. Since the breech face impression of all shots fired remained constant, it provided a basis for evaluating the intra-variability of breech face scores, and allowed for the examination of cartridge cases in firearms where the firing pin has been modified or replaced.

The data was evaluated to test the following hypotheses: (1) there is a higher correlation between the same load sizes shot from the same firearm (or the intra-variability of different load sizes fired by the same firearm is smaller than the inter-variability of varying load sizes); and, (2) fired ammunition will have higher breech face and firing pin scores when comparing intra-firearm scores and inter-firearm scores.

The data was exported into Netica™, a program for designing decision diagrams. A Bayesian network was created using the data to represent the variability relationships graphically. The output was a likelihood ratio estimating the probability of the prosecutorial hypotheses relative to the probability of the defensive hypotheses thus providing an indication of the weight of the evidence.

Firing Pin, IBIS, Mossberg Model 500

A28 Second and Third Generation Legal Highs

Annessa Burnet, 5510 Milan Ave, Cincinnati, OH 45212; Nicholas Culverhouse, 1201 Univeristy Blvd, Birmingham, AL 35294; Geanee' Quinney, BS, Birmingham, AL; and Elizabeth A. Gardner, PhD, UAB, Dep of Justice, UBOB 210, 1530 3rd Avenue, S, Birmingham, AL 35294-4562*

After attending this presentation, attendees will have understanding of the emergence of second- and third-generation legal highs.

This presentation will impact the forensic science community by presenting a selection of the emerging drugs of abuse that drug chemists may encounter in casework in the near future.

On July 9, 2012, President Obama signed the Synthetic Drug Abuse Prevention Act of 2012, intended to control chemicals designed to mimic marijuana and amphetamines. On July 12, 2012, "*Wired Science*" declared the ban obsolete. The legislation was in response to two emerging drugs of abuse: spice and bath salts. When the public first became aware of these drugs in 2008, bath salts were primarily the cathinone analogs, methylone, mephedrone, and methylenedioxypyrovalerone (MDPV). Spice, sold as synthetic marijuana, was not a cannabinoid at all. The psychoactive substances in spice were cannabinoid agonists, chemicals that bound to the CB1 and CB2 cannabinoid receptors. The most prevalent were the JWHs developed by John W. Huffman in the 1990s. A few examples are JWH-018, JWH-073, JWH-019, JWH-200, JWH-250, JWH-081, WH-122, and JWH-398.

Individual states were the first to respond. By late 2011, over 30 states had banned the cathinones and several of the spice ingredients. The online vendors immediately responded with new "legal highs." Some even had state-specific websites. The most prevalent second-generation legal highs were naphyrone, butylone, and 5, 6-methylenedioxy-2-aminoindane (MDAI). The cannabimimetics were extended to include C8 homologs, AM2201, AM678, and many more JWHs.

As quickly as one class of legal highs is banned, new drugs are put on the market. They are sold online, in gas stations, and in head shops. They are often disguised as "bath salts" or "plant food." These substances are of concern because numerous incidents of overdose, organ damage, and even death have resulted from their consumption. The drugs are untested and unregulated. Distributors have no quality assurance and there is no guarantee that a person is receiving the drug they intended to purchase.

The objective of this project is to purchase new legal highs as they are offered online and in local head shops. The information found in this study is disseminated to poison control centers and lawmakers to help in treatment of patients by health professionals, to warn the public about the dangers of these substances, and to aid policy makers in preventing their distribution.

The samples are generally in the form of a powder or plant material. Each sample is ground in a mortar and pestle to homogenize the material and ensure a representative sample. The powders are extracted by two methods; an acid/base and extraction directly into hexane. Plant materials undergo an additional sonication step in both the acid extraction step and the direct hexane extraction. The samples are analyzed by gas chromatography and mass spectroscopy. If identification cannot be determined by the mass spectra, ESI and NMR are used to determine the structure.

In this study, several legal highs were analyzed for active components. The legal high, "synthacaine" was ordered online and found to contain a mixture of methiopropamine (MPA) and benzocaine. MPA is a thiophene-based analog of methamphetamine. Another drug, sold contains a mixture of MPA and MDAI. MDAI is a drug that can produce effects similar to MDMA. Other substances analyzed include legal highs containing 6-APB, of wich all contained the second-generation canniabimimetics, UR-144, XLR-11, A-796,260.

Legal Highs, Cannabimimetics, Cathinones

A29 Effect of Organic Modifiers on Separation of Fluorescently Labeled Phenethylamines in Capillary Electrophoresis

Britt E. Turnquest, BSc, 11200 SW 8 St, Miami, FL 33199; and Bruce R. McCord, PhD, Florida Int'l Univ, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will gain better insight into the role of organic modifiers in electrophoretic separations of fluorescently-labeled phenethylamines. The relationships between concentration of the fluorescent tag, 5-(4,6-dichloro-s-triazin-2-ylamino)fluorescein (5-DTAF), labeling efficiency, and peak resolution will be discussed.

This presentation will impact the forensic science community by detailing the optimization parameters of a potentially excellent screening method for trace amounts of phenethylamines and other related compounds, which are highly efficacious at low doses.

In electrophoresis, electric potential is applied at the ends of a capillary filled with an electrolytic solution resulting in the generation of an electric field. This field causes the movement of the electrolyte, causing any analytes present to be separated based on their mass-to-charge ratios. Due to the small inner diameter of these capillaries, sample and reagent volumes used are in the nanoliter range making it very cost-effective. Due to the short optical path length required for

capillary columns, a commonly utilized detection method for this separation technique is laser-induced fluorescence. This is because of its high sensitivity and specificity, which allows for the detection of compounds in the ng/mL range. For this study, five commonly encountered drugs and precursors (used in illicit preparations) were investigated: amphetamine, methamphetamine, norephedrine, ephedrine, and methylenedioxyamphetamine (MDMA). Since fluorescence is not a property native to any of these analytes, they must first be coupled to a fluorescent molecule, in this case 5-DTAF, in order to make them compatible with the technique. This process is known as fluorescence derivatization.

Given their small size and overall similarity in structure, the phenethylamines investigated all have similar pKa values and migration rates. Due to this, coelution of peaks is a commonly encountered difficulty. To overcome this and improve the separation between the individual drugs assessed, modifiers were added to the run buffer to alter the electro-osmotic flow and thus the velocity of the bulk solution as well as vary the migration rates of the analytes through their interactions with them. These modifiers included various β-cyclodextrins and organic solvents. As a result, the individual drugs separate into distinct zones. As they pass through the detection window on the way to the cathode, samples are irradiated by the laser. The signal produced from this excitation and subsequent emission is then collected by the detector and converted into an electropherogram for interpretation.

Drug standards were dissolved in analytical-reagent grade methanol for storage at 4°C. Prior to analysis, samples were diluted to appropriate concentrations using deionized water from a ultrapure water purification system and methanol. For this method, a micellar running buffer comprised of 50mM borate, pH 9.5/15mM β-cyclodextrin (β-CD) was used for the separation of the analytes. A background electrolyte of 50mM borate, pH 9.5 and a derivatization buffer of 0.5M $NaHCO_3/Na_2CO_3$, pH 9.5 were also utilized. Experiments were conducted using a CE-based analytical system unit interfaced with a computer. The fused-silica capillary was 60.5cm (effective length 50cm) with an internal diameter of 50µm. An argon ion laser was used as an excitation source (488 nm) and electropherograms were recorded by monitoring the emission intensity at 520nm. New capillaries were conditioned by thorough rinsing with 0.1M sodium hydroxide, deionized water, and micellar running buffer in series.

Phenethylamines, Electrophoresis, 5-DTAF

A30 A Step Toward the Development of Methods for the Analysis of Fingerprint DNA

Levi L. Borrego, BS, 2911 Fletcher Ave, Apt 131, Lincoln, NE 68504; Nicholas J. Eurek, BS, 3002 Merrill St, Lincoln, NE 68503; Ray Wickenheiser, MBA, Montgomery Co Police Crime Lab, 2350 Research Blvd, Rockville, MD 20850; and Ashley Hall, PhD, Univ of Nebraska, 103 Entomology Hall, Lincoln, NE 68583*

The goals of this presentation are to provide information about the components of a deposited fingerprint sample, and to discuss a technique for the generation of a positive control with analysis of the results.

This presentation will impact the forensic science community by providing basic information about the components of a touch DNA sample originating from a fingerprint, while also discussing and presenting methods for DNA analysis using the standard, widespread acceptance of such techniques.

"Touch DNA" is contained in the cells deposited by a person's physical contact with an object such as a hard surface, that is, the deposition of a fingerprint. Studies have shown that is it possible to amplify both mitochondrial and nuclear DNA from fingerprints, and this could provide valuable evidence in many circumstances. However, the biological origin of the DNA in fingerprints is not completely clear. It may arise from sources such as epithelial cells trapped in skin oils or from cell-free DNA found in body fluids. An elucidation of these mechanisms could prove invaluable in the forensic analysis of samples.

The goal of the project presented here was to study basic characteristics of deposited fingerprints to aid in the development of techniques for the collection and analysis of this touch DNA. The first step was the generation of a suitable positive control for use in the experiments. A quantifiable, non-variable sample containing DNA and other components that mimicked a fingerprint (i.e., deposited cells in a chemical matrix) was required. A simple, cost-effective technique was developed for the production of these controls. Briefly, the most abundant chemical components comprising a fingerprint were combined proportionally to make the "fingerprint solution." Buccal epithelial cells were collected and suspended in the fingerprint solution. They were treated to reduce clumping and counted in a hemocytometer. The number of cells was equated to the DNA content of the solution, which allowed a known quantity of DNA to be used as a positive control while retaining the chemical characteristics of a fingerprint.

The cell/fingerprint suspension was used two ways: (1) it was deposited on a hard surface and spread with the use of a small roller to mimic a fingerprint; and, (2) it was added directly to an extraction reaction to allow for an estimation of the number of cells lost during the deposition procedure. Early in the project, these control samples consistently showed extraction yields greater than 100 percent, indicating the need to more carefully examine the components of a body fluid extract, especially when it contains limited template DNA. In subsequent studies, the source of the DNA in each type of sample was considered. Origins of the DNA such as endogenous extracellular sources, contamination from various collection methods, and contamination introduced during the procedure were examined. The results will be discussed here and the procedures for the generation of a positive control will be presented.

Fingerprints, DNA, DNA Profiling

A31 Forensic Analysis of Carpet Fiber Samples Using Direct Analysis in Real Time Coupled to an Accurate Time-of-Flight Mass Spectrometer

Torki Zughaibi, MS, 12413 Dorforth Dr, Fairfax, VA 22033; and Steiner Robert, BS, 700 N 5th St, Richmond, VA 23219*

After attending this presentation, attendees will understand how the analysis of carpet fiber samples in forensic laboratories involve a series of different tests, including the comparing of fibers microscopically, through the use of micro-chemical and micro-solubility tests, FTIR microscopy, etc. This study will attempt to test the ability of the DART®-AccuTOF™ for fiber analysis in either a screening or confirmatory capacity.

This presentation will impact the forensic science community by demonstraiting how DART®-AccuTOF™ was able to correctly identify and distinguish the various polymer classes and sub-classes (i.e.; Nylon versus Polyester as well as Nylon 6 versus Nylon 6/6). Although it is destructive, the rapidity of the technique along with its high power of discrimination makes it a favorable test to be either added to the series of tests, or can even replace a few of them.

Fibers are associative evidence that is encountered in numerous forensic circumstances. They can be found in crime scenes that involve breaking and entering, hit and runs, and even rape. This study focused on nylons, polyesters, and olefins, which are the most frequently encountered carpet fibers. An attempt to analyze the multiple polymer types was done using Direct Analysis in Real Time (DART®) coupled with accurate mass spectrometry (AccuTOF™). Twelve nylon, polyester, and olefin polymer standards were used to optimize parameters for the analysis of carpet fibers. A DART® helium gas temperature of 275°C was chosen as an optimum for analysis due to the differences in melting point for the various polymer types. Use of collision-induced dissociation to enhance fragmentation increased the power of discrimination, albeit decreasing sensitivity. A function switching method between 20 and 30 volts was established in order to provide greater spectral detail, while

minimizing fragmentation which would lead to an even more cluttered spectrum. Minimal sample preparation was needed to analyze the samples; however, due to the small sample gap between the DART® ceramic and orifice, care was taken in order to not obstruct the orifice with the samples. This involved sampling the carpet fibers using a pair of tweezers, which was taped to a dowel, held tightly with a clamp. The main disadvantage of this process is that it is a destructive technique. All 12 polymer standards were successfully differentiated and identified using DART®-AccuTOF™ based on the presence of their monomers and associated dimers and trimers. A total of 32 carpet samples were analyzed in this study. Carpet samples of known compositions were correctly identified by class, and the remaining carpet samples of unknown compositions were also correctly identified following FTIR identification. In addition to identifying polymer class, the sub-class was identified in some cases such as nylon 6 versus nylon 6/6. All carpet fiber spectra demonstrated an intense peak at 282 Da, which was attributed to oleamide, a slipping agent that is used to enhance the extrusion of the fiber strands through the spinneret in the fiber-making process. The results demonstrate the capability of DART®-AccuTOF™ being implemented as an addition to the series of tests conducted to analyze carpet fibers. In addition to carpet fibers, other types of fabric and materials may also be analyzed using this technique. Reproducibility studies may allow for the use of this technique to directly compare known and questioned fiber evidence.

DART® AccuTOF™, Carpet Fibers, Nylon

A32 Searching for the Elusive Spermatozoa: Revisiting Seminal Fluid

Kelsey R. Sakaida, Kyle A. Williston, Kimberly A. Strong, and Reena Roy, PhD, Penn State Univ, Forensic Science Program, 107 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will understand how to find rare human spermatozoa on a low budget without resorting to expensive equipment and software.

This presentation will impact the forensic science community by teaching the practicing biologist how to detect human spermatozoa when they are extremely rare in a specimen and also mixed with spermatozoa of other animals and other human body fluids.

Forensic crime laboratories analyze evidence from various types of sexual assault cases. The most likely source of male DNA in sexual assault cases comes from semen, which contains male cells commonly known as spermatozoa. Although most of the sexual assault cases involve humans, forensic bestiality cases are also common, and differentiating human male cells from animal spermatozoa becomes a necessity. In such cases, it is important to confirm the presence of human spermatozoa for the investigators and attorneys to bring charges against an assailant.

Examining such evidence to identify spermatozoa requires a great deal of time and effort using stains such as Kernechtrot-Picroindigocarmine (KPIC) staining, commonly used in the crime laboratories for the visualization of sperm. In some instances, because of the rarity of the spermatozoa in the evidence, an analyst may not be able to detect the KPIC-stained heads of the spermatozoa.

The goal of this research was to manually identify human spermatozoa where mixtures of human and animal spermatozoa exist. Some of the simulated evidence samples contained body fluids such as blood and saliva as well as seminal fluids from humans and animals. Another objective was to detect rare human spermatozoa from slides that have been prepared from vaginal swabs collected several days after coitus and where the cells have been dyed with dyes commonly used in the crime laboratories. The project included re-staining these KPIC-stained slides with immunofluorescent dyes to enhance the detection of the male cells.

SPERM HY-LITER™ technology in conjunction with fluorescent microscopy and specific computer software to detect spermatozoa is a novel method in the forensic community. This immunofluorescence staining technique is specific for human sperm cells since it does not stain animal spermatozoa, human epithelial cells, or other types of body cells that may be present in the sample. In some instances, where the victim does not report the crime for several days and spermatozoa may become rare and difficult to detect, this immunofluorescent technology can detect rare spermatozoa among many other non-human spermatozoa and human cells. This technique also allows the detection of rare spermatozoa present as one of the components in a complex mixture of other body fluids. The microcopy and the software to search for the stained spermatozoa are expensive, and budgetary constraints may not allow a laboratory to use such tools.

In this research, SPERM HY-LITER™ was used to stain human and animal spermatozoa. Once stained, these cells were analyzed manually by a fluorescent microscope which did not have the expensive computer software necessary for the automatic detection of stained human spermatozoa. The goal of this research was to identify human spermatozoa where a mixture of human and animal spermatozoa may exist. Another objective was to be able to detect rare spermatozoa even after obtaining vaginal swabs several hours after coitus. In one of the aspects of the study, slides were prepared from vaginal swabs and stained with KPIC. Once the spermatozoa were visualized, the cells were re-stained with fluorescent dye. In all of the instances, human spermatozoa were identified from various samples analyzed by this method.

The results obtained from this research would benefit the other forensic biology laboratories as they can use this technology accurately and efficiently for identification of spermatozoa without straining the budget.

Spermatozoa, Animal Semen, Human Body Fluid

A33 A Comparison of Mitochondrial DNA Species Identification Techniques of Questioned Animal Samples

David R. Foran, PhD, Michigan State Univ, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; Andrew B. Fischer, 20950 Hogan Rd, Manchester, MI 48158; and Matthew E. Stoloff, 30367 Kingsway, Farmington Hills, MI 48331*

After attending this presentation, attendees will understand several PCR-based methods available for determining the origin species of biological material and the advantages and disadvantages of each.

This presentation will impact the forensic science community by introducing a variety of established DNA-based methods that are used to identify the species of origin of tissues or other biological materials and describing extensive experiments for their comparison regarding successful PCR amplification, sequencing, and identification of their species of origin.

It is not uncommon for legal authorities or forensic practitioners to be confronted with biological material of unknown origin. From these, two questions arise: (1) “Is the material human?”; or, (2) “What is the species of origin?” The former can be key in missing persons cases when a search turns up biological material, while the latter is important when material clearly animal in origin, but otherwise undefined, is encountered.

Modern DNA methodologies have allowed molecular biologists to identify regions of the animal genome that are similar enough among species such that they can be successfully PCR amplified using universal primers, while still varying enough between primers so that a more precise origin can be determined, be it species, genus, etc. The region between primers is sequenced, and the resultant sequence undergoes a query using Basic Local Alignment Search Tool (BLAST: NIH’s on-line database of DNA sequences). This database has so much information available that a clean sequence virtually always results in matches in the database that are specific to a species. In this way, the species of origin of biological material is confirmed.

Multiple laboratories have developed and published protocols for molecular species identification. Virtually all are based on mitochondrial DNA loci that readily fit the conserved primer/variable internal region criteria needed for the assay. The first of these came from Alan Wilson’s

molecular evolution laboratory at UC Berkeley, and many others have followed, including the Michigan State University laboratory. MtDNA loci utilized the range from the most highly conserved mtDNA genes to the least conserved loci. Each of these species identification loci has its potential advantages and drawbacks, including overall universality, ease of amplification, ease of sequencing, and specificity.

In the current study, all mtDNA-based methods for animal species identification available, including those used in house, were compared based on the above criteria. The list of loci examined, their numerical location based on the human mtDNA reference sequence, and amplicon length, are displayed in Table 1.

Primer	Region	Base Pair Length
12S	1071-1199	128
16S 1	2489-2716	227
16S 2	2676-3007	331
Cytochrome Oxidase I	5926-6609	683
Cytochrome b 1	14724-15915	1191
Cytochrome b 2	14816-15173	357
Control Region 1	15995-16498	503
Control Region 2	15908-16498	590
Control Region 3	15735-16498	763

Sixty-six species were examined, consisting of 27 mammals, ten fish, seven birds, five reptiles, three amphibians, nine insects, one centipede, one millipede, one spider, one earthworm, and one crustacean. Amplification was attempted on each based on the loci listed in Table 1, and graded as either positive, weak positive, or negative. From there, a subset of species that produced amplicons, consisting of one white tail deer, bobcat, lake white fish, frog, bearded dragon, English sparrow, house centipede, click beetle, pill bug, and earthworm, was reamplified and the same primers were used for forward and reverse sequencing. Sequences were aligned and edited, and a BLAST search was conducted. The sequences were then scored for BLAST accuracy (correct species identified) and uniqueness (sequence differed from other species).

The most useful loci in regards to amplification of the widest range of species included 12S, 16S 1 and 2, and cytochrome oxidase I, all of which amplified in a large majority of species. In contrast, cytochrome b 1 faired poorly overall, most likely due to the large size of the amplicon. Of the three control region loci, CR 3 amplified in the most diverse set of species, while the other two were effective in mammals and birds, but less so in the remainder.

The best generated sequence data overall was 16S 1 and cytochrome b2. BLAST search results of quality sequences were consistent with the known species, although the small size of the 12S and 16S 1 amplicons often resulted in complete matches with related organisms, thus precise species identification was not possible. In other instances, it is likely that the explicit species, or locus from that species, was not in the database at all. For instance, there are over 900 species of click beetle in North America, yet only one showed up in the database for 16S 1, and none for cytochrome b 2, indicating the specific species studied was not represented. This is a clear limitation of the technique in general; however, species most likely to be investigated by forensic scientists tend to be well represented in the database. Overall, utilizing mtDNA for species identification is an effective and widely applicable tool, while the locus, primers, and amplicon sizes utilized require careful consideration.

A34 Identification of Body Fluid Traces Using Raman Spectroscopy: Toward Practical Application

Vitali Sikirzhytski, MS, Aliaksandra Sikirzhytskaya, MS, and Igor K. Lednev, PhD, SUNY-Albany, 1400 Washington Ave, Albany, NY 12222*

The goal of this presentation is to describe the development of a novel method for non-destructive, confirmatory identification of body fluid traces on the crime scene and in the laboratory. Attention will be focused on the most recent development of the method for characterization of contaminated samples, mixtures of body fluids, and possible substrate interferences. The attendees will also have a better understanding of the recent advancement of this application of Raman spectroscopy. The implementation of advanced statistics for automatic analysis of spectroscopic data and the evaluation of the accuracy and reliability of the conclusions made will be discussed.

This presentation will impact the forensic science community by offering the potential to greatly impact the accuracy and effectiveness of biological stain analysis for forensic purposes.

The identification of traces of body fluids discovered at a crime scene is a major part of forensic investigation today.[1] The three most common fluids found are blood, semen, and saliva, and there are several methods used currently to distinguish one from another. Blood can be presumptively tested by using different color spot tests, but these tests are destructive to the sample and can also produce false positives. Semen is similar in that there are destructive presumptive tests as well as confirmatory tests. Saliva; however, has no confirmatory tests. Most presumptive tests can be performed in the field, but some sample preparation such as extraction is often necessary. Most confirmatory tests must be done in the laboratory. The main problem with these tests is the destruction of the sample. The forensic science community is in great need of a reliable, non-destructive, on-field method for identification of all common body fluids.

Raman spectroscopy is a technique that is increasing in popularity among the different disciplines of forensic science. Some examples of its use today involve the identification of drugs, lipsticks, and fibers, as well as paint and ink analysis. The theory behind Raman spectroscopy is based on the inelastic scattering of low-intensity, non-destructive laser light by a solid, liquid, or gas sample. Very little or no sample preparation is needed, and the required amount of material tested with a Raman microscope can be as low as several picograms or femtoliters. A typical Raman spectrum consists of several narrow bands and provides a unique vibrational signature of the material. Typically, non-resonance Raman spectroscopic measurements do not damage the sample. The stain could be tested in the field and still be available for further use in the laboratory for DNA analysis. A portable Raman spectrometer is a reality now that should allow for use at the crime scene.

Reported here is the latest development of a new method for identification of body fluid traces using Raman spectroscopy combined with advanced statistics. Multidimensional Raman spectroscopic signatures of dry traces of sweat and vaginal fluid were developed in addition to the signatures of semen, saliva, and blood reported earlier.[2-4] Combined software was developed for the identification of all major body fluids and the evaluation of the accuracy and reliability of the conclusions made. The method was expanded for the application to blood and semen samples contaminated heavily with sand, dust, and soil.[5] The ability of the method to detect and identify small amounts of semen and blood in their mixed samples will be reported.[6] Potential interferences from common substrates will be discussed.

This project was supported by Award No. 2011-DN-BX-K551 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

A35 Optimized Centrifugal Methods for Separation of Semen From Superabsorbent Polymers for Forensic Analysis

Lucy Camarena, BS, 220 Three Rivers Dr, El Paso, TX 79912; Bailey K. Glasscock, BS, 1020 W Main St, Box 843079, Richmond, VA 23284-3079; Nicolle Hardell, BS, 1020 W Main St, Box 843079, Richmond, VA 23284-3079; and Sarah J. Seashols, MS, Virginia Commonwealth Univ, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will gain an understanding of the challenges in separating cellular material from the Superabsorbent Polymer (SAP) materials and the fibrous matrices found in evidence such as diapers, sanitary napkins, absorbent medical pads, and other related forensic evidence, and a protocol that can successfully separate the cellular material from the substrate.

This presentation will impact the forensic science community by describing best practices for isolating semen from evidence containing absorbent and superabsorbent materials, and the impact that SAPs has on downstream DNA analysis.

The best evidence to connect a perpetrator to a sexual assault is the confirmed presence of semen, which through forensic examination can prove sexual contact by verifying ejaculation and/or penetration. Sexual assault cases can involve evidentiary items such as sanitary napkins or diapers, which contain superabsorbent polymers (SAPs). SAPs are cross-linked polymeric materials that can absorb and maintain large amounts of aqueous solutions without compromising structure. Ejaculation of semen onto these SAP-containing substrates results in cellular material, including spermatozoa, becoming entangled in the SAP gel-like mesh. Thus, separation is difficult and the likelihood of a typable spermatozoa yield is questionable. Additionally, visualization and proper identification of spermatozoa through microscopic examination can become problematic when SAPs are present; therefore, common practice involves working with only the top cotton or paper layers of these types of evidence to avoid SAPs whenever possible.

The success rate of obtaining DNA profiles from SAP-containing evidence has not been evaluated in a systematic fashion. It has historically been assumed that residual SAPs in the purified DNA extract can interfere with and create complications for downstream forensic applications. Therefore, an evaluation on the effects of SAPs on forensic DNA processes was necessary, as was the development of a simple, efficient protocol for separating cellular material from evidence containing SAPs. A number of centrifugal-filtration methods were evaluated to determine best practices for isolating biological materials from SAP-containing evidence. In order to select the most effective filtration device, excisions of commonly used sanitary napkins, diapers, and adult incontinence products containing 100 µL depositions of 1:5 human semen were filtered utilizing five different types of centrifugal filters. The selection of the best filter was based on spermatozoa yield, DNA yield, and ease of use. The resulting filtrates were microscopically examined for presence of spermatozoa and percent yields were calculated and compared. DNA from each sample type was isolated using a differential organic extraction method and was evaluated for DNA yield and quality. Shifts in Internal Positive Control (IPC) cycle thresholds and melt curves were assessed to address possible inhibition caused by the presence of SAPs. Results indicate that polyester fabric-layered basket filters were simplest to use and resulted in significantly higher spermatozoa and DNA yields than other centrifugal filter methods. No indication of significant inhibition by residual SAPs was observed in any of the filtered DNA extracts.

A sampling comparison was made between the top cotton or paper layer of the SAP-containing substrates versus taking the entire substrate excision. This set of experiments sought to determine the best sampling method as determined by spermatozoa visualization and DNA yield. Results indicated that sampling the entire excision of the SAP-containing substrates yielded a significantly higher quantity of visualized spermatozoa and DNA yield than just sampling the top layer of the evidence. As no PCR inhibition from the SAPs was observed in the entire excision samples, it is therefore recommended that the full depth of SAP-containing evidence be sampled for spermatozoa identification and DNA analysis in forensic casework.

In conclusion, filtering samples taken from evidence containing SAPs greatly improves the screening process of spermatozoa identification and makes these samples easier to work with for downstream processes. The optimized filtration method also allows for subsequent separation of the sperm and non-sperm fractions, and processing of biological samples using a variety of validated forensic DNA isolation protocols. There is a significant increase in sperm and DNA yield when the entire excision is filtered in comparison to the common practice technique of taking only the top layer in order to avoid the SAP gel portion. The yields of spermatozoa and DNA purified from these filtered samples show promise that usable STR profiles can be obtained.

Seminal Fluid, Absorbent Polymers, Spermatozoa

A36 Evaluation of DNA Extraction Efficiency

Erica L. Butts, MFS, Jamie L. Almeida, MS, Margaret C. Kline, MS, and Peter M. Vallone, PhD, NIST, 100 Bureau Dr, MS 8314, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand the importance of evaluating extraction efficiency from a known amount of DNA, learning that the observed recovery value range was significantly lower (20 to 30 percent) than many reported extraction efficiency calculations using the number of full STR profiles produced.

This presentation will impact the forensic science community by bringing attention to the amount of DNA unrecovered during the extraction process. The evaluation of the amount of unrecovered DNA could lead to more efficient methods to recover higher percentages of DNA from the extraction and purification processes.

Forensic DNA typing requires a specific quantity of input DNA (typically 0.5 – 1.0 nanograms) to generate an optimal Short Tandem Repeat (STR) profile. For reference samples, the amount of DNA collected on a standard buccal swab or blood punch is generally in excess of that which is needed for testing (on the order of hundreds of nanograms (ng)). Typically, extraction efficiency is evaluated by determining the number of samples that produce a full STR profile divided by the total number of samples processed. Less attention has been paid to the amount of DNA unrecovered during the extraction process from the original sample. Determining the amount of unrecovered DNA after the extraction process requires the original amount of DNA to be known prior to extraction, which is not the case in reference or casework samples. The importance of evaluating the theoretical yield versus the functional yield is in cases when the initial amount of available DNA is low. Within the extraction process, a majority of the DNA sample is lost, which has minimal impact on reference samples because enough DNA is recovered for an STR profile, but can have a significant impact non-reference samples within a laboratory. In these cases, it would be beneficial to obtain an extraction recovery that is closer to the theoretical yield than the functional yield. Evaluating the amount of unrecovered DNA could lead to more efficient extraction methods to recover higher percentages of DNA from the extraction and purification processes.

Extraction efficiency experiments were conducted to evaluate the percentage of DNA recovered through two extraction methods: a salting out procedure and use of the Qiagen EZ1 Advanced XL extraction robot with the DNA Investigator kit.[1] Three DNA sources were tested using varying initial amounts of human cells, previously purified and highly characterized DNA, and liquid whole blood. Controlled amounts of DNA from the three DNA sources were absorbed onto cotton buccal swabs, specimen collection paper, and FTA paper. The cells were spotted onto the swabs and paper in a PCR-compatible buffer suspension consisting of a 1.0 % BSA, 0.9 % NaCl, and 10 mM TRIS solution. Theoretical DNA quantities were estimated in total nanograms of DNA and applied to estimate a recovery percentage for each extraction. Human cells were quantified using a Coulter Counter and suspended within the PCR compatible buffer for each of the appropriate concentrations. The white blood cell count of a healthy individual ranges between 3.5 million and 10.5 million cells per milliliter, and a value of 7.0 million white blood cells per milliliter was used to determine theoretical DNA quantity for all whole blood samples.[2] The theoretical DNA series examined ranged from 24ng to 1800ng for all sample types. All extracted samples were quantified with Life Technologies Quantifiler Human DNA quantification kit in replicates of two. Results indicated that extraction efficiency ranged from 20% to 30% and recovery was independent of extraction method and DNA source. The observed recovery value range was significantly lower than many reported extraction efficiency calculations relying solely on the number of full STR profiles obtained.

Extraction Efficiency, DNA, Forensic DNA Typing

A37 DNA Isolation and Analysis From Skeletal Remains: Novel Methods for Removing PCR Inhibitors

Lisa Hebda, BS, Michigan State Univ, Forensic Science Program, 655 Auditorium Rd, Rm 560A, East Lansing, MI 48823; and David R. Foran, PhD, Michigan State Univ, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will appreciate common difficulties encountered during DNA analysis of skeletal remains and understand the extent to which soil microbial DNA isolation kits can act as an advantageous extraction method for buried skeletal remains. Attendees will also be informed about which DNA extraction methods are most useful for recovering amplifiable DNA from buried human skeletal remains and removing Polymerase Chain Reaction (PCR) inhibitors.

This presentation will impact the forensic science community by disseminating whether microbial DNA isolation kits are more effective at purifying DNA away from PCR inhibitors than are commonly used DNA isolation methods, as these kits have never been assessed for their effectiveness in extracting clean DNA from skeletal remains.

DNA analysis of skeletal remains is crucial in order to identify missing persons, victims of war, and individuals in cases of mass disaster. Unlike reliable sources of DNA such as buccal swabs, challenges arise with skeletal DNA analysis for numerous reasons. The harsh conditions skeletal remains are often recovered from are not conducive to DNA preservation, such as wet environments or the heat of a fire. The presence of PCR inhibitors is also a common hindrance with skeletal remains, particularly if they have been buried or are otherwise in prolonged contact with soil. Likewise, components of the bone itself, such as calcium or collagen, can inhibit PCR, and thus the removal of PCR inhibitors during DNA extraction is critical for successful forensic DNA analysis.

Previous researchers have compared DNA extraction methods from skeletal material, including standard phenol-chloroform organic extraction and commercially available kits. In these studies, the kits had low DNA recovery, instances of PCR inhibition, and resulted in poor quality STR profiles.[1,2] Organic extraction recovered higher quantities of DNA; however, this method also resulted in PCR inhibition.[2] Although commercial DNA isolation kits are easy to use and claim to remove PCR inhibitors, none have been optimized for the highly compromised skeletal remains that are often encountered by forensic scientists, which is presumably why they have been found lacking for skeletal analyses. This led to the question of whether commercially available kits that are specifically designed to isolate and purify DNA from soil samples that are high in PCR inhibitors such as humic and fulvic acids might be advantageous when testing buried skeletal remains.

In the research presented here, the ability of microbial DNA isolation kits to recover amplifiable bone DNA and remove PCR inhibitors was compared with other common extraction methods. DNA extraction systems included a PowerSoil® DNA Isolation Kit (MoBio), a SoilMaster™ DNA Extraction Kit (EpiCentre), a standard organic extraction, and a QIAamp® DNA Investigator kit (QIAGEN), which has a specific protocol for DNA isolation from bone. Since the soil kits are not designed for extraction of human materials, a preliminary study was conducted to determine if reagents contained in the kits were contaminated with human DNA. Blank extracts from the soil DNA kits failed to amplify with human mtDNA primers. Next, DNA extractions were performed on bone powder obtained from drilling cow femur segments to determine whether the standard protocols supplied with each are adequate for DNA isolation from bone. The PowerSoil® kit standard protocol did not consistently result in amplifiable DNA. The protocol was then optimized by altering the mechanical/chemical digestion step, including substituting a hot lysis for the mechanical digestion.

In addition to DNA recovery, each extraction method was tested for its ability to remove the PCR inhibitors calcium, collagen, and humic acid, which are associated with buried skeletal remains. Inhibitor removal was assessed by amplification or no amplification of control mitochondrial DNA, by adding the purified extract to the reaction. Each extraction method was then used on bone powder produced by drilling cow femur sections buried in soil for a range of time: one day, seveb days, thirty days, and three years. DNA was quantified by a real-time PCR TaqMan assay targeting the Melanocortin-1 Receptor gene, developed by Lindquist *et al*.[3] Inhibition was assessed by comparing cycle threshold values of the internal positive control. Since failure to amplify DNA is a common challenge encountered with skeletal remains, successful amplification of both mitochondrial and nuclear DNA was compared for each extraction method to see which recovered amplifiable DNA more often. The four extraction methods were then tested on various human skeletal remains, including bones from the medieval period, which had previously shown PCR inhibition during DNA analysis. After comparing the microbial DNA isolation kits to organic extraction and a standard DNA extraction kit for inhibitor removal, quantity of bone DNA recovered, and success of mitochondrial and nuclear DNA amplification, the effectiveness of microbial DNA extraction kits for use on skeletal remains was determined, as well as the most optimal extraction method.

DNA, Skeletal Remains, PCR Inhibition

A38 Girls Not Allowed: Erase the Mixture

Randee S. Sedaka, and Grittney K. Tam, BS, Penn State Univ, Forensic Science Program, 107 Whitmore Laboratory, University Park, PA 16802; and Reena Roy, PhD, Penn State Univ, Forensic Science Program, 325 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will learn how to separate male and female DNA fractions in sexual assault cases without going through the cumbersome differential extraction procedure.

This presentation will impact the forensic science community by discussing a procedure that can be used for identifying the semen donor and separate the DNA of the male donor from the epithelial cells of the victim.

Forensic science laboratories process numerous cases involving sexual assaults. When the victim goes to a health care facility, a sexual assault kit is used to collect body fluids from various orifices. The swabs used to collect fluids from vaginal, rectal, and oral cavities often contain a mixture of the victim's epithelial cells and seminal fluid from the suspect. If the victim does not report the crime within a few hours, the number of epithelial cells from the victim can overwhelm the number of sperm cells present in the sample collected from the victim. Normally, a time-consuming and cumbersome differential extraction procedure is used in an attempt to separate the sperm DNA from the epithelial DNA. The resulting sperm DNA profile may yield a mixture of sperm and epithelial cell DNA even after repeated differential extraction wash steps.

The Erase Sperm Isolation Kit (Paternity Testing Corporation) can degrade DNA from epithelial cells, while leaving the spermatozoa intact. The DNA from the epithelial cells is selectively degraded by nuclease capable of digesting the DNA that is in solution. The sperm cell membrane protects the DNA inside the sperm heads and the nuclease has little effect in the protected DNA. This process makes it possible to obtain a single source sperm cell autosomal DNA profile from samples that also contain overwhelming amounts of epithelial cell DNA. Therefore, it is possible to obtain a single source male DNA profile from a mixture of seminal and vaginal fluid using the reagents in the kit.

The goal of this study was to determine if the Erase Sperm Isolation Kit could separate sperm cell and epithelial cell DNA from post-coital swabs, and from samples containing mixtures of body fluids. The objective was to generate single source male and female DNA profiles from various mixtures containing female body fluids and seminal fluid containing spermatozoa.

Swabs containing a mixture of seminal fluid and vaginal epithelial cells were collected at regular intervals and mock swabs containing a mixture of various female body fluids and seminal fluid were created. Portions of the post-coital swabs and the body fluid mixtures were digested in sterile tubes using the Erase Sperm Isolation Kit method. After digestion, the sample was centrifuged to pellet intact sperm cells. The supernatant was transferred from the original tube into a new tube. DNA was extracted from the supernatant containing the non-sperm fraction. Next, the nuclease was added to the original tube containing the sperm fraction in order to degrade the DNA free in solution. After the appropriate incubation period, the nuclease was inactivated and the sperm fraction was then lysed and purified. DNA was purified from both the non-sperm and sperm fractions using two methods: the Qiagen DNA Investigator Kit and organic extraction. Samples which contained mixtures of saliva, blood, and seminal fluid were subjected to the same procedure. Prior to lysing the sperm fraction, the pellet obtained from the sperm fraction was examined for the presence of spermatozoa using Kernechtrot Picroindigocarmine staining method and microscopy.

DNA was quantified using the Quantifiler® Human DNA Quantification Kit and amplified using commercially available PCR Amplification kits. The amplified products were injected on the AB 3130xl Genetic Analyzer, followed by analysis with SoftGenetics GeneMarker® HID software.

The results of the study showed that complete, single source male and female autosomal STR DNA profiles could be generated from swabs containing mixtures of seminal and female body fluids using the Erase Sperm Isolation kit. The method is cost effective and eliminates labor intensive and lengthy procedures used in standard differential extraction.

DNA, Differential, Extraction

A39 Automating the Differential Digestion Process in the Analysis of Sexual Assault Evidence Using Selective Degradation

Helena G. Wong, MS, and Jennifer S. Mihalovich, MPH, Oakland Police Dept, Criminalistics Div, 455 7th St, Rm 608, Oakland, CA 94607; and George Sensabaugh, DCrim, Univ of California, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720*

The goal of this presentation is to describe the methods of automating the differential digestion process using selective degradation of non-sperm DNA. The effects of using a degradative agent on sexual assault evidence samples will be discussed.

This presentation will impact the forensic science community by demonstrating that the selective degradation differential digestion process can produce high yield and high-quality DNA profiles given the optimal parameters. Successful application of this process allows the ability to process more sexual assault evidence in a shorter amount of time, aiding in decreasing the backlog in many forensic science laboratories.

Forensic science laboratories are faced with an increase in demand for sexual assault evidence analyses. Lacking sufficient analysts to perform the time-consuming, labor-intensive work required for DNA analysis, the large number of requests quickly results in an overwhelming backlog. This high demand has led laboratories to transition to automation for processing cases in a more efficient manner. While many areas of DNA analysis have adopted automation, the differential digestion process remains a time-consuming, manual task.

An automated differential digestion protocol was developed using selective degradation. The current differential digestion process requires multiple wash and centrifugation steps to remove residual epithelial DNA from the sperm fraction. The selective degradation technique replaces these labor-intensive steps by using a degradative agent, DNase I, to digest the remaining epithelial DNA. The use of DNase on evidence samples and its effect on DNA yield and DNA typing quality was assessed. Studies were performed on semen stains stored for an extended period of time (up to 60 years) and on semen samples subjected to heat, humidity, and multiple freeze/thaw cycles to evaluate the effects of DNase on environmentally compromised sperm samples. Sensitivity, reproducibility, and contamination studies were performed on a robotic liquid handler used to automate the differential digestion process. The automated protocol utilized 96-well plates for high efficiency and incorporated microscope slide preparations for the confirmation of the presence of sperm.

Initial trials of the selective degradation process resulted in lower DNA yield. Samples digested with the selective degradation process recovered approximately 30% of the sperm fraction male DNA when compared to the same sample digested with the conventional method. An explanation for the loss of sperm DNA was incomplete deactivation of DNase prior to sperm lysis. DNase activity is directly related to the divalent ion concentration so multiple experiments were performed to optimize the Mg^{2+} and Ca^{2+} concentrations. Results showed that decreasing the Ca^{2+} concentration from 125mM to 5mM significantly increased the DNA yield compared to the conventional method.

STR DNA typing for samples subjected to the initial, non-optimized selective degradation process resulted in poor DNA typing quality. DNA sample input of 1.5ng produced profiles with low peak height levels ranging from ~100-500 RFUs and peak height imbalances. The poor typing data may have been caused by inhibition and degradation. Inhibition was eliminated as a possible cause through controlled experiments. Degradation caused by DNase was tested by decreasing the amount of DNase used from 360 units to 18 units. Decreasing the amount of DNase resulted in significantly improved STR DNA typing

data. The peak height levels were approximately three times that of the same sample digested with 360 units of DNase.

Environmentally compromised sperm samples were digested using the conventional method and the selective degradation method. DNA quantitation showed no statistical difference in the DNA yield for the samples prepared using both methods. No difference in the STR DNA typing data between both sets of samples was observed. Most samples resulted in full DNA profiles with satisfactory peak heights. A few samples yielded partial profiles with low peak heights. These results were observed using both conventional and selective degradation methods, indicating that compromised sperm samples were able to withstand DNase treatment.

Sensitivity, reproducibility, and contamination studies were performed on an automated robotic liquid handler. Sensitivity studies showed that full DNA profiles were obtained from samples with DNA yield as low as 150pg (~2 sperm/3µL). In samples where no sperm were observed microscopically, the STR DNA typing data resulted in either no or few alleles detected. Quantitation data from the reproducibility studies demonstrated that the robot was very consistent in the manipulation and preparation of the samples. Contamination studies showed no signs of contamination in the automated selective degradation differential digestion process.

Through the use of the selective degradation method, automation of the differential digestion process was achieved without having to compromise on the quantity and quality of the DNA obtained.

Selective, Degradation, Automation

A40 Separation of Complex DNA Mixtures From Touch Evidence

Jared Latiolais, MSc, Bode Technology Group, 10430 Furnace Rd, Ste 107, Lorton, VA 22079; Andrew B. Feldman, PhD, and Lin Lin, MSc, Johns Hopkins Univ, Applied Physics Laboratory, 11100 Johns Hopkins Rd, Laurel, MD 20723-6099; and Sarah Cavanaugh, MS, and Robert A. Bever, PhD, Bode Technology Group, 10430 Furnace Road, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will gain an understanding of next generation sequencing and its potential application to the forensic field through deconvolution of complex DNA mixtures from evidentiary items.

This presentation will impact the forensic science community by introducing a future capability that has the potential to separate complex DNA mixtures of five to seven individuals, including low copy contributors.

DNA sequencing technology is advancing rapidly in the form of Next Generation Sequencing, and the amount of catalogued genetic human data being generated has created an explosion of possible applications. The Bode Technology Group is currently applying the use of Next Generation Sequencing to the deconvolution of complex forensic mixtures from low copy number, degraded, and touch objects. To this end, Bode has designed, developed, and tested a field functioning forensic process for separating complex deoxyribonucleic acid (DNA) mixtures of five to seven individual sources of DNA and producing distinct profiles for each source using pyrosequencing-based deep amplicon sequencing chemistry. By combining the power of a pyrosequencingbased Next Generation Sequencing platform such as the bench topsized Roche 454 GS Jr. sequencing system with a novel forensic bioinformatic software pipeline, mixtures of seven or more individuals from mock evidentiary touch samples have been successfully sequenced and separated using multiple panels of highly multiplexed forensically relevant loci.

Data will be presented from an ongoing research effort to deconvolute mixtures of both mitochondrial DNA and nuclear Y chromosome Short Tandem Repeat (Y-STR) amplicons using a bioinformatic software suite developed through a collaboration with The Johns Hopkins University Applied Physics Laboratory. Data produced by the mixture separation software suite show highly sensitive detection of low copy contributors. When applied to mixtures of between two and seven individuals sequenced at mitochondrial hypervariable and Y-STR loci, minor contributors were successfully detected below a 1:100 ratio level, far outreaching the limit for common forensic capillary electrophoretic instruments and currently available mixture deconvolution software applications. Given a maximum number of sequences per read of between 50,000 and 120,000, there is a tradeoff among several factors such as the number of multiplexed loci, the number of contributors to a mixture, and necessary sensitivity. Thus, to develop a working understanding of the limits of this system, a series of mixture samples were created changing these variables.

Several sample types were examined including: dilution series of nascent human DNA and mock touch samples created from fingerprints (handled objects for varying degrees of time), multiple biological fluids, and substrates in complex mixtures consisting of between 1-8 different contributors at different relative concentrations. Multiplexes of the mitochondrial hypervariable regions HVI/HVII and standard Y-STR loci were created, balanced, and optimized into panels compatible with the 454 GS Jr. sequencing system. The raw data files are directly imported into the software, where all of the sequence reads at each locus are detected and then separated. Each unique sequence is binned and analyzed for error. Using a ratio-driven algorithm, alleles are re-associated to the most likely contributor of origin with associated likelihood ratio values. The system also offers the potential to detect all alleles in a mixture, determine inclusion and exclusion statistics, and even search against databases and generate match statistics accordingly. Ultimately, this system will be available for use in the course of routine forensic casework and thus can be an important future tool in the broader forensic science community.

Next-Gen Sequencing, Mixture Separation, Mixture Analysis

A41 Error Tradeoffs in Human Identity Comparisons: Determining a Complexity Threshold and Exclusion Criteria for DNA Mixture Interpretation

Jacob S. Gordon, MS, Boston Univ, Biomedical Forensic Sciences, 72 E Concord St, Rm R806D, Boston, MA 02118; Robin W. Cotton, PhD, Boston Univ, Biomedical Forensic Sciences, 72 E Concord St, L1004, Boston, MA 02118; and Catherine M. Grgicak, PhD, Boston Univ, Biomedical Forensic Sciences, 72 E Concord St, Rm R806D, Boston, MA 02118*

This goal of this presentation is to introduce an alternative framework for making determinations of exclusion versus inclusion for DNA mixtures that is based on running Monte Carlo simulations on a probabilistic computer model of individual and mixed human genotpyes. This method is then applied to laboratory mixture data, and the results are compared with those for the simulated mixtures.

This presentation will impact the forensic science community by emphasizing how error rates associated with DNA profile interpretation are crucial to responsible determinations of a reference's exclusion or inclusion in an evidence sample. The error characterizations demonstrated in this study are useful in a number of ways. The simulated results can be used by a laboratory to inform the establishment of a preferred interpretation range by selectively optimizing between false positives and false negatives. Alternatively, after empirically determining a level of drop-out associated with evidence samples of varying starting DNA template, an informed decision regarding exclusion of a known as a potential contributor to an item of evidence will be presented. Traditionally, such samples were reported as uninterpretable or inappropriate for comparison.

DNA analysts considering a forensic evidence sample and a reference sample (e.g., from a suspect) have three options when rendering a decision with regard to the consistency between the samples: exclusion, inclusion, and inconclusive. Complicating this determination is the reality that DNA profiles originating from forensic

mixture evidence may not be fully observed due to allelic drop-out and/or the presence of overlapping alleles. Different analyst inclinations and laboratory standards exist for informing an analyst's decision; typically—and particularly for samples demonstrating some degree of allelic drop-out—less than exactly 100% allelic consistency between known and questioned samples are not automatically precluded from inclusion in an evidence sample. In tolerating some measure of absence of a reference sample's alleles in an evidence sample, the potential for two kinds of errors exists: In a case in which an individual could not have contributed to an evidence sample, there is the potential for false inclusion; in a case in which an individual could have contributed, there is the potential for false exclusion. In selecting a particular decision criterion to inform determinations of inclusion or exclusion, a tradeoff between these errors exists. A lax decision criterion minimizes false exclusions at the expense of false inclusions while a strict criterion eschews false inclusions at the expense of greater numbers of false exclusions. The relevance of a decision criterion is greatest for low-template samples and for samples that are mixtures of multiple contributors since both are likely to experience allelic drop-out and thus to occupy a potential gray area between certain exclusion and likely inclusion.

In this study, for a given level of allelic drop-out, 10,000 simulated mixtures are compared with databases of 10,000 simulated excluded and included reference individuals. In order to generate credible genetic profiles, the phenomena of allelic drop-out and profile mixing of two contributors are modeled. Comparisons between the reference and simulated mixtures at drop-out levels ranging from 0 to 0.9 are performed. Given this framework, the universe of possible decision criteria is explored. Receiver Operating Characteristic (ROC) curves, a type of analysis originally applied to assessing World War II radar performance, are adopted as a paradigm for summarizing the tradeoff of both types of errors and confirm that higher rates of drop-out result in increasingly higher incidences of error. Specifically, ROC analysis of the two-person mixtures showed that drop-out rates >0.3 result in false positive rates >0.01 and false negative rates >0.15. Here the false positive rate represents the proportion of reference standards that were incorrectly included as a potential contributor. The false negative rate is the proportion of standards that were incorrectly excluded.

ROC analysis can be used to inform the establishment of a preferred operating point by selectively optimizing between false positives and false negatives to accord with prudence. Alternatively, after empirically determining a level of drop-out associated with a particular laboratory or with evidence samples of varying starting DNA template, an informed decision can be made regarding the number of allelic discrepancies that may be tolerated before that rate of false inclusions becomes too large.

The specification of error bounds can also designate an operating region, outside of which the interpretation of an evidence profile cannot be made with the required accuracy. Whether a given evidence profile is a candidate for interpretation is a function of its associated level of drop-out. Evidence profiles shown to lie outside of the acceptable error bounds due to their level of allelic drop-out are said to fail to meet a "complexity threshold" for determinations of inclusion or exclusion. No statistics should be calculated for such samples, and the only responsible determination with respect to reference inclusion/exclusion is "inconclusive" or "uninterpretable." For evidence profiles possessing levels of drop-out that are deemed interpretable, this same "complexity threshold" can be employed to establish a laboratory's decision criteria with respect to tolerating allelic discrepancies. The resulting prescription for determining that a reference is included as a contributor to an evidentiary stain would conform with premeditated, laboratory-selected error rates and the decision regarding whether to compare the questioned sample to a reference would be made before examining a known DNA profile.

Forensic DNA, DNA Mixtures, DNA Interpretation

A42 Developmental Validation of ArmedXpert™: Forensic Mixture Deconvolution Software for Short Tandem Repeat Data

Rhonda K. Roby, PhD, UNT Health Science Center, Forensic & Investigative Genetics, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; and Dennis J. Reeder, PhD, Reeder Analytical Consulting, 7094 Glen Abbey Ct, Frisco, TX 75034*

After attending this presentation, attendees will learn of the advances made in software algorithms for deconvolution of STR data generation from forensic casework.

This presentation will impact the forensic science community by introducing changes to mixture analyses of DNA samples.

With the major advances made in capillary electrophoresis instrumentation, more precise color separation, and improved chemistries, it is even more apparent today that mixture data from forensic casework have a significant amount of information that are not fully evaluated and summarized. ArmedXpert™, a software mixture deconvolution program, is designed to automate the tedious and numerous calculations required to thoroughly review a mixed STR DNA result. ArmedXpert™ not only aids the forensic DNA analyst in these routine, time-consuming computations, but it also provides an array of significant other functions. ArmedXpert™ was subjected to a rigorous validation study where it was evaluated with known mixed data sets of two- and even three-person mixtures. At the end of the study, actual casework data files from adjudicated cases were evaluated and compared to the submitted final case reports.

ArmedXpert™ allows the user to check ladders, to check controls, to detect possible stutter, to perform matching between evidence samples and references, and to evaluate possible contamination with staff profiles. The software is designed to perform CODIS functions, conduct mixture interpretation with two to three contributor mixtures, view simulated electropherograms, chart data, perform various biostatistical analyses for single and multiple source samples, and print and save data. The stated functionality of each of these features was confirmed during the developmental validation process.

The developmental validation study of ArmedXpert™ entailed testing of three main software specifications: compatibility, QC checks and matching, and interpretation. For compatibility, different operating systems were subjected to the software to verify the ability of the software to perform as expected. All menus and functions were subjected to verification testing. In addition, different data files were imported to verify successful upload and functionality. The control checks, formatting of output files, and comparisons demonstrated full utility. Mixture interpretation tools were evaluated for display features, accurate and reproducible calculations, and application of defined thresholds. In addition, all statistical calculations were confirmed by manual testing and comparison to other software programs. The output reporting and CODIS CMF files were also verified.

Lastly, the software was evaluated for applying the appropriate thresholds and stutter and color-coding features as described. Significant studies were conducted to confirm the correct reporting of all allele calls. The Mixture Interpretation section of ArmedXpert™ produces a list all possible combinations for each locus based on the user-defined thresholds. This list provides the proportion of DNA of the minor and major contributors of the mixed sample. The graphical visualization tool provides the user with an easy visual assessment of the proportions identified per locus for the mixed result. The combinations, thresholds, proportions, and bar chart tool were all tested with known mixtures at varying concentrations.

ArmedXpert™ is a software program that can be easily adapted and implemented into the forensic analyst's toolbox. This program has many features that will assist forensic analysts to fully evaluate and summarize their data. ArmedXpert™ can be used as a stand-alone program or can support DNA analysts in the arduous task of mixture interpretation, and seamlessly import data for statistical evaluations. This developmental validation study demonstrates that the software meets the defined specifications and performs as expected.

ArmedXpert, Deconvolution, Mixture

A43 Large-Scale Evaluation of ArmedXpert™ for 2 - 4 Person DNA Mixture Analysis

Lashon Stephens, BS, 1 Innovation Dr, North Charleston, SC 29419; Roman Aranda, PhD, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; Lawrence A. Presley, MS, USACIL, 4930 N 31st St, Forest Park, GA 30927-5205; and Brigid O'Brien, PhD, USACIL, 4930 N 31st St, Bldg 925-S, Forest Park, GA 30297*

After attending this presentation, attendees will understand the effectiveness of ArmedXpert's™ ability to deconvolute Short Tandem Repeat (STR) DNA mixture data.

This presentation will impact the forensic science community by demonstrating the accuracy, effectiveness, and limits of the ArmedXpert™ program.

ArmedXpert™ is an Excel-based software program created with the purpose of assisting DNA analysts in deconvoluting two-, three- and four-person DNA mixtures. This software program uses Short Tandem Repeats (STR) and Y-STR DNA profiles, and displays the possible combinations for the various contributor scenarios. The effectiveness of this program relies on statistical probabilities and subjective interpretation from the user. The main goal of this research is to determine how accurate and effective ArmedXpert™ is at assisting forensic scientists to deconvolute DNA mixtures under varying concentrations and conditions.

In this study, two-, three-, and four-person DNA mixtures were generated and initially profiled by the Boston University School of Medicine. This pilot study evaluates the examiners' ability to interpret a DNA mixture profile from a mixture data set. The Boston University study contains over 2,000 mixture combinations, which were generated with various contributor numbers, concentrations, injection volumes, and amplification kits. The effectiveness of ArmedXpert™ was determined by analyzing the examiners' ability to use the software to correctly identify allele calls, determine the major, minor, and number of contributors, and the statistical random match probability (RMP) of each contributor when compared to the known Boston University data set. The examiners' input was entered into an spreadsheet-based macro program that calculates the partial genotype accuracy, residual frequency of the known and calculated RMPs, and the failure rate of missed allele calls. This spreadsheet macro will also determine if the calculated allele calls from the DNA analyst match the alleles from the Boston University data set, and if an incorrect allele was called. The partial genotype accuracy calculates the DNA analysts' ability to call the correct alleles when compared to the known DNA mixture profile. An average of these metrics will be calculated to determine the extent that ArmedXpert™ assists DNA analysts at mixture interpretation when compared to analysts that deconvolute without software assistance. Mixture interpretations with incorrect allele calls will be averaged separately from the correct allele calls. Statistical analysis, such as a chi-squared test, will be performed on the overall results to determine how effective ArmedXpert™ is at assisting DNA analysts at deconvoluting DNA mixtures.

In the future, a large-scale study of DNA examiners will be conducted to determine the overall metrics of the mixture evaluations. These metrics will be used to determine if ArmedXpert™ can effectively assist DNA analysts in interpreting DNA mixture analysis. Because there is no universal standard for analysis of DNA mixture, the results from the study may vary depending on the experience of the DNA analyst. The effectiveness of ArmedXpert™ may be influenced by the DNA analysts' familiarity with the software program and their ability to determine the major, minor, and number of contributors.

A44 Quantitative PCR for Rapid Gel Electrophoresis-Based Pre-STR Mixture Detection

Laura C. Oliver, MS, 1908 Moonwind Pl, Richmond, VA 23238; Todd W. Bille, MS, and Steven Weitz, MS, National Laboratory Center, 6000 Ammendale Rd, Ammendale, MD 20705; and Tracey Dawson Cruz, PhD, Virginia Commonwealth Univ, 1000 W Cary Street, PO Box 842012, Richmond, VA 23284*

After attending this presentation, attendees will learn a potential method for a screening technique to identify mixtures at the qPCR stage of DNA analysis.

This presentation will impact the forensic science community by introducing a quick screening method to identify a mixture DNA profile prior to STR amplification.

Forensic DNA units currently do not have a way to accurately determine if a mixture is present prior to the CE analysis stage. This can be detrimental to labs, like the ATFE, that only have a limited sample amount with which to work. When DNA samples are below 2ng at ATFE, half of the sample is used for amplification. If the Identifiler™ STR analysis shows a mixture profile with all the allele peaks below threshold, then the lab does not have enough remaining sample to re-amplify using increased DNA input. If the lab had a procedure to suggest a sample is a mixture early in the process, then ATFE would be able to make key adjustments to their amplification technique in advance. For example, the amount of DNA sample amplified could be increased in order to raise the minor contributor alleles above thresholds. Additionally, examiners could further concentrate samples or increase injection times on the genetic analyzer to allow for improved results. This study is aimed to develop a modified quantitation assay that would allow for mixture detection pre-STR amplification. If successful, identifying a mixture at the quantitation stage would allow for adjustments to be made with a sample prior to amplification and analysis, such as using the full sample elution instead of the standard half sample or combining swabs taken from the same surface.

In this study, the goal was to develop a multiplex qPCR assay that would incorporate either two Single Nucleotide Polymorphism (SNP) markers or D1S80 into the existing Investigator® Quantiplex quantitation reaction for mixture identification. SNPs were chosen that have a minor allele frequency above 10% to increase the likelihood of detecting the minor component of a mixture. These SNPs included rs5030240, rs385780, rs433342, and rs4540055. Primers were designed using Primer BLAST through NCBI. These primers were designed such that the three different alleles would be able to be distinguished from one another when run on a gel. This was achieved by adding poly-T tails of varying lengths to the end of the primer containing each of the different alleles. D1S80 was also chosen based on its well-established PCR chemistry and primer sets. The 16 bp repeat with over 22 alleles together with a high level of heterozygosity across populations increased the likelihood that a mixture DNA profile would be seen. The selected primers were tested for visibility and discrimination with ten DNA samples using the Lonza FlashGel® system. The Lonza FlashGel® system using precast 2.2% agarose DNA cassettes can run at high voltages, and complete DNA migration within 2 - 7 minutes.

Product gels showed bands at the expected sizes for all four SNP markers, and all reagent blanks were clear. However, resolution of the alleles was not sufficient for allelic discrimination. The D1S80 gels showed bands at expected sizes and alleles could be discriminated from one another. Mixture samples amplified with D1S80 could also be discriminated on the gel system; however, the D1S80 primers appeared to interact unfavorably with the Investigator® Quantiplex reaction when incorporated into the qPCR reaction. Further studies should be conducted to look for alternate ways of incorporating these or other markers into the quantitation reaction. Additionally, primer redesign or new detection methods are possible development techniques to improve current allele discrimination. Ultimately, this identification would result in a decrease in sample consumption issues as well as a time savings for forensic DNA labs when analyzing casework contact DNA.

qPCR, DNA Mixtures, SNP Markers

A45 Comparison of Two Immunochromatographic Test Strips for the Detection of PSA

Jillian Conte, MS, Laura M. Cronin, MSFS, Jennifer K. Sears, BS, and Christian G. Westring, PhD, 2300 Stratford Ave, Willow Grove, PA 19090*

After attending this presentation, attendees will have gained further insight into the sensitivity and specificity of two commercially available immunochromatographic tests for the detection of Prostate Specific Antigen (PSA also known as p30). Of particular interest are potential concerns regarding the specificity and sensitivity of immunological-based assays in forensic-type casework. The detection of endogenous p30 from controlled vaginal swabs raised potential concern for the application of these methods in the forensic community. Furthermore, some assays demonstrated the loss of cellular material prior to microscopic analysis and/or downstream analysis.

This presentation will impact the forensic science community by raising awareness of the limitations that exist with current immunochromatographic test strips employed by forensic practitioners.

The brentamine blue spot test for acid phosphatase (AP) is often used as a preliminary screening test for suspected semen stains. Given its limited specificity, suspected semen stains must be analyzed microscopically for the presence of spermatozoa. If spermatozoa are not present, suspected semen samples may be tested for the presence of PSA in conjunction with microscopic examination. PSA is present in high concentrations in seminal fluid but is also found in lower concentrations in amniotic fluid, breast milk, vaginal secretions, and female urine. Current testing methods that exist for the detection of PSA, such as double immunodiffusion, are both time consuming and lack sensitivity. Internal validation of several commercially available immunochromatographic tests for the detection of PSA was conducted. Validation of two independent assays was performed to evaluate the sensitivity, reproducibility, stability, and specificity of each test.

Known semen samples were detected down to a 10^{-4} dilution in both test strips, with reproducibility of positive results from a 10^{-3} dilution. Positive results for the AP test were observed in dilutions down to 10^{-2}. Confirmatory identification of spermatozoa was detected in samples containing dilutions down to 10^{-4} through microscopic analysis. The use of deionized water as an extraction buffer had no adverse effects on test sensitivity or specificity results. Specificity of the tests was demonstrated through negative results in all body fluids tested with the exception of male urine and vaginal secretions. The addition of more vaginal swabs from females with complete sexual and menstrual cycle history was obtained. These samples demonstrated a surprising false positive rate of approximately 30% for PSA for both tests. Chemically treated samples were used to demonstrate the stability of both test strips. One of the immunochromatographic strips indicated significant loss of cellular material, both epithelial cells and spermatozoa, when the test extract was used for microscopic detection of spermatozoa in downstream testing.

Based on these analytical results, both of the immunochromatographic assays under evaluation demonstrated comparable sensitivity and specificity for the detection of PSA from forensic-type samples. The loss of cellular material that was observed microscopically in this study can have serious consequences in DNA investigations and can significantly impact a forensic case. The lack of specificity for PSA as a seminal marker raises concerns regarding the implementation of immunochromatographic-based tests for the detection of PSA in forensic-type casework.

Seminal Fluid, Vaginal Secretions, Rapid Test Strips

A46 DNA Quantification by Real-Time PCR (qPCR) and Short-Tandem Repeats (STRs) Amplification Results

Silvia Zoppis, MD, and Manuela Rosini, MSc, Dept of Legal Medicine, Viale Regina Elena 336, Rome, 00161, ITALY; Alessio D'Alessio, PhD, Dept of Legal Medicine, Largo Francesco Vito,1, Rome, 00168, ITALY; and Carla Vecchiotti, PhD, Dept of Legal Medicine, Viale Regina Elena 336, 00161, Rome, ITALY*

After attending this presentation, attendees will understand: (1) principles of genetic analyses on forensic samples; (2) the importance of a valid quantification technique; and, (3) the issues related to the analysis of low template DNA samples.

This presentation will impact the forensic science community by highlighting the importance of the DNA quantification step in forensic casework in spite of the increasing sensitivity of last generation commercial kits for STR analysis that allow the detection of allelic peaks from extremely low DNA quantities (even with concentrations far below the limit of detection for the specific quantification kit).

Determining the amount of DNA in a forensic sample is fundamental for PCR-based analyses because if on one hand an excessive amount of template may cause the appearance of additional or out-of-scale peaks, on the other hand, a low quantity can cause the appearance of stochastic phenomena affecting the PCR reaction and the subsequent interpretation of typing results. In the common practice of forensic genetics laboratories, the quantification results provided by qPCR assume the role of "boundary line" between the possibility for a given DNA sample to be subjected or not to the subsequent analytical steps, on the basis of an optimal amount of DNA in the range indicated by the manufacturer of the specific commercial kit.

However, some studies have shown the possibility to obtain STR typing results even with an extremely low DNA concentration or, paradoxically, equal to zero. Regardless of the amount of DNA used for the quantification of the testing sample, certain software is able to use the standard curve to calculate concentration values far below the manufacturer's reported optimal detection limit (0.023ng/µL). Consequently, laboratories have to face the critical decision to interrupt the analyses, giving up the possibility to obtain a genetic profile—although partial—or to try the amplification of the extract with the awareness of the interpretation issues that this implies.

The quantification results obtained by qPCR performed on numerous samples from specimens of forensic interest, subjected to DNA extraction using magnetic beads will be presented. Following the quantification step, the extracts were subjected to DNA amplification and STR typing using last generation commercial kits. Samples that showed quantification values below the limit of detection for the method were included in the analysis in order to check the existence of a correlation between the DNA quantification results by qPCR and the possibility of obtaining a genetic profile useful for identification purposes.

In spite of the increasing sensitivity of last generation commercial kits for STR analysis, as demonstrated by the ability to detect allelic peaks from extremely low DNA quantities (with concentrations far below the limit of detection for the specific quantification kit, even corresponding to 0 or "Undetermined"), the results obtained show a correlation between qPCR quantification values and STR typing results. Thus, the qPCR method is confirmed as being a useful and valid instrument for both qualitative and quantitative evaluation of genetic samples for human identification purposes.

Quantification, Real-Time PCR (qPCR), Short Tandem Repeats

A47 Evaluation of Half Reaction Volumes of the AmpFℓSTR® Identifiler® Plus Forensic Amplification Kit in STR Analysis

Michael A. Donley, MS, Harris County Institute of Forensic Science, 1885 Old Spanish Tr, Houston, TX 77054; and D. Nicole Methner, PhD, Mark Powell, MS, and Roger Kahn, PhD, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will have a better understanding of how reduction of reaction-mixture volumes of the multiplex PCR system IdentifilerPlus® Forensic Amplification Kit from Applied Biosystems affects amplification of the Short Tandem Repeat (STR) markers in the kit and the corresponding interpretation of forensic DNA profiles from these markers.

This presentation will impact the forensic science community by demonstrating the effectiveness of STR amplification with the IdentifilerPlus® kit when the reaction volume is reduced by half. Utilization of half-reaction volumes of the IdentifilerPlus® kit will provide a significant savings to a forensic science laboratory; however, these data show that caution should be exercised when interpreting genetic profiles generated from low-DNA input quantities.

Many forensic science laboratories have transitioned to using the AmpFℓSTR® IdentifilerPlus® Forensic Amplification Kit for STR analysis to streamline evidence processing by increasing sensitivity, increasing resistance to PCR inhibitors, and reducing the time for DNA amplification. Each IdentifilerPlus® kit contains the reagents to amplify 16 STR loci, including the 13 core CODIS markers, for approximately 200 samples. At a cost of over $17.00 per sample, using full reaction volumes for every sample may be unnecessarily expensive. This study was performed to evaluate the effectiveness of DNA amplification when the total volume of IdentifilerPlus reactions is reduced by half.

Purified DNA samples containing heterozygous alleles at all loci with the exception of amelogenin (female) were amplified in duplicate on an ABI 9700 thermocycler using the recommended 28-cycle protocol. Samples were amplified with the IdentifilerPlus kit using half the volume of reagents and template DNA as the volume recommended by ABI, for a total reaction volume of 12.5µl. They were then injected on an Applied Biosystems™ 3130xl Genetic Analyzer for 2, 4, or 6 seconds, and the resulting data were analyzed with GeneMapper ID. A DNA target range of 0.001-1.25ng was assessed to determine the effects of half reaction volumes on the sensitivity of amplification, locus detection, stochastic threshold, and peak height ratios (PHR). The results of these studies were also compared to the values obtained from the previous internal validation of the IdentifilerPlus system at the full reaction volume of 25µl.

For the amplification sensitivity study, the high DNA input samples in half reactions produced similar peak height values when compared to full reaction volumes. The target DNA input for half reaction volumes of the IdentifilerPlus kit was determined to be 0.5 – 1.0 ng, the same quantities recommended and validated for full reaction volumes. Importantly, the stochastic threshold increased from 145 RFU for full reactions to 325 RFU for half reaction volumes, making half reactions much less useful for evidence samples.

The PHR for half reactions were similar to those seen in our previous study of the IdentifilerPlus® kit using full reaction volumes. These data suggest that PHR is not affected by using half reaction volumes with greater DNA input amounts, i.e., more than 0.2ng. However, with lesser DNA target amounts, i.e., less than 0.2ng, the percentage of heterozygous peaks with PHR >60% was consistently greater than 80%, while at half reaction volumes, the percentage of heterozygous peaks >60% PHR was lower, in the 60-80% range.

The increase in stochastic threshold and PHR variability at lower DNA quantities suggest that input amounts of 0.75ng or higher are more useful and more reliable for half reactions. Results of tests for reproducibility, accuracy, and precision will be presented. The Harris County Institute of Forensic Sciences processed 1,560 known DNA samples from January through May 2012. The use of half reaction volumes for IdentifilerPlus would provide a savings of over $13,000 within this time period alone.

In conclusion, the use of half reaction volumes of the IdentifilerPlus amplification kit may be a viable option for processing known forensic DNA samples where an unmixed sample and a high quantity of DNA is expected. This would result in a significant cost savings for the laboratory. For unknown samples, the doubling of the stochastic threshold makes the use of half-reaction volumes unsuitable.

Identifiler® Plus, Half Reactions, Amplification

A48 High Throughput SNP Typing Based on Invader® Assay on Integrated Fluidic Circuits

Hiroaki Nakahara, PhD, Koji Fujii, PhD, Tetsushi Kitayama, MS, and Kazumasa Sekiguchi, PhD, N'tl Research Institute of Police Sci, 6-3-1, Kashiwanoha, Kashiwa, JAPAN*

After attending this presentation, attendees will understand the effectiveness of a high-throughput multiplex SNP (single nucleotide polymorphism) typing system utilizing integrated fluidic circuits (IFCs), which are fluidic lines designed on a detection disc forming 2,304 reaction chambers.

This presentation will impact the forensic science community by providing an approach for multiplex invader assay SNP typing in thousands of reactions. Dozens of SNP loci in dozens of DNA samples can be quickly detected at low cost.

SNP typing has advantages in forensic identification, because SNPs are abundant in genomic DNA and are easily detected using an automated high-throughput system. The primary benefit of SNP typing is more successful typing of degraded samples compared with other methods, including short tandem repeat (STR) typing, because of their small target size. SNPs, however, are bi-allelic and large numbers of loci must be analyzed to increase the power of discrimination. To obtain a comparable discriminatory power to that of the commonly used fifteen loci STR typing kit, more than 40 SNP loci must be typed. In addition, the analysis of this many loci should be simple, cheap, and rapid. Common SNP typing procedures, such as the TaqMan assay, the cycling probe assay, the single primer extension assay, or the Invader assay, cost a few dollars for each locus. Thus, typing 40 loci would cost more than a hundred dollars.

In this presentation, high throughput and low cost multiplex SNP typing using the Invader assay in IFCs on a BioMark HD System produced by the Fluidigm Corporation are introduced. In this system, reactions proceed in a few nanoliters of solution enclosed in small chambers, rather than the commonly used microliter-scale reaction tubes. The flow of reaction mixtures and DNA sample solutions are automatically controlled and filled in separated chambers by air pressure, without interdiffusion. The volume of each reaction mixture is very small and thus the total cost of analysis is low. In the device, the temperature of the reactions is controlled and the fluorescence of each chamber is detected and recorded in real time. Using this system, we attempted to analyze 32 SNPs that had been validated in our previous study.[1]

DNA samples were collected from 48 individuals who had given their informed consent to our experiments. Their SNPs were analyzed in our previous study and confirmed by direct sequencing. The Invader assay for the amplified products of the 32 SNP loci by multiplex PCR were carried using Universal General Purpose Reagent (Third Wave Japan Co.) injected into the chambers on the detection disc. The intensities of two types of fluorescence, FAM and Yakima Yellow, in each chamber were detected every 20 seconds during the reaction, which used isothermal heating at 63°C for 30 minutes. The genotypes of each locus were determined from the increasing fluorescence curve of the chart in which both fluorescence intensities were plotted, as reported previously.[2] Triplicate typing for each sample was carried out to verify the results. Using the IFCs system, high-throughput and low cost multiplex SNP typing could be achieved. The reaction and detection time for 48 samples in the device was only approximately 40 minutes, not including one hour of PCR amplification and the 30 minutes taken to

inject the samples into the chip. The cost for each SNP locus was less than 25 cents. Furthermore, this system can also perform digital PCR as another application of IFCs. Digital PCR is a quantitative analysis method commonly used in gene expression studies. It is expected that the application of IFCs will be effective for resolving the problem of DNA mixtures in forensic casework analyses, when used in the quantitative detection of different alleles.

A49 Validation of the Applied Biosystems® 3500 Genetic Analyzer With a Comparison of the Identifiler® Plus and PowerPlex® 16 HS Amplification Kits

Emilie C. Dembia, BS, 2007 7th Ave, Apt 815 A, Huntington, WV 25703; Sarah A. Chenoweth, MS, Anne Arundel Co Police Dept, Crime Laboratory, 8495 Veterans Hwy, Millersville, MD 21108; and Jennifer Hayden, MS, and Pamela J. Staton, PhD, Marshall Univ, Forensic Science Center, 1401 Forensic Science Dr, Huntington, WV 25701*

The goal of this presentation is to demonstrate the ability of the Applied Biosystems 3500 genetic analyzer to produce complete and accurate forensic DNA profiles with a variety of sample types under a variety of different conditions. It will also provide a comparison of two commonly used amplification kits from the two major manufacturers of forensic analytical supplies for consideration by forensic laboratories. A denaturation study shows the ability for laboratories to validate procedures without the denaturation and snap cooling step prior to a run on an instrument such as the AB 3500. This has the potential to increase efficiency in forensic casework analysis. This validation can also serve as a starting point for future validations of the AB 3500 genetic analyzers.

This presentation will impact the forensic science community by validating the Applied Biosystems 3500 genetic analyzer and the comparison of the PowerPlex® 16 HS and Identifiler® Plus amplification kits on this instrument will provide the forensic science community with information that will allow laboratories to make informed decisions about the kits and equipment that would be best suited to their needs.

Applied Biosystems® 3500 series of genetic analyzers is the newest technology available for forensic casework analysis and has not yet been widely adopted by the forensic community. As such, there are limited studies available that involve the performance of amplification kits commonly used on these instruments. The Anne Arundel County Crime Lab is currently upgrading from an AB 310 genetic analyzer to an AB 3500 genetic analyzer. The internal validation of this AB 3500 included a comparison of the PowerPlex® 16 HS and Identifiler® Plus amplification kits using casework samples and the manufacturer's recommended protocols to determine if one had any advantages over the other, when used in conjunction with the AB 3500. Analytical and stochastic thresholds were calculated for both a 7-second and a 15-second injection time, which were validated for casework analysis on this AB 3500. Precision, contamination, sensitivity, concordance, reproducibility, and stutter studies were also performed during this validation. The AB 3500 generated complete and accurate forensic DNA profiles with both kits and both injection times over a wide range of DNA target amounts at amplification. However, the AB 3500 was able to generate more complete profiles for lower level single source samples and mixture samples using PowerPlex® 16 HS, when the same target amount of DNA was used at amplification in each kit. Powerplex® 16 HS was also shown to generate higher peaks across each dye channel on the AB 3500 when compared to Identifiler® Plus. Aside from this difference in sensitivity, there were no significant differences in performance between the PowerPlex® 16 HS and Identifiler® Plus amplification kits on the AB 3500. A denaturation and snap cooling study showed that the denaturation and snap cooling step in the laboratory's standard operating procedures had no effect on the data produced by the AB 3500 with either kit. As a result of this validation, the Anne Arundel County Crime Lab will continue to use the PowerPlex® 16 HS amplification kit for casework analysis on their newly validated AB 3500 with a standard operating procedure that does not include the denaturation and snap cooling step prior to an instrument run. Extended use of the POP 4 polymer pouch was also investigated beyond the recommended 7 days on the instrument after opening. Storing the POP 4 polymer in the refrigerator after opening, when it is not in use on the instrument, was shown to extend the useful life of the polymer by several weeks. Future studies may include manipulation of the amplification cycles with Identifiler® Plus to see how the sensitivity of this kit can be improved for lower level single source samples and mixture samples. There is also a tendency for the D13 and D5 loci to dropout more frequently in lower level samples than other loci with both PowerPlex® 16 HS and Identifiler® Plus on both the AB 3500 and the AB 310, which was used in this validation for concordance studies. Future studies could be undertaken to determine the cause of this imbalance.

AB 3500, PowerPlex® 16 HS, Identifiler® Plus

A50 Internal Validation of the AmpFℓSTR® Yfiler™ Amplification Kit on a Life Technologies™ 3130 Genetic Analyzer

Kathleen F. Jacque, BS, 13377 Woodland Ct, Big Rapids, MI 49307; Lynnett P. Redhead, MS, 7600 Barlowe Rd, Landover, MD 20785; and Sarah E. Bowen, MS, and Pamela J. Staton, PhD, Marshall Univ, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will understand the process of an internal validation of the AmpFℓSTR® Yfiler™ PCR Amplification Kit on a Life Technologies™ 3130 Genetic Analyzer and the efficiency of the amplification kit to reliably amplify and produce complete and accurate Y-Short Tandem Repeat (Y-STR) profiles. The following properties are taken into account: threshold, sensitivity, contamination, precision, concordance, reproducibility, male-female mixtures, male-male mixtures, and stutter.

This presentation will impact the forensic science community by increasing throughput of casework and reducing backlog, which is one of the main problems many laboratories face. By utilizing the Y-STR selectivity to amplify STRs, the AmpFℓSTR® Yfiler™ PCR Amplification Kit can be utilized in mixture samples to help reduce interpretation time. Before implementing the AmpFℓSTR® Yfiler™ PCR Amplification Kit, an internal validation is necessary to ensure that performance in the laboratory is concordant with the performance demonstrated by the manufacturer.

The successful validation of the AmpFℓSTR® Yfiler™ PCR Amplification Kit may reduce the time spent on mixture interpretation and can increase the throughput of the Prince George's County Police Department DNA Laboratory. Y chromosomal short-tandem repeat (Y-STR) amplification is of interest at Prince George's County Police Department DNA Laboratory due to the overwhelming number of cases with complex mixtures that the analysts encounter annually. Y-STR amplification targets the male component, the Y chromosome, and can be utilized in cases where the male component is of interest. The AmpFℓSTR® Yfiler™ PCR Amplification Kit is a multiplex assay that amplifies 17 loci located on the Y chromosome: DYS456, DYS389I, DYS390, DYS389II, DYS458, DYS19, DYS385a/b, DYS393, DYS391, DYS439, DYS635, DYS392, Y GATA H4, DYS437, DYS438, and DYS448. The resulting profile is a human male haplotype. In autosomal amplification, loci from several different chromosomes are amplified in

one reaction, and in the case of mixture samples can be difficult to interpret. Using a male specific kit, such as the YFiler™ kit, male profiles can be isolated and aid in interpretation, especially in conjunction with a genotype produced from autosomal analysis. The internal validation of the Yfiler™ kit followed the SWGDAM validation guidelines along with a comparison of analytical threshold calculations. The analytical threshold calculations were completed using two different sample type runs using a 5second capillary electrophoresis injection. The samples included capillary electrophoresis run negative samples and YFiler™ amplified samples (including samples, positive controls, and reagent blanks). For the run negative analytical threshold calculations, the average and standard deviation of the baseline height (disregarding internal size standard pull up or known artifacts) and separated by dye channel. The analytical threshold using YFiler™ amplified samples was calculated by evaluating average height and standard deviation of the baseline between allelic peaks (disregarding artifacts such as pull up and stutter). Through both sample type calculations, the optimal analytical threshold was found to be 150 relative fluorescent units (RFU) for a 5-second injection time. A 10-second injection time also utilized a 150 RFU analytical threshold, while a 200 RFU analytical threshold was utilized for a 15second injection time. Full profiles were produced for a 5-second injection time from a DNA input concentration of 2.0ng/µL to 0.250ng/µL, with full profiles produced from 0.125ng/µL in six of 10 samples, and an average of 11 loci for 0.0625ng/µL. For a 10 second injection time, a DNA input concentration from 1.0ng/µL to 0.250ng/µL produced full profiles, with full profiles produced from 0.125ng/µL in all but one of 10 samples, and an average of 14 loci for 0.0625ng/µL. Full profiles were produced for a 15-second injection time from 0.50ng/µL to 0.125ng/µL, with full profiles produced from 0.0625ng/µL in two of ten samples. In the male-male mixtures, a full profile from the minor male component was identified up to a 1:5 ratio and a 1:1:1 male mixture produced full profiles for all male contributors. In the female-male mixtures, a full Y-STR profile was obtained at ratios up to 1:1. Inhibition was observed at ratios above 1:1, with an average of six loci called in the 1:100 male to female ratio. A full male profile was produced from a 1:1:1 male to female to female mixture. The studies illustrate that the Yfiler™ kit successfully amplifies evidence samples from adjudicated cases, is male specific, and precise.

Y-STRs, Internal Validation, Y-Chromosome

A51 Validation of the Applied Biosystems® 3500xL With PowerPlex® 16 HS

Christopher W. Thatch, BS, 16 Curry Ln, Milford, OH 45150; Danielle Imes, MS, 843-849 N 8th St, Philadelphia, PA 19123; and Valerie K. Bostwick, MS, and Pamela J. Staton, PhD Marshall Univ, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will understand the procedures of the internal validation performed at the Philadelphia Police Forensic Science Bureau on the Applied Biosystems® 3500xL with PowerPlex® 16 HS. Attendees will learn which settings were selected to optimize the use of this chemistry with the instrument as well as the results of the various studies performed.

This presentation will impact the forensic science community by the sharing of information in regards to the validation of a relatively new platform to the field of forensics, the Applied Biosystems® 3500xL Genetic Analyzer. This instrument will soon replace the Applied Biosystems® 3130 Genetic Analyzer as the primary capillary electrophoresis instrument used in forensic DNA laboratories. This validation also incorporated a frequently used amplification chemistry, Promega Corporation's PowerPlex® 16 HS.

An important aspect of forensic science is the need to validate new chemistries and instrumentation for use with STR analysis. An internal validation must be performed on these new methods and technologies prior to implementation in laboratory standard operating procedures. This validation must demonstrate the ability of the procedure to obtain reliable results, the ideal conditions to obtain these results, and the limitations for this new procedure. An internal validation was performed for the Philadelphia Police Forensic Science Bureau through the National Institute of Justice Technical Assistance Program on the use of PowerPlex® 16 HS amplification chemistry with the Applied Biosystems® 3500xL Genetic Analyzer. The 3500 Genetic Analyzer is a relatively new platform to the field of forensic science and offers many advantages over the previously used Applied Biosystems® 3130, such as, an improved mechanical pump, new laser technology, more consistent temperature control, prepackaged consumables, and reduced power requirements. Data files are also saved in .HID format and analyzed with GeneMapper® ID-X (Applied Biosystems). The PowerPlex® 16 HS amplification chemistry, released in 2009, added hot-start Taq directly to their mastermix, eliminating the need to purchase this reagent separately, an advantage over the previously used PowerPlex® 16 kit. PowerPlex® 16 HS also offers the ability to perform direct amplification procedures, as well as an increased ability to perform in the presence of inhibitors.

This internal validation incorporated a variety of studies to demonstrate the reliability and reproducibility of this instrument with the PowerPlex® 16 HS chemistry. These studies included the determination of an appropriate analytical threshold through SWGDAM approved methods, a stochastic threshold, an injection time and voltage that provided optimal peak heights and peak height ratios, a sensitivity range to provide the optimal input amount of target DNA, heterozygosity ratios, and stutter percentages for comparison to manufacturer-recommended values. Studies were run simultaneously on both the 3130xL and 3500xL instruments for the duration of the validation study. The results from the 3500xL were compared with data collected from the 3130xL to demonstrate concordance. Results collected for various other studies were also compared between the two platforms including stutter ratios and mixture interpretations. Samples were also analyzed to demonstrate reproducibility across multiple amplifications and runs, and were compared with the expected results from previously analyzed non-probative casework samples. These non-probative casework samples demonstrated various extraction methods and substrates typically encountered in the Philadelphia Police Forensic Science Bureau. The comparison of these results demonstrates instrument concordance.

Overall, results from the 3500xL were observed to contain peaks of a greater intensity when compared to the 3130xL. The instrument also provided accurate profiles with few artifacts across a wide range of input target DNA. Based on the findings of these studies, specific settings were recommended to be incorporated into the standard operating procedure of the Philadelphia Police Forensic Science Bureau. These settings included a set analytical threshold across all dye channels, a stochastic threshold value to assist in the determination of true homozygote peaks, an optimal target DNA range, laboratory specific stutter ratios, and mixture interpretation guidelines. The instrument produced reliable results with the PowerPlex® 16 HS amplification chemistry and the use of this chemistry with the 3500xL was recommended for future use.

PowerPlex® 16 HS, 3500xL, Validation

A52 Validation and Comparison of the AmpFℓSTR® Identifiler® Plus PCR Amplification Kit to Identifiler®, MiniFiler™, and Yfiler® for the Pinellas County, Florida Forensic Laboratory

Sarah E. Barr, BS, 2007 7th Ave, Apt 815, Huntington, WV 25703; Chad V. Summerfield, MS, 13204 Chipout Ln, Hudson, FL 34669; Season E. Seferyn, MSFS, 8 Hapgood Hill, Huntington, WV 25705; and Pamela J. Staton, PhD, West Virginia Univ, Forensic Science Center, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will gain an understanding of the Identifiler® Plus amplification chemistry's performance in various studies as compared to the Identifiler®, MiniFiler™, and Yfiler® chemistries.

This presentation will impact the forensic science community by providing information about capabilities and limitations of Identifiler® Plus under various conditions and on different instruments. By comparing this amplification chemistry to other available chemistries, forensic laboratories will have advanced insight into which chemistry may be best suited for their specific needs.

Using these protocols, amplification of DNA samples must occur prior to capillary electrophoresis in order to generate the desired human identification profile required for presentation in court proceedings. The type of amplification chemistry used in this process can affect the profile obtained from the sample. The Identifiler® Plus amplification chemistry from Applied Biosystems was selected for this study as it contains a reportedly improved master mix, with AmpliTaq Gold® DNA Polymerase already added to the mix as well as an enhanced formula to reduce Polymerase Chain Reaction (PCR) inhibition of samples. The kit is designed to provide improved sensitivity to enable use with low template DNA samples, while also allowing for more effective analysis of mixture samples. Identifiler® Plus uses fluorescent multi-color dyes to analyze 15 loci with alleles with overlapping size ranges. It follows the same design as Identifiler®, but is an improvement on the MiniFiler™ chemistry, which only amplifies nine loci. Yfiler amplifies 17 Y-STR loci, so direct comparisons could only be made for certain studies.

An internal validation of Identifiler® Plus was performed for the Pinellas County Forensic Laboratory in Largo, Florida. Eight validation studies were performed, including accuracy, precision, recovery, linearity/sensitivity, range, mixture, carryover, and ruggedness. Accuracy was determined from non-probative samples that simulated casework, mixture samples created from positive controls, and all positive controls used in the validation. Precision was measured from the standard deviations of 48 allelic ladders and the 250 base pair (bp) peak of all samples in the validation. A sensitivity study was used to measure linearity, in that a range of DNA concentrations were amplified in order to establish the optimal concentration for successful amplification. 9947A and 007 control samples were used to create mixture ratios ranging from 19:1 to 1:19. Ruggedness was determined by amplifying the samples using three different thermal cyclers. All negative controls used in the validation were analyzed for contamination. The results were compared to the results of samples amplified with Identifiler® as well as results from previous Identifiler®, MiniFiler™, and Yfiler® validations. All samples were amplified for 28 and 29 cycles to determine the ideal PCR cycle number for Identifiler® Plus. Additionally, the limit of detection and sensitivity samples were run on three different genetic analyzers (two 3130 genetic analyzers and one 3130xl genetic analyzer) to ascertain any discrepancies between the instruments.

The results of the validation supported the use of 28 PCR cycles with Identifiler® Plus. The samples displayed greater sensitivity than Identifiler® and were comparative to MiniFiler™ and Yfiler®. Results of the precision study fell within manufacturer recommendations. Samples demonstrated 100% accuracy and no contamination was present in any of the negative controls used in the validation. Samples run at different times and on different thermal cyclers were consistent with expected results and with each other. Mixture samples could be resolved and full profiles of the minor contributor were generated down to 6:1 and 1:9. The samples run on the 3130xl genetic analyzer displayed greater sensitivity than samples run on the 3130 genetic analyzer, but limit of detection stayed the same for both instruments.

Identifiler® Plus, Validation, Amplification

A53 Detection of Differentially Methylated Parental Allele in Imprinted Gene SNRPN Using MS-SSCA

Hongmei Xu, PhD, Yun Zhao, MS, Hui Li, MS, and Ziqin Zhao, MS, 138 Yixueyuan Rd, Shanghai, PEOPLES REPUBLIC OF CHINA*

After attending this presentation, attendees will learn a new method to identify differentially methylated parental alleles.

This presentation will impact the forensic science community by using MS-SSCA in dried blood spots to identify differentially methylated parental alleles.

In a classic forensic paternity test, the obligatory gene often cannot be determined in motherless cases, or when the mother and child share the same heterozygous genotype. Recently, the combination of Single Nucleotide Polymorphism (SNP) typing and genomic imprinting has shown promising potential in paternity testing or personal identification. SNPs are the most abundant type of human polymorphism, and became valuable markers for forensic identification and paternal testing. Determining the parental origin of SNPs is helpful to some cases. Genomic imprinting is the phenomenon where the two alleles of some genes are differentially expressed according to their parental origin. DNA methylation pattern of an imprinted locus is unique to each allele. The parental origin of specific methylation status at the imprinted loci provides a new means to detect the obligatory gene without genealogical analysis. Classic techniques to detect the differentially methylated parental alleles are methylation-specific PCR (MSP) and post-digestion PCR. The established procedures; however, often require relatively large amounts of DNA. In daily practice, samples submitted for analysis might contain very small amounts of poor quality material, as is often the case with forensic stain samples, while dried blood spots have become preferred forensic samples in many forensic laboratories, as they are easy to collect, transport, and store. In this study, a new technique was developed that only requires small amount DNA to identify the obligatory gene in forensic paternity testing. First, a modified, more efficient method of bisulfite genomic sequencing in dried blood spots was tested. Briefly, the genomic DNA extracted from 3mm dried blood spots using QIAamp micro kit was treated with sodium bisulfite (EpiTect) followed by methylation-specific PCR (MSP) and Sanger sequencing. The imprinted region the gene, small nuclear ribonucleotide protein N (SNRPN) was examined for differential methylation. The data shows efficient DNA extraction and full conversion of unmethylated cytosine to uracil. Second, the methylation-sensitive single-strand conformation polymorphism (MS-SSCA) method to detect the parental origin of the allele of SNP locus rs220030 (C/T) was used. The SNP locus rs220030 is found in the promoter region of the maternal imprinted gene SNRPN. Rs220030 (C/T) in maternal imprinted gene SNRPN was typed using the TaqMan SNP Genotyping assay. The methylated status of maternal and paternal alleles were determined by MS-SSCA on four family trios with heterozygous children. The results have shown that MS-SSCA has great potential in the discrimination of differentially methylated parental alleles of imprinted genes in forensic paternity testing. This study suggested that bisulfite treatment of genomic DNA, combined with classical non-denaturing polyacrylamide electrophoresis can become a new parental origin determination method in imprinted genes for forensic purposes.

DNA Methylation, Methylated Parental, MS-SSCA

A54 Evolving Strategies to Mitigate the PCR Inhibitory Compounds Found in Carpet Backing

Deanna M. Calabrese, Carrie A. Thomas*, and Michael S. Adamowicz, PhD*, Univ of New Haven, 300 Boston Post Rd, West Haven, CT 06516*

After attending this presentation, attendees will have a better understanding of the possible benefits of potential approaches to processing carpet samples for DNA analysis in order to avoid the effects of polymerase chain reaction (PCR) inhibitory compounds found in the backing layers of interior carpet.

This presentation will impact the forensic science community by providing experimental evidence indicating that the PCR inhibitory compounds in carpet backing are concentrated in different layers of the carpet. Results will also be presented that show that by only using a portion of the backing layer, the effects of the inhibitors can be mitigated or eliminated entirely. This study may suggest potential changes to extraction protocols that laboratories may implement in order to increase

the quality of the DNA profiles of samples collected from interior carpeting.

A common feature of most residential homes, as well as many commercial and public structures, is carpeting. Evidentiary biological samples such as blood and semen are often collected from crime scenes in the form of stains soaked into this interior carpet. Highquality DNA profiles can be challenging to develop from these samples due to the presence of PCR inhibitors that interfere with the amplification process. In this study, 40 interior carpet samples were collected from different manufacturers and commercial vendors and assessed for PCR inhibition. The carpet was broken down into its four basic components: the fibers, the first backing layer, the binding/adhesive layer, and the second backing layer. Each component was examined individually and the backing layers were examined together in all combinations in order to identify if the PCR inhibitors were localized or were contained in more than one component of the carpet structure. None of the carpet fibers demonstrated any significant levels of PCR inhibition; however, 65% (26/40) of the intact carpet backing layers demonstrated significant to total inhibition of PCR product as measured with the Applied Biosystems Quantifiler® human DNA kit. When separated into individual layers, or in combinations of two out of the possible three layers, PCR inhibition was most often apparent with the first backing layer and the binding/adhesive layer. The second backing layer demonstrated little, if any, inhibitory effects on PCR. These results were further supported when the samples were amplified using the Promega PowerPlex® 16 HS short tandem repeat kit. Samples extracted from the first backing and the binding/adhesive layers demonstrated a reduced or absent STR signal, while samples extracted from the second backing layer were rarely affected. Data were collected showing that the PCR inhibiting compounds co-extract with the DNA; extracts of DNA-free carpet were not themselves inhibitory. Diluting the inhibited samples was effective at restoring signal in some instances, but not in all of them, indicating that a more efficient strategy to process samples would be to avoid the inhibitory agents to the greatest extent possible. Dilutions can also involve multiple trials, wasting sample that may already be in low quantity.

In summary, two of the three layers that constitute the backing layer of interior carpeting are indicated as containing the compounds responsible for the PCR inhibition observed when working with biological samples extracted from carpet. The carpet fibers and the second backing layer do not demonstrate significant levels of inhibition. While forensic DNA examiners could ideally avoid any PCR inhibition by only processing the fiber layer, in a sample of low quality and/or quantity, isolating every possible bit of DNA may be necessary to ensure the best possible profile. Additionally, the fiber layer is the part of the carpet most often cleaned in an attempt to destroy evidence, and therefore is not always available. In these cases, examiners will need to use the carpet backing; however, this study indicates that only the second backing layer should be used in order to avoid the PCR inhibitory effects of the two other layers.

DNA, Carpet, PCR Inhibitors

A55 STR Profiling of Bloodstained T-Shirts Submerged in a Freshwater Lake

Jason G. Linville, PhD, UAB, UBOB 210, 1720 2nd Ave S, Birmingham, AL 35294-4562; and Ryan F. Smith, BS, 1420 10th St S, Apt 223B, Birmingham, AL 35205*

After attending this presentation, attendees will have a greater understanding of how bloodstains are affected by submersion in freshwater environments for variable periods of time.

This presentation will impact the forensic science community by providing data relevant to the effects water submersion has on the appearance, DNA quantities, and STR profiling of bloodstains submerged in freshwater environments for variable periods of time.

The success of DNA analysis is affected by the environment and substrate from which the sample is recovered. The rate of DNA degradation depends on light exposure, water content, temperature, and the presence of microorganisms that may result in physical, chemical, and biological degradation of the genomic DNA. Extreme environments, such as submersion in water, can greatly reduce the likelihood of successful short tandem repeat (STR) genotyping. Submerged samples are exposed to the contents of the water, which may introduce inhibitors, or degrade the bloodstain itself. Another factor acting on the bloodstain is the mechanical action of water removing cellular material from the substrate, washing away valuable evidence. To date, some research has focused on developing methodology for extracting and typing DNA from corpses, tissue, and bone that have been immersed in water; however, little has been done to explore the possibility of testing bloodstained clothing recovered from an aquatic environment. Bloodstains found on submerged clothing may offer investigators information regarding the identity of the victim and foreign DNA that may belong to a suspect or witness to the crime.

DNA extraction and DNA typing of bloodstains immersed in water have not been extensively studied. It can be envisioned that in certain circumstances where a body is absent and only circumstantial evidence, such as bloodstained clothing, may be the investigators' only piece of biological evidence. Dried bloodstains have been extensively examined for successful extraction and typing. However, these same studies have not been performed on bloodstains following submersion in water.

The goal of this study is to determine the effect water submersion has on the recovery and amplification of DNA from bloodstained T-shirts submerged in a freshwater lake for periods ranging from two minutes to 90 days. Based on the success of previous research on submerged samples, this study evaluated and compared two extraction methods, a phenol-chloroform method and the manufacturer's protocol for a commercial, silica-column-based kit. This study will serve as a baseline, utilizing whole blood and a cotton substrate to minimize degradation and possible inhibitors other than what is introduced by the aquatic environment.

All bloodstains recovered from the lake, deionized water controls, positive controls, and negative controls were divided and extracted using two methods: a commercial, silica-column-based kit, and an organic extraction method. DNA was quantified using real-time PCR, and STR profiles were generated using a commercial multiplex kit.

Preliminary results suggest that bloodstains submerged for up to 24 hours are viable for obtaining quantifiable amounts of DNA capable of producing full Short Tandem Repeat (STR) genotypes. Findings have also shown that the appearance of the bloodstain following recovery from the lake does not necessarily correlate to the success of DNA analysis. The preliminary results from bloodstains submerged in deionized water indicate greater quantities of DNA from the same time periods, suggesting that either the water currents or contents impact the amount of DNA retained by the substrate.

DNA Analysis, Bloodstains, Submerged

A56 Validation of an Alternative for DNA Extract Purification Using the QIAamp® DNA Mini Kit in mtDNA Analysis

Ashley M. Collins, MS, Constance L. Fisher, PhD, and Erica M. Ames, MS, FBI, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will learn that the QIAamp DNA mini kit is a viable alternative for extract purification from hairs, blood, and buccal samples for mtDNA analysis.

This presentation will impact the forensic scientific community by providing a study that compares extraction methods through mtDNA amplification yields.

The purpose of this study was to determine if an alternative method for DNA extract purification using the QIAamp® DNA Mini Kit is comparable to the current method of Phenol Chloroform Isoamyl Alcohol (PCIA) purification for hair, blood, and buccal samples. Side-by-side comparison of the QIAamp® purification with the PCIA purification

method was assessed by yield of amplified mitochondrial DNA, overall sequence quality, and contamination susceptibility.

To test DNA extraction from hairs, 12 hairs from 10 different individuals of known sequence were extracted and purified with both methods (exception: 2 hairs from extensions made from human hair were not previously sequenced). Hair cuttings effectively represented samples of 2 cm, 1.5 cm, 1 cm, and 0.5 cm in length. Twice these lengths were initially cut (no root material was used), ground in a microtissue grinder in Stain Extraction Buffer (SEB), and incubated at 56°C for two hours to overnight. The extract volume was split into two—one purified with PCIA and the other purified using the manufacturer's instructions for the QIAamp® DNA Mini Kit. The hair samples were amplified for two subregions of HV1 and HV2: "HV1b" spanning positions 16160-16390 and "HV2b" spanning positions 178-408 using 36 cycles. Post-amplification yields were measured using the DNA 1000 assay on the Agilent Technologies 2100 Bioanalyzer instrument. Cycle sequencing was performed using the Big Dye Terminator v.1.1 Cycle Sequencing kit. Post-cycle sequencing clean up was performed using the CentriSep™ columns and then run on a 3130xl Genetic Analyzer capillary electrophoresis instrument for visualization of the sequence products.

In addition, 10 total blood and buccal samples from different individuals of known sequence were extracted and purified with both methods using a similar experimental design to the one described above. For blood samples, approximately 1.5mm^2 cuttings were taken, and ¼ of a swab was cut for buccal samples. The DNA extracts from the blood and buccal samples were amplified for the Whole Control Region (WCR, spanning nucleotide positions 15998-616) using 32 cycles. Post-amplification yields were measured using the DNA 7500 assay on the Agilent Technologies 2100 Bioanalyzer instrument.

There was no effective difference in the yield of amplified mitochondrial DNA based on length of starting material for the hairs between the extracts purified with the different methods. In fact, no overall pattern emerged in the data to indicate one method consistently provided a higher yield over the other for hairs, blood, or buccal samples. A vast majority of the samples exhibited little to no difference in the amount of amplified mitochondrial DNA when comparing the two procedures. One exception was a single observation of a threefold higher difference in amplified mitochondrial DNA yield for one bloodstain sample purified with PCIA. However, the extract from the corresponding QIAamp® purification for that bloodstain appears to have been inhibited, since dilution of the extract was required for successful amplification. It is also important to note that two other bloodstains had a 1.7-1.9 fold higher yield with QIAamp®. Both these observations, taken with the fact that all yields for the blood samples were relatively low, indicate caution is necessary when making the decision as to which treatment to use when processing bloodstains. There was virtually no difference in the sequence quality generated or the number of length variants detected between the two purification methods. The results also indicate little difference between the two methods with respect to the incidence of contamination, despite the higher number of manual manipulations with the QIAamp® columns. Therefore, using the QIAamp® DNA Mini Kit for purification for hair, blood, and buccal samples is a viable alternative to PCIA purification.

Extraction, mtDNA, Comparison

A57 Evaluation of Commercial Kits for Co-Extraction of RNA and DNA From Human Body Fluids

Andrew J. Schweighardt, PhD, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; Kristina A. Scott, MS, 4008 Farrington Ct, No 101, Woodbridge, VA 22192; Courtney M. Tate, PhD, 433 E Merrill, Indianapolis, IN 46225; and Kathryn A. Harper, MS, and James M. Robertson, PhD, FBI, CFSRU, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will learn that for situations for which both RNA and DNA are desired from the same evidentiary sample, valuable material and time can be saved by simultaneously processing the sample using various commercial kits.

This presentation will impact the forensic science community by providing information that may aid forensic scientists in making a decision as to which commercial kit to use for the dual extraction of RNA and DNA. Attributing a stain recovered from a crime scene to a particular anatomical tissue may aid in predicting the success of DNA profiling efforts, as well as helping to reconstruct the crime. RNA is transcribed in a tissue-specific manner and, thus, the reverse transcription of RNA and subsequent amplification of tissue-specific markers have been developed to supplement more conventional methods of body fluid identification. The simultaneous extraction of both RNA and DNA from the same stain is desirable in order to use the least amount of evidence in the analysis.

The purpose of this study was to evaluate several dual extraction methods for their ability to provide DNA and RNA of sufficient quality and quantity for successful downstream applications. Blood and saliva samples were collected from 30 donors. A preliminary study was performed with blood spotted onto cotton swabs for 10 donors. In order to establish a reference to which the dual extraction kits could be compared, samples were purified with traditional DNA and RNA extraction methods (i.e., organic extraction, Ambion® RNAqueous®, and TRIzol® Plus). The dried spots were co-extracted using the Zymo Research ZR-Duet™ DNA/RNA MiniPrep kit, the Qiagen® AllPrep DNA/RNA Mini kit, the Norgen Biotek RNA/DNA/Protein Purification Plus kit, and the Fisher SurePrep™ RNA/DNA/Protein Purification kit. Purified RNA was reverse transcribed to cDNA. Both DNA and cDNA were quantified by real-time PCR. Amplification of cDNA was carried out using primers for fluid-specific markers and purified DNA was amplified using primers for STR markers. All amplicons were detected on a capillary electrophoresis instrument.

Quantification of the DNA extracts indicated that the highest average concentrations were observed with the Zymo and Qiagen kits (0.828 and 0.318 ng/uL, respectively). The lowest average concentrations were observed with the Norgen and Fisher kits (0.013 and 0.007 ng/uL, respectively). The peak heights and the frequency of artifacts or aberrations such as allele dropout were used to assess the quality of the STR profiles generated from co-extracted DNA.

The ability of each kit to yield RNA extracts free of genomic DNA contamination without relying on optional DNase treatments was examined. Laboratories that analyze nuclear DNA are unlikely to allow the incorporation of DNase in the workflow. The detection of a housekeeping gene (beta-2-microglobulin) and a blood-specific marker (erythroid delta-aminolevulinate synthase) were used to assess the ability of co-extracted RNA to yield successful identification of the body fluid source tissue.

The results of the preliminary study were used to select the best of the four kits for further analysis of both blood and saliva samples from the remaining 20 donors. In addition to assessing extraction efficiencies and the quality of genetic profiles generated, the co-extraction methods were evaluated for cost, user-supplied reagents, sample processing time, hazardous waste generation, and required bench skills. Stand-alone DNA or RNA purification methods generally offer better extraction efficiency, but co-extraction methods may still provide a complete genetic profile while simultaneously identifying the tissue source of the stain from which a profile has originated.

RNA and DNA, Co-Extraction, Body Fluid Profiling

A58 Comparative Evaluation of Methods to Remove Exogenous DNA From Tooth Samples

Kelly Desouza, BS, Harris County IFS, 1885 Old Spanish Tr, Houston, TX 77054; Rebecca S. Mikulasovich, MS, 4737 Merwin St, Houston, TX 77027; and Michael A. Donley, MS, and Roger Kahn, PhD, Harris County IFS, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will have an understanding of the development of a decontamination method that is effective for the removal of nanogram quantities of exogenous DNA from tooth samples.

This presentation will impact the forensic science community by demonstrating the effectiveness of a decontamination method that will remove amounts of exogenous DNA from a tooth expected from normal handling by examiners not protecting the samples from contamination. Forensic laboratories will be able to adopt this method to prevent contamination of these types of samples.

This presentation will summarize the evaluation of several methods for the removal of exogenous DNA deposited during previous examination, handling, or comingling of forensic tooth samples. All treatments for tooth and bone decontamination, including the original Harris County Institute of Forensic Sciences (HCIFS) method, were tested by adding and attempting to remove increasing amounts of DNA from teeth. An optimal method for DNA removal was identified and subsequently validated for use on forensic casework tooth and bone samples submitted to the HCIFS laboratory.

DNA extracted from tooth samples can provide powerful information in both forensic casework and missing person identification. The presence of surface DNA contamination from previous examinations or comingling can provide misleading or confusing results, however. This study approached systematically the development of a method to effectively remove surfacecontaminating DNA by assessing a variety of removal methods in various combinations. These techniques included prolonged soaking in bleach and/or deionized water, rinsing with deionized water and/or ethanol, and exposure to UV irradiation.

Sixteen combinations of the techniques were tested for their ability to remove five levels of exogenous DNA, at 5ng, 10ng, 25ng, 50ng, and 100ng. One combination, treatment "M," comprised of 10 minutes of exposure to 5% bleach, to deionized water, and to UV irradiation at 120,000 µJoules/cm^2 followed by a physical scrub and an ethanol rinse was the most effective method. Treatment M removed all but 0.4% of the highest level of exogenous DNA, a 36-fold improvement from the original HCIFS method.

Using the improved decontamination method M, results were reproducible, with no exogenous DNA detected for eight of the ten animal tooth-human saliva samples tested. Two samples, dosed with 25ng and 50ng amounts of exogenous DNA, yielded DNA residual amounts of 0.04ng and 0.16ng, respectively. For those two samples, 4.0% and 6.0% of the donor profiles were observed, on average, with standard deviations of 0.14 and 0.04, respectively. All other samples, with donor DNA amounts ranging from 0.1 to 22.4ng of DNA, yielded negative amplification results (that is, no alleles detected). Six of the ten samples decontaminated using the original HCIFS method yielded sufficient exogenous DNA to produce full STR profiles.

All non-probative human tooth samples cleaned using treatment M produced single-source profiles from the tooth donors only; no exogenous DNA was detected. Using the original HCIFS method, one tooth, a molar with 1µL of human saliva containing 22.4ng of DNA added, yielded a mixture of DNA from the exogenous DNA source and the tooth donor. These results indicate that treatment M is a more effective method for decontamination of a tooth than the original HCIFS procedure, removing substantially more exogenous DNA than all other methods tested. The procedure known as treatment M, a multi-step process removing exogenous DNA, may be of general utility of cleaning teeth prior to analysis.

Tooth, Bone, Decontamination

A59 Internal Validation of the AmpFℓSTR® Identifiler® Plus PCR Amplification Kit and Comparison to Identifiler® for the Boston Police Department Crime Laboratory

Allison Gapinski, BS, Forensic Science Center, 1401 Forensic Science Dr, Huntington, WV 25701; Julie K. James, MS, One Schroeder Plaza, Boston, MA 02120; and Misty Marra, MSFS, and Pamela J. Staton, PhD, Forensic Science Center, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will be well-informed of the performance of the Identifiler® Plus amplification chemistry on reference and mock casework samples as compared to the Identifiler® amplification chemistry.

This presentation will impact the forensic community by comparing and contrasting the performance of Identifiler® versus Identifiler® Plus, and discussing the improvements and limitations of Identifiler® Plus so DNA laboratories may determine which amplification chemistry is best suited for their individual needs.

Amplification is an important step in the process of generating a DNA profile, allowing as little as a few cells to generate millions to billions of copies so that the sample DNA can be detected. The amplification kit selected can affect the quantity and quality of results obtained. Therefore, great care should be taken in choosing the DNA amplification kit that is best suited for the needs of the laboratory. The Identifiler® Plus amplification chemistry is an improvement over the first generation Identifiler® amplification kit. While both kits amplify the same loci with the same primer sequences in the same concentrations, the Identifiler® Plus amplification kit has demonstrated improved performance on severely inhibited samples, greater sensitivity, improved performance on mixture samples, a cleaner baseline, and a reduced number of artifacts due to an improved primer manufacturing process. The Identifiler® Plus amplification kit is able to amplify a lower target amount with the same or better sensitivity as the Identifiler® amplification kit. The Identifiler® Plus amplification time is also one hour shorter than Identifiler® time.

An internal validation was performed for the Identifiler® Plus amplification kit at the Boston Police Department Crime Laboratory. The results of the validation support a protocol of amplification for 28 PCR cycles with a DNA target input of 0.75ng and an injection time of 10 seconds on a 3130xl genetic analyzer. The validation studies confirmed the precision stated by the manufacturer for the kit and showed full concordance in allele calls with the Identifiler® amplification kit. The sensitivity studies showed that full singlesource profiles above the analytical threshold could be obtained from a target input of 0.125ng, but not all peaks were above the stochastic threshold at that target. Reproducibility in allele calls and peak heights was also seen in samples that were amplified two weeks prior. Mixture studies demonstrated that the Identifiler® Plus amplification kit was able to detect a mixture sample when the minor component was present as 5% of the total DNA and that a full profile from the minor component was often generated when present as 25% of the mixture sample. A full profile for the minor component was rarely obtained when the minor component was present as 10% of the total mixture. No contamination was found in the negative controls throughout the validation studies.

The Identifiler® Plus internal validation instituted a double threshold for analysis, with an analytical and stochastic threshold put in place. This varied greatly from the single calling threshold that was in place with the Identifiler® amplification kit. Amplification with Identifiler® Plus on touch DNA and degraded samples provided more allele calls than when the samples were amplified with Identifiler®, due to both the increased sensitivity and performance of the kit, as well as the lower analytical threshold in place for calling. However, many alleles that had previously been able to be used for statistical purposes in the Identifiler® amplification samples were now falling between the analytical and stochastic threshold for the Identifiler® Plus samples. These alleles were no longer able to be used in statistics and could be used for exclusions only. Nevertheless, the Identifiler® Plus amplification kit provided more

information overall and should be considered for use over the Identifiler® amplification kit.

Identifiler® Plus, Validation, Comparison

A60 An In-Depth Look: 412 Property Crime Cases From the Low-Country Region of South Carolina

Season E. Seferyn, MSFS, 8 Hapgood Hill, Huntington, WV 25705; Sarah E. Barr, BS, 2007 7th Ave, Apt 815, Huntington, WV 25703; Judith Gordon, MS, Charleston Police Dept, Forensic Services Division, 180 Lockwood Blvd, Charleston, SC 29403; and Jason Chute, MSFS, and Terry Fenger, PhD, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will understand what constitutes a property crime according to South Carolina legislation and will be introduced to potential patterns and trends noted in this study of 412 cases and 879 questioned samples. Questioned samples and sample types will be explored as to which resulted in profiles and/or CODIS hits.

This presentation will impact the forensic science community by highlighting the questioned samples and sample types that produced DNA profiles. The types of samples analyzed (blood, saliva, and touch) as well as whether the crime was against a residence, public building/business, person, or vehicle will be discussed.

The low-country region is a geographical region that includes Charleston, South Carolina and the surrounding counties. The four agencies that submitted cases for this project included: the Mount Pleasant Police Department, the Charleston Police Department, the Charleston County Sheriff's Office, and the North Charleston Police Department.

According to South Carolina Legislature, Chapter 11, Offenses against Property, a property crime includes arson, burglary, housebreaking, robbery, and robbery of a person operating a motor vehicle. The distinction between burglary and breaking and entering will also be noted.

In total, 879 questioned samples were processed and analyzed as part of this project. Of the questioned samples 378 were blood, 151 were saliva, and the remaining 350 samples belonged to the category "touch." A brief description of items in this category will be explained. Of the blood samples 94% produced DNA results, additionaly, 64% of the saliva samples and 25% of the touch samples resulted in DNA results.

Of the cases submitted, 36% of the cases were crimes against a residence, 30% of the cases were crimes involving a public building or business, and 33% of the cases were against a vehicle. Less than one percent of the cases submitted were committed against a person. Although all three major categories of crimes had roughly the same number of cases, the types of samples collected (blood, saliva, and touch) differed greatly. Those samples that produced a DNA profile and/or a CODIS hit will be discussed and compared in each of the three categories.

The results were surprisingly variable. One may anticipate that similar percentages of blood, saliva, and touch samples would be collected at a crime against a residence, public building/business, person, and vehicle, but that does not appear to be the case. Hypotheses will be discussed as to why those differences may have occurred.

This presentation will be followed by a comparison presentation regarding the property crimes cases analyzed from different states. In total, the project will involve three locations and over 1,800 cases. A snapshot of an additional future study will also be noted in this poster. It will briefly address what percentage of each case resulted in a conclusion in the adjudication process.

The trends noted across these 412 cases will be presented. It is recommended that persons in the field, especially individuals involved with the collection of evidence and those involved in DNA analysis should become familiar with the patterns visible in this study.

Property Crime, South Carolina, DNA

A61 Multivariate Statistical Evaluation of Bacterial rRNA16S V4-V6 Sequencing to Identify Soil Evidence

James Hopkins, BA, and David R. Foran, PhD, Michigan State Univ, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the forensic identification of soil samples based on next-generation sequencing and multivariate statistical analysis of 16S ribosomal RNA bacterial sequences.

This presentation will impact the forensic science community by introducing a novel molecular approach to soil identification. The advantages of assaying bacterial 16S rRNA loci compared to traditional physical and chemical evaluation of soil samples will be illustrated with an emphasis on the implementation of statistical methods for mathematically confident soil identifications.

Forensic soil analysis has historically been conducted through physical and chemical examination, including color determination, particle size distribution, and chemical component analysis. While these procedures have met with some success, there are a number of shortcomings, including lengthy preparation times, the amount of sample available for testing, subjectivity of results, and inconclusive data. Development of methods that reliably and statistically show soil origination is imperative.

Over the last eight years, forensic biologists at Michigan State University have been examining various molecular methods for characterizing and identifying soil samples based on their microbial populations. Early investigations using Terminal Restriction Fragment Length Polymorphism (T-RFLP) analysis showed that bacterial communities tend to differ among soils but often produce extremely complicated profiles, making reproducibility difficult. Further, these methods do not allow statistical analyses. Quantitative Polymerase Chain Reaction (qPCR) was then employed to assess if proportional comparisons of specific bacterial populations could differentiate soils. Pairwise comparisons of soil samples showed potential for differentiating them; however, not all soils could be completely separated.

With recent advances in technology, sequencing large quantities of DNA is both feasible and relatively inexpensive, making it a viable option for forensic utilization. In this study, soil samples from a wood lot, a marsh, and a yard were collected over time, and DNA was isolated. Using barcoded universal bacterial 16S rRNA primers, which allow for multiple samples to be sequenced and differentiated bioinformatically, the V4–V6 regions were amplified and sequenced using high-throughput pyrosequencing. Sequence files were processed using the software "mothur," where barcodes and sequences too short or with ambiguous base calls were removed, and informative sequences aligned. A square phylip-formatted distance matrix was produced showing the pairwise distances between each sequence in the data set with a cutoff of distances greater than 0.30. Bray-Curtis and Sørensen indices were also calculated to exemplify the compositional dissimilarity between the samples. Additionally, the sequences were clustered into operational taxonomic units, which are bins composed of sequences 97% or more similar, based on the average neighbor method.

Nonmetric Multidimensional Scaling (NMDS) and Principal Component Analysis (PCA) were employed to evaluate the reproducibility of the analysis, and to examine which was more appropriate for the data set. NMDS is a numerical ordination technique that searches for a true best solution to the explicitly chosen axes. It has advantages over PCA in that it does not assume linear relationships within the data and is outside the restraint of the eigenvalue-eigenvector technique. However, NMDS is limited in that, being a numerical technique, it allows the possibility of different outcomes under the same conditions, and may not identify the true best solution based on computational limitations. PCA is an analytical ordination technique that identifies relationships based on variance. The first principal component, or axis, is plotted to include the greatest variance within the data set. A second principal component is then plotted perpendicular to the first along the axis of the second greatest variance. More principal

components can be plotted; however, three is usually sufficient to elucidate relationships and more than three becomes difficult to visualize. PCA has advantages over NMDS in that the plot produced is easily understood and clearly illustrates relationships within the data set as well as reducing subjectivity in that axes are chosen based on the linear relationships in the data.

The ability to identify unknown soil samples via these techniques was then investigated. "Questioned" samples were picked blind from the original soil plots and processed as above. Based on both NMDS and PCA plots, the questioned samples were statistically included within the appropriate soil site. Likewise, samples 10 feet from the original collection sites were tested. The methodology proved useful for both assigning the origin of soil, and giving a percent confidence of association to that group. Plots designed by the software are easy to understand and explain in court. Furthermore, the addition of statistical confidence allows the technique to be more readily accepted as a reliable identification process, and helps meet *Daubert* considerations thus, this methodology has clear utility for forensic scientists.

Soil Identification, Multivariate Stats, DNA Pyrosequencing

A62 Internal Validation of the PowerPlex® Y23 Amplification Kit for Use in Forensic Casework

Jessica K. Tokarz, BS, 120 Riverview Dr, Barboursville, WV 25504; Scott C. Milne, BS, and Sarah E. Hardy, BS, Colorado Springs Police Dept, Metro Crime Laboratory, 705 S Nevada Ave, Colorado Springs, CO 80903; Pamela J. Staton, PhD, Forensic Science Center, 1401 Forensic Science Dr, Huntington, WV 25701; and Kathleen A. Mayntz-Press, MSFS, PO Box 6638, MD 1150, Phoenix, AZ 85005-6638*

After attending this presentation, attendees will understand the added advantage for using a Y-Chromosome Short Tandem Repeat (Y-STR) amplification kit in forensic DNA testing and the ability of PowerPlex® Y23 to perform effectively in the Colorado Springs Metro Crime Laboratory.

This presentation will impact the forensic community by demonstrating the robustness, reliability, and reproducibility of PowerPlex® Y23 in a forensic DNA laboratory setting through comparison with other commercially available Y-STR amplification kits and full validation.

Over the past decade, forensic laboratories have come to rely on commercially available Y-STR kits as a fundamental tool in forensic DNA casework where the identification of male specific DNA is essential. In an admixed sample, foreign DNA from a male is often masked by high levels of female DNA. Autosomal STR (short tandem repeat) analysis in admixtures often results in a DNA profile with major female alleles and minor male alleles. The minor male alleles are either difficult to distinguish from stutter peaks in the mixed profile or absent due to preferential amplification of the female DNA. However, the male-specific nature of Y-STR analysis allows for targeted amplification of male DNA with no amplification of female DNA, even when present in the mixture at high levels. Additionally, Y-STR analysis is advantageous in sexual assault cases involving multiple male assailants where autosomal STR analysis is ambiguous regarding the number of contributors to the mixture. Furthermore, Y-STR analysis is valuable in cases where mixed gender DNA cannot be segregated by differential extraction, such as evidence from azoospermic or vasectomized males and blood-blood or blood-saliva mixtures.

The initial stage of this study focused on the comparison of three commercially available Y-STR kits: the eleven loci PowerPlex® Y kit (Promega Corporation), the sixteen loci Yfiler™ kit (Applied Biosystems-Life Technologies), and the twenty-three loci PowerPlex® Y23 kit (Promega Corporation). Precision, sensitivity, and mixture interpretation capabilities were compared for the purpose of identifying the optimal kit for implementation at the Colorado Springs Metro Crime Laboratory. In these comparisons, all three kits demonstrated comparable performance in precision and mixture interpretation. On the other hand, PowerPlex® Y exhibited superior sensitivity over Yfiler™ and PowerPlex® Y23, with less allelic drop out at DNA target concentrations below 0.125ng/µL. Despite an increase in allelic drop out at low concentrations, however, Yfiler™ and PowerPlex® Y23 exhibited an increase in the number of allele calls overall compared to PowerPlex® Y at the same concentrations. PowerPlex® Y23 provided significantly more allele calls for all concentrations tested and was therefore chosen for full internal validation.

During internal validation, PowerPlex® Y23 was examined for precision, sensitivity, mixture interpretation, stutter, analytical and stochastic thresholds, reproducibility, concordance, and contamination. Precision of the 3130 AB Genetic Analyzer using PowerPlex® Y23 was evaluated using an allelic ladder. The average standard deviation for each allele at all loci was calculated. All loci as well as all alleles within each locus exhibited an average standard deviation value less than 0.15, indicating compliance with the 95% confidence interval. Sensitivity data was collected for DNA target concentrations of 0.0312, 0.0625, 0.125, 0.25, 0.5, 1.0, and 2.0ng/µL with amplicon loads of 1, 2, and 3µL at injection times of two, five, and ten seconds. For standard run parameters of 1µL amplicon load and a five second injection, the target DNA concentration range capable of producing a full profile was 0.125 to 2.0ng/µL. However, the recommended target DNA concentration range is 0.5 to 1. 0ng/µL. Increasing the amplicon load resulted in little success in generating additional allele calls where allelic drop-out had occurred. However, increasing injection time generally increased the number of allele calls, but did not result in a full profile at concentrations lower than 0.125 ng/µL. Decreasing the injection time from five to two seconds successfully decreased pull-up and extraneous artifacts in overloaded samples. Previously extracted non-probative samples as well as DNA standards were used to determine reproducibility and concordance. Since the Colorado Springs Metro Crime Laboratory does not currently perform Y-STR typing, each sample was amplified using Yfiler™ and PowerPlex® Y23. All samples produced reproducible results, and all alleles shared between Yfiler™ and PowerPlex® Y23 kits exhibited 100% concordance.

Y-STR, Forensic DNA Testing, PowerPlex® Y23

A63 A Study of Recombination Between 15 X-Chromosomal Short-Tandem Repeat Markers in Multigenerational Family Pedigrees

Toni M. Diegoli, MFS, 115 Purple Heart Dr, Dover AFB, DE 19904; and Michael D. Coble, PhD, 100 Bureau Dr, MS 8312, Gaithersburg, MD 20899-8312*

After attending this presentation, attendees will have a better understanding of the considerations involved in utilizing multiple Short Tandem Repeat (STR) markers located on the X chromosome after viewing the results of an NIJ-funded study into the recombination rate of 15 X chromosomal STR (X STR) markers that have previously been shown to be highly polymorphic in United States populations.

This presentation will impact the forensic science community by providing an understanding of how the organization of 15 X STRs across the chromosome affects their practical application in the forensic laboratory while increasing awareness of their potential utility. In addition, this presentation will describe one of the hurdles that must still be addressed for this marker system prior to routine use, prompting other scientists and laboratories to contribute to the accumulation of this important foundational data.

X-chromosomal STR (X STR) markers have recently been recognized as useful tools to supplement traditional kinship testing in the forensic setting. Development of assays allowing the multiplex detection and analysis of various combinations of X STRs has spawned numerous publications reporting the standardization of repeat structure and distribution of allele frequencies in a number of populations across the globe. However, far fewer studies have been published exploring the

practical implications of utilizing markers located on a single chromosome.

According to the 1991 report of the International Society for Forensic Genetics (ISFG; formerly ISFH (Hameogenetics)) relating to the use of DNA polymorphisms in paternity testing, questions of independent assortment must be addressed for any forensic marker system. For autosomal STRs, this ensures that the product rule can be used to multiply individual marker frequencies together to determine the overall rarity of a profile. It does not preclude the use of linked markers, however, Y chromosomal STRs, for example, are linked to one another and are considered together as a group called a haplotype. Haplotype frequencies are measured directly from population data, and the counting method is used to determine the rarity of the profile. It follows that X chromosomal STRs may require a combination of the two techniques: the organization of several physically close markers into linkage groups, forming haplotypes, whose frequencies could then be multiplied together once independent assortment of the groups or "blocks" was established. Early linkage studies produced a map of the X chromosome that divided 16 X chromosomal STRs into four linkage groups and most subsequent studies have employed this model when considering markers to include in novel multiplexes as well as a currently available commercial X STR kit.

At the Armed Forces DNA Identification Laboratory, two multiplexes consisting of a total of 15 X STR markers (DXS 89, DXS9902, DXS7132, DXS7130, DXS6795, DXS10147, DXS8378, DXS7423, HPRTB, DXS101, DXS7424, GATA31E08, GATA172D05, GATA165B12, and DXS6803) have been characterized and allele frequencies determined for several different populations. In order to evaluate the organization of these markers into the four proposed linkage groups, 58 families (832 individuals) satisfying the requirements of linkage study (multiple generations and offspring) have been acquired and investigated. In this presentation, the results of this NIJ-funded study, demonstrating recombination between markers within the same proposed linkage group as well as confirming a mutation rate for X STRs on the order of 10^{-4} will be presented. These results confirm the hypothesis that for these 15 markers, recombination is not a negligible factor in the statistical interpretation of an association between individual and/or family profiles.

Recombination, Linkage, X STRs

A64 Cell Surface Hydrophobicity of Biothreat Agents: A Novel Forensic Signature for the Attribution of Microbial Biocrimes

Jessica M. Haithcock, BS, 6006 Sugarbush Dr, Richmond, VA 23225; Cristina Stanciu, and Gabrielle Vita, 1015 Floyd Ave, Rm 2015, Richmond, VA 23284; and Christopher Ehrhardt, PhD, 1015 Floyd Ave, Grace E. Harris Hall South, Rm 2014, Richmond, VA 23112*

After attending this presentation, attendees will understand the significance of the growth medium composition on bacterial signatures, the analytical considerations for microbial hydrophobicity assays, and the forensic issues associated with microbial threat agent identification and characterization.

This presentation will impact the forensic science community by introducing a new technique that can assist future biocrime investigations. Because an organism's hydrophobicity phenotype is influenced by taxonomy and the laboratory conditions used for culturing, analyzing these signatures may help provide leads and/or exclude suspects during a forensic investigation.

The Amerithrax investigation in 2001 highlighted the need for forensic signatures that can rapidly identify a threat agent and determine the laboratory in which it was cultured. Since 2001, many methods have been developed to identify the species or strain of organisms in evidence recovered from a biocrime; however, few forensic signatures exist that indicate the culturing conditions of a threat agent and, therefore, the lab of origin. The few signatures that do exist require significant amounts of sample (~$1x10^6$ cells) that is often prohibitive in a forensic investigation. Most strikingly, there are no analytical techniques that simultaneously provide both types of information.

One promising strategy for addressing this need is analyzing an organism's cell surface hydrophobicity. The surface hydrophobicity of microorganisms is influenced by the proteins, lipids, and carbohydrates present on the membrane. The presence of these extracellular substances is affected by the nutrients in the growth medium and varies between culturing environments (i.e., different laboratories). Procedures for measuring bacterial hydrophobicity are well documented and include microbial adhesion to hydrocarbons (MATH) and hydrophobic interaction chromatography (HIC). These techniques are rapid (<10min per sample), relatively inexpensive, and simple to execute. Despite these advantages, MATH and HIC have never been applied biothreat agents in a forensic context.

The goal of this study was to test whether the cell surface hydrophobicity could be used to determine the species/strain of an organism, the cell type (vegetative or spore cell), and the growth conditions used to cultivate an unknown organism (*e.g.,* peptone- or tryptone-containing medium). The following organisms were used for all experiments: *Bacillus cereus* T-strain (*BcT*) vegetative cells, *BcT* spores, and *E.coli*. The cell surface hydrophobicity of each sample was measured using MATH and HIC techniques. For the MATH assay, spectrophotometric absorbance was measured for the initial and final cell concentrations of the bacteria suspended in 1xPBS that had been mixed with equal volumes of hexadecane. The HIC assay involved applying the bacterial suspension (in dH_2O) to a HP Ion Exchange column and measuring the proportion of microbes adhering in the column.

Results from the MATH assay showed that *E.coli* has a higher surface hydrophobicity than *BcT* vegetative cells (30% and 16% adhesion, respectively). In addition, *BcT* spores had a higher affinity for hexadecane than *BcT* vegetative cells (57% and 16% adhesion, respectively). *BcT* spores grown in six different medium formulations showed little variation in hydrophobicity with all samples ranging between 60% and 70% adhesion to hexadecane. ANOVA analysis of the MATH data confirmed that there were no significant differences in hydrophobicity across the six growth media types.

Results from the HIC assay also showed *Escherichia coli* and *Bacillus cereus* vegetative cells had different levels of hydrophobicity, 25% and 50% retention in the column, respectively. In addition, *BcT* spores had an affinity for the HP Ion Exchange approximately 20% higher than *BcT* vegetative cells (51% and 61% retention, respectively). An increase of ionic concentration of the suspension increased the affinity of the *BcT* spores by approximately 25%. This suggests *BcT* spores are sensitive to ionic interactions on cell surface and functionalized substrates. Given that sporulation media differs in nutrient and metal availability, the HIC assay may be a good indicator of culturing conditions. Since the MATH assay was demonstrated useful for species identification and discrimination between cell types, the combination of these two hydrophobicity assays may be a powerful technique for forensic characterization of unknown organisms in a suspected biocrime.

Bacillus Cereus, Biocrime, Hydrophobicity

A65 Maximizing mtDNA Testing Potential With the Generation of High-Quality mtGenome Reference Data

Rebecca S. Just, MFS, 1413 Research Blvd, Bldg 101, 2nd Fl, Rockville, MD 20850; Melissa K. Scheible, MFS, 15245 Shady Grove Rd, Ste 335, Rockville, MD 20850; Spence A. Fast, MS, Kimberly S. Andreaggi, MFS, and Jennifer L. Higginbotham, MFS, 115 Purple Heart Dr, Dover AFB, DE 19902; Elizabeth A. Lyons, MFS, 7320 N Canal Rd, Lansing, MI 48913; Jocelyn M. Bush, MSFS, Michelle A. Peck, MFS, and Joseph D. Ring, MS, 115 Purple Heart Dr, Dover AFB, DE 19902; Toni M. Diegoli, MFS, 115 Purple Heart Dr, Dover AFB, DE 19904; Alexander W. Röck, PhD, and Walther Parson, PhD, Muellerstraße 44, Innsbruck, AUSTRIA; and Jodi A. Irwin, PhD, 1413 Research Blvd, Bldg 101, 2nd Fl, Rockville, MD 20850*

The goals of this presentation are to inform attendees of the need for complete mtGenome reference data for forensic applications, and to report an automated, high-throughput laboratory processing workflow for the generation of high-quality mtGenome haplotypes.

This presentation will impact the forensic science community by developing mtGenome reference data, which meet the highest forensic standards, and making the data publicly available via a web-based search engine to permit their use for forensic casework.

Mitochondrial DNA (mtDNA) testing in the forensic context requires appropriate, high-quality population databases for estimating the rarity of questioned haplotypes and, in turn, the strength of the mtDNA evidence. Since 2003, the Armed Forces DNA Identification Laboratory has been systematically generating mtDNA data to augment available reference population data and, ultimately, to improve the framework upon which forensic mtDNA typing is based. These data; however, and indeed all available forensic mtDNA reference databases (SWGDAM, EMPOP), only include information from the control region (CR). While this information is obviously strengthening the foundation upon which current mtDNA identification efforts are based, these data do not adequately prepare the field for the recent and rapid advancements in mtDNA typing technologies that will soon facilitate the acquisition of entire mitochondrial genome (mtGenome) information from forensic specimens. Novel assays that quickly and easily access mtDNA coding region data for increased discrimination are now available in the form of single nucleotide polymorphism assays, sequence specific oligonucleotide strips, mass spectrometry instrumentation, and next generation sequencing technologies.

Currently; however, there is a lack of appropriate, randomly-sampled and high-quality entire mtGenome reference data suitable for forensic comparisons. Thus, this funded project intends to: (1) increase the large-scale availability of high-quality entire mtDNA genome reference population data; and, (2) improve the information technology infrastructure required to access/search mtGenome data and employ them in forensic casework. The specific goals and objectives of this large-scale databasing effort are the development of 450 complete, high-quality mtGenomes spanning three U.S. population groups, and structure and query modifications to the publicly-available EMPOP database.

To assure the generation of the highest quality mtGenome profiles, a laboratory processing workflow in which nearly all pipetting steps — from initial sample placement through sequence detection — are performed robotically, and employing a rigorous data review process. Amplification of the complete mtGenome is achieved via eight overlapping fragments, with a total of 11 samples (and the appropriate negative controls) amplified per 96-well plate. Each mtGenome is then sequenced in 135 reactions, providing redundant and overlapping forward and reverse sequence coverage across the entire molecule. This optimized, highly automated protocol reduces overall data generation costs, hands-on laboratory time and — most importantly — opportunities for human error by substantially decreasing the number of manual production steps and the extent of sample reprocessing necessary to construct complete mtGenome haplotypes.[1] The data review process follows a strategy previously used for the production of high-quality mtDNA CR sequences, which includes raw data review by no fewer than three scientists, and entirely electronic data transfer with two additional profile reviews.[2] To further assure data reliability, completed mtGenome haplotypes are compared to PhyloTree to confirm phylogenetic consistency across the eight amplicons.[3] In addition, private mutations, heteroplasmies, and transversions are re-reviewed in the raw data.

The presentation will describe the application of this workflow to the development of more than 200 complete mtGenomes from anonymized blood serum samples as part of the NIJ-funded databasing effort. The workflow reliably produced high-quality data from DNA inputs down to at least 10 pg, and the majority of samples did not require any manual reprocessing to generate complete haplotypes. The efficacy of automated processing combined with a rigorous data review strategy in preventing errors with this multi-amplicon protocol was evident from the absence of problems detected at the stage of phylogenetic data evaluation. Ultimately, this project will provide the forensic community with reliable, complete mtGenome reference data and a means to access, search, and use the data in forensic casework.

Mitochondrial DNA, Reference Data, Data Quality

A66 New Strategies to Overcoming PCR Inhibition Using Mutant Taq Polymerases and PCR Enhancers

Hanna J. Bennett, BS, 375 S 9th St, Box 2654, San Jose, CA 95112; Hillary B. Nguyen, 1912 Bluewood Cir, San Jose, CA 95132; and Steven B. Lee, PhD, San Jose State Univ, 1 Washington Sq, Macquarrie Hall 521, San Jose, CA 95192*

After attending this presentation, attendees will gain an understanding of how inhibitors found in DNA extracts such as phenol-chloroform, humic acid, collagen, and calcium affect Polymerase Chain Reaction (PCR) amplification, and whether mutant Taq DNA polymerases and PCR enhancers will aid in overcoming the inhibition to recover a DNA profile.

This presentation will impact the forensic science community by providing potential strategies to overcome PCR inhibition that may be found in low template, low quality DNA samples such as samples resulting from degraded skeletal remains. Selection of amplification strategies and downstream methods, such as the inclusion of PCR enhancers and/or new mutant Taq polymerases, will likely improve typing on crude, inhibited samples encountered in missing person, mass disaster, and cold cases.

Since its introduction in the mid-1980s, the use of DNA profiling in forensic science has revolutionized the justice system on a worldwide scale. DNA profiling is comprised of multiple steps and procedures including DNA extraction, quantification, and amplification using PCR. PCR has permitted the analysis of very low quantity, low quality DNA samples. Crime scene samples, however, are often found in very poor condition and are often mixed with extraneous materials that may co-extract with the DNA.

There are several known, commonly encountered inhibitors to PCR: calcium, collagen; humic acid; hematin; melanin; indigo dye; detergents; and, phenol-chloroform used in DNA extractions. These inhibitors may interfere with the cell lysis or capture of components necessary for DNA extraction by causing DNA degradation and/or inhibiting DNA polymerase amplification of target DNA. A review on forensic implications of PCR inhibition was recently published.

Although the causes of PCR inhibition are still not fully known, three mechanisms have been proposed. These include: (1) binding of inhibitor to Taq polymerase; (2) blocking of amplification sites due to inhibitor-template binding; and, (3) decreasing processivity due to interaction of the inhibitor with Mg^{2+} cofactors or other components of PCR.

Detection and overcoming PCR inhibition are critical challenges faced by forensic molecular biologists and many others such as microbiologists studying soil samples, molecular evolutionary biologists studying ancient remains and preserved samples, molecular ecologists studying animal excrement, molecular pathologists studying preserved and mounted specimens, and molecular archaeologists and anthropologists studying ancient human remains. Commonly utilized methods for overcoming inhibition in the forensic DNA community include: (1) diluting the samples (thereby also diluting inhibitors in the sample); (2) additional cleaning of the sample by purification; (3) including additional DNA polymerase and Bovine Serum Albumin; (4) utilizing STR multiplexes that are inhibitor resistant such as Minifiler, Identifiler Plus, and Powerplex 16HS; and, (5) adding PCR enhancers.

In this study, a mutant Taq polymerase and two different PCR enhancers were tested for their ability to overcome inhibition: Omnitaq (DNA Polymerase Technologies); PCR enhancer cocktail (DNA Polymerase Technologies references 19 and 20); and, PCRboost (Biomatrica).

Omni taq is an inhibitor-resistant Taq polymerase mutant and PCR enhancer cocktail (PEC) consists of a mixture of nonionic detergent, L-caritine, D-(+) trehalose, and heparin. PCR and STR boost are proprietary enhancers from Biomatrica, Inc. Previous tests have shown improved amplification using PCRboost from DNA samples containing indigo dye, hematin, humic acid, and phenol chloroform.

This presentation explores the amplification enhancement of OmniTaq, PEC, and PCR boost on low quantity and low quality DNA samples that contain varying amounts of inhibitors (Phoh, humic acid, collagen, and calcium). Enhancement were evaluated on replicate 1, 0.5, and 0.25 ng samples with and without inhibitors at different concentrations using qPCR (Plexxor HY) and STR multiplex typing (Identifiler, Identifiler plus, Identifiler Direct, and Powerplex 16HS).

PCR Inhibition, Mutant Taq, PCR Enhancement

A67 Development of a Scorpion-Based Multiplex qPCR Assay for Pre-Screening Mixture Detection

Hope E. Parker, BS, 3212 Stuart Ave, Unit D, Richmond, VA 23221; Todd W. Bille, MS, Bureau of ATFE, Nt'l Laboratory Center, 6000 Ammendale Rd, Ammendale, MD 20705; Laura C. Oliver, BS, 1908 Moonwind Pl, Richmond, VA 23238; and Tracey Dawson Cruz, PhD, Virginia Commonwealth Univ, 1000 W Cary St, PO Box 842012, Richmond, VA 23284*

After attending this presentation, attendees will gain an understanding of the use of tri-allelic SNPs in mixture identification, how tri-allelic SNPs can be incorporated into existing qPCR multiplexes using Scorpion probes, and the importance of developing a pre-screening mixture detection assay for use in forensic casework.

This presentation will impact the forensic community by providing results of attempts to develop a qPCR multiplex capable of human quantitation, PCR inhibition, and mixture detection via tri-allelic SNPs. This work presents steps toward a pre-screening mixture assay that could help alleviate the low-level mixture deconvolution and interpretation issues faced by all forensic laboratories.

Mixture analysis of genetic profiles can be challenging for even the most experienced forensic DNA analysts. The interpretation and deconvolution of mixtures is only further complicated when the sample being analyzed is categorized as touch or contact DNA because one or both contributors' peaks often fall below the analytical threshold. Unfortunately, in the current workflow of forensic laboratories, mixture detection is not possible until the final interpretation of genetic profiles. Traditionally, forensic DNA mixtures are identified by the presence of three or more STR alleles at two or more loci. This identification method is not desirable because it is the last step in the workflow. The sample may have already been processed or consumed in such a way that analysts cannot go back and increase the input of DNA to STR amplification without significant modifications to the SOP. Previously, D1S80 and tri-allelic SNPs were evaluated for their ability to identify mixtures in a qPCR assay using the Lonza FlashGel® system for detection of alleles. Non-specific priming and gel resolution of heterozygous alleles, however, were problematic using this system. The development of a new Scorpion-based, 6-dye qPCR system for pre-amplification mixture detection could help alleviate these issues and improve both the mixture deconvolution and low-level DNA difficulties faced by forensic laboratories. Early knowledge of a mixture can provide an analyst with information that could alleviate sample consumption concerns, identify whether or not amplification input should be adjusted, and decide if surface swabs from the same item should be combined. The human DNA quantitation step provides an appropriate place to incorporate such an assay because it occurs early in the workflow and is easily multiplexed. The information allows analysts to meet the optimal DNA input range for amplification in an effort to avoid interpretation issues in the final genetic profiles. A molecular marker capable of incorporation into existing quantitation multiplex kits such as the Qiagen Investigator™ Quantiplex kit are tri-allelic SNPs. Tri-allelic SNPs are small in size, which is important in degraded samples, but also polymorphic enough to identify the presence of two individuals in a sample. Successful incorporation of tri-allelic SNPs into a quantitation multiplex requires an appropriate primer, probe, and detection system. Duplex Scorpion primers will be utilized and designed for tri-allelic SNPs rs5030240 and rs4540055 so that the primer covers the polymorphic region at the 3' end. Primers are tagged with a fluorescent molecule on the 5' end with each color corresponding to a particular SNP allele. This approach, under the correct amplification conditions, will allow for preferential amplification of the primer that is complementary to the SNP compared to the mismatched primers. Mixture detection will be possible with the interpretation of amplification curves using the Rotor-Gene Q thermal cycler, which has seven color channel detection capabilities. Initially, primer sets will be created for rs5030240 and rs4540055, and will be optimized separately in single source samples using the ABI 7500 thermal cycler. Next, primers will be multiplexed into a single amplification reaction and tested in single source samples using the ABI 7500. If successful, the primer sets will then be optimized using the Rotor Gene Q and eventually incorporated into the Qiagen Investigator™ Quantiplex kit. This multiplex will then be used to identify fabricated mixture samples and results compared with detection using the ABI 3130 genetic analyzer. It is expected that fabricated mixture samples will be identified using this system and that significant progress towards a multiplex capable of human DNA quantitation, assessment of PCR inhibition, and mixture detection will be made.

Mixtures, Tri-Allelic SNPs, qPCR

A68 Comparison Study of the QIAcube® to Manual Differential Separation: Man Versus Machine

Jessica M. Lowney, BS, 800 Miller Dr, Oregon, WI 53575; Mark Guilliano, PhD, 20524 Lansing Ter, Ashburn, VA 20147; Joshua Stewart, MSFS, 1401 Forensic Science Dr, Huntington, WV 25701; and Pamela J. Staton, PhD, Forensic Science Center, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will have a better understanding of the uses of QIAGEN's QIAcube®, and may be better able to decide whether it is an appropriate instrument for use in their laboratories.

This presentation will impact the forensic science community by helping an analyst to streamline his or her workflow, as well as increasing consistency between analysts in sexual assault processing.

Sexual assault is a serious public safety concern worldwide, with the resulting caseload backlog posing significant challenges for forensic science laboratories. Each sexual assault kit is likely to contain a number of samples with female-male mixtures on which a differential extraction must be performed. Differential extraction is the process of separating sexual assault victim epithelial cells from the perpetrator

sperm cells in order to obtain an assailant profile. Unfortunately, differential extraction is a lengthy process, requiring repeated pipetting and centrifugation. Furthermore, the quality and consistency of separation may be variable between individuals. Because of the reagent cost, time, and manual work involved in working with these cases, sexual assault backlogs have unfortunately become commonplace. In an effort to identify ways to reduce these backlogs and benefit a scientist's workflow, it is worth evaluating the qualities of automated processes. This study focused on determining the utility of the QIAGEN QIAcube® for differential separation of samples, and compared it to the current manual method. The QIAcube® was originally designed to extract nucleic acids and proteins, and it is capable of centrifuging, vortexing, pipetting reagents, and extracting a supernatant from a pellet. This study evaluated the QIAcube's® abilities, and a custom protocol, to perform differential separations on up to 12 mock sexual assault samples at a time. Experiments included a cross-contamination study using mixed female blood and semen; a sensitivity study based on a 1:3 serial dilution of semen, with and without female epithelial cells present; a reproducibility study, utilizing mixed female epithelial cells and semen; as well as a matrix or mock evidence study, consisting of a mixture of female epithelial cells and semen pipetted onto different fabric types and swabs. All studies were performed by a novice student using the QIAcube®. For comparison, the sensitivity and reproducibility studies were also performed by one or more experienced analysts, using a validated manual separation and wash procedure. Each method was evaluated with respect to cost-effectiveness, time efficiency, reproducibility, and sensitivity. The QIAcube® did prove to be a very efficient way to perform differential separations, with excellent sensitivity, and superior reproducibility. There was no sign of cross-contamination between samples, even though the tubes remain open all at once in the machine. Conversely, more reagents were wasted with the automated method. Furthermore, loading the instrument proved to be difficult at first; but it was easier to train a novice on the instrument than it was to train the novice to perform manual differential extraction. The instrument may not add hours of hands-free time, with the need to prepare the reagents and set up the instrument; however, it is possible to push "Go" and walk away for about 30 minutes while the machine performs all of the centrifuging and pipetting. Lastly, the factor of general human error—for example, bumping a tube and having to re-pellet sperm cells — is eliminated from the extraction process. In conclusion, the use of the QIAcube® has the potential to help a scientist work more efficiently simply by freeing an analyst or technician from repetitious pipetting and centrifuging.

Sexual Assault, Backlog, Automation

A69 Improved Extraction Efficiency of Human Mitochondrial DNA From Hair Shafts and Its Implications for Sequencing of the Entire mtGenome From a Single Hair Fragment

Erin S. Burnside, MS, Brittania J. Bintz, MSc, and Mark R. Wilson, PhD, Western Carolina Univ, 111 Memorial Dr, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will gain an understanding of a novel protocol for extraction of mitochondrial DNA (mtDNA) from hair shafts, learning how this improved extraction method, when coupled with whole-genome amplification strategies, can increase the discriminatory power of mtDNA analysis by providing sequencing data that extends to regions of the mtGenome that are not routinely analyzed in forensic science laboratories.

This presentation will impact the forensic science community by providing insight into how optimized extraction and whole genome pre-amplification methods for difficult sample types can improve the utility of mitochondrial DNA analysis using both traditional Sanger sequencing and next generation sequencing platforms.

Forensic scientists are often faced with the challenge of limited or degraded samples, where a full nuclear DNA profile may be difficult to obtain. In these instances, mitochondrial DNA (mtDNA) analysis can be particularly useful, as mtDNA is more easily recoverable from challenging sample types such as hair shafts and bone. Existing extraction protocols generally yield enough mtDNA from two centimeters of hair shaft to reliably sequence two hypervariable regions (HV1 and HV2) located in the non-coding control region of the mtGenome. However, HV1 and HV2 comprise only about 4% of the entire mtGenome. This, coupled with the fact that mtDNA is, by nature, less discriminatory than nuclear DNA, limits the current utility of mtDNA analysis. The main objective of this research is to maximize the mtDNA extracted from two centimeters of hair shaft so that more mtGenome sequence information may be obtained for comparison to a reference sample, leading to a higher discriminatory power of mtDNA analysis.

In this study, a novel method for extracting mtDNA from hair shafts is described, which combines traditional methods with two kit-based extraction methods (Qiagen® QIAamp® DNA Investigator and Applied Biosystems® PrepFiler® Forensic DNA Extraction Kits). Comparison studies were conducted as follows: 13 two-centimeter hair fragments were subjected to the traditional manual grinding/organic extraction method and 14 two-centimeter hair fragments were processed using the newly developed extraction method.[1] All purified hair extracts were quantified using a custom real-time quantitative PCR (qPCR) assay specific for human mtDNA.[2] Hair fragments processed using manual grinding/organic extraction yielded an average of 31,440 copies per extract (60µl elution volume), while those processed using the optimized method yielded an average of 270,100 copies per extract (50µl elution volume). Not only do these results indicate a consistent nine-fold increase in mtDNA concentration, but the optimized method is also less time-consuming and can be completed in approximately four hours.

Following optimized hair extraction, targeted PCR methods were used to prepare the mtDNA for traditional Sanger sequencing. Preliminary results indicate that 84.6% of the entire mtGenome can be amplified from a single hair extract using these methods. The resulting amplicons were sequenced on an Applied Biosystems® 3130*xl* Genetic Analyzer. In addition, mtDNA was enzymatically fragmented and tagged with adaptors using Nextera® XT DNA Sample Preparation Kit, and then sequenced using an Illumina® MiSeq® Personal Sequencer. Hair extracts were also subjected to whole genome amplification (WGA) using the Qiagen® RepliG® Mini Kit in an attempt to further increase the analyzable amount of mtDNA for downstream applications. While previous efforts to pre-amplify mtDNA using various WGA methods were largely unsuccessful using extracts processed with manual grinding and organic extraction, a two-fold to 16-fold increase in mtDNA concentration has routinely been achieved when using extracts processed with the optimized method. WGA pre-amplified material was also fragmented using Nextera® XT DNA Sample Preparation Kit and sequenced using an Illumina® MiSeq® Personal Sequencer. Results of all Sanger and Next Generation sequencing studies were compared to reference sequences generated using blood or buccal samples obtained from donors and the Applied Biosystems® MitoSEQr™ Resequencing System protocol and will be presented.

mtDNA, Extraction, Sequencing

A70 Evaluation of PowerPlex® 18D and PowerPlex® 21 With Buccal Samples Collected on Non-Treated Paper

Daniel Watsula, MS, and Koya D. Reams, MSFS, 10430 Furnace Rd, Ste 107, Lorton, VA 22079; Lana L. Ramos, MS, 7378 Michigan Isle Rd, Lake Worth, FL 33467; and Jangbir Sangha, MA, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees understand how to achieve a high first pass success rate when performing direct amplification of 1.2mm or 2mm punches from buccal samples on non-treated paper with PowerPlex® 18D and PowerPlex®21.

This presentation will impact the forensic science community by demonstrating the feasibility of two new direct amplification kits for the processing of reference samples, exploring the feasibility of increasing the size of the standard punch from 1.2mm to 2mm for direct amplification.

The efficiency of reference sample processing for databasing and paternity purposes has been greatly increased by the development of direct amplification systems. DNA samples can be collected and stored on non-treated matrices, such as the Bode Buccal DNA Collector™, until sample processing is required. The Promega Corporation has recently released two direct amplification kits, PowerPlex® 18D and PowerPlex® 21 for samples collected on both treated and non-treated collection paper. This presentation will describe the studies with each amplification system to obtain optimal results from samples collected with the Bode Buccal DNA Collector ™.

Direct amplification of reference samples eliminates the need for the time-consuming extraction and quantification steps encountered in routine processing. Eliminating these steps will save time, but it can also lead to additional amplification reactions and costs as normalization does not occur. Cellular deposition varies from individuals resulting in either excessive or inadequate samples. Eating, drinking, medicine intake, health status, and non-cooperation during sample collection will all affect the number of cells deposited onto the collection paper. This variation in cellular deposition can either lead to over or under amplification if the procedure is not optimized. Optimizing the amplification parameters to account for sample variation reduces re-sampling and re-amplification, while increasing the processing efficiency of the laboratory.

Evaluation studies optimized procedures for sampling, cell lysis, thermal cycling parameters, spectral calibration, and ABI Prism® 3130 Genetic Analyzer injection parameters for both PowerPlex® 18D and PowerPlex® 21.

These optimized parameters with PowerPlex® 18D resulted in a first pass success rate of >86% for a full 25µl reaction using a single 1.2mm punch. The remaining 14% failed internal quality standards due to either over amplification or capillary electrophoresis issues (spikes, migration, or ILS problems). Complete profiles were obtained from all one hundred (n=100) samples tested without re-sampling or re-amplification.

In addition to displaying the first pass success rate for a full reaction with PowerPlex 18D, this research demonstrated the first pass success rates for 1.2mm samples (n=100) in a 12.5µl half reaction incorporating and eliminating the 20-minute lysis incubation step.

The optimized procedures for obtaining a high first pass success rate for both full reaction (25µl) and half reaction (12.5µl) will be discussed when utilizing a single 1.2mm punch with the PowerPlex® 21 amplification system. When dealing with an aged sample, or a sample with poor cellular deposition due to one of the causes previously mentioned, a 2.0mm punch may produce better results. This presentation will display results for sample processing with 2.0mm punches with PowerPlex® 18D and PowerPlex® 21, instead of the standard 1.2mm punch. Increasing the punch size can increase the chances of obtaining a complete profile using the same parameters utilized on high-quality samples.

Direct Amplification, PowerPlex® 18D/21, Half Reaction

A71 Forensic Mixture Analysis: Pre-Emptive Separation of Whole Cells With Flow Cytometry and MHC Class I Allele Tagging

Lee M. Dean, BS, 6365 Elko Rd, Sandston, VA 23150; Jamie Sturgill, PhD, 1101 East Marshall St., Richmond, VA 23298; Sarah J. Seashols, MS, Virginia Commonwealth Univ, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079; and Christopher J. Ehrhardt, PhD, Virginia Commonwealth Univ, Dept of Forensic Science, 1015 Floyd Ave, Rm 2015, Richmond, VA 23284*

The goal of this presentation is to introduce a novel technique for the separation of complex biological mixtures of samples from multiple individuals using flow cytometry. Attendees will become familiar with Major Histocompatability Complex (MHC) Class I glycoproteins, the nature of antibody staining for cell isolation, as well as the basic principles of flow cytometry and how they will aid in the separation of complex mixtures.

This presentation will impact the forensic science community by providing an alternative approach to complex mixture analysis, one that physically separates an individual's cells from a mixture before STR amplification and analysis. This has the potential to produce multiple single source STR profiles from an evidentiary sample composed of two or more individuals in cases such as rape.

The MHC is an extensively studied region of genes that play a key role in the human immune system. It is divided into three major subgroups denoted by class I, II, and III, and has been found to be the most polymorphic region of genes yet to be identified. The forensic potential of this region lies in the multitude of alleles observed in the human population. MHC class I genes, which are the focus of this study, are referred to as the human leukocyte antigen (HLA) and are denoted by the classical HLA-A, HLA-B, and HLA-C; but may also include non-classical HLA-E, HLA-F, and HLA-G. Further, each HLA is defined by multiple subtypes, each with a unique allele grouping (e.g., HLA-A*02). MHC Class I molecules were chosen as the region of interest due to their expression on all nucleated cells. This is in contrast to more heavily researched alleles in the MHC region such as HLA-DQα, a class II molecule that lacks expression in semen. This presentation aims to describe how polymorphisms within the MHC Class I region can be used to separate individuals from an evidentiary sample using flow cytometry, a technique widely embraced by both the medical and research communities.

For this research, the goal was to take advantage of these MHC features to develop a new forensic technique that utilizes fluorescently tagged HLA antibodies specific for allele subgroups to differentiate individual contributions to a biologic mixture. Antibodies for the classical HLA alleles (ABC) were used to tag blood, semen, and epithelial cells from several different donors. Results show that the levels of MHC expression vary among all biological fluids tested. Blood, with the highest expression, resulted in 81% of all cells being separated from negative controls. Semen, with the lowest expression, produced 8.1% positive selection. It was found that flow cytometry is a fast, economical, and efficient way to separate whole cells from a mixture. It has also been shown that the prevalence of HLA molecules produces strong immuno-staining characteristics that are clearly distinguishable from controls. Initial experiments indicate that flow cytometry is a viable option for forensic mixture separation and could be quickly integrated into a forensic laboratory due to the availability of flow cytometers in nearly all major hospitals and research facilities. Physical separation of cells prior to cell lysis offers numerous advantages over trying to decipher complex electropherograms prior to SNP and STR analysis. Initial research into this technique could provide an alternative for the analysis of common biological samples.

Flow Cytometry, Biological Mixture, MHC Class I

A72 Detection of Male DNA in the Vaginal Cavity Following Digital Penetration Using Y-Chromosome Short-Tandem Repeats

Kayla R. Sween, BS, 639 Fox Farm Rd, Asbury, NJ 08802; and Janine Kishbaugh, MS, and Gina Hampson, MS, Cedar Crest College, Forensic Science Program, 100 College Dr, Allentown, PA 18104*

After attending this presentation, attendees will understand the value of collecting sexual assault forensic evidence (SAFE) kits from child sexual assault victims and female victims who have been digitally (finger) penetrated. Attendees will also become aware of how analysis of vaginal swabs has been optimized with application of using Y-chromosome short tandem repeats (Y-STRs) to establish a time interval in which a deoxyribonucleic acid (DNA) haplotype can be obtained from vaginal swabs following digital penetration.

This presentation will impact the forensic science community by displaying the value of collecting evidence from sexually assaulted adolescents as well as females that report digital penetration.

Analysis of sexual assault cases can be challenging if there is no report of vaginal-penile penetration, and the difficulty of analysis increases as the time interval extends between the incident and the report. Sexual assault evidence kits are not commonly collected in the majority of cases if there is only a report of digital penetration; this is due to the belief that there will not be enough DNA from the perpetrator to be detected. The value of Y-STR genotyping has been previously established in sexual assault cases where autosomal short tandem repeats (STRs) are not suitable.[1] This allows for low copy number DNA from the male perpetrator to be detected, eliminates the need for mixture interpretation, and allows for a longer window of detection.

This study has determined that male DNA can be detected from swabs collected from the vaginal cavity following digital penetration. Initial samples analyzed prior to method optimization resulted in detection of 10 of 12 alleles. The purpose of this study is to optimize the methodology used to detect male DNA from the collected vaginal swabs. The second goal is to establish a time interval in which a meaningful Y-STR haplotype can be obtained post digital penetration and determine the likelihood ratio of obtaining Y-STR haplotypes at 1, 6, 12, 24, and 72 hours post-digital penetration.

The optimization of analysis included varying parameters of existing commercial protocols. A modification of a DNA IQ™ extraction protocol was used to maximize the initial concentration of DNA extracted from the vaginal swabs. Other modifications to the analysis method included the elimination of a quantitation step prior to amplifying the DNA extract using PowerPlex® Y to amplify only male DNA. Additional optimization steps included concentration of some of the DNA from the collected samples prior to amplification. Slight alterations to the capillary electrophoresis protocols were also made to maximize detection of the male DNA.

To obtain the samples that would simulate a sexual assault kit, male-female couples were asked to abstain from sexual activities for a given period of time prior to collection. The couples participated in vaginal-digital penetration for a discrete period of five minutes. Female participants collected four swabs prior to penetration as a control, and four swabs at each of the five time intervals. The vaginal swabs were then processed using the optimized protocol from above to allow for the greatest detection of male DNA. To date, results have shown that full PowerPlex® Y profiles have been obtained from vaginal swabs collected one hour following consensual digital penetration

Y-STR, Sexual Assault, Digital Penetration

A73 Application of Pressure Cycling Technology (PCT) in Differential Extraction

Deepthi Nori, MFS, 1260 SW 104th, Apt 209, Miami, FL 33174; and Bruce R. McCord, PhD, Florida Int'l Univ, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the principles behind a rapid and efficient method of extracting sexual assault evidence using a pressure-based protocol that is designed to burst open and extract DNA from male sperm cells in rape kits or other mixed forensic stains.

This presentation will impact the forensic science community by providing a better understanding of how the application of pressure pulsing can be used for more specific detection of individual cells that will enable rapid and selective processing of sexual assault evidence.

Separating the sources of DNA from different contributors to a stain reduces the difficulty associated with mixture analysis and data interpretation. The processing and interpretation of such mixed DNA samples has long been recognized as a bottleneck in forensic DNA analysis. Organic differential extraction is the most commonly used method to isolate sperm DNA from sexual assault evidence. This two-step extraction procedure involves selective digestion of epithelial cells in the first step, followed by isolation and digestion of sperm cell pellet. The major disadvantages of this technique are incomplete separation of sperm and non-sperm fractions, particularly in samples that are overwhelmed by large numbers of female epithelial cells relative to sperm cells, and the time-consuming nature of the process.

The objective of the study was development of a method using Pressure Cycling Technology (PCT) combined with reagents to selectively disrupt sperm or epithelial cells and recover DNA. The extraction procedure is performed utilizing the Barocycler® NEP 2320, a commercially available instrument from Pressure Biosciences, Inc., equipped with a hydrostatic pressure chamber that generates alternating cycles of ambient and high pressures with a range of 5 to 45 kpsi. Samples such as cotton swabs or cuttings of cloth can be directly extracted using this technique by simply placing them in a pressure cell along with an appropriate buffer.

The current study involves the application of pressure cycling technology in the selective digestion of sperm cells from evidence mixtures collected from different substrates with an emphasis on the role of buffer composition on sperm DNA yields and increase in selectivity of extraction. The cells were extracted into 1X PBS buffer (pH 7.4) with varying buffer compositions and subjected to a pressure of 45,000 psi. This pressure treatment was followed by phenol chloroform isoamyl alcohol purification to obtain a clean DNA sample devoid of salts and proteins for successful downstream analysis. The purified DNA was quantified with Promega Plexor® HY system followed by an STR analysis using Promega PowerPlex® 16 HS system.

The results indicate that selective extraction of sperm DNA is possible from mixtures in the presence of appropriate buffers. These observations were applied to different substrates and mixtures with varying ratios of sperm and epithelial cells to determine the selectivity of the extraction. The quality of the DNA recovered from pressure treatment was assessed by performing STR analysis using Promega PowerPlex® 16 HS system. Preliminary data indicate the potential of PCT application in analyzing samples from sexual assault cases, in particular, indicating improved extraction of sperm DNA at high pressures when compared to epithelial cells.

Differential Lysis, Pressure, Sexual Assault

A74 An Evaluation of MicroRNA Stability and Internal Standard Selection for Forensic Body Fluid Identification

Sarah J. Seashols, MS, Virginia Commonwealth Univ, Dept of Forensic Science, 1101 E Marshall St, Richmond, VA 23284-3079; William T. Budd, PhD, Virginia Commonwealth Univ, School of Medicine, Dept of Biochemistry, 1101 E Marshall St, Richmond, VA 23298-0551; and Zendra E. Zehner, PhD, Virginia Commonwealth Univ, Dept of Forensic Science, 1101 E Marshall St, Richmond, VA 23298-0551*

After attending this presentation, attendees will gain an understanding of microRNA expression in biological fluids, specifically, the advantages of microRNA analysis as a potential method of forensic body fluid identification.

This presentation will impact the forensic science community by familiarizing scientists with the concept of microRNA analysis for body fluid identification purposes, a relatively new area of research in forensic science, focusing on the stability of microRNA targets after being subjected to contamination and physical treatment conditions similar to those seen in crime scene evidence.

While forensic DNA analysis has reached a level of maturity in the forensic science field with regards to the sophistication of the techniques and confidence in the results, the equally important question of body fluid identification has lagged behind, and could still be considered to be in a primitive state. While there is widespread confidence in the DNA profile generated, there is often significantly less assurance of the identity of the body fluid from which the DNA profile was developed. It is common during trials for attorneys to categorically accept the STR analysis, but probe the forensic scientist on the source of the DNA that generated the profile. Because of this dichotomy, significant efforts have been made over the past ten years in order to develop forensic serological techniques of a more discriminatory nature.

Recently, there has been some work in the forensic science field in regards to exploring microRNAs (miRs) for a molecular-based, forensic body fluid identification method. MiRs are small structures that specifically repress protein expression through binding to messenger RNA (mRNA) in the cytosol. There are no known postprocessing modifications, and thus miRs are simpler, and potentially less problematic for detection than proteins and mRNAs. Because of their small size and lack of a poly-A tail, miRs are inherently less susceptible to degradation than mRNA. Additionally, miRs are very hardy, and have been recovered from highly compromised samples including Formalin-Fixed Paraffin Embedded (FFPE) tissue. In serum, miRs have been shown to survive harsh conditions such as boiling, low or high pH, cycles of freeze-thaw, and extended storage. Moreover, there is considerable evidence that many miRs are encapsulated in an exosome, which, depending on the microRNA and the secretion process, could be membrane-based or protein-based. Because of this, recent studies have shown that samples can even be treated with RNase enzymes and the encapsulated miRs are still detectable. This implies a high degree of stability of the species, and therefore, a very good possibility that if body-fluid specific miRs are found and described, a very robust miR method for forensic body fluid identification could be developed.

Biological evidence is naturally compromised when it is left or deposited under nonsterile conditions of a variety of environmental factors and chemical contamination. This study evaluated microRNAs under environmental and treatment conditions that forensic evidence could be subjected to. Blood, urine, semen, and saliva were collected and samples exposed to chemical treatment, prolonged high temperatures, and multiple freeze/thaw cycles. No differences were observed in microRNA levels using qRT-PCR, regardless of the number of times the sample had been frozen and thawed. Similar results were observed with other treatment methods. Detection of various internal reference controls typically used as standards (RNU6B, SNORD48, etc.) were found to vary between body fluids, which could potentially complicate studies attempting to compare relative expression levels of target miRs between biological fluids. Evaluation of additional forensically relevant body fluids, as well as more candidate internal control miRs, should be evaluated before target miRs specific for each biological fluid can be chosen and evaluated for implementation.

MicroRNA, Semen, Blood

A75 Improved Discrimination of Duct Tapes Using Carbon and Hydrogen Isotope Ratio Variations in Duct Tape Polyester Web Fibers

Gerard J.Q. van der Peijl, PhD, PO Box 24044, The Hague, 2490 AA, NETHERLANDS; Ines Muegler, PhD, Laan van Ypenburg, Den Haag, 2497GB, NETHERLANDS; Wendy Verburg, MS, Cornelis de Wittlaan 8, 3211AG, Geervliet, NETHERLANDS; and Marianne Schrader, PEng, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague, 2497 GB, NETHERLANDS*

After attending this presentation, attendees will understand the forensic isotopic information contained in duct tape web materials.

This presentation will impact the forensic science community by providing additional isotopic tools for in-depth duct tape investigations.

At the Netherlands Forensic Institute (NFI), Isotope Ratio Mass Spectrometry (IRMS) is used in combination with other techniques (visual, FTIR, LA-ICP-MS, etc.) to investigate potential relations between different materials in forensic investigations. A prominent example material is (gray) duct tape as it is now commonly used in Dutch households and often found at crime scenes. If a visually similar tape is retrieved during, e.g., a search at a suspects home, a request is almost always made to compare the tape materials. If tapes are not discriminated using visual comparison (color, thickness, width) and FT-IR, other techniques such as LA-ICP-MS and IRMS are used to investigate chemical and isotope characteristics.

Duct tape mainly consists of three different layers: (1) a polyethylene backing film; (2) a network of cotton or polyester fibers (web); and, (3) an adhesive layer (glue, often isoprene based). The web is a network of cotton or polyester fibers usually woven with length and crosswise threads commonly referred to as warps and wefts, respectively.

Previous work has shown that isotope ratios (d13C and d2H) of the backing film isolated from the adhesive layer can be of value in making discriminations. The value of the forensic evidence is increased by considering isotope ratios (d13C and d2H) of the backing film in isolation from the adhesive layer. The background variation of carbon and hydrogen isotope ratios from the backing was evaluated using 44 duct tape rolls of major brands randomly purchased in the Netherlands (van Breukelen *et al*., 2010).[1]

To date, the NFI gray duct tape collection comprises 120 tape rolls. Results will be presented on the discrimination of these rolls based on the backing d13C and d2H ratios.

Secondly, the added forensic value of d13C and d2H ratios for the cotton/polyester layer in duct tapes will be demonstrated. Because the isotope discrimination between different batches produced during a short production period was weak using the backing material only, an analytical procedure was developed and validated to determine d13C and d2H from the isolated web material. The warp and weft threads are found to have, in general, different d13C and d2H values; differing e.g., up to 2.5% in d13C values. This difference may be explained by the manufacturing process where presumably raw materials from different sources or batches are used for warp and weft threads, providing an additional level of discrimination. The d13C and d2H isotope variation of warp and weft bundles, as well as within individual warp and weft threads, is shown to be insignificant.

Nineteen gray duct tapes were investigated using this web method. Using the additional isotope information of the warp and weft threads, 17 of these tapes could be discriminated.

Results will also be presented from the application of this web method to representative samples from seven production rolls provided by the Dutch producer “Supertape.” The samples from these rolls of

12m length (produced between March 21, 2007 and April 12, 2007 to manufacture small tape rolls) were indistinguishable based on their backing d13C and d2H isotope ratios. It will be evaluated how much discrimination improves if the d13C and d2H isotope ratios of the polyester web are included.

Duct Tape, Web, IRMS

A76 A Multichannel Microfluidic Cartridge for Rapid Forensic DNA Analysis

Brian Root, PhD, 705 D Dale Ave, Charlottesville, VA 22903; Jeffrey A. Hickey, MS, 10202 Palmer Glen Ct, Oakton, VA 22124; Carmen R. Reedy, PhD, and An-chi Tsuei, MS, 705D Dale Ave, Charlottesville, VA 22903; Michael Egan, BS, 9211 Corporate Blvd, Rockville, MD 20850; Robert Lovaglio, BS, Lawrence Dirks, MEng, and Orion Scott, PhD, 705D Dale Ave, Charlottesville, VA 22903; Douglas South, ME, 9211 Corporate Blvd, Rockville, MD 20850; Peter Trost, PhD, 9221 Corporate Blvd, Rockville, MD 20850; Darren Albert, BS, 9211 Corporate Blvd, Rockville, MD 20850; James P. Landers, PhD, Dept of Chemistry, McCormick Rd, Charlottesville, VA 22904; and Joan M. Bienvenue, PhD, 8801 General Griffins Ct, Fredericksburg, VA 22407*

After attending this presentation, attendees will understand the development and functionality of a system developed for fully-integrated microfluidic forensic DNA analysis.

This presentation will impact the forensic science community by demonstrating the advantages of using a microfluidic system for DNA analysis, including a reduction in analysis time, footprint of the microfluidic cartridge, and a reduction in consumables required for end-to-end analysis that ultimately will allow forensic scientists to process more samples.

STR typing is the accepted gold standard for human identification, and is now successfully employed in forensic, civil, and military laboratories. Although highly successful and reliable, the process typically requires 8-10 hours to complete under routine conditions, employs large sample volumes, costly reagents, and is labor-intensive. Additionally, samples are susceptible to contamination as they are exposed to the environment at multiple points during sample processing. Transitioning sample processing and analytical methods to the microscale format will permit automation, miniaturization, and integration, providing the end user a system capable of expedited, cost-effective analysis in a closed system that reduces sample handling and possible contamination.

Previously, a system capable of performing PCR and ME on a plastic chip following LE in a tube was presented. Although this system was capable of detecting 16-18 STR loci in <75 minutes, it required human intervention prior to PCR and was not capable of performing true end-to-end DNA testing.

The work presented here highlights improvements to the fully-integrated system. The transition to a plastic microfluidic cartridge for fully integrating sample preparation, PCR, and ME is described, and is the first step toward cost-effective analysis using a single-use chip with reagents on-board. With the improved system, expedited purification of DNA from crude samples is performed, and a mixture of DNA and commercially-defined PCR reagents are guided into chambers on a device for quadriplexed PCR analysis. Rapid amplification of 16-18 STR loci is achieved through use of an IR laser for non-contact heating and a non-contact method for temperature sencing. A six-fold reduction of the conventional amplification time is feasible while still achieving STR profile quality required for forensic interpretation. Simultaneous amplification of multiple samples is presented, demonstrating the capability of increased sample throughput. Following PCR, precise fluidic control allows for movement of the amplified product into the separation domain of the device. Electrophoretic separation of the amplified fragments is performed with five-color fluorescence detection using an improved detection system capable of multiplexed detection. Single-base resolution is achieved during a separation that requires <12 minutes, a three-fold time reduction from conventional separation and detection processes. A software system allows for all processes to be completed without user intervention, including automated and accurate allele calling of samples from multiple donors. An overview of the functionality of the integrated instrument capable of accepting the microfluidic cartridge will be presented, with data supporting the capability of the microfluidic system for rapid, automated, end-to-end genetic analysis for human identification.

DNA, STR, Microfluidic

A77 Development of an Integrated Microdevice for DNA Extraction and Amplification of Forensic Samples Using Infrared-Mediated Heating and Centrifugal Force

Teresa Sikes, BSc, 2612 W Main St, Apt 1, Richmond, VA 23220; Yiwen Ouyang, BSc, Hillary Sloane, BSc, and James P. Landers, PhD, Univ of Virginia, Dept of Chemistry, McCormick Rd, PO Box 400319, Charlottesville, VA 22904-4319; and Tracey Dawson Cruz, PhD, Virginia Commonwealth Univ, 1000 W Cary St, PO Box 842012, Richmond, VA 23284*

After attending this presentation, attendees will have a better understanding of the importance of micro-total analysis systems (μTAS) for forensic DNA applications, the challenges faced with integration, and the barriers to the adaption of macroscale work to a microscale format.

This presentation will impact the forensic science community by describing a conceptual integrated DNA extraction and amplification plastic microdevice for use in PCR analysis of STR multiplexes. This work presents a step toward a μTAS that eliminates the use of expensive processing and bulky external attachments.

The value of μTAS for forensic DNA analysis lies in the potential to reduce contamination by eliminating sample transfer steps, which contribute to sample loss and reduce the acquisition of a full STR profile. Additionally, cost and lab space required for equipment, reagents, and laboratory time and effort required to perform each step in preparation for analysis is reduced. The pioneering of two key technologies, infrared (IR)-mediated heating for PCR and DNA extraction via ZyGEM chemistry, has allowed for greater possibilities in the microfluidic analysis of DNA, especially for forensic samples. IR-PCR expedites amplification with 30 cycles completed in 30 minutes followed by established, successful detection, and separation of STR loci. ZyGEM offers faster reaction times, reduced sample handling, and elimination of PCR-inhibiting reagents, while maintaining performance equal to traditional methods, making it ideal for use in an integrated microdevice. The goal of this study is to integrate DNA extraction and amplification by exploiting these technologies onto a single microdevice utilizing a centrifugal platform. Previous work has accomplished integration with the use of valve systems requiring syringes, external pumps, and other bulky, expensive attachments. However, simple valves, such as hydrophobic and one-way, single-use valves can be employed on a centrifugal platform using various speeds to effectively direct flow. In addition, no barrels or column attachments are required as the swab cutting is added directly to the microdevice, with DNA elution accomplished with the addition of reagents and spin-directed flow to an extraction chamber.

In this study, a poly (methyl methacrylate) (PMMA) microdevice was designed for ZyGEM-based DNA extraction and amplification from a buccal swab. The microdevice was manufactured in-house by laser ablation and thermal bonding. The thickness of PMMA was chosen to minimize the thermal mass of the microdevice. Heating was provided by an IR-lamp positioned below the chip. Chip design and microfluidic optimization was accomplished through a series of dye tests: blue dye

represented DNA extract while yellow represented PCR reagents. Various spin times and speeds were tested to establish the optimum parameters. The design included ZyGEM elution and extraction chambers, valves for channel sealing and metering of extract and PCR reagents, and an IR-PCR chamber. One-way, single-use "tape" valves were used to stop back flow from the extraction and PCR chambers and prevent evaporation during heating. Tape valves exploit the properties of PCR film and double-sided tape to effectively close a channel providing single-use, one-way valves for metering and channel sealing. A hydrophobic valve, for metering, connected the extract reservoir to the PCR reaction chamber. This valve "opened" once the chip was spun at a velocity such that the centrifugal force exerted on the liquid forced it through the channel. The reservoir was designed to allow for accurate volume delivery of the extract in the previously determined extract: PCR master mix ratio. PCR reagents were loaded on the microdevice and directed into the PCR chamber with the extract. Accurate metering was necessary to achieve the appropriate proportions of PCR master mix to DNA extract for successful PCR. The centrifugal platform was chosen to increase throughput (two chips must spin simultaneously to balance the system; multiplexing with four or more chips is possible) and to minimize manual interaction with the device. After establishing microfluidic control for the integrated device, ZyGEM and PCR chemistry, on-chip with IR-mediated heating, will be optimized for buccal swabs. The results of the micro-extraction and amplification will be compared to a tube-based ZyGEM extraction, followed by traditional PCR amplification via a block thermocycler.

The preliminary results suggest accurate metering can be achieved on a centrifugal platform with this newly designed integrated device. Successful integration in this system, coupled with the ease of fabrication, promotes progress towards a simple sample-in, answer-out microdevice.

Integration, Centrifugation, Microdevice

A78 Integrated Direct Amplification and Hybridization-Induced Aggregation for End-Point Detection of the Human TPOX Locus From Whole Blood

Briony C. Strachan, MSci, Hillary Sloane, BSc, Jacob C. Lee, and James P. Landers, PhD, Univ of Virginia, Dept of Chemistry, McCormick Rd, Charlottesville, VA 22904*

After attending this presentation, attendees will gain an understanding of the development of single chamber, direct amplification of whole blood, followed by label-free visual detection of the product through hybridization-induced aggregation (HIA).

This presentation will impact the forensic science community by introducing a microfluidic method that presents the possibility for the direct amplification of the TPOX locus for the rapid verification of the presence of human blood. This work demonstrates the use of a micro-total analysis system for forensic onsite analysis.

Microfluidic devices offer numerous advantages to current forensic analyses, including low sample consumption and a reduction in analysis time, combined with the ability to deliver a closed "sample in-answer out" multi-process system within a single device, preventing sample loss and contamination.[1] Microfluidics presents an eventual economical option, with the ability to rapidly fabricate plastic microdevices using CO_2 laser ablation. In addition, using infrared-mediated heating and fan-assisted cooling, PCR is completed in half the conventional time, with instrumentation costing a fraction of that for a block thermocycler.[2] Progress toward a fully-integrated device has become simpler with the recent development of direct blood amplification, enabling the removal of the DNA extraction domain within the microdevice.

Here, a master mix capable of this chemistry, combing a commercially-available neutral proteinase and *Pwo* DNA polymerase, enabling customization of the components is presented. Initially, this was demonstrated in a conventional 25µL tube PCR reaction, amplifying the TPOX allele using 1µL of whole blood as the template. The PCR product was separated on a microchip electrophoresis platform, demonstrating successful amplification of the alleles within the TPOX locus. Since *Pwo* is a high-fidelity polymerase, no non-specific amplification was observed, which was seen as problematic with an alternative direct blood PCR kit. In addition, the successful amplification of the TPOX locus was achieved from 1µL blood stains on filter paper, cotton, cotton-polyester, and demin substrates. To confirm this amplification was human-specific, blood samples from a rhesus monkey, a rabbit, a mouse, and a dog were processed in the same manner, resulting in no peaks, confirming the specificity of the assay for human samples.

Translating this direct tube-based PCR method to a microdevice has the potential to significantly decrease the time required for the reaction, and if this could be linked to a label-free read-out, integration would allow for immediate results without further sample handling. Recently, a visual, label-free end-point detection that utilizes hybridization of biotinylated oligonucleotide probes bound to 1µm streptavidin-coated paramagnetic particles to the complementary (target) sequence was reported.[3] A rotating magnetic field agitates the particles, exposing the bead-bound oligonucleotide for hybridization to the target sequence to form an aggregate; visual detection of the aggregates confirms the presence of the target DNA. This is visually distinguishable from sample without target DNA where the particles remain dispersed. Cellular debris associated with the enzyme-based DNA liberation step did not result in any false aggregation, confirming that the particles only aggregate when adequate target copies are available as a result of successful amplification. This circumvents the requirement for fluorescent tags, an amplicon separation step, and skilled labor, while providing a highly sensitive, accurate method for specific DNA sequence detection in less than two minutes.

In summary, the rapid detection of a fragment of the TPOX gene directly from whole blood on a single device is facilitated by a microfluidic network that links the PCR and an aggregation domain, and requires no external apparatus to control fluid flow. This work presents a total micro analysis system, capable of identifying the presence of the TPOX allele from human blood using a plastic microdevice, integrating single chamber, infrared-mediated, direct PCR and visualized aggregation, in 60 minutes.

Direct PCR, Microdevice, Human Identification

A79 Development of a Direct Amplification Method for Exemplar and Pseudo-Exemplar Reference Samples Using Identifiler® Plus

Ashleigh Zeile, BS, 1328 Neel St, Huntington, WV 25701; and Mechthild K. Prinz, PhD, and Theresa A. Caragine, PhD, OCME, Dept of Forensic Biology, 421 E 26th St, New York, NY 10016*

The goal of this presentation is to explore methods of direct PCR amplification for processing exemplar and pseudo-exemplar reference samples.

This presentation will impact the forensic science community by evaluating methods of direct PCR amplification that eliminate the need for purification and quantitation, greatly reducing the time and cost for analysis, offering DNA analysts a more effective means of processing reference samples.

Pilot studies comparing the AmpFℓSTR® Identifiler® Direct PCR Amplification Kit and AmpFℓSTR® Identifiler® Plus PCR Amplification Kit were conducted to determine which amplification system best fits the needs of the Office of Chief Medical Examiner of New York City. The goal of these experiments was to establish a standard protocol that will account for variability of DNA amounts among reference samples.

Identifiler® Direct is a PCR amplification kit optimized for amplifying blood samples spotted onto FTA® cards that have not been extracted or quantified. Use of non-FTA® collection methods, according to Applied Biosystems (ABI), requires pretreatment with Prep-and-Go Buffer™. To potentially bypass this step, various sampling techniques and thermal cycling parameters were tested. The ABI GeneAmp® PCR System 9700 thermal cycler and the ABI 3130xl Genetic Analyzer were used for amplification and separation, respectively, and all data was analyzed with GeneMapper® ID v3.2.1. Initial results showed that partial profiles were obtained for buccal samples and non-FTA blood cards. These profiles displayed many N-bands. Due to the additional time required to process samples using the Prep-and-Go Buffer™, other less costly amplification kits were then considered.

Another method of direct PCR amplification utilizes Identifiler® Plus, which is optimized to overcome inhibition. The chemistry of the kit enables unpurified extracts to be directly amplified. Buccal swabs and blood spotted onto Whatman® non-FTA® paper were incubated in 0.2% Tween® 20, 0.1mg/mL Proteinase K, and 2.4% Trehalose in TE^{-4} for 30 minutes at 56°C followed by five minutes at 99°C. An aliquot of neat extract was directly amplified using a half reaction of Identifiler® Plus (5.0µL Reaction Mix, 2.5µL Primer Set). Experiments with various cutting sizes, extraction volumes, aliquots for amplification, and thermal cycling parameters were conducted using samples containing a wide range of DNA. In order to generate results for all samples, the 29-cycle protocol was implemented. In addition, the final elongation time was increased to 60 minutes to minimize N-bands observed at Amelogenin only. Full profiles were obtained for all samples tested with only 30% of the samples needing an additional injection on the 3130xl Genetic Analyzer at lower parameters due to oversized peaks.

Reproducibility, sensitivity, and stability were also evaluated. A large number of different donors were tested, each in duplicate on different days and using different instruments. To decrease the amount of DNA collected, donors were instructed to abbreviate the amount of time they swabbed their mouths. More controlled sensitivity studies with known amounts of DNA were also performed. In order to compromise buccal specimens, swabs from previously tested donors were stored under accelerated aging conditions. Although for most samples, protocol adjustments were unnecessary, in a few cases with very low yields of DNA, the amplification aliquot volume was increased.

Methods were also optimized for pseudo-exemplar samples such as bottles, cans, cups, straws, cigarette butts, and chewing gum. One uniform protocol that encompassed all of these sample types was developed with the exception of different-sized cuttings for each substrate. Preliminary results showed that over 98% of all samples yielded full profiles, with 15% requiring a second injection at either a higher or lower parameter on the 3130xl Genetic Analyzer.

In brief, implementing a short extraction step followed by direct amplification with Identifiler® Plus proved to be a cost-effective method to profile true and pseudo exemplar samples in a single day or less. For the overwhelming majority of samples, full profiles were generated using standard parameters. For a select number of samples, an additional injection on the 3130xl Genetic Analyzer with more or less sensitive parameters and/or increased template volume for amplification was required. In both cases, the initial STR results could be evaluated to accurately predict the additional step(s) needed to preserve both time and cost.

Direct Amplification, Exemplar, DNA Analysis

A80 An Evaluation of Direct PCR Amplification

Reena Roy, PhD, Penn State Univ, Forensic Science Program, 325 Whitmore Lab, University Park, PA 16802; and Daniel E. Hall, BS, Penn State Univ, Forensic Science Program, 107 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will understand the concept of direct amplification from nine different substrates. Attendees will also appreciate the method that allows the scientist to generate autosomal and Y-STR profiles from substrates without the cumbersome steps of extraction and quantitation.

This presentation will impact the forensic science community by informing the forensic DNA analyst of a faster, less expensive approach to obtaining DNA profiles from bodily fluids using eight commercially available amplification kits.

The objective of this research was to generate complete autosomal STR profiles from body fluids using direct amplification and various commercially available STR amplification kits. Attempts were also made to detect the Y-profile from male body fluids using 1.2mm punches and the AmpFℓSTR® Yfiler™ kit following direct amplification.

STR analysis of blood and buccal samples is often used in the fields of forensic biology and genetics for casework, paternity testing, and convicted-felon DNA profiling. A primary advantage of direct amplification without purification of DNA is the high throughput of databank samples. Direct amplification of DNA stored on various types of substrates reduces the time required to obtain a DNA profile, thus reducing cost and increasing efficiency.

FTA® cards are suitable for criminal offender DNA database samples and casework reference samples. The preservative in these cards contains proprietary chemicals to protect DNA molecules from nuclease degradation, and to protect the host matrix from bacterial growth. DNA from biological samples deposited on FTA® paper and similar commercial storage devices has been found to be stable for a period of several years when stored at ambient temperature. A primary advantage of FTA® paper and similar substrates is their ability to provide consistent results without quantification, and the procedure can be automated.

Direct amplification kits contain improved PCR buffer cycling protocols that can overcome inhibitors during PCR amplification steps. Most collection media for storing dried body fluid samples contain chemicals that are capable of lysing cells (which may contain PCR inhibitors) to preserve DNA within a sample. Using devices without lysing chemicals, such as the Bode DNA Collector, requires an additional lysis step, or else amplification quality may be poor and allelic dropout may occur. Some of the amplification kits listed above have been optimized with enhanced reagents for direct amplification. However, it may not be cost effective for crime laboratories to use these direct amplification kits. Kits such as the PowerPlex® 16 System and the AmpFℓSTR® Yfiler™ Amplification Kit require the addition of polymerase in the reaction.

The following nine collection media were used for this study: proPRIME*i* Indicating Micro, 705 Micro, Blood Direct #1 and #2, Collection Card, CEP swab from FITZCO, EasiCollect from Whatman, FTA Indicating Micro, and Bode DNA Collector. Blood from two deceased individuals and saliva from three living donors were used in this study. The three single-source saliva samples and two single-source blood samples were deposited on each of the 45 collection devices.

A 1.2mm punch of each of the 45 substrates containing one body fluid was amplified with PowerPlex® 18D, PowerPlex® 16 HS, PowerPlex® 16, and PowerPlex® 21 Systems from Promega Corporation, and AmpFℓSTR® Identifiler® Direct, Identifiler® Plus, and Identifiler® PCR Amplification Kits from Applied Biosystems following each manufacturer's recommended conditions. Similarly, 1.2mm punches of the substrates containing male body fluids were amplified with AmpFℓSTR® Yfiler™ PCR Amplification Kit.

Results from the eight kits mentioned above were compared. Both blood and saliva samples appeared to yield complete DNA profiles. Two different reaction volumes were attempted with substrates that yielded

complete profiles from single source samples, the first using the manufacturer's recommended volume, and the second using half of the reaction volume suggested in the protocol. For some of the substrates, thermal cycling conditions were modified as necessary to generate complete DNA profiles.

Another goal of this research was to demonstrate that direct PCR amplification can be applied to commercially available kits not intended for direct amplification. The results indicate that it is possible to do so.

Direct Amplification, STR, Y-STR

A81 Protocols for Rapid Amplification of STR Typing Kits: The Use of "Non-Standard" Thermal Cyclers

Peter M. Vallone, PhD, 100 Bureau Dr, Gaithersburg, MD 20899-8314; and Erica Butts, MFS, 100 Bureau Dr, MS 8314, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand the principles of rapid PCR amplification of STR loci, characteristics of rapid PCR thermal cyclers, and applications of rapid DNA typing.

This presentation will impact the forensic science community by detailing protocols used for rapid PCR amplification and how these methods can be implemented into forensic laboratories and commercial integrated forensic DNA typing devices. The potential of reducing the required PCR amplification time may also benefit laboratories typing single-source reference samples.

There is a growing interest in developing methods capable of processing a single-source reference sample (e.g., a buccal swab) to an STR profile in under two hours. The ability to develop a protocol for the rapid typing of forensic STR markers is of specific interest to the forensic DNA and biometric communities. This would allow for a faster sample-in-answer-out turnaround time as well as the potential for higher throughput capabilities. One critical component of a rapid workflow involves the reduction in time required for multiplex PCR amplification of the core STR loci.

Initial tests of various commercial thermal cyclers with two- and three-step PCR cycling protocols were carried out and compared for genotype accuracy and DNA template sensitivity with a set of previously extracted single-source DNA templates. Work with various "non-standard" thermal cyclers in combination with faster processing DNA polymerases has resulted in decreasing the PCR amplification time to less than 20 minutes for a 16 locus commercial DNA typing kit.

Approximately one nanogram of DNA template was amplified in a total volume of 10 microliters. The PCR primers used for the amplification came from a commonly used commercial STR typing kit, and were used without any further modifications. Both the two- and three-step PCR protocols employed a hot start at 95 degrees for one minute for the activation of the DNA polymerase. The cycling parameters for the 2-step protocol consisted of 28 cycles of 95°C for five seconds followed by 61°C for 15 seconds. The cycling parameters for the 3-step protocol consisted of 28 cycles of 95°C for 5 seconds, 58°C for 10 seconds, followed by 72°C for 10 seconds. Both protocols employed a 72°C incubation step for one minute post cycling to promote complete PCR amplicon andenylation. The required cycling time for the two- and three-step PCR thermal cycling protocols ranged from 15-36 minutes depending on the specific thermal cycling being tested.

The rapidly generated PCR products were then diluted into a formamide solution and prepared for separation and detection by capillary electrophoresis. At least 15 unique samples were typed for the evaluation of each rapid PCR protocol on each of the thermal cyclers. The analysis of capillary electrophoresis data of the PCR products indicated good peak balance for heterozygous loci (median values were greater than 0.8), strong signal intensity (on average over 1,000 relative fluorescence units on a commonly used peltier block thermal cycler) and minor adenylation and PCR artifacts. Stutter artifacts were not significantly different when comparing the two- and three-step thermal cycling protocols. Genotyping results were concordant with PCR amplification conditions utilizing standard thermal cycling procedures (which require at least three hours).

The PCR conditions and cycling parameters developed were robust enough to routinely amplify 250pg of template DNA. These conditions can potentially be applied in a laboratory setting for faster generation of STR profiles while maintaining the robustness and reliability required by the forensic typing community.

PCR, Rapid DNA, Forensic DNA Typing

A82 Evaluation of Direct PCR for Forensic DNA Profiling and the Development of a Direct PCR Multiplex

Yuvaneswari C. Swaran, PhD, No 16 Lorong Jambu Susu, Taman Sri Delima, 52000, Kuala Lumpur , MALAYSIA; Lynn Dennany, PhD, Marielle Vennemann, PhD, and Lindsey Welch, PhD, Univ of Strathclyde, Dept of Pure and Applied Chemistry, 204 George St, Glasgow, G1 1XW, SCOTLAND; and Adrian Linacre, PhD, Flinders Univ, School of Biological Sciences, GPO 2100 Bedford Park, Adelaide, AUSTRALIA*

After attending this presentation, attendees will understand the basic principles of direct PCR and how it can be used in the analysis of forensic DNA profiling. Other items for discussion include the use of direct PCR with various types of samples retrieved from commonly encountered porous and non-porous substrates, the effect these substrates have on the recovery of DNA, and, finally, the development of a novel multiplex that has been validated to be used with direct PCR.

This presentation will impact the forensic science community by providing insight into the benefits of using direct PCR compared to conventional DNA profiling protocols to analyze various biological samples for DNA profiling. This research also focuses on the development and validation of the direct PCR multiplex for the simultaneous amplification of autosomal and Y- STRs, and two internal PCR controls for the identification of sample quality.

The goal of this research was to evaluate the use of direct PCR with different types of biological samples and to develop a direct PCR multiplex. Direct PCR is a technique in which DNA samples are subjected to PCR without having to first undergo extraction and quantification. With different extraction techniques, there is an associated loss of DNA which is caused by extraction inefficiencies. The multiple tube changes during extraction also introduce the opportunity for contamination and handling errors. With direct PCR, better DNA profiles could be obtained faster and cheaper as there is no loss of DNA associated with extraction steps and it does not use expensive commercial extraction and quantification kits. In this study, genomic DNA preparations and buccal cell counts of various concentrations were deposited on commonly encountered substrates, recovered, and amplified using direct PCR before subjecting them to capillary electrophoresis. The electropherograms obtained were compared to those obtained using the standard DNA profiling protocol which involves extraction prior to amplification and fragment analysis. Direct PCR was found to be more successful than the conventional DNA profiling protocol and was further tested with fingerprints, touch DNA on fabric, and blood and semen stained fabrics. All these tests were successful with direct PCR, indicating that this technique has the potential to be incorporated into routine forensic DNA testing. Supplementary tests were carried out to compare the efficiency of the swabbing technique utilized throughout this study and the effect that different substrates had on DNA recovery. Four non-porous substrates—glass, stainless steel, plastic, and ceramic—and four types of dyed fabrics—white cotton, light blue denim, nylon, and brown cotton—were used and the resulting DNA profiles were evaluated. The results obtained from this experiment indicated that the substrate on which DNA is deposited affects the amount of DNA retrieved, and, subsequently, the generation of DNA profiles. Several commercial multiplexes were used to amplify these samples using direct PCR and it was found that some of these multiplexes were more suitable than others for amplifying using direct

PCR and several pitfalls were identified. With this in mind, a novel multiplex consisting of five autosomal and two Y-STRs, which also provides the inhibitor status of the sample, was developed and validated with direct PCR samples. This multiplex also addresses the issues of sensitivity and robustness that were encountered with the commercial multiplexes tested. This direct PCR kit successfully amplified various mock crime scene samples without prior extraction, while being able to amplify as low as 25pg of pristine DNA. Allelic ladder, panels and bins were created to be used with this multiplex to aid in sample designation when subjected to capillary electrophoresis.

Direct PCR, DNA Profiling, Multiplex Development

A83 Field Forward Rapid DNA Analysis Outside the Laboratory: A Ruggedized System for Fully Automated Generation of STR Profiles

Eugene Tan, PhD, NetBio, 830 Winter St, Waltham, MA 02451*

After attending this presentation, attendees will learn of recent advances in rapid DNA analysis systems that enable forensic sample analysis to be performed rapidly in field-forward settings, mechanisms for long-term reagent storage at room temperature to support field-forward operation, and instrumentation features that enable transportation to and operation of rapid DNA analysis instruments in the field.

This presentation will impact the forensic science community by introducing a fully integrated, samples-in to answers-out short tandem repeat (STR) analysis system that offers the potential for use in a wide range of out-of-laboratory settings, including police stations, borders and ports, military checkpoints, and the battlefield.

Applications for the generation of STR profiles in the field include forensic investigations, determination of battlefield friend or foe, verification of kinship in immigration cases, and victim identification at mass casualty sites. To fully impact these applications, however, Rapid DNA Analysis systems must be ruggedized to allow transport and field-forward operation. Critically, all system reagents must be stable at room temperature for extended periods as many of the projected sites of operation are not amenable to refrigerated storage.

The system to be presented is immediately operational with full functionality after transport and capable of generating STR profiles from buccal samples in approximately 83 minutes without the need for a technical operator. To enable room temperature storage and stability, all reagents are stored within a single-use BioChipSet. Certain reagents, including the PCR reaction mix and Internal Lane Standard are lyophilized. The remainder, including electrophoresis and guanidinium-based purification reagents, are stored in liquid form in sealed aliquots within the BioChipSet. The liquid reagents are automatically released and the lyophilized reagents are automatically resuspended during sample processing. For example, the lyophilized PCR reaction mix is resuspended by an aliquot of the purified DNA solution generated during processing. Approaches to reagent storage and automated release will be discussed.

The Rapid DNA Analysis system was designed to be readily transported to and operated in the field. The instrument can be uncrated and set up in less than 15 minutes, is ready for use without any recalibration or adjustments, and can be operated with AC voltage between 90V to 260V (50 or 60 Hz) using utility or generator power. Several design features have been incorporated to provide ruggedization for field-forward operation including: (1) shock isolation and vibration dampening features in the mechanical chassis to protect the highly sensitive optical subsystem; (2) temperature control features to maintain electrophoresis run temperature to within one degree even with wide swings in ambient temperature; (3) lane-finding software to automatically align the optical detection system for each run; and, (4) partitioning of subsystems to protect against shock and vibration. The completed system was tested to MIL-STD 810F for transport. These tests included:

- Transit Shock – The instrument was crated, raised 12" above a solid concrete floor and dropped as prescribed in the test procedure.
- Bench Shock – The instrument was placed on a laboratory benchtop and raised on one side with by 4" and released, as prescribed in the test procedure.
- Vibration Testing – The crated instrument was placed on a vibration table and exposed to the vibrational frequencies for truck transportation as prescribed in the test procedure.

Data for the MIL-STD tests, automated subsystem tests, and functional tests will be presented to demonstrate that the system meets or exceeds all requirements for STR analysis in field-forward operation.

Rapid DNA, Ruggedization, MIL STD 810F

A84 Rapid DNA Analysis: Fully Integrated, Fully Automated Generation of STR Profiles From Buccal Swabs

Eugene Tan, PhD, James W. Schumm, PhD, and Richard Selden, MD, PhD, NetBio, 830 Winter St, Waltham, MA 02451*

After attending this presentation, attendees will have learned how fully-automated STR profile generation from buccal swabs can be performed without a technical operator in the laboratory, police station, or field-forward settings.

This presentation will impact the forensic science community by offering a fully integrated, samples-in to answers-out Short Tandem Repeat (STR) analysis system that offers the potential for use in a wide range of out-of-laboratory settings, including police stations, borders and ports, military checkpoints, and the battlefield.

This presentation describes development of a Rapid DNA Analysis system consisting of a modular platform that allows customization to perform a wide range of nucleic acid analyses. Independent microfluidic modules developed include those for DNA purification, DNA quantitation, highly multiplexed amplification, DNA sequencing, electrophoretic separation and detection, and related control, analytical, signal processing, and expert system profile determination software. The system consists of a fully automated instrument and a single accompanying BioChipSet cassette that can be used by non-technical personnel in laboratory, office, or field-based settings while dramatically reducing the time required to perform STR analyses. This presentation summarizes the successful application of the methodology in generating CODIS-quality DNA profiles in 83 minutes from buccal swabs without human intervention.

The Field-Deployable Accelerated Nuclear DNA Equipment ("ANDE") is operated by inserting five buccal swab samples into a BioChipSet, placing the BioChipSet into the instrument, and pressing the start button. The instrument provides all the subsystems required for the completion of STR analyses, including the power, thermal cycling, pneumatic, optical, ruggedization, process control, and computer subsystems. The instrument interfaces to the BioChipSet using a number of features, including a pneumatic manifold to allow fluids to be driven, thermal features to maintain appropriate temperatures during PCR and electrophoresis, optical paths to allow excitation and detection of separated STR fragments, and electrical connections to support electrophoresis. Attendees will become familiar with several critical features of the instrument and BioChipSet including:

- The BioChipSet contains all reagents on-board, factory pre-loaded. The user does not load or otherwise handle reagents. Several reagents are lyophilized (e.g., amplification reaction mix) and others are in liquid form (e.g., purification reagents). All reagents are stable at room temperature.
- The BioChipSet is closed: each buccal sample is processed through its own sealed processing path and samples and reagents do not have any contact with the instrument itself.
- To limit handling requirements, the BioChipSet is a single disposable plastic component. The operator has nothing to connect. No opening, filling, or other handling of the

disposable piece is required, minimizing the possibility of cross-contamination.

- Buccal swabs lock into separate purification positions so that once loaded they cannot be moved to another location. An RFID chip in the swab cap is detected by the instrument lid to identify the swab location within the BioChipSet.
- The instrument is ruggedized to MIL STD 810F for shock and vibration. This allows it to be moved within the forensic laboratory, transported for use outside of the laboratory, or used in a police station or field-forward setting. Instrument autocalibration readies the instrument for use within 15 minutes of setting it up.
- The instrument contains an on-board computer and touch screen monitor for interfacing with the operator, and the instrument's wireless, USB, and Ethernet connectivity options can be configured to user requirements. Also based on user requirements, the system includes an expert system for conversion of electrophoretic traces to CODIS/NDIS-compatible profiles and .cmf output, GPS-tagging of data products with time and location data, and an internal database to store instrument-generated profiles.

Description of the instrument design, the processes conducted in automated processing, and data characterizing the output generated from the fully integrated multiplex STR instrument-biochipset-expert system format will be presented.

Rapid DNA, Expert System, ANDE

A85 A Fast STR Genotyping Process for Time-Sensitive Situations

Nancy Laurin, PhD, and Anick De Moors, MSc, RCMP, Forensic Sci and ID Services, Tech and Science Development, 1200 Vanier Pkwy, Ottawa, ON K1G 3M8, CANADA; and Chantal Frégeau, PhD, RCMP, Forensic Sci and ID Services, Tech and Science Development, 1200 Vanier Pkwy, Ottawa, ON K1A 0R2, CANADA*

After attending this presentation, attendees will learn about different approaches aimed at reducing the time to generate STR profiling results, including a short lysis step, extraction on the Promega Maxwell 16 System and rapid PCR protocols, and about their integration into a single accelerated analytical process.

This presentation will impact the forensic science community by providing options and feasible alternatives for laboratories interested in gaining analytical efficiencies or to expedite sample processing, offering strategies compatible with standard forensic laboratory equipment.

Significant efforts are being devoted to the development of methods enabling rapid generation of short tandem repeat (STR) profiles in order to reduce turnaround times for the delivery of human identification results from biological evidence. Moreover, in some circumstances, the need for rapid human identification might be critical for police investigations. Different approaches were investigated to achieve flexibility for processing biological evidence. Combining these accelerated protocols into a single analytical process enables generation of STR profiles for human identification within five hours.

Reduced incubation times at 56°C for the lysis of biological samples were evaluated (30 min to 4 hours) and the results were compared to the usual overnight incubation. A quick DNA extraction method using the Promega Maxwell 16 System (27 min/16 samples) was also explored and the results were compared to the RCMP automated DNA IQ extraction protocol on TECAN robotic workstations. A variety of single-source and two-person mixture samples were subjected to different lysis conditions and extraction methods. With the exception of old blood on FTA cards, a 30-min incubation was sufficient to obtain similar or higher DNA yields compared to the longer incubation times. DNA yields were enhanced for some challenging fabrics, likely due to a reduced quantity of dye/chemicals leaching out of the fabric and interfering with the extraction by DNA IQ. While comparable STR profile quality was usually obtained, improvement in inter-loci balance was noted for the 30-min lysis step for saliva and buccal samples. Similarly, DNA yields and profile quality were shown to be equivalent using the quick DNA extraction method on the Promega Maxwell 16 when compared to the current RCMP DNA IQ method.

By modifying the cycling conditions and combining the use of a DNA polymerase optimized for high-speed PCR (SpeedSTAR HS) and of a more efficient thermal cycler instrument (Bio-RAD C1000), it was possible to reduce the amplification process time to 26 minutes. No modification to the commercial AmpFℓSTR® Profiler Plus or Identifiler primer mix was required. Mock and casework single-source and two-person mixture samples were used. Compared to standard amplification protocols, the fast amplification procedure demonstrated similar sensitivity, peak height ratios, and overall profile balance. Minor alleles in mixtures were reliably typed. An increase in the n-4 stutter ratio (2.2% on average for all loci) for profiles amplified with the fast protocol was noted compared to the standard protocols. Complete concordance was obtained with profiles previously generated with a standard amplification protocol for mock case samples and for casework samples.

Together, these protocol modifications provide interesting options to current laboratory processes to expedite the generation of STR results, especially in circumstances requiring quick actions. Other strategies to further reduce turn-around time included the evaluation of the Qiagen Investigator HYres quantification kit and profile generation on an Applied Biosystems 3500/3500xl Genetic Analyzer. The cycling procedure of the Investigator HYres cuts off approximately 30 minutes in the quantification step compared to the Applied Biosystems Quantifiler Duo. Comparable human and male DNA yield values were obtained for both systems from forensically relevant DNA samples. Excellent STR profile quality was demonstrated from biological samples submitted to the entire accelerated analytical process in less than five hours.

DNA, STR, Accelerated Process

A86 How Distant Relatives Influence the Efficiency and Error Rate of Familial Searching

Rori V. Rohlfs, PhD, 5407 Dover St, Apt B, Oakland, CA 94609; Erin Murphy, JD, NYU, School of Law, 40 Washington Square, S 419, New York City, NY 10012; Yun S. Song, PhD, Univ of Cal, Dept of Statistics, 321 Evans Hall 3860, Berkeley, CA 94720; and Montgomery Slatkin, PhD, Univ of California, 1005 Valley Life Sci Bldg, Berkeley, CA 94720*

After attending this presentation, attendees will gain a sophisticated understanding of familial searching arising from realistic population genetics and the presence of distant relatives in DNA databases. Since the utility of familial searching is predicated on relatives being present in these databases, it is important to consider how these relationships affect the practical application of familial searching techniques. Specifically, attendees will see how while familial searching effectively identifies first-degree relatives, distant relatives are also very commonly misidentified as first-degree relatives, calling into question the effectiveness of large database familial searching.

This presentation will impact the forensic science community by bringing to light important caveats affecting familial searching, which may lead to increased false identification rates. Depending on the demographics of DNA databases, these false identification rates may be unacceptably high, potentially influencing decisions about the use and implementation of familial searching methods. This is particularly relevant considering the continuing rapid rise in use of familial searching.

Familial searching is now being implemented in several states and is under consideration for national application as a tool to aid cold case investigations. The consequences of adopting the familial searching criteria used by the state of California, as described by Myers *et al*., (2011) are considered.[1] A simulation study, in which randomly generated profiles of related and unrelated individuals, comprising of a 13-locus CODIS genotype and YFiler® Y-chromosome haplotype, were considered for first-degree relationships as carried out through the Myers protocol for relative identification, was conducted. The Myers protocol powerfully identifies first-degree relatives who share a Y-

chromosome, with an 80-99% probability, depending on the population background of the individuals in question. For unrelated individuals, there is a low probability of false identification as first-degree relatives. The Myers protocol showed low probabilities of falsely identifying totally unrelated individuals as first-degree relatives, supporting the method to distinguish first-degree relatives from unrelated individuals. However, for more distant Y-haplotype sharing relatives (half-siblings, first cousins, half-first cousins, or second cousins), there is a substantial probability of incorrect identification as first-degree relatives. For example, there is a 3-18% chance of identifying a first cousin as a full sibling, with the probability depending on the population genetic background of the individuals in question. The California familial search policy is likely to identify a first-degree relative if their profile is in the database and it poses little risk of falsely identifying an unrelated individual in a database as a first-degree relative. However, importantly, there is a substantial risk that a somewhat more distant Y-chromosome sharing relative whose profile is in the database will be wrongly identified as a first-degree relative, with the consequence that their immediate family will become the target for further investigation. In this outcome, the familial search is ineffective in identifying the true relative and may convincingly lead investigators to futilely consider distant relatives who may not even be aware of their relationships to the true relative in question. Importantly, this risk of unprovoked investigation falls disproportionately on those groups that are over-represented in state and federal databases, particularly African Americans and Latinos.

A87 NIST STRBase Resources to Aid Work With New STR Kits and Loci

John M. Butler, PhD, NIST, 100 Bureau Dr, MS 8312, Gaithersburg, MD 20899*

After attending this presentation, attendees will learn about the creation of resources on the STRBase website to aid the understanding of new DNA tests, developed after new short tandem repeat (STR) loci were required for European and U.S. forensic DNA databases.

This presentation will impact the forensic science community by describing online resources under development at the National Institute of Standards and Technology (NIST) that supports work with new DNA tests.

With new short tandem repeat (STR) loci being required for European and U.S. forensic DNA databases, a number of new DNA tests have been developed in the past few years. Attendees will learn what resources exist on the STRBase website to aid their understanding of these new DNA tests.

For the past 15 years, NIST has maintained the Short Tandem Repeat DNA Internet DataBase (STRBase), which is located at http://www.cstl.nist.gov/biotech/strbase. The purpose of STRBase has been and continues to be an attempt to bring together the abundant literature and information in the forensic genetics field in a cohesive fashion in order to make current and future work easier. New materials are regularly added to expand the information contained on the STRBase website.

Information on the STRBase website is contained in hypertext markup language (HTML) files that were created primarily using a editor and website administration tool. Over 1,900 files now exist containing more than 10,000 printed pages of information that are connected with over 5,000 hyperlinks. An additional 2,300 hyperlinks connect various information on STRBase to other internet websites, including over 350 direct links to various organizations, journals, academic and forensic institutes, commercial sites, genetic genealogy labs, parentage testing labs, and legal sites dealing with forensic DNA (see http://www.cstl.nist.gov/biotech/strbase/weblink.htm). Thus, STRBase is not a true searchable "database" but rather a collection of information with interconnected files. Since July 2006, resources that are added to STRBase are now tracked on a "recent updates" page: http://www.cstl.nist.gov/biotech/strbase/updates.htm.

STR fact sheets are the centerpiece of STRBase. These fact sheets list information regarding genomic location, GenBank accession, repeat structure, reported PCR primer sets, observed allele sizes and sequence structure, commercially available allelic ladders, common multiplexes, and mutation rates. All 24 core or common STR loci used in current commercial STR kits are available. Multiplex assay and kits are visually summarized by locus-specific allele size ranges and dye colors with each locus name hyperlinked to the appropriate STR fact sheet. Labs worldwide continue to contribute to knowledge regarding rare alleles such that we now have catalogued over 600 variant alleles and 300 tri-allelic patterns.

Numerous presentation slides, NIST publications and presentations, software programs, and other useful information are available for download and use by the forensic genetics community. Materials from more than 40 recent workshops consisting of thousands of slides covering capillary electrophoresis, low-copy number DNA testing, mixture interpretation, qPCR DNA quantitation, Y-chromosome and mtDNA analysis, and validation are available for use at http://www.cstl.nist.gov/biotech/strbase/training.htm.

NIST's Applied Genetics Group has also updated NIST Standard Reference Material (SRM) 2391c with certified and informational values for commonly used autosomal and Y-STR loci. The information available from NIST's latest SRM will be discussed.

STRBase has been well received and widely used by the forensic DNA community and additional resources for the website continue to be created. In 2005, NIST adopted STRBase as an official Standard Reference Database (SRD) giving further credence to the value of the information contained in the website.

Forensic DNA, STRBase, Internet Resources

A88 Results of DNA Processing of Unselected Sexual Assault Evidence

Sarah Kelley, BS, Michael A. Donley, MS, Michal L. Pierce, MS, Katherine Welch, MSFS, and Roger Kahn, PhD, Harris County IFS, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to offer an overview of the results of sexual assault kit processing and compare the final disposition of cases with the DNA results obtained.

This presentation will impact the forensic science community by offering a comparison to studies of testing of backlogged sexual assault kits stored for long periods by law enforcement agencies at a variety of locations in the country.

Sexual assault kit backlogs are at the forefront of controversy in the forensic science community. A number of jurisdictions across the country have reported backlogs of thousands of untested sexual assault kits in law enforcement property rooms or laboratory evidence storage. There are differing opinions as to the usefulness of forensic testing in these backlogged cases. Community groups, victim's rights advocates, and some victims have called the backlogs justice delayed or denied. Studies by others are underway to test the backlogged evidence and to determine if timely analyses would have been helpful. A retrospective study of the testing of all sexual assault evidence without delay collected in the jurisdictions served by the Forensic Genetics Laboratory of the Harris County Institute of Forensic Sciences (HCIFS) is presented.

The HCIFS serves approximately 2,000,000 of the 4,000,000 people in Harris County outside the city of Houston, providing forensic DNA testing services to more than 60 law enforcement agencies. HCIFS policy requires all collected sexual assault kits to be submitted directly to the laboratory without being sent first to the property room of the submitting agency. HCIFS tests all evidence within approximately 60 days and has no backlog of untested kits. The purpose of this study is to identify the outcomes of a set of completed and adjudicated sexual

assault cases. The study is unique in that it includes *all* collected sexual assault cases, not just those for which DNA testing was not originally requested.

Cases received during 2010 were assessed for this project. For each of these cases, information was gathered from the complainant's narrative from the kit's medical report, law enforcement offense records, DNA reports, CODIS hit information, and court records. Data included whether a sexual assault kit was collected and the amount of time that elapsed between the assault and the evidence collection. Complainant and suspect information included their ages and relationship, if any. The assaults were categorized by a large number of variables including whether there was evidence of drug-facilitated sexual assault, whether the suspect ejaculated, and whether the victim knew the attacker. DNA results documented whether a suspect known was submitted for comparison, whether semen and/or male DNA was detected, and whether the suspect known matched a profile in the evidence. Additionally, the final disposition of the case and the number of CODIS offender hits and forensic hits were also tracked.

Preliminary data indicates that foreign DNA was detected in 60% of cases. A profile was entered into CODIS in 83% of these cases. A CODIS offender hit or forensic hit was returned in 24% of the cases, and 45% of the offender hits in these cases were to offenders not identified during the investigation. The preliminary data show that charges were filed in 35% of the cases. Conference attendees will be provided comprehensive information from the data set. The value of DNA testing of all sexual assault kits collected versus testing of only selected kits will be discussed.

Sexual Assualt Kit, DNA, Backlog

A89 Processing One Million DNA Samples: Lessons Learned From a Decade of Offender Databasing

Michael Cariola, MFS, Erin Sweeney, BS, Manzar Ahmed, MS, and Megan Meyer, MS, Bode Technology Group, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will learn: (1) a variety of tools and methods that can improve the efficiency and quality of offender databasing processing; (2) the importance and impact of selecting the most appropriate procedures and technical specifications; and, (3) how to recognize factors that significantly affect turn-around time, cost, efficiency, and overall productivity within their own forensic DNA laboratories.

This presentation will impact the forensic science community by discussing methods that DNA databasing laboratories can use to increase productivity, improve quality, and decrease costs in order to effectively manage and reduce offender DNA sample backlogs.

As a result of expanding offender collection legislation and demands to reduce DNA backlogs across the country, laboratories are continually confronted with meeting the challenges of an increased workload while following strict budgetary constraints. Additionally, with the increase in arrestee legislation, there is a higher demand to process DNA reference samples in much shorter turnaround times, which can often lead to inefficiencies within the laboratory. Through the processing of more than one million DNA database samples for the U.S. national database (CODIS), and more than 10 years of experience in high throughput DNA database sample processing and analysis, this study has identified a variety of methods described in this presentation that other laboratories can use to eliminate time-consuming and costly inefficiencies to increase throughput and reduce DNA backlogs.

This presentation will address ways to optimize the collection and testing process, and improve the first pass success rates of databasing samples. Maximizing the first pass success rate allows the laboratory to minimize re-testing, re-amplifications, re-injections, and ultimately simplifies data review. In order to achieve full optimization, a variety of processing, analytical, and quality factors were identified and evaluated based on overall impact and ease of implementation within the laboratory. Substrate options were carefully examined and evaluated, and a variety of extraction techniques were compared to determine which methods yielded the highest quality DNA while minimizing cost and processing times. Additionally, through experience, testing, and cost analysis reports, it was determined that maintaining a proper balance of automated and manual procedures is more productive and efficient than relying on just one method.

The selection of appropriate technical specifications is also highly critical. Specifications such as imbalance ratios, minimum relative fluorescent unit (RFU) values, and ceiling thresholds should be carefully considered. These factors can be key drivers of first pass success rates and dramatically influence reprocessing rates and cost. In addition, the importance of implementing a Laboratory Information Management System (LIMS) program that has been specifically designed for high-throughput processing of databasing samples is explained. The use of an LIMS program allows a laboratory to effectively track samples starting from accessioning through analysis and reporting, and should include extensive quality control checks specific to high-throughput testing. Additionally, the number of samples processed together within a batch has a large impact on cost and productivity. Factors such as collection rates, turnaround times, and staffing should be carefully considered when determining the appropriate batch size both for in-house processing and for outsourcing.

Knowing the limits of each step can also aid in the development of an effective database analyst training program. It has been documented that new analysts can be effectively trained within six weeks and be fully independent once the FBI QAS six-month training requirement is fulfilled. Finally, analyst productivity tracking has shown that analysts will be approximately 40% more efficient in their second or third year than analysts in their first year. This determination facilitates project planning, personal development goals, and the ability to meet expectations in even shorter turnaround times.

Database, Efficiency, Backlog

A90 The Impact and Benefit of Expanding the U.S. Core Autosomal STR Markers

Becky Hill, MS, and Margaret C. Kline, MS, NIST, 100 Bureau Dr, MS 8314, Gaithersburg, MD 20899; David L. Duewer, PhD, NIST, 100 Bureau Dr, Gaithersburg, MD 20899; and John M. Butler, PhD, NIST, 100 Bureau Dr, MS 8312, Gaithersburg, MD 20899*

After attending this presentation, attendees will: (1) understand the benefit and potential impact of expanding the U.S. core autosomal STR markers for DNA database searches; and, (2) get an overview of the next-generation multiplex kits that include these additional markers.

This presentation will impact the forensic science community by demonstrating how DNA database searches can be benefitted by additional STR loci.

The original core set of 13 Combined DNA Index System (CODIS) autosomal short tandem repeat (STR) loci were selected in November 1997 and are required by the Federal Bureau of Investigation (FBI) for upload of DNA profiles to the national DNA database.[1,2] As the number of profiles stored in the National DNA Index System (NDIS) continues to increase each year (>10 million total profiles), the likelihood of adventitious matches becomes greater. Expanding beyond the 13 core loci is critical to reduce the potential of these types of matches occurring within the database, to increase international compatibility for data sharing, and to increase discrimination power in missing persons cases.[3]

In November 2009, the European Union adopted five new autosomal STR loci as part of their expanded European Standard Set (ESS), including D12S391, D1S1656, D2S441, D10S1248, and D22S1045. These new ESS STR loci were selected based on discussion over the past few years within the European Network of Forensic Science Institutes (ENFSI).[4,5] Unfortunately, only eight of the current 13 U.S. core loci overlap with data being gathered in the United Kingdom and most other European nations. All five of these new loci are being considered for the expansion of the U.S. core set to provide greater capabilities for international comparisons when necessary. Also,

D2S1338 and D19S443 are recommended as two new additions to the original 13 core loci because they are commonly used worldwide as well as in the United States. Almost half of the U.S. national database already contains data for these loci. Finally, it has been suggested that the DYS391 locus be added to confirm amelogenin null alleles sometimes present in DNA profiles.[3]

In the past few years, Promega Corporation and Life Technologies have released several new next-generation STR multiplex kits that enable complete coverage of all of these additional loci plus the 13 U.S. core loci. These multiplex kits have been extensively tested in the National Institute of Standards and Technology (NIST) laboratory, allowing the probability of identity calculations to be made with different sets of loci and population statistics, including allele frequencies, observed alleles and genotypes, polymorphism information content (PIC) and heterozygosity values for each locus, to be determined with a standard set of unrelated U.S. population samples. With this information, it has been possible to thoroughly characterize these new STR loci beyond the original 13 CODIS core loci to determine the impact that this additional information will have on database searches.

A summary of these results, including STR locus population statistics for the new STR loci, will be shown in order to help assess the benefits of adding additional loci to the current 13 CODIS core loci.

Forensic DNA, STR Multiplex Kits, New STR Loci

A91 UV-Visible Microspectrometer Parameters That Affect Spectral Quality, Reliability, and Power of Discrimination

Dale K. Purcell, MS, City Univ of New York, John Jay College, 445 W 59th St, New York, NY 10019; John A. Reffner, PhD, 97 Ocean Dr E, Stamford, CT 06902; Thomas Kubic, JD, PhD, 8 Pine Hill Ct, Northport, NY 11768; and Fran Adar, PhD, 3880 Park Ave, Edison, NJ 08820*

After attending this presentation, attendees will benefit by gaining a deeper understanding of how UV-visible microspectrophotometry (MSP) spectral data quality, reliability, and discrimination power are improved through testing and controlling critical instrumental parameters, specifically, attention to sample preparation and using polarized light when analyzing optically birefringent samples.

This presentation will impact the forensic science community by recommending guidelines for collection of high-quality spectral data and interpretations in ultraviolet-visable MSP analysis.

Microanalysis of transfer (trace) evidence involves the application of a microscope and microscopical techniques for the observation, collection, documentation, and analysis of micrometer-size particles. Microspectroscopy is the union of microscopy and spectroscopy for microanalysis. Microscopy is the art and science of creating, observing, recording, and interpretation of magnified images. Analytical spectroscopy is the science of studying the absorption, reflection, and emission of electromagnetic radiation to determine the structure and chemical composition of materials. Both microscopy and spectroscopy contribute specific scientific information about a material's structure and composition. Both scientific methodologies originate with optics and the interaction of radiant energy with matter. Microspectrophotometry is perhaps one of the oldest microanalytical techniques with roots traced to the microspectrograph in the mid-1800s when used by Henry Clifton Sorby in order to compare the transmission spectrum of light traversing different directions in crystals. Microspectrophotometry has various contrast methods. These techniques continue to be used today in forensic science laboratories for the characterization and comparison of naturally colored and dyed or pigmented transfer evidence such as architectural, automotive, and artistic paints, natural and synthetic fibers, color-dyed human and animal hairs, thin polymer films, and minerals.

This research reports the critically important role of factors such as: (1) using a research PLM with a circular rotating stage to precisely orient the sample; (2) controlling the orientation of polarizer in the condenser; (3) the quality of the spectrometer used to record transmittance; (4) importance of slide and cover slip; (5) using a refractive index oil that closely matches the refractive index of the specimen to minimize scattering and lensing effects; and, (6) the proper treatment of data, including spectral normalization, in order to determine real variance in the data. This research reports how wavelength accuracy was determined using a combination of mercury-argon and krypton line sources. Photometric accuracy was determined using a series of neutral density filters. The system's noise was determined by measuring root mean square (RMS) noise of the transmittance. The results of this research will be presented in a two-prong approach: instrumental parameters and sample-dependent factors.

Frequently, inherent instrument-induced polarization effects are not realized by the untrained user. Spectral data collected on fibers and films demonstrate that instrument-induced polarization may result in erroneous interpretations, false exclusions, and false inclusions based on changes to spectral features such as bathochromic or hypsochromic peak shifts, and hyperchromic or hypochromic intensity shifts. The results will also demonstrate that sample preparation and specimen orientation are critical to obtaining high-quality (high signal-to-noise) data. Specimens are generally not flat or parallel materials so physical characteristics such as cross-section morphology, varying levels of pigmentation, variations in dye uptake, and degree of delustrant will all effect the quantitative transmittance level, the quality of the spectral data, and the degree of spectral consistency. The results will demonstrate that proper data processing (normalization) will minimize and control sample variations due to sample thickness (pathlength) and sample concentration variations in the specimen.

In conclusion, the proper use of the microscope is critical to obtaining reproducible, high-quality, high-resolution data which is essential for optimum spectral differentiation. When the operator systematically controls as many instrument parameters as possible, the quality of the spectral data is improved, which results in a higher signal-to-noise and better spectral discrimination. The goal of this presentationis that the guidelines that will be presented will be considered for adoption by SWGMAT, ENFSI, and other forensic science technical groups.

Microspectroscopy, Trace Evidence, Criminalistics

A92 Utilizing Comprehensive Gas Chromatography Coupled to Fast-Scanning Time-of-Flight Mass Spectrometry for the Analysis of Forensically-Relevant Samples

Frank L. Dorman, PhD, Penn State Univ, 107 Whitmore Lab, University Park, PA 16802; Jessica Westland, MPS, Penn State Univ, 107 Whitmore Lab, State College, PA 16802; Jack Cochran, BS, 110 Benner Cir, Bellefonte, PA 16823; and Kari L. Organtini, MSc, Adrienne W. Brockman, BS, and Emily X. Ly, BS, Penn State Univ, 107 Whitmore Lab, University Park, PA 16802*

After attending this presentation, attendees will gain an understanding of the technique of comprehensive gas chromatography, or GCxGC, and how this technique can aid the forensic chemist for a variety of analyses including fire debris and drug analysis. Additionally, the benefit to the legal system will also be discussed, where the output from this technique may be more easily explainable and understandable to the court.

This presentation will impact the forensic science community by educating potential users of this technique as to its abilities, and how they might be used in a variety of analytical methods to provide greater data quality, and also easier comprehension to a non-scientific audience such as the legal system.

Comprehensive GCxGC is a relatively recent technique available to separations scientists. Largely credited to Phillips, this technique has recently become more user-friendly, robust, and accepted in the scientific literature.[1,2] Additionally, several systems are now available to potential users, which increases the potential for application to the field of forensic science.

This presentation will address the fundamentals and instrumentation for GCxGC. Specifically, the use of cryogenic modulation GCxGC coupled to Time-Of Flight Mass Spectrometry (TOF-MS) will be discussed, allowing for an increase in chromatographic peak capacity and sensitivity for many complex separations. This increase in peak capacity allows for higher data quality when analyzing complex samples. Through the examples of fire debris and drug analysis, this presentation will demonstrate that GCxGC-TOF-MS should be considered as a viable analytical technique in the forensic science field because: (1) it allows for the classification of compounds based upon chemical functionality, thus allowing for tentative peak assignment even in the absence of reference standards; (2) it allows for greater peak resolution which improves both qualitative id and quantification accuracy; (3) it allows for data display that is much more easily explained to members of the legal community who may not have years of analytical chemical education and experience; and, (4) it may allow for identification of marker compounds and other trace compounds that are obscured for a variety of reasons in more conventional analyses.

Specific examples of pharmaceuticals in wastewater samples and data from an arson case will be presented to briefly demonstrate the benefits of this technique. The analysis of drugs in wastewater may allow for spatial and temporal resolution of usage in a population, but the analysis conditions are difficult using conventional approaches. Many of the drug compounds and metabolites are at very low levels of concentration relative to the variety of co-extractable, or matrix, compounds that are also found in wastewater. If these matrix compounds are not resolved in the chromatographic analysis, they may either obscure the trace compounds or bias the mass spectrum such that detection becomes difficult. GCxGC-TOF-MS data will be shown in comparison to GC/MS data to demonstrate the utility of the technique.

Equally, fire debris samples present a difficult separation. Most potential accelerants are hydrocarbon-based distillation fractions, and contain a large number of individual compounds. In some cases (diesel and kerosene, for example), these materials can be difficult to distinguish from one another, especially once they have been weathered either through evaporative loss or through combustion. Again, the increased peak capacity and selectivity of GCxGC-TOF-MS will be compared to the more conventional GC/MS technique to demonstrate the benefits of the use of this technique to the forensic community.

Fire Debris, Drug Analysis, GCxGC/TOF-MS

A93 Present Status of Gas Chromatographic Stationary Phases Being Used in Forensic Science

Thomas A. Brettell, PhD, Cedar Crest College, 100 College Dr, Allentown, PA 18104*

After attending this presentation, attendees will have a better understanding of how the different stationary phases used in gas chromatography (GC) are being applied to separating various analytes encountered in forensic science laboratories.

This presentation will impact the forensic science community by providing information on the different gas chromatographic stationary phases available and how they are being utilized for the separation of analytes in different matrices found in forensic science.

GC is a separation technique that has been used in most analytical laboratories for over 50 years. Most crime laboratories, especially those performing toxicological and controlled substance analysis have at least one gas chromatograph in their laboratory. To date, there has not been a survey of GC users specifically targeted at the forensic sciences. *LCGC North America* magazine has published surveys in 1990, in 1995, and in 2003 of GC users in the chemical industry.[1-3] Several changes have occurred in the industry and in forensic science since these surveys. For example, many environmental laboratories, which at one time represented one-third of all analytical laboratories that used gas chromatographic columns, have been closed. In recent years, many pharmaceutical laboratories have also closed or consolidated resources, outsourcing much of their analytical work outside the United States. In addition, there are now more forensic laboratories performing GC and GC-mass spectrometry (GC/MS) than there were 20 years ago. In 1995, forensic laboratories only represented 2.6% of the laboratories surveyed and in 2003 the forensic laboratories representation increased to 6%.[2,3] The increased prevalence of gas chromatographic instrumentation in the crime laboratories is directly attributed to the reduced cost and availability of instrumentation, particularly the table-top gas chromatograph-mass spectrometer (mass detector). New manufacturers of gas chromatographic columns and new and improved column technology have also emerged, making a larger variety of stationary phases available.

With all of these changes taking place and new designer drugs challenging controlled substance and toxicology laboratories daily, it was thought that a survey of the use of gas chromatographic stationary phases for different applications would be of interest to the forensic community. Surveys were mailed to over 100 random selected crime laboratories and forensic scientists around the country. The results of these surveys will be presented. In addition to the surveys, the application of GC and GC/MS in recent proficiency tests was also investigated. Finally, the forensic science literature was searched from 2007–2012 to assess the use of different stationary phases, the technical specifications of the columns, and how each were applied to separate various analytes found in forensic samples, i.e., various drugs and toxins of interest in controlled substance and toxicological analysis, fire debris samples, pyrolysis GC, etc. Not surprisingly, preliminary results indicate that capillary columns are overwhelmingly being used in crime laboratories. Columns of 0.2 to 0.25- and 0.32mm i.d. in a range of lengths of 12 to 30-m lengths are the most popular. 100% Methylsilicone, 5% phenylmethylsilicone, polyethylene glycol, and 50% phenylmethylsilicone continue to be the most popular stationary phases.

Forensic Science, Gas Chromatography, Stationary Phases

A94 Application of Raman Spectroscopy to the Forensic Analysis of Drugs, Controlled Substances, and Fibers

Sergey Mamedov, PhD, 3880 Park Ave, Edison, NJ 08820; and Tameika James, MPhil, and Judith Mowatt, PhD, 2 ½ Hope Blvd, Kingston, JAMAICA, WEST INDIES*

After attending this presentation, attendees will learn of the application of Raman microscopy to drugs and fiber analysis.

This presentation will impact the forensic science community by providing methodology and technical details of using micro-Raman analysis of drugs, controlled substances, and fibers.

Raman spectroscopy and infrared spectroscopy are complementary techniques often used for the identification of compounds. Raman spectroscopy; however, offers several advantages over infrared spectroscopy. Raman spectroscopy is a light-scattering technique whereby light from a laser interacts with a sample producing scattered light of different wavelengths. The scattered light which is specific to a particular compound is funneled to a detector enabling chemical identification.

Raman analysis has been recognized to have potential for solving a wide variety of problems associated with forensic science. Early motivation was to identify substances/contaminants that appeared in crime scene evidence and manufactured products; however, it was quickly applied to all types of materials analysis.

Raman spectroscopy is very applicable in the field of forensic science. It uses a technique that offers a non-destructive and non-contact method of analysis. Only a small amount of sample is required and little or no sample preparation is necessary. It allows for trace analysis, and sampling can be done directly through transparent evidence bags and packaging such as glass and plastics. It covers a wide spectral range, from 1000cm^{-1} to 4000cm^{-1} making the technique ideal for the identification of both organic and inorganic substances, which includes drugs, pharmaceuticals, explosives, fibres, inks, paint, etc. Bulk analysis and screening of opaque materials such as powders is also possible. Raman spectroscopy also allows for the identification of the components of non-homogeneous samples and automated high-definition Raman mapped images can be obtained.

The purpose of this paper is to demonstrate some of the forensic applications of Raman spectroscopy. In particular, the capability of Raman spectroscopy to differentiate between drugs of similar structure will be demonstrated. That is, Raman spectroscopy has the capability of detecting even slight differences in the chemical composition of a drug and, therefore, plays a vital role in helping to determine when drugs have been illegally manufactured. In order to illustrate the abovementioned, spectra of the two main forms of cocaine (hydrochloride and base) will be highlighted in this paper as well as the ability to identify drugs in plastic bags/containers.

In an effort to aid law enforcement personnel and the public at large, investigations have been geared toward the ability of Raman spectroscopy to identify a variety of polymers used in fibers. This is very important as the presence of fibers at a crime scene has often been instrumental in the process of solving crime. “Fingerprints” of nylon 6, Kevlar, poly-styrene, PET, poly-propylene, and some others, along with different types of nylon (nylon 6, nylon 66, nylon 12, and others) will be presented.

Data will be collected using both a 633nm and a 785nm lasers. Comparison of the drugs and fibers will be done using similar wavelength lasers.

Raman spectra will be presented and method development including statistical analysis will be described. It will be shown that a search can provide quick identification of materials whose spectra have been collected in a library, or just matched to suspect material samples.

Drugs, Fibers, Raman

A95 An Investigation Into the Volatile Organic Compounds Released From Submerged Remains

Norma I. Caraballo, BSc, and Kenneth G. Furton, PhD, Florida Int’l Univ, Dept Chemistry & Biochemistry, 11200 SW 8th St, CP 344, Miami, FL 33199*

After attending this presentation, attendees will have a better understanding of the chemistry of death, also known as thanatochemistry, the volatile organic compounds (VOCs) that evolve from decomposing remains and how they are affected by water.

This presentation will impact the forensic science community by providing results on a new facet in the study of decomposition that includes the assessment of VOCs from submerged remains, under controlled conditions.

Depending upon the environmental conditions and surroundings of the body, the decomposition process starts immediately after death and initiates with autolysis. In this stage, intra- and extracellular enzymes present within the body cause molecules and cells to break down, leading to the second phase of the decomposition process known as the putrefactive stage. The degradation of cells that occurs during autolysis creates an ideal environment for anaerobic microorganisms to break down large molecules, such as carbohydrates, nucleic acids, proteins, and lipids, causing the release of gases, which range in functionality (e.g., amines, sulfur-containing, acids, alcohols, etc.), as well as discoloration and bloating.[1,2] Thereafter, active decay is said to begin. In this phase, the body is no longer bloating and the decomposition process continues with additional degradation of proteins and fat. The subsequent stage is advanced decay, which is where the body dries up and remnants (e.g., skin, cartilage, etc.) are present. This stage paves the way to the final phase of decomposition, skeletonization. It is at this point that only bones and hair remain.[3]

The decomposition process is highly influenced by the environment that surrounds the body. Factors, such as moisture, temperature, presence of scavengers, and oxygen availability, can alter the manner in which a body decomposes and, thus, the liberation of volatile organic compounds. Previous studies have evaluated the effects of soil on the evolution of VOCs from both humans and analogues.[3,4,5] However, little to no research has been conducted on the VOCs that evolve from submerged remains. According to Osterkamp,[6] the increased use of water-search canines emphasized the importance of thoroughly understanding the VOCs released from submerged remains to improve canine performance in locating drowned individuals. As previously mentioned, there are a variety of factors that can affect the manner in which a body decomposes and water is another important aspect to consider. The decomposition process of a body submerged in water can either be reduced or accelerated depending upon the type, temperature, pH, and flow rate of water.

This study used Headspace Solid-Phase Microextraction (HS-SPME) coupled to Gas Chromatography-Mass Spectrometry (GC/MS) to evaluate the volatile organic compounds that are released from decomposing submerged remains. Freshly killed human cadaver analogues were placed into water and allowed to decompose while subsequently being monitored at different time intervals to assess VOCs that were being released. The compounds detected ranged in functionality from acids to sulfur-containing; moreover, the type and abundances of compounds detected changed over time, which was expected since mammalian decomposition is a process and not a single event. The results obtained were then compared to a previous study that evaluated the VOCs that were released during the decomposition process of non-submerged human cadaver analogues. Differences, as well as similarities, in the compounds detected will be discussed in this presentation, as well as the impact that water has on the release of VOCs from decomposing submerged remains.

Submerged Remains, Decomposition, Volatile Organic Compounds

A96 What Can Be Done to Save Criminalistics?

Peter R. De Forest, DCrim, PO Box 141, Ardsley, NY 10502*

The goals of this presentation are to: (1) raise awareness of the disparity between the potential of criminalistics to contribute to the justice system and its actualization; and, (2) to draw ideas and suggestions from the audience for overcoming the considerable obstacles to the realization of this potential.

This presentation will impact the forensic science community by pointing out ways in which the scientific potential of criminalistics can be enhanced to contribute to justice.

Perhaps, one would think the first question to be asked is: Is criminalistics worth saving? However, in order to address that question, there are some other questions that need to be answered. For example, what is criminalistics? What is its function? Does it contribute something of value? Do we have consensus on these questions? Let's throw out some thoughts for consideration. Before attempting to tackle the question of what it is, it should be sserted that I very strongly advocate that criminalistics is capable of contributing. Criminalistics is capable of establishing the "ground truth" in difficult criminal and civil investigations based on the physical evidence record. No other mode of investigation (eyewitnesses, interrogation, confession, etc.) has anything approaching this same powerful potential to offer. The alternatives are more error prone as well. Is this same potential realized in practice? Clearly, it is not. Why not? Can we enumerate the reasons?

Lets look at what's wrong; however, a general definition of Criminalistics should be provided first. Perhaps it is a definition which can be agreed upon using the AAFS structure as a model and starting point. We all hold some reasoning or ideas of why we are members of the Criminalistics section and not another. What are the attributes and foci of those of us in the Criminalistics Section that define us? Could it be said that we are scientists whose focus is applying scientific thinking, scientific knowledge, and scientific methods to the interpretation of physical evidence from suspects, victims, and crime scenes? How many of us engage in this practice in the broadest sense? How many of us, by choice or not, act more like technicians than scientists, and are restricted to testing samples in a more or less reactive manner? The anecdotal evidence I have is that most of us (worldwide) are not given the opportunity to formulate and address whole scientific questions. We are constrained to a reactive role where someone else, typically a nonscientist, poses the scientific questions to be addressed in a given investigation, and therefore, we are unable to provide the most value. It may seem obvious to us that a scientist is the best qualified to pose a scientific question. Strangely, it doesn't seem as though this view is widely shared, or perhaps even thought about. If this trend toward the reactive role were to continue, could we not be replaced by automatons and easy-to-operate, field-deployable instruments? This would be the end of criminalistics. Whether appreciated or not, it would be the end of scientific input to investigations. On the surface, it would appear to be cost-effective, but investigations and valid evidence interpretation at the adjudicative stage would suffer immeasurably. Is this alarmist? I don't think so.

Now that we may have somewhat of a consensus on what criminalistics is, and perhaps a consensus on what is wrong with our field, a discussion of remedies can begin.

Criminalistics, Science, Investigation

A97 The Laboratory Report Project Part 1: Content Analysis of Laboratory Reports

Megan King, BS, IUPUI, Forensic Science Program, Indianapolis, IN 46201; Jay A. Siegel, PhD, 8334 Tilly Mill Lane, Indianapolis, IN 46278; and Whitney Reed, BS, IUPUI, Forensic Science Program, Indianapolis, IN 46201*

After attending this presentation, attendees will understand how content in typical forensic science laboratory reports are submitted as the result of the analysis of evidence.

This presentation will impact the forensic science community by informing attendeesof the status of laboratory reports today in various disciplines and jurisdictions so that crime lab directors can compare their practices with those of the community at large.

This project is a result of recommendation #2 of the National Academy of Sciences (NAS) Report on Forensic Science—"that forensic science laboratory reports follow a standard, scientific format". Testimony before the NAS Forensic Science Committee indicated that too many laboratory reports were little more than "certificates of analysis" that contained only descriptive information about the evidence and the results of the analysis, without any information about the methods and procedures used, and little or no presentation of the data and how the conclusions were reached. It was felt by the Committee that this type of report wasn't reflective of the scientific nature of forensic science analysis. Before developing such a standard, it is important to know what is currently being submitted in the way of lab reports. With the help of the American Society of Crime Lab Directors, forensic science lab directors were asked to submit specimens of redacted laboratory reports and/or report format templates in several disciplines including drugs, DNA, fingerprints, questioned documents, toxicology, and trace evidence. The only demographic information that was sought was the governmental level of the laboratory (federal, state, regional, local). More than 400 laboratory reports were ultimately received. The reports were first categorized by laboratory type and then by report type. A spreadsheet was created that listed all of the sections of a model laboratory report that would be expected: demographics of submission, request for analysis, description of the evidence, methods and materials of analysis, analytical procedures, results (data), discussion of the results, and conclusions including limitations and sources as well as magnitudes of possible errors or uncertainties in the conclusions. Each of the laboratory reports was then analyzed to determine which of these sections were present in that report. After this was completed, each type of report (drugs, DNA, etc.) was examined separately to determine what sections were most commonly found and what sections were not usually present. Determinations were made to see if particular types of laboratory reports were more complete (in the sense of having the most sections) than other types of reports. The data were then analyzed to determine if there were significant differences between laboratory reports generated by federal, state, regional, or local laboratories, and, if possible, whether differences existed between public and private laboratories. On the basis of the data collected in this study, attempts will be made to determine if it is possible or desirable to develop a model template that all laboratory reports, regardless of jurisdiction and regardless of report type, or does it make more sense to develop a set

of templates that reflect the type of analysis being done; that is a different type of report for a drug case from a fingerprint case. Consideration will be given to the needs of prosecutors and defense attorneys to be able to quickly determine the results of a forensic science analysis for the purposes of decision making in the adjudicative process – this might take the form of an "executive summary" of the report.

Laboratory Report, NAS, Model Lab Report

A98 The Laboratory Report Project Part 2: Proposed Standards for Forensic Laboratory Reports

Whitney Reed, BS, IUPUI, Forensic Science Program, Indianapolis, IN 46201; Jay A. Siegel, PhD, 8334 Tilly Mill Lane, Indianapolis, IN 46278; and Megan King, BS, IUPUI, Forensic Science Program, Indianapolis, IN 46201*

After attending this presentation, attendees will be able to discuss the proposed criteria for forensic science laboratory reports that are being offered by various organizations, including the American Society for Testing and Materials, the American Bar Association, the American Society of Crime Lab Directors, and specific disciplines within the forensic science community, such as questioned document examiners and firearms/tool marks examiners.

This presentation will impact the forensic science community by presenting the information needed to reach consensus on how scientific lab reports should be compiled.

This presentation is the second of a two-part study of laboratory reports that are issued by forensic science laboratories at the conclusion of their analysis of various types of evidence. The first part of this study was the collection of more than 400 redacted forensic science laboratory reports from members of the American Society of Crime Lab Directors and then content analysis to determine what is actually present in forensic science laboratory reports. This project included reports from several sections of laboratories including drugs, toxicology, DNA, fingerprints, documents, etc. and specimens were solicited from federal, statewide, regional, and local laboratories. The impetus for the study came from the Forensic Science Committee of the National Academy of Sciences that issued its report in 2009. One of the recommendations of the Committee was that forensic scientists adopt a standard laboratory format that presents analytical findings in a rigorous scientific format. Partly as a result of the NAS Report, several organizations have developed models for forensic science laboratory reports. Some of these organizations are in the area of general science, others in the criminal justice system, and still others in forensic science itself. This presentation will relate the major features of all of these organizational recommendations. The goal will be to determine if there is a consensus among organizations as to the content of laboratory reports. The overall study will address the issues of whether there ought to be a single model for all of forensic science, regardless of the type of laboratory report or the jurisdiction of the reporting laboratory, or would it be better to have standard formats for each discipline within forensic science. Whatever standards are ultimately adopted, if any, they must meet the needs of science and criminal justice. A good scientific laboratory report is complete and transparent. It presents all processes and procedures, data, results, conclusions, and limitations including sources and magnitudes of possible error. The current practice in forensic science is for laboratory reports to not contain all of these sections, especially the raw data. Forensic science laboratories feel that this requirement is unduly burdensome, it can be handled by discovery, and all of this detail is not needed, appreciated, or read by attorneys or judges. This project will explore these tradeoffs and possible solutions. The NAS Committee felt strongly that laboratory reports must be scientifically rigorous and complete if forensic science is to be recognized as legitimate science. Discovery is an imperfect means for getting at all of the facts and data present in many forensic science cases.

Laboratory Report, NAS, Model Lab Report

A99 Is There a Need for a (Forensic) Science Ombudsman?

Max M. Houck, PhD, PO Box 6250, Arlington, VA 22206; and Christine Funk, JD, 919 Vermillion St, Ste 200, Hastings, MN 55033*

The goals of this presentation are to learn the role of an ombudsman in an organization, the suggested role of a scientific ombudsman, and the benefits of such a position in forensic laboratories regarding quality, ethics, operations, and safety.

This presentation will impact the forensic science community by offering a novel approach to the mitigation of inevitable conflicts that arise in organizations and, with the creation of a scientific ombudsman, could stop or even prevent some failures that are all too common in the profession. The impact on the profession could be significant.

Conflicts arise within any organization; the role of an ombudsman is to act as a neutral, independent arbiter and mitigator of procedural or ethical conflicts. An ombudsman operates within an organization but outside the traditional hierarchy, typically answering only to the highest authority in the hierarchy. As inside "outsiders," ombudsmen act as informal, impartial sources trained in conflict resolution, providing safe places to share concerns, facilitate early resolutions, and help answer complex or sensitive questions.

Repeated and persistent failures of process and quality control at various forensic science laboratories and service providers suggest the need for a Scientific Ombudsman (SO), one that would not only address the standard questions of conflict in an organization, but also issues of scientific conflict, such as method development, process and protocol application and execution, training and competency testing, proficiency testing, scientific ethics, testimony, and reporting. Lapses in the scientific systems within laboratories, such as North Carolina, Nassau (NY), Houston (TX), and St. Paul (MN) point to the need for internal corrective mechanisms that are outside the traditional hierarchy of laboratory management, especially for those working within a police culture which operates under different mores and norms than would a scientific one. Organizations have already adopted the role of the ombudsman, such as in North Carolina; while laudable, there is a persistent need for an ombudsman whose background includes science and particularly forensic science. For example, in a recent case, this exchange occurred.

> Attorney: "You dont, in your lab, have a lot of the basic minimum standards in place?"
>
> Scientist: "I guess I don't know what the minimum standards are."

At first glance, this may seem to be a quality issue, but if the lack of standardization or even the awareness of it is institutionalized in a laboratory, the concerned scientist cannot turn to management. Management is the source of the problem. Another example would be where laboratory policy requires an inconclusive reporting statement when evidence from the person in question is lacking, causing a scientist to consider this an exclusion; the supervisor rejected the scientist's concerns.

The role of the SO would be similar to a standard ombudsman but with important differences. Any ombudsman is neutral, independent, confidential, and informal. Neutrality means that everyone is treated with equal respect, regardless of status or rank. The ombudsman has no stake in the outcome but rather acts as an advocate for an equitable process and outcome while navigating potential conflicts of interest. Independence means that the ombudsmans position is located in the hierarchy such that it reports directly only to the highest levels of management. Confidentiality; however, is necessary to help resolve conflicts at the lowest levels possible. The only time an ombudsman would release any information without the approval of the complainant would be instances of imminent threat or harm. Finally, an ombudsman is informal: no records (other than statistics) are kept and the ombudsman does not participate in any formal judgment processes.

The SOs role would be the same as any other ombudsmans with several important additions. Beyond the skills and training of a typical ombudsman (e.g., alternative conflict resolution methods), the SO needs to have a science education and career experience, a deep understanding of forensic issues, and training in ethics, quality, and

accreditation; additionally, the SO would need a deep understanding of the criminal justice system, the constitution, and the rights of the accused. The benefits to a forensic laboratory of having an SO include increased productivity, improved management, cost savings in personnel (reduction in lawsuits, turnover, and union issues), cost reductions in legal staff, and other benefits, such as improved morale and reduced illegal or unethical behavior. Many of these benefits involve significant cost savings for the laboratory. The SO is successful if the office is seen as safe, accessible, and credible; employees help themselves to resolve issues; and the management has feedback to improve the organization. The SO is in a unique position to identify and communicate new opportunities and innovations.

The concept of a scientific ombudsman has the potential to improve forensic science operations, effectiveness, and professionalism.

Ombudsman, Negotiations, Professionalism

A100 Tacit Knowledge, Deliberate Practice, and the Development of Expertise in the Forensic Sciences

Walter F. Rowe, PhD, George Washington Univ, Dept of Forensic Science, 2100 Foxhall Rd NW, Washington, DC 20007*

After attending this presentation, attendees will understand the concepts of tacit knowledge and deliberate practice and the role these concepts play in the development of expertise in forensic science.

This presentation will impact the forensic science community by emphasizing the need for forensic examiners to develop personal programs of deliberate practice (research, continuing education, and critical case review) in order to attain the highest level of professional expertise.

This paper reviews recent research on the development of expertise (defined as a high level of performance in a given field) and examines the ramifications of this research for graduate education in the forensic sciences. It will also examine the nature of the scientific knowledge, which students must absorb and then look at the means by which this knowledge is presented to students. The 2009 National Academy of Sciences Report, "*Strengthening Forensic Science in the United States: A Path Forward"* stated: Forensic science examiners need additional training in the principles, practices, and contexts of scientific methodology, as well as in the distinctive features of their specialty. Training should move well beyond intern-like transmittal of practices to teaching that is based on scientifically valid principles.

While no one would contest the value of more education in scientific methodology, the denigration of intern-like training is problematic. According to philosopher Michael Polyani, sociologist Harry Collins, and others, all scientific fields have a component of tacit knowledge—knowledge obtained by deep immersion in groups that possess it. Tacit knowledge comprises knowledge that cannot be gained by reading scientific texts or even by reviewing the peer-reviewed research literature in a discipline. Moreover, tacit knowledge is required for the development of expertise in a scientific discipline. Intern-like transmittal of practices within a scientific discipline is a legitimate mechanism for the conveyance of tacit knowledge (as is on-the-job training in a forensic science laboratory). Doctoral programs in the experimental sciences have long consisted of intensive, intern-like exposure to the practices of the particular field of study. Such exposure is an essential antecedent to conducting doctoral level research.

Extensive research by K. Anders Ericsson and his colleagues has shown that high levels of performance in fields such as athletics, music, and science are the result of long periods of what Ericsson has termed deliberate practice. Deliberate practice means not merely repeating the same tennis swings or pieces of music over and over again. Rather it means pushing the envelope, tackling more and more difficult activities. Deliberate practice also involves a considerable degree of critical self-reflection. According to Ericsson, approximately ten years or 10,000 hours of deliberate practice are necessary for the attainment of true expertise in a field.

The typical graduate student in the forensic sciences begins his or her graduate degree program after completion of four years of study. Only a small part of undergraduate study would qualify as deliberate practice. Even after the student obtains his or her graduate degree in forensic science and moves into a forensic laboratory (perhaps completing a short on-the-job training program), the student is well short of the ten years or 10,000 hours of deliberate practice required to attain true expertise. While reading the scientific literature and attending workshops allow the bench forensic scientist to remain current in his or her field, such activities do not constitute deliberate practice. Moreover, case work in general does not constitute what Ericsson means by deliberate practice. Case work in many forensic science fields is routine and does not challenge the forensic examiner to extend his or her skill set.

Graduate degree programs in forensic science should have three goals: reinforcing students' grasp of scientific methodology, conveying tacit knowledge in the students' fields of concentration, and developing habits of deliberate practice in students. Faculty in graduate forensic science degree programs must possess the tacit knowledge in their respective fields of expertise and may need their own programs of deliberate practice to achieve true expertise. The habits of deliberate practice that graduates can carry into their further careers could include ongoing forensic research, and critical reviews of completed cases. Other approaches to continuing deliberate practice will also be discussed.

Tacit Knowledge, Deliberate Practice, Expertise

A101 Results From the 2009 BJS Census of Publicly Funded Forensic Crime Laboratories

Matthew Durose, MS, Bureau of Justice Statistics, 810 7th St NW, Washington, DC 20531; Kelly A. Walsh, PhD*, Justice Policy Center, Urban Institute, 2100 M St NW, Washington, DC 20037; and Andrea Burch, MS, Bureau of Justice Statistics, 810 7th St NW, Washington, DC 20531*

After attending this presentation, attendees will learn about the state of U.S. publicly funded forensic crime laboratories in 2009 as captured by a national census, which was designed to collect data on a wide range of public laboratory characteristics. Also, the federal agency that commissioned the collection, the research organization that performed the data collection, and the process that each organization undertook to finalize the survey, collect, and analyze the data will be discussed.

This presentation will impact the forensic science community by presenting national-level estimates of public laboratory workload, budget and operations as reported for the year 2009, a one-of-a-kind data collection effort that may influence state and federal legislation, help shape forensic science policy, and aid those seeking to conduct research on the local, state, and federal forensic science systems.

Publicly funded forensic crime labs are a vital component of the criminal justice system, receiving millions of pieces of evidence from law enforcement investigations each year. Within the criminal justice system, there is an ever-increasing reliance on forensic evidence, as well as increasing concern over the role of the nation's forensic crime labs in processing the evidence, issuing laboratory reports, and their subsequent use in legal proceedings.

The Bureau of Justice Statistics' (BJS) Census of Publicly Funded Forensic Crime Laboratories is a recurring data collection that provides a national picture of the services and resources devoted to forensic laboratory activities across the country. This data has been used to help inform policy making and planning at all levels of government. The 2002 and 2005 censuses documented the backlogs in requests for a wide range of forensic services, including controlled substance identification, firearm/tool mark analysis, and latent fingerprint examination. Previously, public attention had been focused almost exclusively on DNA backlogs. A third census was fielded in 2010 and 2011 to capture

detailed data on the workload and operations of the more than 400 federal, state, and local publicly funded forensic crime labs operating in 2009.

This presentation will examine the forensic services provided by publicly funded crime labs during 2009 and identify the evidence areas that account for the largest portion of the national backlog. It will also assess changes since 2002 in the budgets, staffing levels, and quality assurances in forensic crime labs, including lab accreditation, proficiency testing, and the resources devoted to research. The presentation will also examine the uses of advanced technologies to process evidence received from criminal investigations and laboratory information management systems to organize and document laboratory operational and experimental data.

The 2009 census achieved a response rate of ninety-seven percent, the highest in the history of this data collection. Therefore, the statistics produced from these data, and reported in this presentation, provide the most nationally representative information to date.

Census, Public Laboratories, Workload

A102 The Challenges of Translating Forensic Science Research Into Practice: Resources, Backlogs, and Accreditation

Gerald M. LaPorte, MSFS, National Institute of Justice, Office of Inv & Forensic Sci, 810 Seventh St NW, Washington, DC 20531*

After attending this presentation, attendees will have discussed major challenges of translating reseach into practice for forensic laboratories, which are limited resources, increased backlogs, and stringent requirements for accreditation.

This presentation will impact the forensic science community by attempting to dissect these challenging issues with an emphasis on the fundamentally important need for research, but even more vital, translating research into practice.

In 2009, the National Research Council, an arm of the National Academy of Sciences (NAS), published, *Strengthening Forensic Science in the United States: A Path Forward* and stated the following: *Forensic science often produces valuable evidence that can be used to successfully prosecute and convict criminals, as well as exonerate the innocent. Based on technological innovations and the evolution of the field in the past several decades, forensic scientists, as a whole, have continued to improve knowledge and better understand methods and practices. After years of general acceptance about theories and fundamental concepts, the criminal justice system is now demanding scientists to demonstrate that the methods and practices employed in various forensic disciplines are based on accurate, reliable, and valid testing.*

Following the NAS Report, there has been an increase in forensic science research throughout the nation and this has been evidenced by a significant increase in funding by the National Institute of Justice (NIJ) for research, development, and evaluation. From 2009 through 2011, NIJ has funded 174 projects for a total funding of $71,280,619, which has resulted in 122 publications, 264 presentations, and 28 final technical reports. Approximately one-third of the total funding since 2009 has been allocated to basic and fundamental research, but the far majority of funding in forensic science still focuses on applied research and new technology. Analytical instruments, software packages for data processing, and database technology in the forensic sciences have evolved at a significant pace over the past two decades. Although forensic laboratories throughout the United States continue to make progress analyzing evidence efficiently and effectively, backlogs continue to be a major challenge for many forensic service providers. Research in the forensic sciences is often perceived solely as a means to strengthen the underlying science, but research, conducted in the appropriate capacity, can be the impetus to increased quality and efficiency. The 2009 Census of Publicly Funded Forensic Crime Laboratories was released in August 2012 showing that resources dedicated to research diminished significantly from 2002 until 2009. With this reduction in resources, it then becomes very difficult to test and implement advanced technology.

What is the underlying cause of these ever-increasing struggles that forensic laboratories must face? Is it lack of resources? Perhaps the stringent requirements necessary to achieve and maintain accreditation, which in effect, reduce efficiency? Or, are the ever-increasing backlogs prohibiting laboratories from embracing new technology? Should laboratories invest more in research as a means to become more efficient? Technology transfer can be a daunting task for any laboratory in terms of resources, and the question often arises whether multiple labs should be conducting tests on materials that are not frequently submitted and require expensive instrumentation. Is outsourcing a viable option for non-routine analysis? This presentation will attempt to dissect these challenging issues with an emphasis on the fundamentally important need for research, but even more vital, translating research into practice.

NAS, Research, Backlogs

A103 Certification and Accreditation: Useful Tools to Work Toward the International Standardization of Forensic Laboratories

Aldo Mattei, PhD, S.S. 114 km 6,400, 98128 Tremestieri, Messina, 98128, ITALY; and Federico Cervelli, PhD, Univ of Trieste, Via Valerio 10, Trieste, 34100, ITALY*

After attending this presentation, attendees will learn a different approach to design certification and accreditation processes of forensic laboratories, which determine complete control of all processes involved, and to fully document each step of the process and reach a reliable and reproducible conclusion.

This presentation will impact the forensic science community by presenting a new idea for revamping internal procedures of forensic laboratories, which use certification and accreditation processes to lower human errors. The ultimate objective is to set the basis for international standardization of procedures.

At the end of 2009, the European Union fixed the rules of the exchange of fingerprint and DNA evidence through the member States. From November 2015, only ISO 17025 accredited laboratories will be allowed to operate in an international context. The current situation across Europe could suggest a successful extension to all laboratories, operating in a national as well as international level. There is the need to create a common basis within the forensic community in order to be able to share not only the results of the analysis, but also the values. The definition of a common set of methods and contents is also highly recommended. Moving from this starting point, a deep analysis of methods and procedures currently used in western countries was carried out with respect to latent fingerprint laboratories, in order to properly model an overall procedure which starts from an item seized at the crime scene and ends in court with an individualization statement, expressed by a forensic expert.

This lecture presents the key factors for the successful accreditation from different perspectives: agencies, laboratory managers, and forensic experts. Initially the most effective way to establish a robust quality system in the forensic laboratory will be discussed. Even if not mandatory, implementing ISO 9001:2008 within the structure, as the preliminary step toward accreditation, is suggested. In a fully certified laboratory, the effort to reach the accreditation causes a minor impact when compared to the scenario where the agency looks for the accreditation ISO 17025 as the only goal.

Later, the focus will be driven on the documentation phase. The results of this phase are crucial for the accomplishment of successful accreditation. The perception of the accreditation process varies with the perspective of the agency, the management, and the practitioners. Documentation, if not properly designed, could cause a backlog increase and operators could start to perceive the accreditation process as an useless legal requirement.

To be able to turn the negative feeling, the implementation of an integral computer-aided documentation system, designed and

customized on the specific human resources and workflow of the single agency, may resolve all disputes on certification and accreditation processes.

The abovementioned concepts clarify that accreditation and certification are directly related to the reproducibility of the measure, but ISO guidelines do not suggest and/or require that the forensic laboratory choose between alternative possible processes.

The accreditation process could be used to critically revise all the internal procedures. The determination of the most reliable techniques, according to the most recent finding of the scientific research in the specific branch, is an important step forward standardization and human error management.

The forensic community must determine the minimum requirements for the forensic laboratories in terms of logistics, instruments, analytical procedures, personnel education level, training, competency, and proficiency testing with professional forensic organizations playing a role of paramount importance to accomplish this task.

Standardization, Accreditation, Certification

A104 High Resolution Fourier Transform Spectroscopy for the Discrimination of Lab Grade Explosive Precursors and Their Shop-Bought Equivalents

Felicity Carlysle, MSc, Centre for Forensic Science, Royal College Bldg, 204 George St, Glasgow, G1 1XW, SCOTLAND; Niamh Nic Daeid, PhD, Univ of Strathclyde, Centre for Forensic Science, 204 George St, Glasgow, G1 1XW, SCOTLAND; and Erwan Normand, PhD, and Michael McCulloch, MD, Cascade Technologies, Glendevon House, Castle Business Park, Stirling, FK9 4TZ, UNITED KINGDOM*

After attending this presentation, attendees will have an understanding of the application of high resolution Fourier Transform infrared spectroscopy for the characterization and discrimination of explosives precursors and how this can be used to inform and develop explosives detection systems.

This presentation will impact the forensic science community by demonstrating the suitability of high resolution Fourier Transform mid-infrared spectroscopy for the discrimination of different brands of shop-bought materials which have the potential to be used as explosive precursors. The work will also explore the ability of high resolution Fourier Transform mid-infrared spectroscopy and chemometric analysis of the resultant data to distinguish shop-bought materials from each other and from their lab grade counterparts.

The development of accurate and sensitive explosives detection systems is an area of significant and substantial growth. The challenges facing the development of such systems are diverse, and, as a result, there are multiple approaches to solving them. However, one factor is constant through these approaches: in order to detect a compound; it must first be characterized in order to identify distinguishing features that can then be targets for detection.

While many explosives detection systems provide the ability to detect an explosive compound when part of an improvised explosive device, another approach is to further expand the capacity to detect explosive precursors as a means of identifying sites of illicit explosives manufacture, or those involved with the production of explosive materials. This has the potential to continue to prevent the production of explosive devices, and identify the bomb makers. Detecting the manufacture of explosive devices prior to completion has the demonstrated and significant benefit of making seized materials safer for the security services to handle and greatly reduces the risk to the public. An increased knowledge of explosive precursor materials would also continue and strengthen the existing understanding and detection of explosive devices as the materials involved will affect the breakdown of the explosive material and may be detectable as this occurs. For example, a hydrogen peroxide-based explosive such as Triactetone Triperoxide (TATP) will emit hydrogen peroxide vapor which can then be detected.

With the increase in the use of homemade explosive devices, there is continued desire to characterize the precursors of these materials. Due to the nature of these explosives, many of the precursor materials are available “off the shelf” and have many legitimate uses. However, the majority of these “off the shelf” chemicals will not be in a pure form, with various additives present to aid in the materials legitimate use. For example, acetone in nail polish removers is combined with perfumes, emulsifiers, emollients, aversive agents, and colorings. This work investigates whether it was possible to discriminate both between lab grade chemicals and their “off the shelf” counterparts, and between different brands of “off the shelf” materials using high resolution Fourier Transform spectroscopy and statistical analysis.

Previous work has demonstrated that high resolution Fourier Transform mid-infrared spectroscopy paired with basic data analysis is a useful tool for the characterization of explosives and explosive precursors. While the information gathered via this technique is a useful resource in its own right, it is also able to directly inform the development of a quantum cascade laser-based explosives detection system.

High resolution Fourier Transform mid-infrared spectroscopy should be particularly suited to the task of discrimination, as the increased resolution allows the system to be capable of resolving minute spectral features. In addition, while the instrumentation is able to look at minute details, it is also able to cover the whole mid-infrared region so the technique can be considered information rich. The impact of the information produced with a spectrum can then be enhanced by statistical analysis of the data.

This presentation reports the result of the comparison of lab grade liquid explosive precursors with “off the shelf” materials. The comparison and discrimination is made both by visual comparison of the spectra produced and also through statistical analysis of the data.

Explosives Detection, IR Spectroscopy, Statistics

A105 The Overlooked Potential of the Absorption of the Explosive Component 2,4-Dinitrotoluene by Disposable Gloves: Extraction and Detection

Eugene Wickenheiser, PhD, and Matthew Brege, N Michigan Univ, Dept of Chemistry, 1401 Presque Isle Ave, Marquette, MI 49855*

After attending this presentation, attendees will understand how vapors from volatile compounds found in explosives can be absorbed by, and later extracted from, polymers and detected using chromatographic methods. The extraction of the explosives from two polymers will be described and detection of the explosive will be illustrated using High Performance Liquid Chromatography (HPLC). HPLC will also be used for the measurement of the kinetic parameters that determine how long an explosive component resides in the polymers.

This presentation will impact the forensic science community by showing how the results of the study indicate that both the nitrile rubber and latex rubber gloves absorb DNT at readily detectable levels. In the experiments reported here, the half-life of the DNT in nitrile rubber was measured to be 15.9 days. In the experiments, the DNT was detectable (HPLC with UV/VIS detection) in nitrile rubber samples 35 days after removing the rubber samples from a container that also held a small open vial containing solid DNT. The results indicate the potential use of the analysis of gloves to support their prior proximity and exposure to explosives. The period of time that the compound will remain detectable in the rubber will depend on the time it is exposed to the compound, the nature of the exposure (e.g., closed or open environment), the environmental conditions once the rubber is no longer exposed to a DNT source, and the detection method (the use of a gas chromatograph/mass spectrometer will extend the detection period).

The absorption of volatile compounds by specific materials is well documented, and is the basis of Solid Phase Micro Extraction (SPME). In SPME, a fiber coated with a specific absorbent is exposed in a container holding a sample, and the volatile compounds released by the

sample are absorbed by the material on the fiber. In this approach, the absorbed compounds concentrated on the fiber are isolated from the bulk of the sample. The absorbed compounds are released from the fiber later for analysis by heating the fiber. Polymeric materials found at crime scenes that possess the innate ability to absorb a volatile compound have apparently not been studied with respect to their potential to absorb volatile evidence. The hypothesis of this study is that specific polymers, for example, those that are found in disposable gloves, have the ability to absorb and retain explosive components which can be extracted later and detected.

In this study, the ability of latex and nitrile rubber polymers to absorb the vapors of 2,4-dinitrotoluene (DNT; a component in several explosive formulations) was studied. The extraction conditions were developed, and the half-life of the DNT in glove samples was determined. The use of DNT is uncommon in consumer products; aside from explosives, its primary use is to synthesize the precursor to azo dyes and polyurethane, both of which are found in consumer and industrial products. The DNT is used to synthesis toluene diamine and two or more synthetic steps later (depending on the product), the toluene diamine is converted to an azo dye or polyurethane. DNT has been reported as an impurity in precursors to polyurethane, and it is present as an environmental contaminant in soil and water in locations where DNT has been produced for the uses stated above.

The results of the study indicate that both the nitrile rubber and latex rubber gloves absorb DNT at readily detectable levels. In the experiments reported here, the half-life of the DNT in nitrile rubber was measured to be 15.9 days. In the experiments, the DNT was detectable (HPLC with UV/VIS detection) in nitrile rubber samples 35 days after removing the rubber samples from a container that also held a small open vial containing solid DNT. The results indicate the potential use of the analysis of gloves to support their prior proximity and exposure to explosives. The period of time that the compound will remain detectable in the rubber will depend on the time it is exposed to the compound, the nature of the exposure (e.g., closed or open environment), the environmental conditions once the rubber is no longer exposed to a DNT source, and the detection method (the use of a gas chromatograph/mass spectrometer will extend the detection period).

The principle established by the presented results will impact the forensic community by alerting the community to the potential use of polymers as evidence when volatile compounds are relevant to the case.

Explosive Detection, Explosive Vaporization, Explosive Absorption

A106 Hydrophobic and Hydrophilic Ionic Liquid Mixtures Used for Explosive Analytes

Yasmin Sarmiento, U.S. Air Force Academy, 2304 Cadet Dr, USAF Academy, CO 80841; Hannah Miller, MS, 2355 Fairchild Dr, Ste 2N353, U.S. Air Force Academy, CO 80840; Candice Bridge, PhD, U.S. Army Crime Lab, 4930 N 31st St, Forest Park, GA 30297; and Matthew J. Bohn, PhD, 1330 Inverness Dr, Colorado Springs, CO 80910*

After attending this presentation, attendees will have a general understanding of the potential applications afforded by mixtures of hydrophobic and hydrophilic ionic liquids, specifically their contributions to improved rate, specificity, and yield with forensic sampling of explosive analytes.

This presentation will impact the forensic science community by leading to the identification of homogenous ionic liquid mixtures that are able to collect a wide range of analytes of drugs and explosives, which is important to the forensic and chemical investigative community in ensuring relative ease and quickness when collecting field evidence.

Within the last decade, ionic liquids have become an increasingly popular topic within all disciplines of science because their unique physical and chemical properties have sparked interest in potential applications and innovative developments. Ionic liquids (ILs) are low-melting salts in their liquid state which are completely comprised of cations and anions. The development of room-temperature ILs in the early 1990s by chemists Wilkes and Zaworotko opened up a gateway toward more specified properties and functional possibilities, most notably advantages such as negligible vapor pressure, extreme thermal stability, customizable tailorability, and recyclability.[1] Especially with today's push for the Green Chemistry movement, it has become a higher priority to reduce or even eliminate the use of hazardous substances within chemical processes. Therefore the utilization of ionic liquids as a replacement for common solvents has been the focus of much research in recent years.[2,3] Depending on the specific ionic liquid, characteristics can range according to hydrophobicity, hydrophilicity, visoscity, conductivity, solubility, and electrochemical window.[3] With over 1,000 ionic liquids reported in literature today, there may be about 10^{18} possible cation/anion combinations—the properties and application possibilities are endless. The purpose of this study is to create homogenous ionic liquid mixtures consisting of a hydrophobic and hydrophilic component in an effort to maximize the range of analytes to be collected, retained, and analyzed quantitatively and qualitatively.

In investigative laboratories, specifically those pertaining to forensic sampling, it is in one's best interest to identify an optimum solvent for a group of compounds, i.e., one solvent for drugs and another for explosives; however, when examiners are working within the field, they are not able to distinguish one from another. For example, if an investigator comes across an unknown white powder, he is unable to tell whether it is cocaine, Triactetone Triperoxide (TATP), or simply powdered sugar. By using an essentially universal solvent, not only will the field agents reduce the amount of items they must carry onto the field, but they also minimize the risk of destroying the sample by using the wrong solvent and, due to the negligible vapor pressure, preserve the sample for analysis.

The approach of this study included tests for homogenous mixtures, solubility tests with four different explosives (TNT, Compound B, RDX, and PETN), which were then analyzed via Direct Analysis in Real Time-Mass Spectrometry (DART®-MS). It is common to have difficulty mixing molecular solvents, but it is considerably more complex when dealing with ionic liquids (salts) since each mixture could result in a binary mixture composed of three or four components as each salt must have an anion and a cation. In order to reduce unnecessary complexity, two ionic liquids with a common ion were selected for the homogenous tests. Out of the 27 mixtures tested, 17 were determined to be homogenous. Solubility tests with TNT were then conducted on the homogenous mixtures, in which six mixtures showed an immediate color change from clear and colorless to a dark purple which turned into a deep blood-red color over time. It is interesting to note that all six mixtures contained the EMIM-BF_4 ion. From previous studies, this drastic color change is suspected to be the cause of a charge transfer complex which reacts only with the TNT molecule. Nine of the remaining homogenous mixtures showed a slight or delayed color change. When the initial six mixtures, containing the EMIM-BF_4 ion, were tested with the other explosives, Compound B and RDX were deemed soluble, whereas PETN was considered only partially soluble or had limited solubility. Compound B was the only other explosive to display a color change within the mixtures, which is expected because it contains 40% TNT and 60% RDX. These samples were characterized via DART-MS, which confirmed the presence of TNT, RDX, and PETN within seconds. It is important to note that all analyte peaks were clean and there was no matrix interference from the collection swab, suggesting that the ionic liquid mixtures were able to not only retain the analyte, but also preserve the swab during analysis. This is an extremely important finding because this shows great potential for improved rate, specificity, and yield for forensic sampling.

Ionic Liquids, Explosive, Drugs

A107 The Influence of Acid Catalysts on Triacetone Triperoxide (TATP) Crystal Morphology

Peter J. Diaczuk, BS, 445 W 59th St, New York, NY 10019-2925; and Jack Hietpas, BS, 641 Park Ave, Apt 3, Syracuse, NY 13204*

Attendees of this presentation will learn about the different crystal morphologies formed as a result of using different acid catalysts during the synthesis of Triactetone Triperoxide (TATP).

This presentation will impact the forensic science community by revealing the considerable difference among crystals depending on the choice of acid, which may contribute to an investigation when the precursors are not known.

The use of improvised explosives for criminal, domestic and international terrorism is an ever-increasing problem. Methods for homemade manufacture of these non-military and non-industrial explosives often require little-to-no background in chemistry. TATP, a relatively exotic explosive, is currently receiving considerable attention because of this ease of procurement of starting materials and very simple synthesis reaction. First documented by Wolfenstein, the synthesis of TATP has been the subject of interest and research by scientists and hobbyists for over a century.[1] The two primary starting materials are easily available in relatively pure form from hardware stores, home improvement centers, and pharmacies, as well as in impure form when mixed with other compounds to create several different commercial products (e.g., bleaching agents, nail polish remover, drain cleaners, and many others). The "impurities" in these commercial products have been successfully studied and analyzed for carry-over into synthesized TATP by several instrumental methods.[2,3] Studies using different acid catalysts and their affect on the finished product have also been performed using instrumental methods.[4,5]

TATP is a powerful explosive but other undesirable properties exclude it as a viable explosive for military, commercial, or industrial use. In addition to its high vapor pressure, resulting in very rapid sublimation even at room temperature, it is far too sensitive to shock, impact, friction, and temperature for it to play a practical role in legitimate use, but these properties haven't discouraged its use in terror bombings (and bombing attempts) worldwide during its resurgence over the past 30 years. The dangers involved in the manufacture and handling of TATP have claimed the lives of many would-be "chemists;" in fact, the material is nicknamed the "Mother of Satan" by terrorist bomb makers due to its deadly instability and unpredictability.

The research presented here builds on previous work detailing the optical properties of two identified TATP polymorphs, and a preliminary study by Miller examining the crystal morphology of TATP synthesized using different acid catalysts.[6,7] This presentation expands on the work of Miller by further detailing the potential linkage between TATP crystal morphology and the specific acid catalyst used during its synthesis. The reagent-grade catalysts used for this study include sulfuric acid, hydrochloric acid, nitric acid, and phosphoric acid. The other parameters of the manufacturing process, including reaction temperature, number of times the precipitate was washed, and the temperature of the sublimation and recrystallization process, were kept identical. After synthesis and subsequent washing of the precipitate, the recrystallized crystal morphologies were clearly distinguishable from each other depending on which of the four acid catalysts was used during manufacture. Crystals catalyzed with sulfuric acid were almost cubic, those with hydrochloric acid were long needles, those with nitric acid were clumps of short needles, and those with phosphoric acid were rosettes. The results from these experiments provide a foundation in which a potential linkage between the acid catalyst used for TATP manufacture and the morphology of the synthesized crystals can be established. This information may potentially help as an investigative lead during initial phases of a bombing event when attempting to determine provenance of TATP samples recovered as evidence.

TATP, Crystal Morphology, Microscopy

A108 Raman Microspectroscopy and Advanced Statistics for Detection and Characterization of Gunshot Residue (GSR)

Igor K. Lednev, PhD, Justin Bueno, MS, and Vitali Sikirzhytski, MS, SUNY Albany, 1400 Washington Ave, Albany, NY 12222*

The goal of this presentation is to describe the development of a novel and alternative method for Gunshot Residue (GSR) analysis.[1] After attending this presentation, attendees will have a better understanding of recent advancements of this application of Raman microspectroscopy for GSR analysis, identification, and discrimination. The implementation of advanced statistics to differentiate experimental Raman spectra collected from non-equivalent GSR samples will be discussed.

This presentation will impact the forensic science community by having the potential to greatly impact the accuracy and effectiveness of shooting incident investigations.

Raman spectroscopy has numerous applications in forensic chemistry. Raman analysis is a technique which can obtain confirmatory class identification of analytes through low intensity laser light scattering. The technique is non-destructive, rapid, sensitive, and requires little or no sample preparation. Furthermore, portable Raman spectrometers are readily available, allowing for crime scene accessibility. Raman spectroscopy offers several advantages over the current methodology for GSR analysis. The technique has been shown to detect components from both the organic and inorganic constituents of GSR. This is contrary to current GSR elemental analysis methods which rely solely on the detection of the heavy metals (lead, barium, and antimony). This is problematic since environmental concerns have led to the increased popularity in heavy metal-free or "green" ammunition. It has been found that in the absence of heavy metals, current elemental analysis techniques are severely hindered when making accurate identification of GSR samples. Additionally, the probability of environmental and manufacturing particles assigned (incorrectly) as being GSR has increased with the onset of "green" ammunition. Until recently, the application of Raman spectroscopy for GSR analysis was largely unexplored, although this approach is not dependent upon detecting

metals, and is more capable of differentiating environmental contaminants and GSR. Therefore, a Raman spectroscopic method displays numerous advantages in specificity when compared to current techniques.

The firearm discharge process could be considered analogous to a complex chemical reaction. Therefore, the chemical composition of the products (GSR particles) is directly related to the chemical nature of the reagents (firearm-ammunition combination) and the conditions of the reaction. Preliminary results show that Raman data collected from GSR particles originating from different firearm-ammunition discharges were successfully classified according to caliber; 0.38 inch and 9mm caliber firearm discharge samples were probed using a 785-nm Raman excitation. Resulting data was treated with statistical methods (performed using Matlab with the PLS toolbox) such as Principle Component Analysis (PCA) and Support Vector Machines (SVM). The results show a high probability of this method to correctly classify data from the two examined calibers. Preliminary results illustrate that the variations between non-equivalent GSR samples can be detected through this method. Since GSR is often collected from a suspect, the application of this method to forensic investigations would provide a link between GSR collected from the shooter and the crime scene.

This emerging technique illustrates the possibility for an on-scene, non-destructive, identification and chemical characterization method for GSR. This method has the potential to greatly impact the forensic science community by increasing the accuracy (and discriminatory power) of GSR detection. The most direct application for this research is a method to exclude a specific firearm-ammunition combination as producing an evidentiary GSR sample. The comparison of a laboratory-generated GSR sample discharge and an evidentiary GSR sample, can be made without extensive preliminary studies.

Gunshot Residue, Spectroscopy, Statistical Analysis

A109 Analysis of Lead-Free Ammunition by Scanning Electron Microscopy Using Energy Dispersive X-Ray Spectroscopy and Discrimination of Samples Using Multivariate Statistical Methods

Seth R. Hogg, BS, 578 S Shaw Ln, Rm 308, East Lansing, MI 48824; Brian C. Hunter, MD, 630 S Saginaw St, Flint, MI 48502; and Ruth Waddell Smith, PhD, Michigan State Univ, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

The goal of this presentation is to explore statistical methods for differentiating non-traditional Gunshot Residue (GSR) samples arising from six non-toxic, lead-free ammunitions. The formulation of non-toxic ammunition excludes the traditional signature composition of GSR, a mixture of lead (Pb), barium (Ba), and antimony (Sb). The removal of the unique combination of these three elements also renders differentiation of non-toxic GSR from environmental sources more challenging.

This presentation will impact the forensic science community by further exploring the combinatorial feasibility of Energy Dispersive X-ray Spectroscopy (EDS) and multivariate statistical analysis through the characterization of relatively understudied non-toxic ammunition. The application of these procedures allows for the statistical comparison of spectra, rather than the potentially more subjective visual comparisons. In turn, the statistical procedures allow comparisons to be made based on mathematical principles with measureable confidence in the comparison.

Traditionally, during the identification of GSR both morphological features of particles and elemental compositions are determined. In most laboratories, the presence of spherical particles containing Pb, Ba, and Sb indicates the definitive presence of GSR. However, the emergence of lead-free ammunition in response to health and environmental concerns requires a broader definition of particle compositions consistent with GSR. Unlike conventional primers, manufacturers of non-toxic ammunition may use vastly different elemental compositions to achieve the final product. For example, aluminum, silicon, potassium, strontium, and calcium may be included in the primer. Thus, no single particle composition can be easily amended to the description of GSR.

This study collected elemental profiles for six commonly available brands of non-toxic ammunition as well as for the most common brand of road safety flare utilized in the United States. Flares were included in the study due to their high strontium content and their potential for similarity in element composition to non-toxic ammunition. For each brand, one box of 9mm caliber ammunition was purchased and five rounds from each box were fired in the presence of three conductive carbon tabs positioned along the trajectory of the bullet, allowing capture of GSR. An additional five rounds from each box were disassembled to remove the propellant and bullet before being fired. These rounds were fired perpendicular to two conductive carbon tabs, allowing for the capture of only primer components. Road flares were burned in the presence of two conductive tabs positioned above the flare to capture any ejected particles during the combustion process.

A carbon tab was analyzed from each of the resulting 61 samples using a Scanning Electron Microscope (SEM). Particles visually consistent with the morphology of GSR were located on the tabs at an accelerating voltage of 20 keV. Once potential particles were discovered, the visual area of the sample was designated as a region of interest and all particles within view were analyzed by EDS. Searching of each sample finished after 30 regions of interest were identified. Each EDS spectrum was analyzed from 0-10 keV for elemental composition determination. Several different data pretreatment methods (including scaling and normalization procedures) were applied to the resulting spectra prior to statistical analysis. The pretreated data were then analyzed using Principal Components Analysis (PCA). This procedure is a useful visualization tool where samples with similar EDS spectra cluster closely in the resulting scores plot while samples with different spectra position further apart. In this study, PCA was first used to investigate association of ammunition by manufacturer, based on the element profiles generated. Then, the association of samples from whole bullets to those from primers only, and the differentiation of actual GSR from a ubiquitous road flare, were also investigated using PCA.

The application of data pretreatment and statistical procedures for SEM-EDS examinations of GSR allows greater confidence in results from a technique that is traditionally thought of as merely qualitative. Likewise, the lessons learned from the EDS analysis of GSR may also be applicable in the comparison of other items of trace evidence based on element composition, for example, comparisons of glass fragments or paint samples.

Gunshot Residue, SEM-EDS, Chemometrics

A110 Uncertainty Considerations for Measuring the Refractive Index of Glass

Eric L. Everts, MS, 5 Hailey Ln, Morgantown, WV 26505; and Suzanne Bell, PhD*, West Virginia Univ, 1600 University Ave, Oglebay Hall, Rm 208, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand the need for assessing uncertainty in glass refractive index measurements.

This presentation will impact the forensic science community by further validating the need to assess uncertainty in all areas of forensic science.

Refractive index has been used for comparison of glass analysis for many years. In this project, refractive index measurements were performed on 63 samples from 41 sources of glass using a glass reflective index system. Each sample was characterized by eight Refractive Index (RI) measurements collected at different places on the sample and some sources were characterized by up to three samples collected at different places on the source. Refractive index is

traditionally thought of as a means of classifying and differentiating glasses, but it is a numerical measurement and as such, should always be accompanied by an estimation of the uncertainty associated with the measured value. This is consistent with the recommendations made in the 2009 National Academy of Sciences Report. This project focused on determining a reasonable and defensible uncertainty estimate for refractive index measurements as taken in a typical forensic setting.

The results of this project reiterated the issue of inherent heterogeneity. This issue becomes more pronounced as the capabilities of the measurement process improve; the readability of RI measurements observed using double polarization light microscopy and refractive index oils may go to three decimal places while the glass reflective index system is capable of reliably determining five decimal places. There were several instances where samples taken from the source produced statistically significant different RI measurements. In casework, the ability to have many samples from a larger source may not be possible and, as a result, such differences could conceivably lead to an incorrect classification of a glass sample. A primary goal of this project was to establish the minimum number of RI measurements that should be taken across a sample to establish reasonable and defensible measurements of intra-sample variability.

Homogeniety of the glass sample is not the only factor of uncertainty in this study; other contributing factors including the calibration curve and instrument drift over time should be considered. In this project, these factors were incorporated into an uncertainty budget table. Here, a conservative approach was taken in which all contributing factors were kept in the budget; rounding at the end to the correct number of significant figures insured that factors were incorporated as their relative magnitudes dictated.

To evaluate the impact of retaining an uncertainty value for each RI measurement, pairwise comparisons of all 41 sources were analyzed to determine when the range of the two results overlapped. Here, the range around each RI was determined in two ways: first, from the standard deviation of the replicate measurements from each sample; and second, from the uncertainty budget, which led to the combined standard uncertainty value. This value was multiplied by a coverage factor of k=2, which roughly corresponds to the 95% confidence level. The number of pairwise comparisons more than tripled from 18 pairwise comparisons using one standard deviation to 74 pairwise comparisons using the expanded uncertainty. This clearly demonstrates the utility of using an uncertainty budget approach for RI measurements. In the event of casework and just the standard deviation was evaluated and used for RI determination, false positives or exclusions could have been made.

Statistical tests were performed on the three major categories of glass in this study; car windows, house windows, and bottles. Only car windows and house windows were found to have a statistically significant difference in their mean RI values; however, when the expanded uncertainty is considered, there is notable overlap between the three categories of glass. Therefore, the results of this study indicated that an RI measurement alone is insufficient to categorize glass based on source. Although this set of 41 sources does not comprise all of the possible sources that one could encounter in casework, the major categories of glass are present. This is also a smaller sample size compared to the larger picture, but the same types of trends are found here that are seen in the FBI study of float glass dating back to the 1960s.

Uncertainty, Refractive Index, Glass

A111 Forensic Glass Discrimination and Classification With Infrared Microprobe Analysis

Brooke W. Kammrath, PhD, Univ of New Haven, 300 Boston Post Rd, West Haven, CT 06516; Nicholas D. Petraco, PhD, John Jay College of Crim Just, Dept of Science, 899 10th Ave, New York, NY 10019; John A. Reffner, PhD, 97 Ocean Dr E, Stamford, CT 06902; and Thomas Kubic, JD, PhD, 8 Pine Hill Ct, Northport, NY 11768*

After attending this presentation, attendees will gain a better understanding of how infrared microprobe analysis can be applied to the forensic analysis of glass.

This presentation will impact the forensic science community by showing how infrared microspectroscopy can be used to aid in the discrimination and classification of glass evidence.

Glass is a ubiquitous material, and as a result, it is commonly recovered as transfer evidence when glass objects are broken during the commission of a crime. Vehicle windows, architectural windows, containers, headlamps, light bulbs, and mirror glasses are some of the major sources of this evidence at a number of crime scenes, including, but not limited to, car accidents, robberies, vandalism, bombings, and homicides. Broken glass is readily transferred to the breaker and to any individual or object in the vicinity of the breaking event; thus it has the ability to associate a suspect with a crime scene location or item and, in some cases, the time of occurrence. The significance of glass evidence is enhanced when the fragments are determined to be indistinguishable in all measured properties from the broken glass object. Conversely, if the recovered fragments differ in their measured properties from the broken glass object, then that glass object can be eliminated as a possible source of the glass from the suspect. The analysis of the molecular structure of glass is a novel forensic method that provides knowledge about glass chemistry that is not currently employed by forensic scientists as well as improves the discriminatory power within this class of transfer evidence.

Infrared (IR) spectra contain extensive information about the molecular structure of the complex silicates in commercial glasses. This research is based on measuring the Attenuated Total Reflection (ATR) mid-IR spectra of soda-lime silicate glasses to detect variations of the molecular structure to assist in the comparison of glass evidence.
The use of ATR mid-IR spectra for the discrimination and classification of glasses was investigated. Discrimination error rates of approximately 5% and classification by end-product (window or container) error rates of less than 2% were achieved with multivariate statistical methods, specifically Principal Component Analysis-Canonical Variate Analysis (PCA-CVA) and Partial Least Squares Discriminant Analysis (PLS-DA).

The mid-IR microprobe analysis of glass requires only minimal additional sample preparation to that which is already done for Refractive Index (RI) analysis and uses IR investigated samples that are the same size and smaller than the ablated hole made in Laser Ablation-Inductively Coupled Plasma-Mass Spectrometry (LA-ICP-MS). Thus, mid-IR microprobe analysis can be used to provide additional discrimination for glass samples that are indistinguishable by RI and too small for elemental analysis. In addition, most forensic laboratories have IR spectrometers and/or microprobes which are used in the analysis of a plethora of evidence types including, but not limited to, paint, fibers, plastics, adhesives, and illicit drugs. Thus, this technique would not necessarily require a crime laboratory to purchase new instrumentation or require extensive training for trace evidence examiners. As a result, the use of ATR mid-IR microspectroscopy for forensic glass comparisons and analysis could potentially be implemented by forensic laboratories immediately and with minimal expense. ATR mid-IR spectral analysis provides information about the molecular structure of soda-lime silicate glass to support other traditional analysis and strengthen the association of this evidence.

Glass, IR Spectroscopy, Chemometrics

A112 Determination of Unique Compositional Patterns in Glasses by Micro-XRF: Multivariate Approach and Statistical Analysis

Sergey Mamedov, PhD, 3880 Park Ave, Edison, NJ 08820*

After attending this presentation, attendees will learn about application of micro-XRF to glass and soil analysis.

This presentation will impact the forensic science community by providing practical information about application of micro-XRF to chemical analysis.

X-ray Fluorescence (XRF) spectroscopy is a useful tool for identification of substances and confirming their identity with little or no sample preparation. New capabilities of the energy dispersive XRF analytical microscope (micro-XRF) enable the recording not only of spectra from small glass particles (as small as 50-100 microns) but also the hyper-spectral image of any object with high spatial resolution (<10 micrometers). Hyper-spectral image is a set of the data which contain information about position of the point along with full XRF spectrum at this point. This means that the data can be mined for unsuspected elements after the measurements have been made, and that statistical methods (multivariate analysis) can produce chemical distributions of the elements (Image analysis) and/or material classification based on Principal Component Analysis, in particular, with association between elements that can aid in identification of bonded phases. For example, statistical analysis of micro-XRF data for glasses can be used to locate the make, model, and year of car by analyzing a glass chip. This presentation will provide practical insights into the application of the micro-XRF to the analysis of glasses and soil.

An XRF analytical microscope was used in this study. This desktop unit utilizes a portable 50W X-ray source for excitation, two switchable (as small as 10 microns) monocapillaries for different spatial resolution, and the unique capability to work in vacuum (enhanced sensitivity for light elements), in partial vacuum, and under ambient conditions. In addition to the XRF spectrum/image, the XRF microscope provides a micro-transmission image of the material. Standard software package includes quantification using fundamental parameters method, basic statistical analysis for multi-point measurements, image analysis, and image processing.

X-ray fluorescence spectrum of the glass strongly depends on X-ray optical system, sensitivity of the detector, and accelerating voltage. In addition, background from the substrate will contribute to the spectrum of the small glass pieces because excitation X-ray penetrates through the glass and interacts with substrate. This effect becomes very important for particle size of 300 microns (or less) or powder. The change in the spectrum due to the shape or size will lead to the different quantification of the sample (different composition). A method which allows one to minimize this effect or take it into consideration was developed. In this presentation, examples of spectra from bulk material, small glass pieces, and powder will be shown.

Spectra of glass from several car manufacturers and commercial glasses (microscope slides, window glasses, fuse glass) in the range of 1.00-40.96 keV (<400 spectra) were collected and analyzed. Because only a few spectra have an additional features in the energy range above 15 keV, spectra were truncated and analysis was done in spectral range of 1.00-15 keV. Standard FPM algorithm without any correction and/or calibration was used to calculate concentration of Na_2O, MgO, Al_2O_3, SiO_2, K_2O, CaO, TiO_2, MnO_2, Fe_2O_3, As_2O_5, and CeO_2 in all samples. This set of concentration to build a data set for PCA was used. All spectra and concentration data sets were scaled before Principal Component Analysis was applied. Correlation between classification based on spectral analysis and concentration analysis will be shown.

Glass, XRF, Analysis

A113 Size Limitations for the Analyses of Float Glass Fragments by LA-ICP-MS: Influence of Fragment Size on Measurement Accuracy and Discrimination Potential for Glass Analysis

Stefan Becker, PhD, Marc Duecking, MS, Peter Watzke, MS, and Peter Weis, PhD, Bundeskriminalamt, Forensic Science Institute, KT 13, Wiesbaden, 65173, GERMANY*

After attending this presentation, attendees will understand principles concerning size limitations for the analyses of float glass fragments by Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS), also addressing such issues as criteria to determine the minimum sample requirements, and effects of deviating from the standard protocol.

This presentation will impact the forensic science community by serving as a key aspect to raise awareness on the limitations of applying LA-ICP-MS in forensic glass analysis.

Over the last two decades, LA-ICP-MS has been proven to be a reliable and powerful technique in forensic glass analysis, especially for the comparative analyses of questioned and control glass samples. Harmonized measurement parameters have been established over time, leading to methods commonly used by the majority of forensic laboratories employing LA-ICP-MS. These methods are using single spot analyzes, multiple sampling positions on a single fragment, 10 Hz repetition rate, a crater diameter 50-80 micrometer, and an ablation time of 50 seconds or more. These methods commonly applied require a material amount for each analysis in the range of 500-1400ng assuming a crater depth of approximately 100 micrometer and crater diameter ranging from 50 to 80 micrometers. Applying six analyses on each glass fragment, the minimum sample requirement for a glass fragment to be suitable for analysis is approximately given by a minimum sample size of 0.4-0.5mm and a minimum thickness of 0.1mm.

In casework, a fair amount of recovered glass fragments might have a maximum-size length smaller than 0.5mm and many glasses exhibit a very small thickness (<0.1mm). Measurement of these fragments can be done with a reduced number of readings (ablation spots) or a shortened transient signal caused by thin fragments leading to depleted/reduced sample information. Based on the significantly smaller sample amount to be transported into the ICP-MS and on shorter integration intervals, a larger standard deviation that has an impact on the match criteria and a reduced discrimination power can be expected.

This presentation will evaluate the effect of smaller sample sizes on the analytical results (i.e., accuracy), and hence the discrimination potential of the method.

In this presentation, results from the investigation on over 70 fragments from three different float glasses will be presented. The selection of the glass samples was based on their different color and thermal history: a green non-tempered float glass (Vegla, Herzogenrath/ Germany), a clear non-tempered float glass (Flachglas, Weiherhammer 1/ Germany), and a green tempered float glass (Libbey Owens Ford, Lathrop CA/ U.S.A) were investigated. Glass fragments of different sizes were selected from each of these glasses and physical properties (size, mass) were documented. Samples were analyzed using a standard LA-ICP-MS method using helium as a transport gas.[1] The effect of the limited sample size on the analytical results and the impact of reduced analytical information on the discrimination power using a standard LA-ICP-MS method were investigated.

The evaluation was done applying pairwise comparisons of the data sets using a modified four sigma match criterion already described in literature.[2] Results of a particular fragment size were compared with the results from different fragments of the same glass and were also compared with the results of glasses of different origin in order to evaluate type one and type two errors. Also, the application of modified ablation parameters with reduced repetition rate and smaller spot size is described and evaluated.

LA-ICP-MS, Float Glass, Sample Size

A114 Discrimination of Fiber Reinforced Plastics (FRP) Using Thermogravimetry (TG)

Yukimi Yamazaki, BS, Yasushi Mandai, and Naoko Otomo, BS, Japan Coast Guard, Reserch Center, 1156 Izumi-cho, Tachikawa, JAPAN*

After attending this presentation, attendees will understand how the analyses of samples concerning collision cases between ships are performed in Japan. In addition, this presentation will introduce the method for identification of Fiber/Glass Reinforced Plastics (FRP/or GRP) using Thermogravimetry (TG).

This presentation will impact the forensic community by demonstrating a method to discriminate between thermoset polymers not only for ships collision cases but also for land criminal cases since TG has not often been used by the forensic community.

In Japan, there are on the average 30 cases a year of hit-and-run collision accidents between ships, as well as some accidents where the crew on duty does not recognize the collision. For investigation of these cases, paints which are transferred from the hull of one ship to another would be the most valuable type of evidence. Paint samples taken from both ships are observed to determine if they have the same appearance (sequence of layers, colors, etc.). Each layer is then analyzed and compared using Fourier-transform infrared microscopy and scanning electron microscope-energy dispersive X-ray spectroscopy.

Smaller vessels such as fishing and pleasure vessels are commonly built of Fiber Reinforced Plastics (FRP) and are surfaced with a “gel coat” often colored white. When FRP ships collide with other ships, pieces of gel coat (sometimes with paints) are likely to be transferred and collected as samples. The gel coat is an unsaturated polyester (UP) resin-based plastic matrix with some pigments and additives. There are traditionally two major types of UP resin used for vessel construction; orthophthalic (ortho); and isophthalic (iso). The major pigment is always TiO_2 because of its color and there are also other pigments/fillers (clay, talc, etc.) included in small amounts. When ships get older, they sometimes have single or multi-layered paint, but newly built FRP ships have no paints on the gel coat (except for antifouling paint on the bottom of the hull). Therefore, it has been recognized to be difficult to characterize gel coats. This presentation will examine the data of gel coat samples which were analyzed in 28 collision cases since 2007. Among the samples from 28 cases, 14 were ortho (10 had paint layer(s) on their surfaces), 13 were iso (four painted), and one was an other type of polymer resin (not painted). Although all 14 ortho samples, six of the iso samples, and the one resin were discriminated by their own IR spectra or by variety of their paint layers, it was difficult to distinguish two pairs and a group (containing four samples) of iso’s without paint on their surface. In order to characterize these gel coats, a further analysis method was required.

TG is a popular method for evaluating polymer properties; however, the use of this technique for forensic purpose has rarely been reported. In this presentation, the result of the TG of gel coats will be introduced. The primary goal of this study was to optimize the experimental conditions; atmosphere, temperature range, heating rate, and sample amount. Several gel coat samples collected from dockyards were analyzed with thermogravimetric differential thermal analyzer (TG-DTA). All of the thermogravimetric curves showed at least three degradation processes under air atmosphere. By comparing the temperatures corresponding to the maximum rate degradations, some pairs of samples which have no differences in IR spectra and elemental analysis had distinct discrepancies. The differences between samples may be attributed to the minor additives and cross-linking structure of polymers.

FRP, TG, Paint

A115 Systematic *In Situ* Identification of Pigments in Paint by Raman Microspectroscopy

Christopher S. Palenik, PhD, Microtrace, 790 Fletcher Dr, Ste 106, Elgin, IL 60123-4755*

The goal of this presentation is to demonstrate ways in which Raman spectroscopy can be incorporated in a forensic laboratory to improve the evidentiary significance of paint evidence.

This presentation will impact the forensic science community by suggesting the first systematic organization of pigment analysis that is broadly applicable to forensic paint analysis.

Colorants (pigments and dyes) surround us in everyday life, yet beyond spectrophotometric comparisons of bulk color, forensic analyses typically ignore the colorants within a sample. This is due in large part to the fact that colorants are present at low concentrations, and pigments are, in addition, typically quite small (<1µm), making them difficult to access analytically. Successes have been achieved through a number of microanalytical methods, including polarized light microscopy, infrared microspectroscopy, microchemistry, micro x-ray fluorescence, and X-ray diffraction; however, the application of each of these approaches is limited by one or more factors such as analytical volume, specificity, sample preparation requirements, or the level of interpretation expertise required.

Raman microspectroscopy suffers from two of its own major limitations, which are fluorescence and the current lack of a systematic approach to pigment identification. Fluorescence can be minimized through the use of multiple laser wavelengths, photo bleaching, and background removal, yet it remains the Achilles heel of the technique, leaving some pigment spectra inaccessible by this method. The second issue, regarding interpretation, is being reduced by the fact that more and more laboratories are obtaining and using Raman systems; however, the framework for analyzing and interpreting paint evidence remains limited. This presentation, whose primary focus is to address this shortcoming, will provide an overview of our past six years of research, which has focused on the development of: (1) a pigment identification scheme; (2) laboratory methods designed to optimize pigment analysis; and, (3) of interpretation and significance studies that will provide a framework for assessing the value and uses of pigment information.

Through the development of an extensive database of pigments (>1,100 pigments and >325 unique pigments), a classification scheme for the systematic identification of pigments was devised. Each pigment in this database has been carefully verified by orthogonal methods and categorized by chemical structure. The Raman spectra and pigment chemistry have been used together to develop a flowchart that permits classification of pigments on the basis of strong peaks, which is intended to be applicable at the bench level. Within the context of an investigation, it also permits an examiner to determine which pigments can (and can’t) be discriminated on the basis of strong peaks in a sample spectrum. This organization provides the first systematic basis for addressing pigment identification in forensic-sized samples. It also shows that of the 325 unique pigments studied, only 38 (~12%) had strong enough fluorescence that no useful Raman scattering was observed (using 514 and 785nm lasers).

Building upon this identification scheme, the second phase of this research focused on the *in situ* identification of pigments in paint, with a goal of systematically addressing the evidentiary significance of pigment identification within a polymer matrix. Various methods of sample preparation and interpretation were evaluated to determine whether any methods are optimal. The analysis focused on a collection of 300+ late model automobile paint samples (comprising over 1,000 paint layers) and several sets of architectural tinting pigments (used to color the majority of architectural paints in the U.S.) collected over recent years.

The color layers in all of these paints (over 500 layers), which included top coats, tinted clear coats, and coordinated primers, as thin as 5µm in cross section, were analyzed by micro-Raman spectroscopy to identify the pigments present. In total, 28 different pigment groups were identified among the automotive paints and 14 pigments were identified within the architectural tinting colors. Paint pairs from the automotive paint collection of the same color code were also characterized by micro-FTIR spectroscopy. These results were interpreted to evaluate the potential applications of Raman spectroscopy in a trace evidence lab, with a specific focus on evaluation of the method as: (1) a fast screening method (for with no preparation); (2) to provide additional discrimination in conjunction with existing micro-analytical methods; and, (3) as a method to provide manufacturer sourcing assistance based on the identification of specific pigments. Each of these applications will be expanded upon in the presentation.

Paint, Pigments, Raman Spectroscopy

A116 Differentiation of Yellow Polyester Fibers With Different Dye Loadings Using Microspectrophotometry and Chemometrics

Eric J. Reichard, BS, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202; Edward G. Bartick, PhD, Suffolk Univ, Dept of Chemistry/Biochemistry, Beacon Hill, 41 Temple St, Boston, MA 02114-4280; Stephen L. Morgan, PhD, Univ of South Carolina, Dept of Chemistry & Biochem., 631 Sumter St, Columbia, SC 29208; and John V. Goodpaster, PhD, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will gain a fundamental understanding of the application of multivariate statistics to the analysis of fibers.

This presentation will impact the forensic science community by touching upon key improvements suggested by the 2009 National Academy of Sciences Report. In particular, human observer error is a potential problem in fiber color comparisons and the use of multivariate statistics could virtually eliminate this issue.

Microspectrophotometry (MSP) is a quick, accurate, and reproducible way to compare colored fibers for forensic purposes. In turn, the use of chemometric techniques applied to MSP data can provide valuable information, especially when looking at a large dataset. As of now, routine fiber color comparisons are made by use of an MSP and the trained eye of a forensic fiber examiner, who examines the overall shape of a fiber's spectrum. Comparisons are made by overlaying the spectra from items of questioned and known origin and determining if similar spectral characteristics are observed. However, minute differences not seen by the examiner can provide valuable information in a relatively featureless spectrum. The use of chemometric techniques like agglomerative hierarchical clustering (AHC), principal component analysis (PCA), and discriminant analysis (DA) can detect these differences and make objective comparisons of complex data possible.

The purpose of this study was to use chemometric techniques to discriminate UV-visible spectra obtained from yellow polyester fibers that had different dye loadings. Research has shown that visually similar yellow polyester fibers can be discriminated based on their UV-visible spectra; however, none have determined if fibers dyed with the same dye, but with different dye loadings, can be discriminated by their UV-visible spectra alone. Background subtracted and normalized UV-visible spectra from 11 yellow polyester exemplars dyed with different concentrations of the same dye ranging from 0.1-3.5% were analyzed by AHC, PCA, and DA. Simple visualization of the overlaid spectra showed the shape of the spectral curve broadened as dye loadings increased. One fiber with an unknown dye loading was determined to have a dye loading between 0.75-1.5% based on visualization of the spectra and subsequent chemometric techniques. AHC and PCA grouped the fibers into three classes ranging from low to high dye loadings. When grouping the fibers into their three classes based on low, medium, and high dye loadings, the classification accuracy was 94%. However, when fibers were grouped individually, the classification accuracy was quite poor (52%). In addition, an external validation study resulted in higher classification accuracy when fibers were grouped into three classes instead of individual groups (95% vs. 50%). Finally, exemplars with similar dye loadings were treated like known and questioned fibers and analyzed by PCA and DA in order to determine if they could be discriminated. Three exemplar comparisons and both class comparisons were considered discriminated based on a classification accuracy of 90% or higher and a receiver operating characteristics curve score of 0.9 or higher.

Overall, chemometric analysis of UV-visible spectra provides an objective means of discriminating similar fibers with different dye loadings.

Chemometrics, Dye Loadings, Fiber Comparison

A117 Examination of Statistical Methods for Analysis of Highly Similar Absorbance Spectra From Textile Fibers

Alejandra Flores, BS, 2782 Sweet Magnolia Pl., Oviedo, FL 32765; Michael E. Sigman, PhD, Univ of Central Florida, NCFS, PO Box 162367, Orlando, FL 32816; and Andres D. Campiglia, PhD, Univ of Central Forida, Dept of Chemistry, 4000 Central Florida Blvd, Orlando, FL 32816*

The goal of this presentation is to report on the evaluation of statistical methods for comparison of textile fibers with highly similar UV-visible absorption profiles.

This presentation will impact the forensic science community by providing information on the use of standard statistical techniques for performing comparison of highly similar microspectrophotometry data from textile fibers.

Discriminating clearly dissimilar absorbance spectra from questioned and known sources is straightforward; however, analyzing two fibers with nearly identical absorbance profiles can prove challenging. The goal of this research is to apply established statistical tests to highly similar absorbance spectra with the intent of evaluating the spectral match at a defined significance level. The nonparametric permutation test, Hotelling's T^2 test and Student's t-test were examined. The Parametric tests were applied to reduced dimensionality data preprocessed by principal components analysis (PCA).

An outside company was contracted to dye two 10 gram swatches of spun nylon 6.6 fabric. One swatch was vat dyed with Acid Blue 25 (M1); the other with Acid Blue 41 (M2). Absorption measurements were collected over the range of 400-725 nm with a microspectrophotometer. Samples of M1 were taken from three different areas (A1, A3, and A5), corresponding to the top left corner, center, and bottom right corner, respectively. Three individual threads (T1 – T3) were cut from both the vertical (D1) and horizontal (D2) directions of M1 in each of the three areas for a total of eighteen threads. After cutting all threads to 1cm lengths, five individual fibers were pulled from each thread (F1 – F5). Fifteen measurements were collected along the length of a single fiber. The spectra along each fiber were collected sequentially, while the order in which each fiber was examined was determined by random numbers drawn from a uniform distribution.

Pairwise comparisons of all fibers from M1 were performed by the nonparametric permutation hypothesis test, returning 100 p-values for each pairwise comparison. An average of 87% of all pairwise comparisons resulted in discriminations at α=0.05. This approach is not dependent upon a normal distribution of the comparative figures of merit. In parametric tests, any deviation from the assumed distribution may shift the actual size of the Type I error; however, in contrast, the actual α level of the permutation test automatically holds because when the null is true, all test statistics are exchangeable, having the identical distribution.[1] The high percent discrimination of fibers from M1 raises questions regarding the sensitivity of the statistical test, given the intended purpose, and possible sources of uncontrolled error in the experiments.

The nonparametric permutation method results were compared with those from the parametric Hotelling's T^2 test and Student's t-test. PCA was performed on normalized spectra from A5 of M1 to reduce the dimensionality of the data. Typically, greater than 99% of the variance was contained in the first principal component (PC1) for all comparisons. The large fraction of the variance contained in PC1 demonstrates the high spectral similarity. Student's t-test performed on the scores from PC1 allowed accepting the null hypothesis (i.e., the spectra were not discriminated by the test) in all of the five pairwise comparisons at $\alpha = 0.05$. Results from the Hotelling's T^2 test on scores from PC1 and PC2 accepted the null hypothesis in two out of five (40%) pairwise comparisons.

To further test the methods, samples from different materials M1 and M2 were analyzed. PCA of highly similar spectra from the two sources contained 98.6% of the variance in PC1 and 99.92% of the variance in PC1 and PC2. The Student's t-test on scores from PC1 accepted the null hypothesis at $\alpha=0.05$ (i.e., two fibers containing different dyes with highly similar spectra were not differentiated), while the Hotelling's T^2 test on scores from both PC1 and PC2 rejected the null hypothesis at the same significance level.

Further studies are focused on defining a statistical approach that can be applied to casework samples while maintaining Type I and Type II errors at reasonable levels.

A118 A Statistical Approach to Discrimination and Match Capability to Provide Scientific Basis for Estimating Significance of Fiber Association in Forensic Practice

Edward G. Bartick, PhD, Suffolk Univ, Dept of Chemistry/Biochemistry, 41 Temple St, Beacon Hill, Boston, MA 02114-4280; Kevin Roberts, 89 Wakefield St, Reading, MA 01867; Stephen L. Morgan, PhD, Univ of South Carolina, Dept of Chemistry & Biochem, 631 Sumter St, Columbia, SC 29208; and John V. Goodpaster, PhD, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will be introduced to the statistical significance of measurement variance of like and unlike fibers and will learn how the estimations of match significance can be made from fiber evidence. This is conducted through the use of multivariate statistical analysis and the product rule of independent variables.

This presentation will impact the forensic science community by demonstrating sources of variability and decision-making processes gained from this research that will serve to advance the forensic significance of class evidence involving fiber examinations.

The presentation will show how to increase the ability to classify and discriminate synthetic and cotton fibers. A library of over 800 well characterized fibers was developed with known dye components. Using visual light microscopy, visible Microspectrophotometry (MSP), and Fourier transform infrared spectroscopy, data was collected on fibers. In this report, studies were done on twenty-one red cotton and twenty-one red acrylic fibers using multivariate analysis. The absorption spectra of fibers from 10 replicate visible microspectrophotometry scans on each fiber were compared by using Principal Component (PCA) and Linear Discriminant Analysis (LDA). The software used in this work was developed at the University of South Carolina. PCA is used to find the directions of maximum variability to reduce the data dimensionality and enable use of LDA to provide projection maps of the data providing best discrimination of fiber groups. After projection into a two- or three-dimensional discriminant maps, discrimination of fiber groups can be judged visually by drawing 95% confidence limit ellipses around each group of points representing replicate spectra from the same fiber. Additional statistical hypothesis testing with Hotelling's T^2 test for the equality of means can be employed as a match criterion. With the aid of multivariate statistics, fibers that are difficult to distinguish by visual comparison can be distinguished. All 21 red cotton fibers, with the exception of two fibers, were distinguished by either PCA or LDA. The two that were not totally separated had the same dyes, but one of the fibers had a finish on its surface. PCA and LDA were also used to compare like fibers to determine how well fiber color matched on similarly dyed fibers. Separate samplings of the same red fiber measured seven weeks and two days apart showed large overlap and high correlation coefficients, thus providing quantitative match criteria. PCA and LDA provided a statistical basis to show the variance of like sample measurements and the discriminating capability of similar but different data. The next step required is to determine the probability of two statistically matched materials, based on measurements, as having come from the same source.

The "gold standard" in forensic science is the approach used in DNA matching by calculating the probability of occurrence of a given combination of alleles in short tandem repeats by the product rule of probability. By knowing the number of fibers in the database with specific color, diameter, cross-sectional shape, and chemical composition, the occurrence percentage of each fiber was determined. The product of the percentages was then calculated to determine the probability of two fibers matching randomly with those characteristics. Probabilities on the order of one in 0.5 million were obtained with such comparisons between fibers, and are valid, provided a sufficiently large and representative database of fiber characteristics is accessible. The improved understanding of sources of variability and decision-making processes gained from this research will serve to advance the forensic significance of class evidence involving fiber examinations.

Fibers, Multivariate Analysis, Statistical Analysis

A119 On the Random Presence and Discrimination of Purple Textile Fibers Collected From Movie Theater Seats

Patrick Buzzini, PhD, West Virginia Univ, 304 Oglebay Hall, 1600 University Ave, Morgantown, WV 26506-6121*

After attending this presentation, attendees will realize how unlikely it is to randomly observe a large number of matching fibers within a given surface and also between different surfaces.

This presentation will impact the forensic science community by providing information, not only related to the ability of microscopical examinations to detect and discriminate microscopic features of textile fibers, but also about the value of the recovery of a large number of matching fibers. This study will benefit trace evidence examiners in cases where a defense strategy would raise an argument such as "the recovered fibers are common and ubiquitous; therefore, this recovery is valueless to this case."

Adhesive tapes have been applied to 150 seats of a movie theater. These public surfaces were targeted for fiber collection because they were considered to be representative of the general population where the study was conducted. The focus of this study was purple fibers: this color was chosen to deviate from the traditional colors like black, blue, or red which are already abundantly reported in the literature. Single purple fibers were searched for using a stereomicroscope and isolated from the tape. To date, 20 seats were searched for fibers: 7,000-8,000

fibers were present on the searched tapes. A total of 62 purple fibers were observed. The single fibers were mounted permanently for conducting microscopical examinations. Methods based on light microscopy are crucial for gathering data about fiber characterization as well as for performing comparisons. The study of the morphology of the fibers is first carried out; this may include the study of the cross-sectional shape. Fibers can thus be classified as natural or man-made. Their thickness can be measured, the presence of delusterant particles can be recorded for man-made fibers, and double polarization techniques are applied to study their optical properties. Fluorescence microscopy is useful to detect luminescence due to the dye content. Plane-polarized light can also be used to study potential dichroic properties of the dyes. The comparison microscope is used to perform intra-source and inter-sources comparisons: the color, thickness, presence and concentration of delusterant particles, surface appearance, and fluorescence properties are compared.

During this study, fibers were initially categorized according to their general class: about 50% of the collected fibers were natural, the most part being cotton. Few wool fibers were observed. About 25% of the fiber samples were of man-made regenerated origin and the other 25% were man-made synthetic types (the most part being nylons and polyesters). The various fiber samples belonging to a given subclass were pair-wise compared using the comparison microscope. The results indicate that this population of purple fibers is highly variable, especially considering the different color shades, their thickness, and their overall morphology. Color resulted to be the highest factor of discrimination. Indeed, a further step of this study will be the application of microspectrophotometry.

After comparison microscopy, a group of eight cotton fibers resulted to be indistinguishable and this was the largest group. Four fibers were recovered from the same seat, while the remaining four were collected from four individual seats. The group of four was confirmed after fluorescence microscopy along with another fiber of the group of eight, while the three other fibers exhibited different fluorescence effects. For cotton fibers, two groups of three indistinguishable fibers were observed: one group had two matching fibers recovered from the same seat. For the other group, the three fibers were collected from three different seats. On the other hand, all the regenerated fibers could be differentiated after comparison microscopy. With regard to the synthetic fibers, three pairs were observed. However, the most useful way to gather information about the recovery of these fibers is to consider the number of groups of purple fibers recovered on a given seat and their size. Most of the purple fibers occurred as individual fibers on the seats. Only one seat had more than two groups of purple fibers (two pairs of cottons and synthetic fibers, respectively). Globally, seven pairs of matching fibers were observed on six seats. Finally, the largest group observed from one seat was only four fibers.

Fibers, Evidential Value, Trace Evidence

A120 Analysis of Allelic Drop-Out Using the Identifiler® and PowerPlex® 16 Forensic STR Typing Systems I: Estimation of Drop-Out Probabilities

Keith Inman, MCrim, Dept of Criminal Justice Adm, 4069 Meiklejohn Hall, 25800 Carlos Bee Blvd, Hayward, CA 94542; Kirk Lohmueller, PhD, Dept of Integrative Biology, 3060 Valley Life Sciences, No 3140, Berkeley, CA 94720; and Norah Rudin, PhD, 650 Castro St, Ste 120-404, Mountain View, CA 94041*

After attending this presentation, attendees will learn how empirically derived drop-out probabilities can be obtained using low-template DNA profiles that were run as part of their laboratory's internal validation studies, and how these probabilities perform well when used on model evidentiary samples. They will then discover how the calculation of dropout probabilities can be incorporated into a likelihood ratio that assesses the strength of the DNA evidence under competing hypotheses.

This presentation will impact the forensic science community by providing a means of assessing the weight of low-template DNA evidence that requires consideration of allelic drop-out, also providing a means to increase accuracy and objectivity in interpreting DNA profiles.

Low-template (LT) DNA profiles continue to present interpretational challenges to the forensic community. Whether the LT contribution comprises the main profile, or whether it is present as the minor component of a mixture, ambiguity arises from the possibility that alleles present in the biological sample may not be detected in the resulting DNA profile. This phenomenon is known as allelic drop-out. This ambiguity complicates both the assessment of the potential number of contributors as well as an estimation of the weight of the DNA evidence for or against specific propositions. One possible solution to estimating the weight of the evidence is to use a likelihood ratio (LR) that incorporates the probability of allelic drop-out $P(D_O)$. Such methods can be improved by including an estimate of the drop-out probability for the specific evidence sample. However, while a vast repository of data exists from which dropout probabilities might be calculated, few empirical studies to determine such probabilities have been performed to date. Here patterns of allelic drop-out are characterized using the Identifiler® and PowerPlex® forensic STR multiplexes in single-source samples generated by the National Institute of Standards and Technology (NIST). Briefly, DNA was adjusted to amplify 100pg, 30pg, or 10pg from each of two individuals. Each of the six samples (three concentrations of each of the two individuals) was amplified 10 times with both the Identifiler® and PowerPlex® 16 kits using the standard number of PCR cycles suggested by the manufacturer. Thus, a total of 60 profiles were produced for each kit.

Crucial to the determination of dropout probabilities is the selection of an appropriate detection threshold. A threshold derived from analytical chemistry, designed to properly balance signal and noise, was used to evaluate the samples, as well as thresholds commonly used in forensic DNA laboratories. The effect of these different allelic detection thresholds on observed patterns of drop-out were then evaluated. Drop-out was defined to be the situation where a particular peak known to exist in the sample does not rise above the allelic detection threshold, and, as a result, is not detected in the profile. Not surprisingly, fewer instances of apparent drop-out were found when using a lower detection threshold.

Logistic regression to model the fraction of alleles that dropped out of a profile as a function of the average height of the detected peaks was used. The equation derived from the logistic regression model allowed the authors to estimate the expected drop-out probability for a model evidentiary sample based on the average peak height of the profile. The correlation of the proportion of allele drop-out from a profile with the average peak heights within a particular profile supports using logistic regression to model the relationship between these two variables. In several cases, the parameters of the logistic regression models differed significantly between typing systems, different allelic detection thresholds, and samples. Finally, a positive correlation exists between allele drop-out and allele length; longer alleles tend to drop-out more frequently than shorter alleles, even in good quality samples. These results provide an initial foundation for empirically estimating drop-out probabilities that can be incorporated into LR calculations to assess the weight of complex DNA evidence including LT components.

Dropout Probabilties, Logistic Regression, Likelihood Ratios

A121 Analysis of Allelic Drop-Out Using The Identifiler® And PowerPlex® Forensic STR Typing Systems II: Evaluation of Estimated Drop-Out Probabilities

Kirk Lohmueller, PhD, Dept of Integrative Biology, 1005 Valley Life Sciences, No 3140, Berkeley, CA 94720; Norah Rudin, PhD, 650 Castro St, Ste 120-404, Mountain View, CA 94041; and Keith Inman, MCrim, Dept of Criminal Justice Administration, 4068 Meiklejohn Hall, 25800 Carlos Bee Blvd, Hayward, CA 94542*

After attending this presentation, attendees will appreciate how empirically based drop-out probabilities can be obtained for low-

template DNA profiles. Further, they will learn how a simulation approach can be used to determine the accuracy of the drop-out probabilities.

This presentation will impact the forensic science community by objectively exploring the performance of likelihood ratio approaches to assess the weight of low-template DNA evidence that require consideration of the allelic drop-out. The work presented provides a means to increase the accuracy and objectivity in interpreting DNA profiles.

One major challenge in the analysis of forensic DNA profiles concerns the analysis of low-template (LT) DNA samples. Due to the small number of DNA molecules analyzed, such samples may not yield the complete profile(s) of the contributor(s). It is difficult to correctly interpret such profiles because some of the information may be missing. Further, it is even more challenging to accurately assess the weight of such evidence.

To fill this void, patterns of allelic drop-out were recently characterized using the Identifiler® and the PowerPlex® forensic STR multiplexes in 60 LT single-source samples. Logistic regression was employed to model the relationship between the fraction of alleles that have dropped out of a profile as a function of the average height of the detected peaks. This model allowed the estimatation of the drop-out probability for a simulated low-template LT evidentiary sample based on the average peak height of the profile. These estimated drop-out probabilities could then be incorporated into a likelihood ratio (LR) to assess the strength of the LT DNA evidence.

However, one concern is that there were several statistically significant differences in the relationship between peak heights and drop-out between different samples and experimental conditions. The practical effect of these differences remained unclear. Thus, previous work was expanded and extensive simulation studies were performed to evaluate the accuracy and practical applicability of estimated drop-out probabilities.

Each of the LT DNA profiles, simulating an evidentiary profile, was compared with the profile of a suspected contributor. For each of these comparisons, two different LRs were computed. The first one used the estimated drop-out probability. The second LR used the true drop-out probability. If the estimated drop-out probabilities are accurate, then the LRs calculated using them should be similar to those calculated using the true drop-out probability.

Two different types of comparisons between LT profiles and suspected contributors to assess how well the drop-out estimator functions were analyzed. The first type of comparison evaluated the true contributor as the suspected contributor of the LT DNA evidence. The second type of comparison evaluated a true non-contributor as the suspected contributor of the LT DNA evidence. Here, the suspected contributor was a random individual simulated from a U.S. population database with European ancestry. For all comparisons, LRs were calculated using the Balding and Buckleton (2009) R program.

For both types of simulations, the LRs calculated using the estimated drop-out probabilities were similar to those calculated using the true drop-out probabilities, suggesting that the estimates of the drop-out probability are accurate and useful. This trend holds even when using the data from the PowerPlex® 16 typing system to estimate the drop-out probability for an Identifiler® profile and vice versa. Thus, even though some of the logistic regression model parameters differ significantly from each other across different experimental conditions, they are similar enough to have little practical effect on the final LRs calculated using these estimated drop-out probabilities. This research demonstrates that use of an LR that incorporates empirically estimated allelic drop-out probabilities provides a reliable means for extracting maximum information from LT forensic DNA profiles.

Low Template DNA, Drop-Out, Likelihood Ratio

A122 Effects of Relatedness on Likelihood Ratio Calculations for DNA Mixtures

Adele A. Mitchell, PhD, Mechthild K. Prinz, PhD, and Theresa A. Caragine, PhD, OCME, Dept of Forensic Biology, 421 E 26th St, New York, NY 10016*

After attending this presentation, attendees will understand how relatedness among contributors to forensic DNA mixtures can affect likelihood ratio calculations when unknown contributors are modeled as unrelated, also understanding the related contributors as known in the model can nullify some of these effects.

This presentation will impact the forensic science community by exposing some of the strengths and limitations of likelihood ratios for forensic mixture analysis. Most laboratories wrestle with complex mixture analysis and relatedness among contributors and suspects can further create additional complications.

A likelihood ratio (LR) can be used to assign a statistical weight to a comparison between a DNA mixture obtained from an item of evidence and the DNA profile of a known individual, such as a suspect. An LR is a ratio of two probabilities. In forensic DNA analysis, these are typically the probability of the DNA mixture conditional on a prosecution hypothesis (H_p), often a scenario that includes a suspect, and the probability of the mixture conditional on a defense hypothesis (H_d), where the suspect is replaced by an unknown person. There may be one or more additional unknown persons in either or both scenarios. These unknown persons are most often assumed to be unrelated to one another and to the suspect.

If contributors to a mixture are related to one another or to the suspect and this is not considered in the formulation of the LR, the LR may be conservative or anti-conservative. As a consequence of relatedness, a mixture may appear to be composed of fewer than its true number of contributors, due to allele sharing. If this happens, the scenarios selected for the LR may be incorrect. As a consequence of relatedness between mixture contributor(s) and a non-contributing suspect, the suspect's alleles may appear in the mixture by chance. To explore these two possibilities and their effects on the LR, DNA profiles of related and unrelated individuals were simulated and theoretical mixtures were created.

Suspect profiles and six different types of three-person mixtures were simulated such that the suspect was not a contributor, but one or more of the suspect's relatives were contributors. Mixtures included: (1) two of the suspect's siblings and an unrelated person; (2) one of the suspect's siblings and two unrelated persons; (3) two of the suspect's half-siblings and an unrelated person; (4) One of the suspect's half-siblings and two unrelated persons; (5) The suspect's sibling, parent and an unrelated person; and, (6) two of the suspect's cousins and an unrelated person. Mixtures were also simulated including the suspect as a contributor and without allelic drop-out and drop-in.

Likelihood ratios were computed using the Forensic Statistical Tool (FST), developed and used for mixture analysis in casework by The Office of Chief Medical Examiner (OCME) of the City of New York. FST employs empirically determined drop-out and drop-in rates, so the contributors in the prosecution and defense scenarios need not fully explain the alleles in the mixture. For each mixture, H_p and H_d were formulated with and without the suspect's relatives and the unrelated persons as known contributors to the mixtures. After testing with the suspect, LRs were also computed for the same scenarios using a set of other non-contributors as the "suspect." This demonstrated the range of LRs expected for unrelated non-contributors and was used to determine whether the related suspect's LR was artificially inflated.

Analysis of the simulated mixtures showed that a non-contributing suspect's LR can sometimes be inflated when one or more of the suspect's relatives contributed to the mixture, particularly when the mixture included two of the suspect's siblings. However, this inflation can be mediated by inclusion of the true contributors as knowns in the LR. Therefore, it is important to attempt to obtain elimination samples from individuals related to the suspect if they may be part of the mixture. If it is not possible to obtain the elimination samples, the LR may be computed without known contributors, but it should be emphasized that

the current model treats unknown contributors as unrelated. Ultimately, it may be necessary to develop LR calculation software that can account for relatedness through appropriate algorithms.

Likelihood Ratio, DNA Mixtures, Relatedness

A123 How Inclusion Interpretation of DNA Mixture Evidence Reduces Identification Information

Mark W. Perlin, PhD, MD, and Kiersten Dormer, MS, Cybergenetics, 160 N Craig St, Ste 210, Pittsburgh, PA 15213; Jennifer M. Hornyak, BS, 52 Riethmiller Rd, New Wilmington, PA 16142; Thomas Meyers, MS, 1520 Penn Ave, Pittsburgh, PA 15222; and Walter Lorenz, BS, 1520 Penn Ave, Pittsburgh, PA 15222*

After attending this presentation, attendees will better understand how human review of DNA mixture evidence using the inclusion method reduces identification information.

This presentation will impact the forensic science community by enabling practitioners to preserve more identification information in their DNA evidence, reaching the conclusion that human interpretation may discard considerable DNA mixture identification information that computers can preserve, which can improve criminal justice processes and outcomes.

The combined probability of inclusion (CPI) mixture interpretation method applies thresholds to quantitative STR peak data in order to simplify human review. However, this flattening of peaks into putative all-or-none allele events usually reduces evidential force. The true DNA match statistic is better estimated by a computer model that accounts for peak heights and their variation.[1]

The "weight of evidence" is an additive measure of DNA identification information, calculated as the logarithm of the likelihood ratio (LR) and measured in "ban" information units. Since CPI can be viewed as an LR, this study looked at log(LR) at individual STR loci to determine how CPI reduces match information.

The study examined 615 locus experiments obtained from 41 inclusions in 31 mixture evidence items that had a reported CPI statistic. The items were from 16 cases, and included clothing, weapons, vehicles, vaginal swabs, and skin swabs. Promega PowerPlex® 16 STR electropherograms were developed on an ABI 3130® genetic analyzer, and reinterpreted on Cybergenetics TrueAllele® genetic calculator.

There were 517 loci (84.1% of 615 experiments) for which both CPI and computer match statistics were calculated. At these loci, the computer found an average log(LR) of 0.746 ban per locus, forming a bell-shaped normal distribution having standard deviation 0.590. DNA evidence need not support an identification hypothesis at every locus, as was seen in the 52 (10.1%) experiments having negative log(LR) values.

On these 517 loci, CPI yielded an average log(LR) of 0.489 ban per locus. CPI only reports on loci that support an identification, and is silent about evidence whose weight does not support an inclusion. The CPI weight of evidence values formed a truncated normal distribution. These positive log(LR) numbers had a maximum at 0 ban per locus, monotonically decreased to the right, with a fitted standard deviation of 0.615. Comparison with the better-modeled computer log(LR) distribution showed that: (1) on average, CPI reduces identification information relative to a computer gold standard; (2) CPI discards locus evidence that does not support an inclusion; and, (3) CPI can report an inclusion at a locus where the computer finds no support for a match.

When using CPI, a locus is not reported unless evidence alleles over threshold are seen in the reference genotype. There were 97 loci (15.8% of 615 experiments) at which the computer found a statistic but CPI did not. At the 68 (70.1%) of these unreported CPI loci that had interpretable data, the computer produced log(LR) values in a normal distribution having a mean of 0.659 ban per locus and standard deviation 0.664. At the remaining 29 (29.9%), experiments exhibiting allele dropout or extreme peak imbalance, the computers log(LR) values were all negative, having mean –0.755 ban per locus and standard deviation 0.346. Overall, computer interpretation of loci that CPI did not use contributed additional weight of evidence that favored an identification.

In this study, reported CPI locus statistics with more sophisticated computer reinterpretation of the same mixture data were compared. Whenever CPI produced a result, so did the computer. However, CPI yielded (on average) a lower weight of evidence than the computer; CPI discarded evidence whenever it classified a locus as unfavorable; and CPI reported as favorable some loci that the computer found to be unfavorable. For more accurate and balanced reporting of DNA mixture evidence, laboratories using CPI should progress to more informative interpretation methods.

Interpret Mixture, Inclusion Method, Weight of Evidence

A124 SNPs, Forensic DNA Mixtures, and Population Genetics

Kevin C. McElfresh, PhD, 13580 Groupe Dr., Ste 301, Woodbridge, VA 22192*

After attending this presentation, attendees will have a better understanding of analyzing forensic DNA samples containing mixtures of DNAs.

This presentation will impact the forensic science community by providing advanced analytical capabilities for DNA mixtures that cannot be analyzed using STRs.

The essence of forensic DNA analysis is the comparison of known differences in the human DNA of one sample with the differences of an unknown sample. Match or non-match is based on the sum of the differences between the two samples. If a difference is characterized in binary code of one for complete difference and 0 for no difference, then in a comparison of single source forensic DNA samples, if that sum is zero, the samples match, but if that sum is non-zero the samples do not. The problem lies in the comparison of mixtures of DNAs. In this case, there is the distinct possibility that there is an inclusion hidden beneath the non-zero answer. In the case of STRs, mixtures beyond two individuals virtually negate the ability to attempt an analysis of the zero answer within the non-zero aggregate. Ultra-High Density Single Nucleotide Polymorphism (UHD-SNP) arrays analyzing >5 million loci across the human genome provide an alternative forensic DNA mixture analysis capability due to the smaller number of alleles per locus that are compensated for by the larger number of loci. Thus, the smaller numbers of alleles (two) at an SNP locus allows for the assessment and aggregation of small per locus differences over a large data set and determine the effect of the zero-based inclusion within a non-zero aggregate. The objective of this project was to determine the fundamental effects of reference population and number of SNP loci necessary to correctly assess the contributors to a forensic DNA mixture.

Computer simulations of SNP data done by Homer and Jacobs, using different methods of calculation, both addressed the possible analytical capabilities for mixtures of DNAs within a medical and forensic context (Homer) and in a medical Genome Wide Association context (Jacobs).[1,2] In the computer simulations, the percent contribution to the mixture was simulated and tested using prepared mixtures. In addition to the mixture proportion, there was a clear component of reference population to the analysis. This study has examined those calculations using samples from forensic mixtures utilizing samples from typical forensic crime scenes, e.g., blood/semen mixtures and also complex mixtures of more than two individuals.

A baseline of fundamental characteristics of SNP results was developed using single source match and non-match DNAs taken from blood and semen. These included serial dilution of DNAs and subsequent comparison of the number of loci and the effect of the population analysis on the results. From these studies a clear baseline of Loss of Detection (LOD) and sample analysis criteria were drawn.

Reference populations were built for Caucasian, African, Hispanic and Asian populations. The population specific results were then compared using the Illumina provided SNP cluster file and population specific cluster files using these criteria. The same analysis was then done using mixtures of samples, again taken from forensically relevant sample types. Comparisons of numbers of loci and the effect of the reference populations were analyzed within this context. Specifically, the analysis was geared toward the effect of partial results on the ability to correctly analyze inclusion versus exclusion and also to assess the reference population effects on those answers. As expected, the number of loci, either as a function of sample quality or as a function of DNA concentration, had the largest effect on the ability to analyze the results while the population effects were secondary. In either case, utilization of more than approximately 50,000 SNP loci overcame the localized effects of population structure. The results were then used to determine a set of analytical parameters for the interpretation of UHD-SNP forensic DNA results.

A125 Virginia TrueAllele® Validation Study: Casework Comparison

Mark W. Perlin, PhD, MD, and Kiersten Dormer, MS, Cybergenetics, 160 N Craig St, Ste 210, Pittsburgh, PA 15213; Jennifer M. Hornyak, BS, 52 Riethmiller Rd, New Wilmington, PA 16142; and Lisa C. Schiermeier-Wood, MS, and Susan Greenspoon, PhD, Dept of Forensic Science, 700 N 5th St, Richmond, VA 23219*

After attending this presentation, attendees will better understand why computer interpretation of complex DNA evidence is scientifically reliable.

This presentation will impact the forensic science community by enabling practitioners to make better use of DNA evidence already generated in their laboratory. Human review may greatly understate the evidential value of complex STR data; however, when such data are truly informative, computer reinterpretation can preserve more of the evidence, and bring that strength of match into the courtroom.

Modern criminal justice requires rapid and reliable processing of DNA evidence. Such reliability is a hallmark of admissible evidence, and encompasses sensitivity, specificity, and reproducibility. However, when confronted with complex mixtures or touch DNA, human interpretation can become a challenging task.

The result is that much evidence may be reported with an artificially low DNA match statistic, or is not reported on at all (i.e., "inconclusive"). Mathematical computing can overcome these limitations by statistically separating out contributor genotypes from the DNA mixture. These genotypes are objectively inferred by thorough consideration of the evidence data, and can be compared with reference genotypes to determine match strength.

This case study examined 111 comparisons from 92 items of evidence in 72 criminal cases involving DNA mixtures. For each item, a TrueAllele® computer provided a DNA match statistic that was reported in a supplemental case report issued by the Virginia DFS laboratory.[1] The sensitivity, specificity, and reproducibility of the computer results were examined. Comparison was made to the match information obtained by human review of the same data using Combined Probability of Inclusion (CPI) or modified CPI (mCPI). The study found TrueAllele® computer interpretation to be a reliable method for interpreting DNA mixture evidence.

Out of 111 DNA match comparisons, current mCPI human review could report on 55 of them (49.5%), finding an average match statistic of 156. TrueAllele® computer interpretation had greater sensitivity, providing 102 match statistics (91.9%) with an average value of 86.9 billion. Thus, the computer preserved more of the evidence (91.9% matches by computer, versus 49.5% manually), as well as the DNA identification information it contained (86.9 billion average match statistic, versus 156 manually).

The computer did not simply "add zeros" to the DNA match statistic. In fact, TrueAllele® statistics were lower than the corresponding human CPI values in 15 reported items. Moreover, the computer found no statistical support for a match in some cases. While, on average, TrueAllele® does find more matches and computes stronger statistics, the system objectively examines DNA evidence without any bias towards the defense or prosecution.

In addition to increased average sensitivity, TrueAllele® also maintained excellent specificity. The computer can quantify nonmatch information for exclusionary purposes through a negative log likelihood ratio (or "log(LR)"). In contrast, CPI or mCPI human interpretation methods give only positive log(LR) values, since their match statistics are never less than one. The study examined ten thousand TrueAllele® cross-case comparisons where it was expected to find no match, and found no false positives—the log(LR) was always a negative number. The average exclusionary nonmatch information in this assessment was a log(LR) of -19.693 (1 in 49.3 quintillion).

The computer objectively gave reproducible DNA match statistics. Replicate computer runs on the same evidence data showed a within-item log(LR) standard deviation of 0.305. Thus, on average, independent computer runs on the same evidence item gave statistically similar (within an order of magnitude) DNA match statistics.

DNA, whether single source or complex mixture, can provide compelling evidence that implicates criminals and exonerates the innocent. Current human review of DNA mixture data applies stochastic thresholds that can discard half the evidence and greatly understate the evidential import of what's left. As demonstrated in this casework comparison study, TrueAllele® computer interpretation more effectively preserves DNA evidence and match information. Societal safety and criminal justice may be better served by using this validated computer technology to reliably review complex DNA mixture evidence.

A126 Toward Professionalism in Forensic Mathematics

Charles H. Brenner, PhD, 6801 Thornhill Dr, Oakland, CA 94611-1336*

After attending this presentation, attendees will learn basic standards for writing a methodological paper for quantitative analysis of forensic evidence.

This presentation will impact the forensic science community by increasing skepticism for forensic DNA mathematical papers, most of which fall far short of common-sense minimal standards for logical reasoned exposition.

Attendees will learn from this presentation basic standards for writing a methodological paper for quantitative analysis of forensic evidence. They will consequently have a proper scepticism for forensic DNA (in particular) mathematical papers, most of which fall far short of commonsense minimal standards for logical reasoned exposition.

DNA identification is interesting in offering, more than any other forensic area, scope for explicit mathematical treatment. There are various mathematical problems in forensic genetics beginning with straightforward linking suspect to unknown DNA profile, adding difficulties and complications such as rare haplotypes, database search or mixed sample, and identification via kinship with its many attendant intricacies. They can most clearly and usefully be dealt with through a disciplined mathematical exposition which should be precise and logical — clear statement of the problem and of assumptions, deductive progression of ideas, and justification of assumptions.

Mathematics as a tool has several potential attractions and advantages. Because mathematical writing is explicit in definitions and assumptions, it can provide clear unambiguous communication. The reader should know what is being claimed. Mathematical exposition is logical and deductive. Ideally, the reader is led irresistibly along a linear deductive path. If not irresistibly, at least the exact point of resistance is manifest. Then the reader can say "I disagree with your premise" or can argue that step D doesn't follow from step C; a productive discussion is then possible with a good chance for resolution of disagreement.

The paradigm should be: State the problem, formulate it mathematically, state premises (inevitably including a model, since this is applied mathematics), justify the premises (i.e., validate the model), derive the result. A paper which simply gives a recipe for calculation without any stated justification is professionally deficient. Yet papers meeting even these basic standards are almost non-existent.

SWGDAM instructions on rare haplotype matching don't even state a problem but instead begin by proposing how to calculate a haplotype frequency.[1] The reader who realizes that (population) frequency is not (matching) probability and that the evidential problem concerns probability, is left slack-jawed at the post with nothing with which to disagree while the paper gallops off into (irrelevant) mentions of formulas and ideas lacking not only foundation but lacking any chain of reasoning.

In the 90s, the exclusion method for mixtures was simple: If a suspect is "included" then report RMNE, calculated per-locus as the squared sum of the allele frequencies for alleles observed above 100 RFU or so. No one actually wrote down the model but the formula is simple enough that it can be reverse-engineered to deduce what the model must be: The formula assumes that all alleles of a donor will be conspicuous (e.g., >100 RFU) and "included" means all of ones alleles are conspicuous in the mixture. Obviously, this is an absurd model. That it survived and was popular and accepted for years—perhaps still—proves the importance of explicitly writing down models and explicitly deriving and justifying the consequences. *With nothing written down, nothing wrong is written down and errors are less obvious.*

The recent appearance of refining the "exclusion" method by adding a second RFU threshold suggests that RMNE enthusiasts have woken up to the folly and unfairness of the original approach.[2,3] They have not, though, woken up to the importance of models, let alone to justifying their work. Several papers give no mathematical analysis at all; only recipes which, apparently, we are supposed to trust.

The point is not that the method fails. The point is that the adherents of a method have a positive responsibility to show why it works. They have not done a respectably professional scientific job if they don't explain coherently. Otherwise the rest of us—reader, analyst in the laboratory, judge, and accused—ought to be suspicious of the validity of the method.

A127 Inter-Tissue Somatic Mosaicism in Blood, Hair, and Epithelial Cheek Cells at the ABI AmpFℓSTR® Identifiler® Loci and Its Effect on Forensic DNA Interpretation

Katerina Doneva, BS, 1415 N Market Blvd, Ste 3, Sacramento, CA 95834; and Ruth E. Ballard, PhD, California State Univ, Dept of Biological Sciences, 6000 J St, Sacramento, CA 95819-6077*

After attending this presentation, attendees will understand the genetic basis of somatic mosaicism, how it is distinguished from other similar genetic events, how it can be identified and confirmed in a forensic DNA profile, and its significant potential for misinterpretation when comparing DNA profiles of more than one biological source from one donor.

The presentation will impact the forensic science community by helping forensic scientists predict how often they are likely to encounter somatic mosaics in routine casework and whether their frequency is high enough to warrant changes in their procedures for comparing reference samples from suspects with crime samples and collecting samples for NDIS/CODIS database. Even if the frequency is low, several somatic mosaics are likely to be present in NDIS (>10.5 million offender profiles) or CODIS (>2 million offender profiles). The ever-growing CODIS database is currently based on inputting DNA derived from only on tissue origin. The detection of inter-tissue somatic mosaics in this study would suggest that forensic scientists should consider collecting blood, hair, and saliva samples from each offender. This becomes even more important if a partial profile from a crime scene is used to search the database. In addition, past exclusions (particularly those based on one or only a few mismatches) will need to be reassessed, possibly leading to new leads, arrests, and convictions for crimes that are currently unsolved.

Crime solving using DNA relies on the assumption that each bodily tissue of an individual exhibits the same DNA profile. Based on this prevailing assumption, positive identification of a suspect or victim can be made by matching the crime scene sample to a reference sample regardless of the origin of the bodily tissues used for the comparison. For example, a hair found on a ski mask left at a crime scene is assumed to have the same DNA profile as a blood reference sample collected from the person who left the hair. Although this assumption of inter-tissue identity is generally sound, it is not always correct because genetic mutations can cause differences in inter-tissue profiles. Somatic mosaicism is caused by mutations during embryogenesis that lead to differences in the genetic make-up of different tissues in the adult. Differences can manifest in several different ways, depending on how early the mutation occurred and whether the mutation created an allele that the individual did not already carry.

Inter-tissue somatic mosaics can be detected by collecting tissue samples from different parts of a person's body and comparing their Identifiler® profiles. The Identifiler® loci are Short Tandem Repeats (STRs), which tend to mutate more rapidly than other regions of the human genome. Therefore, it is more likely for a person to exhibit mosaicism at these loci than at most other loci in the genome. Somatic mosaicism has been well-researched in the medical community, but few studies have been completed for the benefit of forensic DNA identification.

This is the first forensic-related, multi-year research on somatic mosaicism that incorporates three distinct tissues for analysis (blood, hair, and epithelial cheek cells) from multiple donors. Currently, one out of 352 donors have been identified as a somatic mosaic. The donor's blood and saliva displayed a tri-allelic pattern (11, 12, 13) at the D8S1179 locus. The donor's hair sample also showed a small peak at the 12 allele; however, the allele was not included, because it did not cross the peak height threshold set at 20%. The results of this study indicate that somatic mosaicism can be easily detected as a tri-allelic pattern. Based on the findings, the rate of somatic mosaicism is very low (one out of 352 donors), but several somatic mosaics are likely to be present in NDIS/CODIS.

It is assumed that the DNA profile from a blood drop found at a crime scene can be successfully used to search the CODIS database, even though most of the database samples are generated from a single source (buccal cells). The detection of inter-tissue somatic mosaics in this study would suggest that forensic scientists should consider cross-tissue comparison from each offender. Further research with larger population sizes would benefit the interpretation of DNA casework.

Somatic Mosaicism, Genetic Mutation, DNA

A128 Examination of Rapidly Mutating Y-STR Loci for Increased Resolution of Common Haplotypes

Michael D. Coble, PhD, Becky Hill, MS, and John M. Butler, PhD, NIST, 100 Bureau Dr, MS 8312, Gaithersburg, MD 20899-8312*

After attending this presentation, attendees will be introduced to a set of rapidly mutating Y-STR markers. Population statistics on the specific loci examined and their utility for discriminating closely related males will be presented.

This presentation will impact the forensic science community by introducing the usefulness of a set of rapidly mutating Y-STR loci to increase discrimination among closely related males.

Y-chromosomal STR (Y-STR) testing has become an important tool for forensic investigations, especially in DNA mixture samples where low level male DNA is mixed in a high female DNA background. Presently, two commercial kits of 17 and 23 Y-STR markers are available for the forensic community and provide relatively high discrimination among unrelated individuals with a discrimination capacity greater than 97% (NIST, unpublished data).[1,2] Given the haploid nature of the Y-chromosome, a match between the evidence and the accused is evaluated in terms of how frequently the haplotype is observed in a relevant database. In addition to the limitation of Y-STR statistical results restricted to the size of the database, the current set of Y-STR markers is limited at separating related males such as fathers and sons and brothers.

Recently published rapidly mutating (RM) Y-STR loci with mutation rates from roughly 1 to 7% per meioses were evaluated at NIST using a set of unrelated population samples to determine population genetics parameters such as haplotype diversity and among a set of Father-Son samples to determine the usefulness of the markers for distinguishing related males.[3,4]

Fifteen RM Y-STR markers were organized in three multiplex reactions and amplified according to Ballantyne *et al.*[3] NIST population samples of over 600 unrelated individuals in three U.S. groups: Caucasian, African American, and Hispanics were initially tested.[5] Nearly 400 father-son samples among U.S. Caucasian, African American, Asian, and Hispanics were also tested.[6] Previously all samples have been typed for the two commercially available forensic Y-STR kits.

The study found that the RM Y-STR markers provided increased discrimination and variation among common haplotypes unresolved from the two commercially available Y-STR kits. For the father-son samples, over 21% of the samples tested exhibited at least one mutational event among the RM Y-STRs.

Conclusions: Additional Y-STR loci, especially from rapidly mutating markers, can be useful for increased discrimination among closely related males.

Rapidly Mutating, Y-STR, Population Data

A129 Metal Ions as Forensically-Relevant Inhibitors of PCR-Based DNA Testing

Laura J. Gaydosh, MA, 624 Ponderosa Drive, Hurst, TX 76053; Vallerie H. DeLeon, BS, and Teresa D. Golden, PhD, Univ of North Texas, Dept of Chemistry, 1155 Union Circle, PO Box 305070, Denton, TX 76203; Joseph E. Warren, PhD, 355 NW Hillery, No 813, Burleson, TX 76028; and Rhonda K. Roby, PhD, Univ of North Texas, Center for Human ID, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107*

The goal of this presentation is to introduce metal ions as relevant PCR inhibitors associated with human skeletal remains to the forensic DNA community. The data presented includes sources of metal ions, their expected concentrations in forensic samples, as well as demonstrate the effects of these inhibitors on the genetic results obtained from samples amplified using PCR-based DNA amplification kits. Attendees will be given discrete examples of inhibition phenomena which can occur as a result of interactions between metal ions and DNA or PCR reagents required for testing.

This presentation will impact the forensic science community by expanding the pool of known, forensically-relevant PCR inhibitors associated with human skeletal remains to include metals commonly found in bone samples that have been exposed to the environment or to material culture. The ability to identify samples that contain inhibitors or DNA profiles, demonstrating inhibition will aid decision-making capabilities of analysts and provide a foundation for future research.

Bone samples obtained from human skeletal remains are considered one of the most challenging sample types in the laboratory. Laborious sample processing is required and it frequently yields incomplete genetic results or amplification failure. While this may be caused by and is often attributed to DNA which has been damaged, it can also occur as a result of PCR inhibition caused by the co-purification of metal ions with DNA.

Cadaver bone was obtained through the Willed Body Program at the University of North Texas Health Science Center and its metal content was determined by inductively coupled plasma-mass spectrometry (ICP-MS) by the Department of Chemistry at the University of North Texas. Elemental analysis was performed in solution mode ICP-MS to determine the concentration of analytes, including isotopes: ^{27}Al, ^{43}Ca, ^{63}Cu, ^{57}Fe, ^{60}Ni, and ^{208}Pb. ICP-MS measurements were performed on a -MS System with Autosampler. Acid digestion was used for sample preparation; approximately 100 mg of each sample was weighed out into a polypropylene test tube and dissolved in 2mL of ultra-pure concentrated HNO_3, and then diluted with 100mL of 1% HNO_3. For major and trace metal analysis, dilution factors vary between 20 and 100. All samples were measured in triplicates for statistical analysis.

In order to investigate metal ions as PCR inhibitors, a dilution series was created using certified analytical standards for aluminum (Al), calcium (Ca), copper (Cu), iron (Fe), nickel (Ni), and lead (Pb) in solution. These standards were initially diluted to approximately 21 mM and the pH adjusted between three and five with 3 M NH_4OH and 1 M HCl; subsequent serial dilutions were prepared with DNase/RNase-free distilled water. Final sample solutions were prepared, containing 1ng of control DNA and sufficient metal to yield 7.5mM, 1.25mM, 0.2mM, 0.03 mM, 0.006 mM, and 0.001mM in the 25µL PCR reaction. Duplicate samples were amplified using the AmpF*l*STR® Identifiler® Plus (Applied Biosystems) multiplex system and a HS System. Fragment analysis was conducted via capillary electrophoresis on a genetic analyzer using

10-second injections. STR profiles, including individual allele peak heights and areas, were obtained using ID software and a 50 RFU allele detection threshold. Amplification success was determined by the average allele count, expressed as a percent of the expected number of alleles for the control DNA profile and the effect of inhibitor on the quality of the genetic results was determined by regression analysis and the calculation of Pearson's correlation coefficients.

The elemental analysis revealed isotope concentrations (µg/g) in the cadaver bone were as follows: ^{27}Al, 473-4; ^{63}Cu, 146-5; ^{57}Fe, 366-27; ^{60}Ni, 0.5-0.1; and ^{208}Pb, 165-3. The PCR inhibition studies demonstrated the effective inhibitory concentrations (mM) for amplification was: 0.001-0.006 for Al; 0.2-1.25 for Ca; 0.2-1.25 for Cu; 0.2-1.25 for Fe; 0.2-1.25 for Ni; and, Pb, 1.25-7.5. The effective inhibitory concentrations (mM) for the HS System were: 0.006-0.03 for Al; 0.2-1.25 for Ca; 1.25-7.5 for Cu; 0.2-1.25 for Fe; 0.2-1.25 for Ni; and for Pb 1.25-7.5.

Skeletal Remains, PCR Inhibition, Metal Ions

A130 Maximizing Allele Detection by Selecting Optimal Analytical Thresholds

Christine A. Rakay, MS, 1055 Valley Bluff Dr, Apt 10, Perrysburg, OH 43551-2788; and Joli Bregu, MS, Cheng-Tsung Hu, BS, and Catherine M. Grgicak, PhD, Boston Univ, Biomedical Forensic Sciences, 72 E Concord St, Rm R806, Boston, MA 02118*

After attending this presentation, attendees will learn how the Analytical Threshold (AT) has a significant influence on rates of Type I (false positives) and Type II (false negatives) errors. Attendees will be introduced to Receiver Operating Characteristics (ROC) analysis as a method to compare each type of error in order to provide a method to select optimal ATs and disregard suboptimal ones.

This presentation will impact the forensic science community by providing practical guidelines on how to evaluate the signal-to-noise in order to resolve whether ATs derived from running a set of blanks can be applied during the analysis of samples amplified with low- to medium-DNA input levels and major/minor mixtures. Recommendations regarding the use of ROC will also be given.

Interpretation of DNA evidence depends upon the ability of the analyst to accurately compare the DNA profile obtained from an item of evidence and the DNA profile of a standard. This interpretation becomes progressively more difficult as the rates of Type I and II errors increase. Traditionally, ATs have been chosen to ensure the false detection of noise is minimized. However, there exists a tradeoff between the erroneous labeling of noise as alleles and the false non-detection of alleles (i.e., drop-out). In this study, the effect ATs had on both types of error was characterized. Various ATs were tested, where three relied upon the analysis of baseline signals obtained from 31 negative samples. The fourth AT was determined by utilizing the relationship between RFU signal and DNA input. The other ATs were the commonly employed 50, 150, and 200 RFU thresholds. Receiver Operating Characteristic (ROC) plots showed that although high ATs completely negated the false labeling of noise, DNA analyzed with ATs derived using analysis of the baseline signal exhibited the lowest rates of drop-out and the lowest total error rates. In another experiment, the effect small changes in ATs had on drop-out was examined. This study showed that as the AT increased from ~10-60 RFU, the number of heterozygous loci exhibiting the loss of one allele increased. Between ATs of 60 and 150 RFU, the frequency of allelic drop-out remained constant at 0.27 (+/-0.02) and began to decrease when ATs of 150 RFU or greater were utilized. In contrast, the frequency of heterozygous loci exhibiting the loss of both alleles consistently increased with AT.

Peak height ratios at each of the 7 ATs were also calculated by dividing the peak height of the smaller allele (RFU) by the peak height of the larger allele (RFU) at a locus. Those ratios were then averaged and the standard deviations from the mean were determined. The data show that as the AT decreased, the average PHR decreased, while the standard deviation remained unchanged. The average PHR at ATs of 150 RFU and an AT based on baseline analysis were 0.8 (+/-0.2) and 0.6 (+/-0.2) respectively. The drop in the mean PHR with respect to AT is suggested to be a function of the increased stochastic variation associated with the ability to detect alleles from lower quantities of DNA. This supports the proposition that forensic DNA analysis of low-template samples needs to be accompanied by guidelines appropriate for samples containing small quantities of biological material. Therefore, if a PHR threshold is used to determine the number of contributors when only two distinguishable alleles are present, this data suggests stringent PHR thresholds such as 0.7 are not optimal for samples containing <0.5ng of input DNA.

The Type I and II error rates for major:minor mixtures were also examined and showed the same general trend: lower ATs decrease the level of Type II error. However, if a significant amount of DNA from the major is present (i.e., >0.5ng), non-specific amplified product increases Type I error at low ATs which are derived from examining the baseline noise. Therefore, in order to minimize the detection error rate within the laboratory, different ATs may need to be applied to different sample types (i.e., low-template versus high-template).

Analytical Threshold, Forensic DNA, Error Rates

A131 Technical Challenges of Developing Large Multiplex STR Assays for CE Platforms

Lori K. Hennessy, PhD, Julio J. Mulero, PhD, Chien-Wei Chang, PhD, Robert Lagace, BS, and Dennis Wang, PhD, Life Technologies, 850 Lincoln Centre Dr, MS 404-1, Foster City, CA 94404*

After attending this presentation, attendees will gain a better understanding of the complexity of developing robust assays for human identification.

The presentation will impact the forensic science community by providing a better understanding of how multiplex STR assays are developed for human identification.

Multiplex STR genotyping assays using fluorescent detection and capillary electrophoresis represent the most popular method of human identification due to the highly polymorphic nature of STRs, and their small fragment size (~100-400 bp). These multiplex STR assays have a high discriminatory capacity. For example, when a complete DNA profile is obtained using the 13 CODIS loci, the probability of a chance match with a randomly chosen individual is usually less than 1 in 1 X 10^{12}. These assays have been used as supportive evidence not only to convict the guilty but also to exonerate the innocent. Given the potential consequences of STR evidence, it is important to have robust and reliable assays.

However, obtaining successful co-amplification of all STR loci in a multiplex reaction with good peak height balance between loci, specific amplification, minimal stutter, maximal non-template-dependent +A addition, and no non-specific products which might interfere with proper interpretation of a sample's DNA profile is very challenging. Furthermore, with every new primer set added to the reaction, the complexity of the PCR increases and exponentially increases the possible primer-primer and non-specific interactions. The development of an efficient multiplex PCR reaction requires careful planning and numerous tests and efforts in the area of primer design, balancing reaction components, and optimizing thermal cycling conditions. In addition, the contributions to data quality of oligonucleotide synthesis and purification, elimination of dye artifacts, and electrophoresis conditions need to be assessed.

The forensic community is concerned with many aspects of the assay such as: stutter products, non-template addition, micro variants, null alleles, accuracy, and species specificity since these can pose challenges to accurate data interpretation. They also have unique needs to handle mixtures, degraded DNA samples, PCR inhibition, and contamination since forensic casework samples do not come from a pristine, controlled environment.

Recently, the Combined DNA Index System (CODIS) Core Loci working Group in the United States published a paper stating that the number of current CODIS loci are insufficient to accommodate goals of wider data sharing internationally (greater risk of adventitious matches) and that there is a need for additional information to improve success of obtaining a profile with challenging samples, such as missing person

cases. Thus, it was recommended expanding the required minimal core loci for the database from 13 autosomal STR loci to 19, plus another sex identification marker using a Y-chromosome STR locus and three optional STR loci. This recommendation increases the potential number of markers in one multiplex assay to twenty-three.

In this presentation, an overview of the challenges typically encountered when developing highly multiplexed STR assays for human identification purposes to meet the needs of the forensic community will be presented. Examples of the problems encountered and how they were resolved will be covered. Some of the examples will cover primer design, PCR artifacts, species specificity, electrophoresis, dye artifacts, and intralocus balance.

STR, CE, PCR

A132 Development Criteria for a Next Generation Y-STR Multiplex for Forensic Applications

Julio J. Mulero, PhD, and Lori K. Hennessy, PhD, Life Technologies, 850 Lincoln Centre Dr, MS 404-1, Foster City, CA 94404*

After attending this presentation, attendees will understand different aspects and challenges in designing a Y-Chromosome Short Tandem Repeat (Y-STR) multiplex that can be used for multiple forensic and human identification applications.

This presentation will impact the forensic science community by demonstrating how loci selection in a multiplex might favor one application over the other. On the other hand, if enough loci are multiplexed, it might be possible to apply subsets of these loci for specific applications.

Y-STRs have been used in human identification for over a decade in paternity testing, male lineage studies, and forensic DNA analysis. Y-STRs offer certain advantages over autosomal STR analysis, such as determining the number of male contributors in a sample, multigenerational male lineage studies, and the ability to obtain a male profile in the presence of a high background of female DNA bypassing the need for performing differential extraction of sperm and epithelial cells. Y-STRs can be used for rapid exclusion of suspects. However, the discrimination power of Y-STRs is lower than autosomal STRs and non-exclusion cases may need further investigation.

In recent years, population data for several new Y-STR loci have become available in the published literature. Some of these Y-STR loci are highly discriminating and thus offer good potential for use in forensic DNA analysis. Selection of the Y-STR loci for constructing a multiplex is critical and determines its downstream applications. If the objective is to exclude close patrilineal relatives of the suspect, then markers with a high mutation rate are preferred. On the other hand, in kinship analysis, markers with high mutation rates might prove problematic. In designing a new forensic Y-STR multiplex, the inclusion of currently used Y-STRs should be considered, given that the existing Y-STR databases are already populated with profiles containing this information. New markers could be added to enhance the capabilities of already existing Y-STR multiplexes. These enhancements could combine features such as mini-STRs, the inclusion of highly discriminating markers which could allow for better differentiation of paternal lineages in populations with low Y-chromosome diversity and rapidly mutating markers.[1,2] In addition, a next generation kit should also provide improved performance for profiling of challenging samples when compared to already existing multiplexes. These enhancements include improvements to the overall amplification balance, improved resistance to inhibitors of the PCR, and shorter amplification times.

This presentation will discuss a strategy for the development of an enhanced Y-STR multiplex that combines well-known loci as well as recently characterized, highly discriminating Y-STRs into a single amplification reaction. The presentation will also address how different nomenclatures could lead to potential lack of concordance with already existing published reports in some Y-STRs. Results will show that full profiles are attainable with low levels of male DNA (below 150 pg) and that under optimized conditions no detectable cross-reactive products were obtained from human female DNA, bacteria, and commonly encountered animal species. Additionally, results demonstrate the ability to detect male-specific profiles in admixed male and female samples at ratios greater than 1:1000. The haplotype diversity and discriminatory capacity calculations for the three major U.S. population groups (Caucasians, Hispanics, and African Americans) will also be described.

A133 The Effect of pH on Electroylyte Detection of Fingermarks on Cartridge Cases and Subsequent Microscopic Examination

Simon Liu, HBSc, Univ of Toronto Mississauga, Peel Regional Police, 125 Thorny Vineway, Toronto, ON M2J4J4, CANADA*

After attending this presentation, the attendees will learn the basics of fingerprinting on cartridge cases and the difficulties surrounding this field. Attendees will learn about a new fingerprint enhancement technique on fired and unfired cartridge cases without any damage to the subsequent microscopic examinations.

This presentation will impact the forensic science community by providing a novel fingerprint enhancement technique that works with both fired and unfired cartridge cases without any damage to the microscopic striations.

When cartridge cases undergo the firing process, fingerprints on the cartridge can degrade. Both fired and unfired cartridge cases may be found at crime scenes, or potentially linked to crime scenes, and may contain fingerprints deposited when the firearm was loaded. The metallic, non-porous surface does not retain fingerprints well and they are further degraded by the firing process. The two most common techniques used to enhance the clarity of fingerprints on fired and unfired cartridge cases are gunblue and cyanoacrylate fuming. These methods allow for enhanced visualization on unfired cases. Forensic identification officers, using techniques that work on unfired cartridge cases often apply them to fired cartridge cases without much success. However, fired cartridge cases are still encountered and are on the rise in crime scenes, especially homicides. However, there is currently no method for the visualization of fingerprints on fired cartridge cases. A recent study performed by Jasuja and colleagues demonstrated the use of electrolyte solutions to enhance fingerprints on general metallic surfaces including zinc, aluminum, iron, brass, copper, and non-metallic surfaces such as glass and plastic.[1] This technique has not; however, been applied to cartridge cases. Thus, the purpose of this study is to test the effects of pH electrolyte solutions on the enhancement of the clarity of fingerprints on fired and unfired cartridge cases. The effect of the solution on subsequent microscopic examination of striation was also examined. Microscopic examination (MSE) can determine whether the cartridge case originated from a particular firearm; it is therefore important that fingerprint development techniques do not interfere with MSE.

The experiments involved the immersion of both fired and unfired brass cases into various pH electrolyte solutions to enhance the clarity of deposited latent fingerprints based on the study performed by Jasuja over two time periods.[1] The time of immersion was kept constant. The effect of the fingerprint enhancement technique on the microscopic features on the fired cartridge cases by the Centre of Forensic Sciences (CFS) was subsequently examined.

Fired and unfired cartridge cases were immersed in six pH solutions for 24 hours for two trials. In the first trial, the cartridge cases

were immersed into the solution three weeks after fingerprint deposition. In trial 2, the cartridge cases were immersed right after deposition. The fingerprint clarity was graded and MSE was performed. In trial 1, neutral pH was the optimal pH and trial 2, no optimal pH levels were found in fingerprint clarity enhancement on both types of cartridge cases. In terms of the first trial, it was found that neutral pH based on statistics worked the best; however, in the second trial, no optimal pH was found statistically. It was found later based on the percentage of developed fingerprints that were considered acceptable by the forensic identification officers, that the top two highest percentages were pH 1-3, 3-5. However, it was found based on these microscopic results that these two pH ranges also had the most adverse effects. The use of neutral pH level is suggested since immersion of the cartridge cases in pH 1-3, and 3-5 affects MSE. However, if MSE is not intended after fingerprint enhancements, pH 1-3, 3-5 should be used as it has the highest success rate in enhancing the fingerprints for both types of cartridge cases.

Cartridge Cases, Fingerprints, Microscopic Striations

A134 The Use of mRNA Markers Allowed an Alleged Sexual Assault Casework Solution

Eugenia Carnevali, MD, Hospital of Terni, Via T. di Joannuccio, SNC, Terni, ITALY; Luciana Caenazzo, PhD, Dept of Enviromental Medicine/Public Health, DMM, Legal Medicine Via Falloppio 50, Padova, ITALY; and Massimo Lancia, MD*, and Mauro Bacci, MD, Univ of Perugia, via Del Giochetto SNC, Perugia, ITALY*

After attending this presentation, attendees will gain an understanding about how body fluids analysis can be useful to solve real caseworks, in particular, the use of mRNA markers as a valuable tool to identify the origin of body fluids.

This presentation will impact the forensic science community by providing results from a real casework in a relatively new field of forensic sciences with a little previous research.

Body fluid stains recovered at crime scenes are important types of evidence to forensic investigators. The first step of identifying a particular body fluid is essential since the nature of the fluid is itself very important to insure the correct handling of the sample (e.g., in mixtures from different source).

In the last years, mRNA and miRNA analysis has demonstrated to be a promising method for identification of body fluids: RNA can be isolated simultaneously with DNA, avoiding sample loss, and bypassing conventional body fluids identification methods.[1-3]

First publications showed that RNA can be isolated in suitable quality and quantity from blood, menstrual blood, saliva, and vaginal secretion.[4,5] Afterwards, a number of articles regarding the applications of RNA to further stains as seminal fluid and epithelial cells were published by several authors.

This presentation will present a case report of an attempted rape of a young woman assaulted by a friend's husband. She reported that the violence began with a "finger penetration" and then was stopped before a complete penetration was carried out. Moreover, the woman reported that during the assault, she had a fluid like discharge from her vagina (a fair amount of a reddish liquid) that stained her panties. Three days after the alleged abuse, the woman went to the emergency rescue of a local hospital for a gynecological examination, which did not detect any sign of physical violence.

The panties were collected by the prosecutor and sent to the Istitute of Legal Medicine of University of Perugia in order to evaluate the presence of biological traces attributable to the alleged assailant. Genetic analysis of the reddish liquid stain performed with the commercial DNA kit showed a mixture: the presence of Y-chromosome showed that one of the contributors was a male.

The analysis of Y-STRs performed with the DNA kit on the reddish liquid stain showed a haplotype which, compared with the suspect's haplotype, was a different one. The prosecutor questioned the woman again, she answered the questions, underlining that she did not have any sexual intercourse with any other person the day of the alleged violence. She also reported that five days before the alleged violence she had unprotected sexual intercourse with her partner and had taken a progestin pill.

Thereafter, an analysis of mRNA was performed on the reddish liquid stain, using two different markers: MMP11 (present in the endometrial cells and commonly used for the diagnosis of menstrual blood) and PRM2 (specific for sperm cells).

The analysis of the mRNA was positive for PRM2 and negative for MMP11. The presence of sperm was suggested. Therefore, an analysis of Y-STRs on the victim's boyfriend was performed. The obtained Y-haplotype matched with the Y-haplotype achieved from reddish liquid stain. Probably the reddish fluid discharge from the vagina was the consequence of progestin pill consumption.

Body Fluids, mRNA Analysis, Sexual Assault

A135 Analysis of Fluoro-Phenethylamine Regioisomers Using Electrospray Ionization-Mass Spectrometry and Capillary Electrophoresis

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott St, Vista, CA 92081*

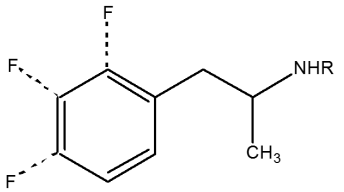
After attending this presentation, attendees will become aware of how ESI-MS and CE techniques can be used to distinguish between 2-, 3-, and 4-fluoroamphetamine and 2-, 3-, and 4-fluoromethamphetamine.

This presentation will impact the forensic science community by providing awareness of alternative methods for analyzing ring regioisomers of controlled substances.

During the past couple of years, local, state, and federal forensic chemistry laboratories have encountered a great array of new designer chemicals. The new compounds are available through the clandestine drug market and have been designed with the intention of circumventing legal regulations. Laboratory submissions containing these new compounds present significant challenges to analysts and laboratory managers due to both the lack of reliable sources of reference materials and the inability to use routine laboratory techniques like gas chromatography-mass spectrometry (GC/MS) to unambiguously distinguish potential chemical variations in the structure of the compounds.

Two types of new designer compounds recently encountered are fluoroamphetamine (FA) and fluoromethamphetamine (FMA), which may be considered structural analogues of controlled phenethylamines. As observed in the structures below, there are three possible phenyl ring regioisomers for each one of these compounds, depending on the location of the fluorine atom. When the fluorine atom is located in position two, three, or four, the resulting compounds are the *ortho*, *meta*, or *para*-fluoro-phenethylamines, respectively. It is believed that

replacement of the hydrogen atom by fluorine facilitates passage through the blood-brain barrier, as the substitute atom increases the lipophilicity of the compound.[1]



R = H (amphetamine) R = CH_3 (methamphetamine)

Analysis of FA and FMA using routine GC/MS conditions results in similar retention times and electron ionization (EI) fragmentation patterns for all three positional isomers of each compound. That is, the unequivocal distinction between 2-FA, 3-FA, and 4-FA, and between 2-FMA, 3-FMA, and 4-FMA cannot be accomplished solely by GC/MS analysis. This presentation will describe application of the techniques of electrospray ionization mass spectrometry (ESI-MS) and capillary electrophoresis (CE) to the analysis of FA and FMA regioisomers.

Analysis of 2-FA, 3-FA, and 4-FA using ESI-MS results in protonated pseudomolecular ions at m/z 154, consistent with the molecular weight of 153 Da. The analogous ions at m/z 168 were observed during analysis of the FMA regioisomers. Collision-induced dissociation (CID) experiments were designed in order to investigate the possibility for distinguishing the regioisomers from each other. To achieve this, the CID conditions were methodically varied between 20% and 30% collision energy, and MS^2 and MS^3 fragmentation data were collected for each of the six regioisomers. Based on the fragmentation patterns observed, it can be concluded that 2-FA and 3-FA cannot be distinguished from each other. However, the fragmentation pattern observed for these two regioisomers can be clearly differentiated from that obtained for 4-FA. This pattern of distinction is statistically reproducible and also repeated within the FMA regioisomer series. That is, 2-FMA and 3-FMA result in similar MS^n fragmentation spectra, which then can be distinguished from that of 4-FMA.

Analysis of FA and FMA regioisomers using routine non-chiral CE experimental conditions resulted in similar migration times for all six regioisomers. Under chiral analysis conditions, the migration times observed changed, but are only slightly distinguishable. However, the use of 2-OH-β-cyclodextrin as a buffer additive did result in noticeable differences between the enantiomeric pairs of each compound. A reproducible pattern of separation is observed which can be used to distinguish between the *ortho*-, *meta*-, and *para*-phenethylamines. The resolution between the *d*- and *l*- enantiomer peaks is observed to increase as the position of the fluorine is changed from four to three to two; that is, as the fluorine atom moves closer to the alkyl chain. For 4-FA and 4-FMA, the enantiomers are practically co-migrating; for 3-FA and 3-FMA the peak separation increases and the presence of 2 enantiomers is evident, although baseline separation is not complete. For 4-FA and 4-FMA, the resolution values measured are twice those observed for 3-FA and 3-FMA, respectively.

This presentation will also include application of the above described ESI-MS and CE techniques during the analysis of multiple unknown case samples. This material included in this presentation is expected to be of interest to other forensic chemistry analysts and laboratory personnel involved in the analysis and evaluation of controlled substance analogues.

Regioisomer, Analogues, Controlled Substance

A136 Micro-Raman Mapping of Dissimilar Inks on Paper

Gary H. Naisbitt, PhD, Andy V. Pham, and Bruce A. Jacoby, Utah Valley Univ, Criminal Justice Dept, MS 286, 800 W University Pkwy, Orem, UT 84058*

After attending this presentation, attendees will be presented with an example of identifying the order of ink deposition where lines cross by micro-Raman mapping using two types of maps, surface, and depth slice, providing a visual interpretation of the analytical data that is easy for juries to understand.

This presentation will impact the forensic science community by demonstrating the use of micro-Raman mapping as a visual technique well suited for courtroom presentations.

When documents are altered, the order of ink layer deposition where lines cross is an important determination confronting questioned document examiners. Knowledge of the top layer suggests the intent of the alternation and knowledge of the lower layer provides information about the document's original content. Together, this information helps establish motive, may suggest a suspect, and establishes a timeline of the crime.

Conventional ballpoint pens were tested by making a figure of a cross with single lines of different inks. Reference spectra were acquired at various locations on the inked legs of the cross where lines of individual inks existed, and for paper at adjacent locations near the inked lines. At the microscopic level, paper composition is inconsistent and ink coverage is inconsistent and incomplete. These difficulties were overcome by averaging several repeated scans at every test location to assure instrument accuracy, followed by averaging all scans of each individual ink and paper to compile representative standard spectra of each component. The same sampling scheme was used in the area where lines crossed.

Micro-Raman analysis does not destroy the sample. Confocal optical design limits the depth of focus to very thin layers, allowing small volumes to be analyzed without interference from the surroundings. Raman excitation was 785nm and spectral response was measured from 850cm^{-1} to 3200cm^{-1} or from 1250cm^{-1} to 1750cm^{-1}. Other instrument settings were 30 second exposure time, 10% laser power, and two accumulations at either 20x or 50x magnification at high confocality.

Maps are like digital photographic images composed of cells (pixels) that hold both the Raman spectrum and photographic information at that location. Steps between cells can progress at 1.0 micrometer increments in either the x or y horizontal directions to produce two-dimensional (2D or x,y) surface maps; or vertically (y direction), to produce depth slice maps that appear as vertical cross sections above and/or below the paper surface.

To show ink locations on the mapped surface, standard reference spectra of paper and each ink were assigned a false color and matched to the spectra in each mapped cell. The location of each component was visualized by redrawing the map with the assigned false colors.

False colored maps require little technical explanation and are easily understood, allowing juries to draw their own conclusions. This frees the expert of the need to express his own conclusion that judges sometimes disallow because it is held to be "subjective."

Micro-Raman Mapping, Ink Analysis, Document Alternation

A137 Raman Spectroscopy as a Non-Destructive Technique to Differentiate Circulatory and Menstrual Blood

Kathleen Barra, BS, 19 Jones St, Setauket, NY 11733; Jennifer J. Maldonado, MS, 265 College St, Apt 2F, New Haven, CT 06510; and Virginia M. Maxwell, DPhil, University of New Haven, Dept of Forensic Science, 300 Boston Post Rd, West Haven, CT 06516*

After attending this presentation, attendees will have learned about the significance of Raman spectroscopy as a non-destructive technique in the differentiation of body fluids at a crime scene.

This presentation will impact the forensic science community by learning a more effective and rapid technique for body fluid identification at a crime scene. The development of portable handheld Raman instruments further allows the investigator to analyze samples in the field to obtain rapid results prior to collection of evidence.

The versatility and non-destructive nature of Raman spectroscopy has lead to its widespread use for rapid analyses in forensic science. The development of portable handheld Raman instruments further allows the investigator to analyze samples in the field to obtain rapid results prior to collection of evidence. Raman is already used to identify fibers, drugs, explosives, lipsticks, ink, paint, bones, fingerprints, and condom lubricants. The benefits of Raman spectroscopy, besides its main characteristic of being non-destructive, include reagent-free and minimal sample preparation, little interference from water, and a sample size as small as several picrograms. In addition, results may be obtained through transparent packaging, thus allowing containment of potentially hazardous or biohazardous materials. Recent research has shown the potential for Raman spectroscopy to definitively and non-destructively identify and differentiate common body fluids including semen, saliva, vaginal fluid, sweat, and blood. Raman spectroscopy also has the potential to distinguish, non-destructively, human, canine, and feline species by their blood spectra using statistical analysis. Blood is the most common body fluid found at a crime scene and, in certain cases, the ability to distinguish menstrual blood from circulatory blood is desirable and may be critical. Current methods for identification of menstrual blood include the use of microscopy, lactate dehydrogenase isozyme identification, Messenger Ribonucleic Acid (mRNA) and Microribonucleic Acid (miRNA) profiling, real time-PCR, and identification of the products of fibrinolysis. These methods are complex, destructive, expensive, and have the potential for false negative results. Current methods for identification of circulatory blood are heme-catalyzed screening tests, which often involve a color change. These tests can be performed at the crime scene, but can have false positives and consume the sample. This research investigates the use of Raman spectroscopy as a tool to rapidly differentiate between circulatory and menstrual blood. Preliminary results have identified the main components of liquid and dried blood as well as investigated the spectra of blood on various substrates. Results show no difference in the spectra across genders and a time study of blood showed an increase in peak intensity of the component fibrin with time. The main components of liquid blood were hemoglobin, fibrin, glucose/L-tryptophan, and L-tryptophan/L-phenylalanine. The same main components were observed in dried blood. However, significant differences in peak patterns were present in liquid and dried blood due to coagulation, which included changes in peak morphology and an increase in peak intensity. The major physiological differences between menstrual blood are related to the ability of blood to clot and the presence of clotting agents, such as fibrin, in the blood. The ready detection of these agents in circulatory blood using Raman spectroscopy shows promise for its further use to identify menstrual blood. Menstrual blood has a non-clotting agent that breaks up clots and therefore affects the fibrin level present. In this study, menstrual blood was collected on gauze pads from female volunteers during two different menstrual periods. The same volunteers provided circulatory blood via a conventional blood draw. Differences in fibrin levels shown by Raman spectroscopy may be linked to the origin of the blood. Subtle differences in spectra were resolved using Chemometrics, specifically R, to show clear differentiation between menstrual and circulatory blood.

Raman, Blood, Fibrin

A138 Separation and Identification of Synthetic Cathinones Using GC/MS, GC-QQQ/MS, and ESI-IMS/MS

Jose R. Almirall, PhD, Florida Int'l Univ, Department of Chemistry, University Park, Miami, FL 33199; and Seongshin Gwak, MS, Dept of Chem and Biochem, 11200 SW 8th St, CP 194, Miami, FL 33199*

After attending this presentation, attendees will learn the use of ion mobility as a separation technique coupled to a mass spectrometer for the analysis of synthetic cathinone and the differences in ionization (ESI vs CI vs EI) in fragmentation and identification of these analytes of interest.

This presentation will impact the forensic science community by making it possible to unambiguously separate the cathinones with IMS faster than with GC/MS, while also preserving the molecular ion due to the soft ionization using ESI.

Cathinone is the main component of the *khat* plant which produces a stimulating effect similar to amphetamines.[1] The ease of online availability of a number of the *synthetic cathinones*, also known as legal highs or bath salts, have led to increased use and abuse over the past few years.[2] In this study, six synthetic cathinones, recently scheduled as Schedule I controlled substances in Florida as of July 2012, 4-methylmethcathinone (mephedrone or 4MMC), 3-fluoromethcathinone (flephedrone or 3FMC), 4-methylethcathinone (4MEC), 4-methoxymethcathinone (methedrone or bkPMMA), 3,4-methylenedioxymethcathinon (methylone or bkMDMA), and 3,4-methylenedioxypyrovalerone (MDPV), were analyzed using a commercially available electrospray ionization-ion mobility spectrometer-mass spectrometer (ESI-IMS-MS), a gas chromatograph-mass spectrometer (GC/MS) using electron ionization (EI), and a GC/MS Triple Quadrupole (QQQ) with both EI and chemical ionization (CI) modes. One of the advantages of using the softer CI and ESI ionization sources is the creation of molecular ions of the easily fragmented compounds and, in the case of ESI, the ability to analyze nonvolatile compounds and ionize compounds in the liquid phase.[3] A fast and selective method is reported that can be used to unambiguously identify this increasingly important class of drugs. A high-resolution IMS was used to separate mixtures of these synthetic cathinones within less than 20ms. The limits of detection were determined and good separations from two-compound mixtures were achieved with typical concentrations of MDPV and other compounds (20:100ppm), and methylone and other compounds (20:100ppm) using ESI-IMS-MS. The analysis of these cathinones was also carried out using GC/MS, which is currently the standard technique used in forensic laboratories, to compare with ESI-IMS-MS. In addition, GC-QQQ-MS with EI and CI modes was used to determine the identification of fragmented ions from these cathinones. The analysis of several actual seized police case samples was also performed using the same instruments to illustrate the utility of the developed IMS-MS and GC-QQQ-MS methods.

These methods, reported for the first time for the drugs listed, make it possible to unambiguously separate the cathinones with IMS faster than with GC/MS while also preserving the molecular ion due to the soft ionization using ESI.

This project was supported by Award No. 2011-DN-BX-K531 from the National Institute of Justice (NIJ), Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the author(s) and do not necessarily reflect those of the Department of Justice.

A139 Determination of Organic Gunshot Residue With Solid Phase Microextraction by GC/MS

Brent A. Casper, BS, University of Kentucky, A061 ASTeCC Bldg, Lexington, KY 40506; and Bert Lynn, PhD, University of Kentucky, A053 ASTeCC Bldg, Lexington, KY 40506*

After attending this presentation, attendees will become familiar with how Solid Phase Microextraction (SPME), coupled with Gas Chromatography-Mass Spectrometry (GC/MS), can be used to effectively detect organic gunshot residue (OGSR) from articles of clothing.

This presentation will impact the forensic science community by providing a quick and efficient method to detect OGSR on a suspect's clothing. Additionally, while utilizing equipment currently present in most labs, forensic labs will be presented with an alternative method to determine if an individual has fired a gun.

Traditionally, GSR has been evaluated by elemental analysis of inorganic particles such as lead, barium, and antimony by the technique of Scanning Electron Microscopy with Energy Dispersive X-ray analysis (SEM-EDX). This method has provided the benchmark for GSR analysis within the legal system for decades. Although the technique of SEM-EDX is very effective, it also has the disadvantage of being time consuming and labor intensive.[1]

As times change, the compositions of ammunitions are also evolving. More environmentally friendly formulas remove lead, and replace it with other less toxic elements such as aluminum.[2] The traditional method of analyzing GSR by SEM-EDX, which relies on the presence of these inorganic elements, is becoming obsolete as manufactures change the composition of their ammunitions to more environmentally sustainable formulas. This has placed the forensic community at a disadvantage when it comes to GSR analysis, but at the same time also gives new opportunities to create alternative methods to solve such problems.

The goal of this study is to determine if OGSR can be captured by SPME and analyzed by GC/MS to establish if an individual fired a gun. OGSR can originate from many components of ammunitions including primers, propellants, and stabilizers—all of which contain different compounds classified as OGSR. Some of these compounds include diphenylamine (DPA), N-nitrosodiphenylamine, ethyl centralite (EC), and methyl centralite (MC). The compounds ethyl and methyl centralite are both unique compounds to OGSR, and can be used as an identifier compound to place a suspect at the scene of a shooting.[3]

For this research, articles of clothing were collected in sealed cans for transportation and analysis. The OGSR was moved from the clothing into the headspace of the can by applying heat in an oven. The SPME fiber was then exposed to the headspace to extract the OGSR. After the headspace extraction, the OGSR was desorbed from the SPME fiber into the heated injection port of the GC/MS for analysis. A 75µm Carboxen-PDMS (Supelco Bellefonte, PA) SPME fiber was chosen to perform the extraction with a Shimadzu GC/MS-QP5000 (Kyoto, Japan) for the analysis. To make the analysis more selective, a selected ion monitoring (SIM) method of known OGSR compounds was used to perform the analysis. Test firings/samples were conducted at a local shooting range.

Preliminary data has demonstrated that a cloth doped with OGSR compounds DPA, EC, and 2,4-dinitrotoluene can be extracted and analyzed with SPME-GC/MS. Initial findings have also shown that when a gun is discharged, a cloud of OGSR does adhere to cloths placed around the shooter, with some of these compounds being extracted when analyzed. Additional experiments are being conducted to determine if a correlation is present between certain compounds and individual brands of ammunitions. The preliminary data has shown that using SPME-GC/MS as the means of extraction and detection will provide a fast and accurate method for the analysis of OGSR evidence.

GC/MS, Organic GSR, SPME

A140 Determination of Useful Yields of Forensically Relevant Compounds by Direct Analysis in Real Time Mass Spectrometry (DART/MS)

Edward Sisco, MS, 6819 Old Waterloo Rd, Apt 1035, Elkridge, MD 21075; and Jeffrey H. Dake, MSFS, 4930 N 31st St, Forest Park, GA 30297*

After attending this presentation, attendees will be familiar with the concept of useful yields and their relevance to the forensic community, while also discussing the topics of useful yields for a number of forensically related compounds, including explosives, narcotics, bank dye, and lubricants.

This presentation will impact the forensic science community by giving an in-depth understanding of useful yields and how they can be improved to better understand the limit of detection and limit of quantification of mass spectrometry analysis. Furthermore, the effects which instrument parameters have on the useful yields of the compounds will be explored. Comparison of the useful yields of the DART®-MS technique to other mass spectrometry techniques will also be discussed.

Useful yield is a term which is not widely used in the Ambient Pressure Ionization Mass Spectrometry (API-MS) realm. It has; however, been utilized in the Secondary Ionization Mass Spectrometry (SIMS) area of study. The definition of useful yields is the ratio of the ionized molecules to the amount of molecules originally present in the sample. This measurement allows for a way to measure the efficiency and practical yields of a given substance through analysis on a specific technique with specific settings. Useful yields can also be used to compare two techniques which are difficult to compare otherwise. By understanding the useful yields it may be possible to determine which technique would provide the best response for a given analyte or class of analytes.

To obtain a useful yield, it is crucial to have a precise understanding of the number of analyte molecules present in the sample. In order to obtain an accurate number, two methods of sample deposition can be used. The first method is a microsyringe, which will deposit a relatively accurate amount of analyte to a substrate. The second and more precise technique is piezoelectric inkjet printing, which allows for the printing of microdroplets of solution onto a surface. Using this technique, it is possible to obtain 1% repeatability and ±10% accuracy in sample deposition.

Useful yields were determined for a number of compounds on an AccuTOF™ DART® mass spectrometer. The DART® source is a commercial-available API-MS technique which is gaining momentum for routine use in casework, and, therefore, is a prime technique for this study. Since there are several different parameters which affect the signal, the useful yields under a number of different parameters were studied. These parameters include gas temperature, orifice voltage, and the addition of a dopant. How much of these factors influence the useful yield is discussed. The analytes which are examined include explosives, narcotics, bank dye, and lubricants. Initial results on the useful yields of explosives show that about one in every 10^8 – one in every 10^9 molecules are ionized and detected. This compares closely to results for other API-MS techniques, including Desorbtive Electrospray Ionization (DESI) and Low Temperature Plasma (LTP). Useful yields from DART®-MS are also compared to both vacuum-based techniques and chromatographic techniques such as SIMS and GC/MS.

DART®-MS, Useful Yields, Explosives

A141 Analyzing Lateral Diffusion of Fingerprint Constituents as a Function of Time Since Deposition

Edward Sisco, MS, 6819 Old Waterloo Rd, Apt 1035, Elkridge, MD 21075; Shin Muramoto, PhD, NIST, 100 Bureau Dr, MS 8713, Gaithersburg, MD 20899; and Greg Gillen, PhD, NIST, 100 Bureau Dr, MS 8371, Gaithersburg, MD 20899*

After attending this presentation, attendees will be aware of how imaging mass spectrometry could be used as a technique to monitor the diffusion of fingerprint constituents as a function of time since deposition. Through the ability to image several different components, the potential for this technique to be able to determine an approximate age of a fingerprint will also be presented.

This presentation will impact the forensic science community by introducing a unique and innovative application of imaging mass spectrometry, more specifically, how imaging mass spectrometry can be used to better understand fingerprints, concentrating on chemical changes in a fingerprint.

Though the imaging of fingerprints has been reported previously using mass spectrometry techniques, the use of the technique as a potential way to monitor the age of fingerprints has not been discussed. Through initial studies, it has been shown that the relative location of certain components in a fingerprint change as the fingerprints age. The general trend appears to be that a number of constituents appear to diffuse out of the ridges of the fingerprints and into the valleys. Furthermore, there appears to be a threshold time after which these compounds have completely diffused and the ridges and valleys of the fingerprint cannot be differentiated using chemical imaging. However, even though the chemical image is indistinguishable, ridges are still optically visible.

The technique which is used to obtain the images is a Secondary Ion Mass Spectrometer (SIMS). The SIMS technique is a high vacuum technique in which a primary ion species—in this case either bismuth or fullerene ions—is accelerated toward a sample and, upon interaction, causes the ejection of secondary ions, which are characteristic of the sample. SIMS is a soft ionization technique, and readily produces the molecular ion of nearly all chemical species. Furthermore, this technique has already been shown to readily detect a number of different sebaceous and eccrine components of a fingerprint. SIMS also provides several benefits over other types of imaging mass spectrometers, such as ambient pressure ionization mass spectrometry, the most important of which is the ability to provide chemical images with spatial resolution of 1µm or better. This is a level of spatial resolution which is difficult to obtain using techniques such as DESI-MS. This high-resolution technique also allows for the simultaneous imaging of all chemical signals present in a fingerprint, which enables monitoring and comparison of a number of different fingerprint components simultaneously.

Initial studies have shown a number of fingerprint constituents diffuse from fingerprint ridges over varying time scales. These changes have been noted to occur over several months, which may provide a way to tell differences in fingerprints over longer times cales than just days to weeks. While changes in the long time scale have been identified, experiments are also being completed to discover changes which provide a way to date on a shorter time scale. Finally, the effects of sample substrate and environmental exposure conditions will be analyzed. An evaluation on the practicality of the technique will also be presented.

Fingerprints, SIMS, Chemical Imaging

A142 Revisiting Glass Fracture Examination and Interpretation in Forensic Casework

Craig L. Heummer, MS, New York City Police Lab, 150-14 Jamaica Ave, Jamaica, NY 11432; Nicholas Petraco, MS, 73 Ireland Pl, Amityville, NY 11701; Mary Eng, BS, New York City Police Lab, 150-14 Jamaica Ave, Jamaica, NY 11432; and Nicholas D. Petraco, PhD, John Jay College, 454 W 59th St, New York, NY 10019*

After attending this presentation, attendees will know about the scientific terminology used in glass fracture analysis, how to avoid common pitfalls when determining the direction of force, and how to distinguish between various types of glass fractures.

This presentation will impact the forensic science community by introducing the proper scientific terminology for describer fractures in glass.

During crime scene investigations and reconstructions involving broken or fractured panes of glass, it is often of vital importance whether or not a location or vehicle was entered from the inside or outside. In burglary investigation, whether a pane of glass was shattered with a tool, struck with a baseball bat, or cut with a glass cutter is crucial information for the investigating detective to know. Whether the glass window was broken or cut from inside the premises or outside the premises is crucial to the burglary investigation. Investigations involving arson can often be advanced by knowing if the glass windows were broken by thermal radiation, a projectile, or some other type of physical force. Events involving firearms, bullet holes, and bullet trajectory can often benefit greatly from a thorough and complete scientific evaluation of the glass fractures. The sequencing of bullet holes is often very important to reconstructing a crime scene or event. Determining which bullet hole was made first, or whether a bullet hole was made from outside-in or inside-out of the premises is often crucial to an investigation. In leaving the scene of accident investigations involving fractured windshields, studying the scattered windshield can often help determine who was driving the vehicle and who was a passenger, where the occupants were siting, how fast the vehicle was going, and much more. Such issues have been studied and discussed by forensic scientists for nearly a century, and many have published their work in the forensic literature.[1-12] Unfortunately, although much of the published information is useful and scientifically accurate, the nomenclature used for fracture marks is often confusing, and has been frequently misused in the scientific literature.[13] In the mid 1980s, two forensic scientists addressed some of these issues; however, more work stills needs to be carried out.[14]

This study delves into the scientific methods and terminology used by those material scientists that study the fractography of brittle materials such as glasses and ceramics. The basic definitions of natural and synthetic glasses, as well as the various types of commercial glass, are presented and discussed. Next, their physical, optical, and chemical properties are reviewed in relationship to how and why these brittle materials fracture. The brittle nature of glass, its elasticity, tensile strength, and the scientific laws and phenomena explaining its behavior are examined and discussed in detail.[15-20]

The proper scientific terminology for commonly used terms such as craters, splintering, rib marks, hackle marks, radial lines, and concentric lines are offered, depicted, and covered in detail. Some common pitfalls in applying the right, rear, radial rule for determining the direction of forces are also advanced. Several case studies are given which illustrate and discuss the scientific laws, and terminology used by the fractography community for describing glass fracture phenomenon and showing how these laws and terms can be applied in forensic casework.

Finally, the goals of this research are to help right these issues in at least the forensic community and to further the use of glass fracture analysis in forensic casework meeting the challenges of the NAS Report on Forensic Sciences.

A143 A Survey of Forensic and Law Enforcement Professionals on Synthetic Drug Trends: A One Year Follow-Up

Lindsey E. Saunders, BS, West Virginia Univ, 1600 University Ave, 208 Oglebay Hall, Box 6217, Morgantown, WV 26506*

After attending this presentation, attendees will gain an understanding of the changes in trends of synthetic drugs throughout the United States that occurred over the past year.

This presentation will impact the forensic science community by demonstrating the change in trends for synthetic drug samples in a one-year period. Synthetic drug compounds are continuously being introduced into the United States; therefore, staying current on changing trends is important for police officers and forensic scientists.

A survey was given to forensic science and law enforcement professionals participating in online continuing education courses during 2011. Due to the rapid changes in synthetic drug compounds and related legislation, a follow-up survey was performed one year later to observe changes in trends in that period. The original survey, as well as the follow-up survey, consisted of the questions listed:

1. In what state do you work?
2. Do you work for a local or state agency?
3. What is your job title?
4. Have you encountered synthetic drugs samples in your position?
5. What synthetic drug compounds are you specifically seeing?
6. How often are you working with synthetic drug samples?
7. Do you perform testing in-house for synthetic drugs?
8. If yes, can you elaborate on your testing protocol?
9. If no, what is the protocol for synthetic samples in your agency?
10. What further information can you provide regarding synthetic drugs?

The original survey showed that 79% of those surveyed had encountered synthetic drug samples in their job position. Of those surveyed, the majority were testing synthetic drug samples monthly, although some were testing samples daily.

The follow-up survey had one additional question added in order to record the number of professionals who participated in related surveys, courses, and articles in order to determine how much information and/or questions they have received in the last year. The purpose of the latest survey is to gather the most up-to-date data possible and present this information to the forensic community. The current survey data will be compiled through January 31, 2013, allowing for the most current data to be presented. Comparing the original survey and the current survey will aid in demonstrating the rapid pace at which these types of compounds develop.

The original survey was given in order to observe overall trends in synthetic drugs from the forensic professional's view, while the follow-up survey will provide the forensic community with a more detailed explanation of what has occurred over the last year in the synthetic drug market. More individual cities and states are enforcing their own bands on specific compounds and groups of compounds; therefore, observing recent trends is important. Synthetic drugs are unable to be classified as easily as other illicit drugs due to the vast number of compounds; therefore, identifying trends may aid in the process of uniformly banning synthetic drugs across the country. Not only will the results demonstrate what is currently being observed throughout the country, but what may be seen in the future. Unlike traditional illicit drugs, synthetic drugs are continually being developed, which causes problems for forensic laboratories due to the lack of identification testing methods. With the rapid development of this group of drugs, published data may quickly go out of date, which is why an up-to-date, one-year comparison survey can benefit the forensic community. Traditionally, a one-year follow-up survey may not present enough data to show change, yet with a market such as synthetic drugs, a year is a large enough time frame for significant changes to be observed.

Synthetic, Drugs, Trends

A144 The Evaluation of Chemical Interferences in Forensic Tape Analysis From FreeZ-It®, Un-Du®, and Super Glue® Fuming

Katie Villarreal, MSFS, 4930 N 31st St, Forest Park, GA 30297*

After attending this presentation, attendees will have a better understanding of the possible chemical interferences contributed from three techniques commonly used by latent print examiners in the beginning stages of latent print examinations on pressure-sensitive tapes.

This presentation will impact the forensic science community by clarifying potential chemical interferences that latent print processing techniques can have on the analysis of pressure-sensitive tapes. The collaboration between trace evidence examiners and latent print examiners in regard to handling the forensic examinations of these tapes is critical in promoting the development of probative information.

Pressure-sensitive tapes are commonly encountered in forensic science casework in the form of restraints, ligatures, blindfolds, mail fraud, and in improvised explosive devices. The potential exists, in cases involving pressure-sensitive tapes warranting both trace evidence examinations and latent print examinations, for one's examination to hinder or impede the other's examination(s). This potential "trade-off" is case specific and must result in close collaboration between examiners from each discipline and investigators and/or litigators. Is there a workflow that would allow for both disciplines to minimize the potential effects that each examination can have on the other? Does the processing conducted by the United States Army Criminal Investigation

Laboratory's (USACIL) Latent Print Branch to protect any potential latent print(s) and DNA evidence hinder trace evidence chemical comparison examinations? Is it pertinent that trace evidence sample prior to any latent print processing or can latent prints take steps to preserve any potential latent prints (and DNA evidence associated with latent prints) up to the step of Super Glue fuming?

This research examined the possibility of minimizing the "trade-offs" that exist between trace evidence and latent prints in regard to the examination of pressure-sensitive tapes by determining if there are any chemical interferences observed in tape processed with FreeZ-It®, Un-Du®, and Super Glue fuming (cyanoacrylate) for three types of tape commonly encountered in casework (duct tape, vinyl/electrical tape, and clear packing tape). The processed tapes and neat samples were analyzed by Fourier Transform Infrared Spectroscopy (FTIR) and X-ray Fluorescence (XRF). All treated and neat samples were analyzed by Attenuated Total Reflectance (ATR). In addition to ATR, the duct tape samples were also evaluated by transmission FTIR (microscope) allowing for evaluation between the techniques. All treated and neat samples for the three different types of tapes were analyzed by XRF in triplicate. Statistics were applied to the XRF data to assist in determining if any significant differences occur in the spectral data.

There is evidence that suggests chemical interferences are present in tapes processed with super glue and analyzed by ATR. Also, there is evidence that supports significant differences in elemental data in duct tape adhesive and duct tape backing treated with FreeZ-It®, Un-Du®, and Super Glue when compared to the neat samples.

Trace Evidence, Latent Prints, Tape

A145 Ball Footprint Classification System

Vera Chuaypradit, BS, 2200 Benjamin Franklin Pkwy, Apt N1701, Philadelphia, PA 19130*

As a result of noticing a low success rate for identifying school children from their infant footprints, the goal of this presentation is to help attendees understand the importance of footprinting newborns correctly in order to obtain a positive identification.

This presentation will impact the forensic science community by assisting officials in identifying children in various cases. By implementing a more thorough methodology in footprinting newborns, the amount of misidentifications can be decreased.

There has been a low success rate for identifying school children from their infant baby prints. Baby prints have historically been used by hospitals as souvenirs for parents. These prints, while valuable in the wealth of information that can be obtained from them, are often taken incorrectly; many prints are obtained from those who have little training in fingerprinting an individual. The art of fingerprinting an individual is key when it comes to footprinting newborns because of the similar technique needed to successfully obtain a suitable print. Even the footprints obtained from twenty newborns at five different nurseries that are known to provide maximum detail only had 11% of prints that were deemed adequate enough for identification by an expert analyst. Research has shown that the development of the arch of the foot around the ages of four and five, results in an unsuccessful identification in children.[1] A study conducted by the California Department of Justice saw that out of 50 subjects, they could only identify a handful.[2] Low success rates have also been found when attempting to identify children using a co-classification system where a researcher utilized two methodologies in classifying footprints.[3] Research conducted from this study has indicated that utilizing a two-dimensional method that focuses solely on the ball of the foot would result in a higher match rate. Similar to the principle of fingerprinting, instead of using the whole hand to classify an individual, the study will show that the imprint of just the balls of the feet will provide a suitable and accurate way for classifying an individual from infancy to adulthood. Creating a classification system solely using the ball of the foot will yield a higher match rate than examining the entire foot. Volunteers have provided their baby footprints for analysis in this project. Additionally, current prints were obtained from volunteers through the ink rolling method for comparison and for the creation of a database. Through comparison of both baby footprints and their adult counterparts, unique characteristics for each individual were dominantly seen in the area of the balls of their feet, but as we moved to the sole and the heel of the foot, unique characteristics were not as prominent. This proves promising in the development of a classification system that would focus mainly on the ball of the foot. Data gathered from this research could be the foundation for a national database in order to help identify children when other methods of identification are unavailable due to cost, lack of DNA exemplars, or time constraints. Implementation of this proposed system would rely heavily on educating numerous hospitals in order to obtain suitable prints for future use in the identification of children as they age.

Footprint, Identification, Classification

A146 Forensic Mitochondrial DNA Analysis of Human Hairs After Exposure to Radiation

Michael D. Brandhagen, PhD, FBI Laboratory, Mitochondrial DNA Unit, 2501 Investigation Pkwy, Quantico, VA 22135; Lara D. Adams, MS, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135; Constance L. Fisher, PhD, FBI Laboratory, Mitochondrial DNA Unit, 2501 Investigation Pkwy, Quantico, VA 22135; Caitlin E. Ferguson, BS, Aaron L. Washington, PhD, and Martine C. Duff, PhD, Savannah River National Laboratory, Bldg 773-43A, Rm 217, Savannah River Site, Aiken, SC 29808; and Keith L. Monson, PhD, FBI Laboratory, Mitochondrial DNA Unit, 2501 Investigation Pkwy, Quantico, VA 22135*

The goal of this presentation is to inform of the effects that radiation type and dosage have on Mitochondrial DNA (mtDNA) analysis of human hairs, allowing one to judge in which situations hair evidence is likely to remain useful for mtDNA analysis, and, therefore, should be collected.

This presentation will impact the forensic science community by understanding how the effects of radiation on the mtDNA analysis of hairs will prevent unnecessary radiation exposure to the individuals that would collect the hair evidence. This presentation will give decision makers more data to help determine whether or not the exposure of evidence to certain levels and types of radiation justifies the potential health risk for the evidence to be collected.

The objective of this presentation is to inform the forensic community of the effects that radiation type and dosage have on Mitochondrial DNA (mtDNA) analysis of human hairs. This will allow one to evaluate in which situations hair evidence is likely to remain useful for mtDNA analysis and; therefore, should be collected. In this way, knowing the effects of radiation on the mtDNA analysis of hairs will prevent unnecessary radiation exposure to the individuals that would collect the hair evidence.

Studies have shown the effects of DNA recovery from gamma irradiated human blood and paper[1] and the effects on nuclear DNA profile analysis from gamma and alpha irradiation of human blood, bone, saliva, and a genomic standard.[2] Here human hairs were irradiated with varying levels of gamma, neutron, beta, and alpha radiation in an attempt to determine the effect of these exposures on mtDNA analysis.

The hair samples were exposed to various levels of the four different types of radiation at the Savannah River National Laboratory, South Carolina, in replicates of five hairs per treatment for each of three individuals. Radiation doses included gamma ($5x10^4$ – $9x10^8$ rad), beta ($5x10^1$ – $1x10^3$ rad), alpha ($5x10^7$ - $5x10^{11}$ MeV), and neutron ($1x10^{10}$ – $1x10^{13}$/cm^2). Hair samples exposed to the highest radiation doses within each radiation treatment were initially extracted, mtDNA hypervariable

regions I and II were amplified, the regions cycle-sequenced and sequenced, and finally the data were analyzed. These procedures followed the FBI Laboratory Mitochondrial DNA Unit Mitochondrial DNA Analysis Protocol (revision 5), with one exception: only one HL60 positive control sample and one negative control sample were amplified and analyzed per mtDNA region, per radiation treatment. When extraction, amplification, or sequencing of mtDNA was not successful within an irradiated sample dose, analysis of additional hairs was attempted. If mtDNA from the additional hairs was not successfully extracted, amplified, and sequenced, then hairs exposed to the next lower dose of that radiation type were analyzed. DNA extraction was successfully attempted on all hairs exposed to the highest dose of each radiation type, with the exception of the gamma $9x10^8$ rad treatment. Hairs exposed to that level of gamma radiation were physically degraded and not suitable for extraction.

Once mtDNA sequences were obtained from irradiated hairs, the mtDNA sequences were compared to mtDNA sequences from nonirradiated hairs from the same individual. These comparison hairs were subject to the same conditions as the irradiated hairs minus the radiation exposure (brought from the FBI laboratory to the Savannah River National Laboratory and back at the same time and stored in the same conditions).

DNA amplification was successful for all hairs exposed to each radiation treatment that were suitable for extraction, with the exception of the $1x10^6$ rad gamma radiation treatment. Only one of five hairs exposed to the $1x10^6$ rad level of gamma radiation produced extracted DNA with successful mtDNA amplification. All hairs exposed to the next highest level of gamma radiation ($1x10^5$), that were extracted for DNA, produced mtDNA amplification products.

Sequences were obtained for all hairs that produced acceptable mtDNA amplification products. These sequences from exposed hairs were identical in type to non-exposed hairs from the same individual. In addition, sequence quality of non-exposed hairs and exposed hairs was comparable, and independent of radiation type.

Collection of hair evidence near or directly from sources of radiation can be hazardous to the individual collector. For example, a gamma dose of 25-40 kGy ($2.5x10^6$-$4x10^6$ rad) is typical for food and pharmaceutical sterilization, and for humans, a whole-body dose of only 0.6-1 Gy (60-100 rad) is fatal almost 100% of the time (the radiation levels in the worst areas of the Chernobyl site are estimated at 200 Gy/hr or $2x10^4$ rad/hr). This study and presentation will give decision makers more data to help determine whether or not the exposure of evidence to certain levels and types of radiation justifies the potential health risk for the evidence to be collected.

Mitochondrial DNA, Hair, Radiation

A147 A Preliminary Study Into the Characterization and Differentiation of Synthetic Wig Fibers

Patrick Buzzini, PhD, West Virginia Univ, 1600 University Ave 304, Oglebay Hall, Morgantown, WV 26506-6121; and Theresa Joslin, BS, 3016 Hyland Rd, Irwin, PA 15642*

After attending this presentation, attendees will learn about the most discriminating features to characterize synthetic wigs when wig fibers are recovered as physical evidence.

This presentation will impact the forensic science community by providing information about chemical and morphological characteristics of wig fibers and their discriminating factors.

Consider a set of fibers that were recovered from the garments of a victim. The analyst will first need to verify if the recovered specimens are hair or wig fibers. If the specimen is from a wig, the analyst has to determine if the specimen has synthetic or natural origin. In having done this, the analyst must then discover identifying characteristics, such as the wig type, and ideally the manufacturer in order to aid in the investigation. The goal of this study is to determine what characteristics of wigs are polymorphs, to develop the most discriminating analytical sequence for microscopic and chemical examinations of wig fibers, and to interpret the value of the results.

Wigs are worn in a variety of settings. Subsequently, there are two main types of wigs: costume and cosmetic. Costume wigs can display a variety of colors and usually have stiff, waxy strands. Cosmetic wigs mimic the appearance of natural hair. The hair used to make wigs can be made of either synthetic fibers or human hair. Nylon, polyester, polypropylene, acrylic, and modacrylic fibers are the most commonly used fibers, with modacrylic being the most prevalent one.

In this preliminary study, a number of samples taken from dark-colored modacrylic, polypropylene, and nylon wigs were collected. These samples of synthetic wig fibers were first visualized under light microscopy using bright field illumination and double polarization. The thickness of each fiber was measured at ten randomly selected positions. Five cross sections were also created from randomly selected positions of each fiber. Various measurements, including, but not limited to, the surface area, circularity, and perimeter, were completed for each of the cross sections. By observing the data distributions through a series of histograms, it was shown that a small amount of wigs had a high degree of intra-variability in both shape and diameter. In some instances, various types and colors of fibers are blended throughout one wig so that it may appear more natural looking for cosmetic use. There was found to be important overlap in the thickness and surface area measurements between wigs. However, it was observed that the cross-sectional shape is a variable feature that can increase the discriminating power of the analytical sequence.

At least 100 different samples of dark-colored synthetic wigs are being collected in the current study. Each sample of synthetic fibers is first examined visually and microscopically. The physical properties of the fibers, such as the color, thickness, and cross-sectional shape are documented. Chemical examinations are conducted by Fourier Transform Infrared (FTIR) spectroscopy and Thin-Layer Chromatography (TLC). The former is used to determine the general polymeric class and subclass when possible (i.e., acrylics). IR data is useful to study the distribution of the fiber types in order to evaluate trends about their rarity of occurrence. The latter method, instead, is used to study the dye content. Dyes are first extracted from the individual wig fibers. This operation allows the obtaining of information about the dye type according to its application mode: acid, basic, or disperse. The consecutive dye elution then informs about the variation of dyes between different wigs. Attempts of dye identification can be made by comparing TLC data of the collected wigs with those of standard dyes. It is important to underline that wig evidence may be recovered as long fibers, about 15cm. This constitutes an advantage because the quantity of evidence will be large enough for applying destructive testing, and in the case of thin layer chromatography, the chances to extract the dye from a single wig fiber are higher.

Wigs, Fibers, Trace Evidence

A148 Using *Pinus* STR Profiling to Discriminate Pollen Samples at the Regional Level: A Potential Tool for Forensic Investigations

Cassandra L. Campelli, BS, 28 Highland Ave, Vernon, CT 06066; Jennifer Sycalik, BS, 1885 Old Spanish Tr, Houston, TX 77054; Christopher Randle, PhD, 1900 Ave I, Huntsville, TX 77341; Craig Echt, PhD, 23332 Success Rd, Saucier, MS 39574; Bruce Budowle, PhD, UNT Health Science Center, Forensic and Investigative Gen, 3500 Camp Bowie Blvd, EAD 310, Fort Worth, TX 76107; and David A. Gangitano, PhD, 14723 TC Jester Blvd, Apt 1118, Houston, TX 77068*

After attending this presentation, attendees will understand the potential to use Short Tandem Repeat (STR) markers to perform DNA profiling of pollen samples from *Pinus echinata*.

This presentation will impact the forensic science community by providing another quantifiable piece of evidence that investigators can utilize to solve crimes and will demonstrate the potential to use short tandem repeat (STR) markers to perform DNA profiling of pollen samples from *Pinus echinata*. The use of a DNA-based STR analysis investigation using primers designed for previously identified STR markers in *P. echinata*, located regionally in southeast Texas for the study of localized population dynamics, may enable discrimination of pollens at regional and local levels. Eventually, this would allow an association between hortleaf pine tree populations or individual pines and associated pine pollen during a forensic investigation.

Advances in plant genomics have had an impact in the field of forensic botany. However, the use of pollen DNA profiling in forensic investigations has not yet been applied. DNA profiling of *P. echinata* pollen using five short tandem repeat (STR) markers is described herein and data supports that there is sufficient genetic variation to discriminate pollen samples at the regional level in southern Texas. Genomic DNA was extracted from pollen and needle samples and then quantified by real time PCR. Species were verified by sequencing the internal transcribed spacer (ITS) regions. DNA was amplified by PCR using fluorescent dyes and the genotype analysis by capillary electrophoresis revealed distinct DNA profiles from trees from 10 selected geographical sites.

This study has demonstrated that a preliminary multiplex STR system, developed from already existing STR markers for *P. taeda* for the study of pine population dynamics, may potentially be used for forensic identification purposes in other pine species. Even though PCR primers were not designed for the particular species of interest, they are sufficiently homologous to enable screening of polymorphic sites as a proof-of-principle for marker evaluation. The use of *P. taeda* primers for the amplification of STRs in the closely related species *P. echinata* was demonstrated to discriminate pollen samples from ten different sites. A DNA extraction method for pollen and a real-time PCR method for accurate pine DNA quantitation were used. In addition, five STR loci from both pollen and needle DNA were successfully typed. DNA profiles obtained from pollen material (*P. echinata*) at ten different sites were perfectly differentiated. When pollen DNA profiles were compared to their conifer donors (reference), no evidence of mixtures was detected for the five amplified STR loci. A population survey indicated the cumulative probability of identity using these five loci could be as low as one in 189. However, a probability to the pollen needle match was not assigned since two out of five markers utilized in this study showed departures from Hardy-Weinberg equilibrium. The causes of Hardy-Weinberg disequilibrium may be due to primer mismatches, small sample size, or the effects of population substructure. Further research is needed to develop a valid statistical approach and a reference database for associations or matches. Despite the departure of markers from Hardy-Weinberg equilibrium, our results strongly suggest that the use of genetic profiling in forensic botany has the potential to offer invaluable evidence in solving crimes where pollen is properly identified, packaged, stored, and analyzed.

Forensic Science, DNA Typing, Forensic Botany

A149 Persistence of Volatile Organic Compounds Associated With Human Decomposition on Carpet Samples

Christopher R. Gore, BS, 1420 10th St S, Apt 218, Birmingham, AL 35205; and Jason G. Linville, PhD*, UAB, UBOB 210, 1720 2nd Ave S, Birmingham, AL 35294-4562*

After attending this presentation, attendees will understand the persistence of chemical residues associated with human decomposition on carpet samples, presenting the "range of detection" for the residues representing putrefied samples, including air flow as a variable.

This presentation will impact the forensic science community by informing attendees of the persistence of volatile compounds associated with human decomposition on carpet samples, giving investigators a better understanding of the presence of select compounds associated with the putrefaction stage of death after a victim's body is removed.

There are few published studies examining the process of human decomposition odor analysis. Recent research suggests that certain chemicals, such as sulfur compounds, are present in early decomposition and can become detected in smaller traces as time progresses. Research is needed to determine the persistence of these Volatile Organic Signatures (VOS) in different environments, especially when the source has been removed. Investigators could determine whether a decomposing body had been removed from a certain location, such as the trunk of a car, by taking an air sample from the location. This study proposes depositing volatile compounds associated with decomposition onto carpet samples, then using SPME to collect and analyze the persistence of these compounds over time.

The volatile compounds chosen for this study were compounds known to be released by human cadavers during the putrefaction stage of decomposition. There are several reasons as to why compounds produced during putrefaction were selected in preference of compounds produced during other stages. Volatile odor compounds cannot be detected during the fresh or autolysis stage. Even though many of the compounds are expected to exist in higher concentrations at the decaying stage rather than the putrefaction stage, the stages of decay and diagenesis can take several months to years to complete. It stands to reason that if a perpetrator had to move the victim's body, the removal would be performed during the first few months since death.

According to the Decompositional Odor Analysis Database, there are 478 separate volatile compounds associated with buried decomposition. Of those 478 compounds, 30 were found to be key substances in human decomposition in soil. Of those 30 substances, 12 are the most significant. They are carbon tetrachloride, toluene, ethane (1,1,2-trichloro-1,2,2-trifluoro), 1,4 dimethyl benzene, benzene, ethyl benzene, decanal, nonanal, hexane, benzenemethanol (alpha-alpha, dimethyl), 1,2 benzenedicarboxylic acid (diethyl ester), and undecane. Cadaverine and putrescine are two notable products associated with human decomposition; however, they have proven difficult to detect due to their low volatility.

This study proposes to adapt previously published headspace analysis method for testing materials that have been exposed to the compounds listed above.[1]

A solution was prepared containing chemicals that might be detected in an enclosed space after a putrefied body has been removed from the area. The chemicals used for analysis were: carbon tetrachloride, toluene, ethane (1,1,2-trichloro-1,2,2-trifluoro), 1,4 dimethyl benzene, benzene, ethyl benzene, decanal, nonanal, hexane, benzenemethanol (alpha-alpha, dimethyl), 1,2 benzenedicarboxylic acid (diethyl ester), and undecanal. The exact quantities of each compound in this solution will be determined following initial experiments detecting the compounds individually.

A total of 20 (2 in. x 2 in.) olefin carpet samples were placed in 20 separate Erlenmeyer flasks. An aliquot of 1mL of the chemically synthesized putrefied sample was deposited onto each carpet substrate. Air samples were taken over an eight-week period.

Ten flasks were sealed with silicone to prevent air from interfering with the samples, and placed in a dark storage area. Ten flasks

remained unsealed in a chemical hood. Each week, a sample from both conditions was collected using headspace-SPME. Once removed from the hood, the unsealed flask was sealed to allow for the headspace sample collection.

The extraction method involved the placement of sorbent material (SPME fiber) into the headspace of the two flask samples. A solution containing either chlorobenzene or bromobenzene was used as an internal standard. For this study, the exposure time for each sorbent material began at 30 minutes. The SPME samples were analyzed using gas chromatography/mass spectrometry.

Volatile Compounds, Decomposition, SPME

A150 Development and Validation of a PCR Amplification Kit: An STR Multiplex System for Teaching and Research Purposes

Erin E. Grefer, BS, 2202 Tree Crossings Pkwy, Hoover, AL 35244; Ellas Aldrich, BS*, 2924 Pawnee Ave S, Apt 3, Birmingham, AL 35205; and Jason G. Linville, PhD, UAB, UBOB 210, 1720 2nd Ave S, Birmingham, AL 35294-4562*

After attending this presentation, attendees will have a basic understanding of the methodologies and techniques needed to create a 4-loci Short Tandem Repeat (STR) multiplex kit for teaching and research purposes.

This presentation will impact the forensic science community by providing the groundwork that teaching and research facilities need to create a cost-effective STR kit. By lowering the cost of each STR reaction, teaching facilities can perform more reactions and therefore, provide their students with more opportunities to improve their techniques in a DNA laboratory with the ability to determine the success of research projects at a fraction of the cost.

Although numerous commercial kits have been developed to amplify STR loci, commercial kits are often expensive. Since these kits are used for discrimination purposes, 16-loci provide the statistical confidence needed for testimony. Since these loci are spread throughout the genome, every allele is inherited independently and the markers are not linked. In this way, a complete profile has powerful discriminatory capability as the probability of individuals with the identical alleles decreases as more loci are analyzed.

Not all facilities that use these kits, require such power of discrimination, resulting in wasted resources. Teachers can demonstrate multiplex STR amplification and analysis using reactions that amplify fewer loci. The purpose of most forensic biology laboratory exercises is to teach the basics of PCR amplification and provide students with hands-on experience setting up and performing the reactions. Although these exercises may also include examining and comparing allelic profiles, making an identification with a high statistical level of confidence is not necessarily an objective. Therefore, using the commercial kits to perform classroom laboratory experiments could be considered wasteful and unnecessarily expensive. A kit that amplifies at least three loci using two dyes would be useful for classes conducting multiplex reactions.

From a research standpoint, a simple kit could be used to screen samples and predict the success of a commercial kit. For forensic DNA research projects, often the objective is to determine whether amplifiable DNA is present in a given sample. The results from less expensive monoplex and multiplex reactions would provide data about whether amplifiable DNA exists at chosen STR loci. A less expensive kit would allow investigators with a limited budget to process more sets of samples and include more samples in a given set. Often, evidence samples, or mock evidence samples, will contain small amounts of DNA (fingerprint residues) or be exposed to harsh environments (fired cartridges). These conditions can result in variation of results within a data set, where some samples may amplify all STR loci included in the reaction, while other samples will not contain any amplifiable DNA. Including more samples in each data set will help investigators better evaluate the variability of results within a given set of samples.

The goal of this project was to develop and validate a more cost-effective STR amplification kit specifically designed for research, screening, and teaching purposes. For this study, 4 STR loci were chosen for amplification, D3S1358, Th01, D8S1179, and vWA. Dye-labeled primers were designed for each loci based on previously published sequence data. A ladder was developed for analysis. Monoplex reactions were performed in order to evaluate the best amplification conditions for each locus. Once the multiplex reaction was balanced to produce even amplification among the 4-loci, a validation study was performed, evaluating thermal cycling parameters, precision, and sensitivity.

STR Multiplex, Teaching Kit, DNA

A151 Preparing Next Generation Sequencing (NGS) Libraries of Human Mitochondrial DNA Using Illumina® Nextera® XT and NEBNext® dsDNA Fragmentase® Technology

Hilde Stawski, BS, Western Carolina Univ, 69 East University Way, Cullowhee, NC 28723; Brittania J. Bintz, MSc, and Erin S. Burnside, MSc, Western Carolina Univ, 111 Memorial Dr, NSB 231, Cullowhee, NC 28723; and Mark R. Wilson, PhD, Western Carolina Univ, Dept of Chemistry/Physics, Forensic Science, Cullowhee, NC 28723*

After this presentation, attendees will have gained insight into the differences between commercially available enzymatic DNA library preparation methods for next generation sequencing, focusing on practical applications of these methods to human mitochondrial DNA sequencing in a forensic context.

This presentation will impact the forensic science community by making recommendations in regards to best practices for NGS library preparation of mitochondrial DNA, specific sample throughput optimization using multiplexing strategies, and chemistry dependent sequencing artifacts commonly encountered.

Forensic DNA casework largely relies on the analysis of short tandem repeats (STRs) from nuclear DNA (nDNA). In some cases; however, nDNA may not be suitable for analysis (i.e., highly degraded DNA or DNA present in quantities too low to obtain an STR profile). In these instances, mitochondrial DNA (mtDNA) is an excellent alternative. MtDNA is a circular genome of approximately 16.5kb, is maternally derived, and is present in 500-1,000 copies per cell versus two copies of nuclear DNA. The combined higher copy number, circular shape of the genome, and location in the mitochondria allow for a greater probability to recover sufficient mtDNA for typing of degraded samples.

Currently, forensic analysts sequence two or three hypervariable (HV) regions found in the non-coding control region of the mtGenome since sequencing of the entire genome is rather labor-intensive. Additionally, sequencing difficulties of the C-stretch and the identification of heteroplasmy in samples can add complexity to the analysis of mtDNA evidence in casework when traditional Sanger sequencing methods are used. These issues can be addressed by introducing next generation sequencing (NGS) technologies to the crime laboratory. NGS is a high-throughput technique that combines hundreds of thousands of sequencing reactions simultaneously, and allows for the sequencing of whole genomes more rapidly. Furthermore, NGS enables deeper analysis of the genome for identification of minor variants since many reads of a single template sequence are obtained.

Library preparation is the primary bottleneck in the NGS workflow, since it can be very time consuming. Therefore, the goal of this research is to compare two enzymatic NGS library preparation methods, Illumina® Nextera® XT and New England Biolabs NEBNext® dsDNA Fragmentase®. The Illumina® Nextera® XT kit is designed exclusively for use with Illumina® instrumentation. This kit uses an engineered Transposome™ to randomly fragment and tag small amplicons with

Illumina® specific adapters. The NEBNext® dsDNA Fragmentase® kit is designed for use with all major NGS platforms, and employs a family of enzymes to nick dsDNA randomly, ultimately allowing for platform specific adapter ligation.

For this study, DNA was extracted from buccal swabs obtained from eight donors according to approved IRB protocol. Long PCR using a highly processive polymerase and novel primer sets designed by the authors was successfully performed on these extracts to independently amplify the mtgenome in two amplicons overlapping at the control region. Additionally, whole genome amplification (WGA) was performed on a series of dilutions of the buccal extracts, to mimic DNA concentrations encountered with compromised samples.

Following mtDNA amplification, samples were treated with either Illumina® Nextera® XT or New England Biolabs NEBNext® dsDNA Fragmentase®. Preliminary data has shown these library preparation methods to be successful with long PCR amplicons derived from pristine DNA, suggesting a streamlined library preparation method for use in databasing laboratories. Next generation sequencing data for these samples has been generated using both the Roche 454® GS Junior and the Illumina® MiSeq® platforms. Each NGS platform and library preparation method gives rise to sequence differences between the samples. More research is currently being conducted in our laboratory to further elucidate causes of these differences.

Next-Gen Sequencing, Library Preparation, Mitochondrial DNA

A152 The Evaluation of Six Different Matrices for the Collection of Touch DNA

Daniel Watsula, MS, and Koya D. Reams, MSFS, 10430 Furnace Rd, Ste 107, Lorton, VA 22079; Lana L. Ramos, MS, 7378 Michigan Isle Rd, Lake Worth, FL 33467; and Jangbir Sangha, MA, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will gain an understanding of the ability for various matrices to collect touch DNA from a variety of surfaces.

This presentation will impact the forensic science community by demonstrating that the DNA yield, determined by RT-PCR quantification, and STR profile quality, determined by capillary electrophoresis, can be significantly impacted by the swab matrix and collection method selected.

Touch DNA samples from crime scenes are frequently collected by law enforcement agencies around the world. These samples inherently contain less genetic material as compared to other biological stains (i.e., blood and seminal fluid). The ability of one swab matrix to collect even a few cells more than another could have a substantial impact on the generation of a complete STR profile.

The collection of genetic material from a surface is only a subset of the overall process. Collecting significantly more genetic material from a surface is beneficial only if the cells are subsequently released from the collection matrix, lysed during the extraction procedure, and purified for downstream applications. The size, shape, composition, and hydrophilic/hydrophobic properties of each matrix play an integral role in a swab's ability to collect and successfully release a touch DNA sample for DNA purification.

This study tested six (n=6) different matrices for Touch DNA evidence collection which were cotton, foam, rayon, knitted polyester, woven polyester, and glass fiber.

Similar to the types of samples that may be encountered during routine evidence collection, a variety of surfaces were evaluated during this study. Flat surfaces such as vinyl and composite wood paneling tiles were evaluated. Curved or fabric surfaces such as a polyvinyl chloride (PVC), knitted gloves, and polypropylene rope were also selected for evaluation. Aside from testing various surfaces, multiple other variables were also studied to determine the impact, if any, on each swab matrix's ability to collect a sample. These variables included multiple methods of swabbing (wet vs. dry collection), different wetting agents (DNA Grade Water vs. Isopropyl Alcohol), the number of swabs used for collection (one vs. two), and the analyst collecting the sample.

During this study, volunteers (n=2-5 depending on the surface) were asked to apply either fingerprints or handprints, handle objects ,or wear gloves at various time intervals over the course of several days. After all samples were deposited, the surfaces were collected and swabbed using each of the six matrices.

Experimental design of this study was controlled as much as possible. Surfaces were cleaned and stored in a controlled area prior to and after sample deposition to limit the possibility of exogenous DNA. Volunteers deposited samples on surfaces within specific dimensions to control the area of sample collection. In addition, control swabs were utilized throughout the study to assess the difference in genetic material deposited on each surface by either the right or left hand.

Data analysis and comparison were aided by the statistical calculations computed using the JMP® Design of Experiments software. The statistical calculations focused on DNA yield and the resulting STR profile with normal amplification parameters.

The results from this study will demonstrate that the difference in DNA yield from samples deposited by the right or left hand were not statistically significant, at a given time point, allowing for paired sample analysis. This study will also demonstrate that statistically significant differences in DNA yield can be obtained through the use of different swab matrices. The resulting differences in DNA yield subsequently affect the ability to obtain a complete STR profile.

Woven polyester, glass fiber, and knitted polyester displayed statistically significant differences compared to the other swab matrices tested in terms of yield or STR profile. Depending on the surface to be sampled, wetting agent utilized, and method of collection, an analyst may find it advantageous to explore nonstandard swab matrices in order to achieve a higher yield of DNA and a more complete genetic profile.

Touch DNA, Swab Matrices, Collection Technique

A153 Metrological Issues Concerning the Analysis of Brazilian Heavy-Metal Free GSR by SEM

Andrea Martiny, PhD, Av Nossa Senhora das Graças, 50 Bldg 27, Xerem, Duque de Caxias, BRAZIL; and Andrea P. Campos, PhD, Av Nossa Senhora das Graças, 50 Bldg 3, Xerém, Duque de Caxias, BRAZIL*

After attending this presentation, attendees will understand issues regarding the size and composition of Gunshot Residue (GSR) particles that may affect and even impair an accurate result.

This presentation will impact the forensic science community by discussing unique metrological issues that are usually overlooked during GSR analysis, recognizing the differences from the pressure to produce environmental ammunitions may impair the accurate identification of GSR by all known methodologies.

Metrology is defined as the science that includes all theoretical and practical aspects of measurement. Although not disseminated among the forensic science and justice communities, it is of utter importance since accurate measurement results can have an impact on the outcome of a trial. Most forensic analysis relies on qualitative techniques, which probably explains why metrology is so overlooked. Yet even qualitative analysis can benefit from metrology. One such example is GSR particle analysis. GSR is probably the most common and at the same time underestimated type of trace evidence, despite the growing number of firearms-related offences in Brazil. GSR particles are generated by a combination of high temperature and high pressure conditions occurring during firearm discharge. Particles are mainly composed of elements from primer mixture (mostly heavy metals) and so are very stable. They are also non-crystalline and circular in shape. The technique of choice is SEM-EDX and results are expressed in qualitative terms: presence or absence of particle types as defined by the ASTM E-1588/10e1 standard. However, the detection of particles and its identification by automated SEM systems is greatly dependent on metrology. For instance, identification is based on particle diameter range and element composition. In this study, metrological aspects of GSR detection were analyzed by SEM. Automated GSR particle

analyzer software base their identification on three parameters: BSE brightness given by Z contrast, circularity factor, and element composition. These parameters rely on the ability of the instrument (i.e., the SEM and the EDX) to measure with accuracy. This implies that the BSE detector and X-ray probe must be adjusted and magnification calibrated.

Validation of the method was performed employing Ted Pella SPS-5P-2 GSR Certified Standard, ENFSI synthetic GSR standard, and an in-house GSR-like sample containing LaCe(Fe) particles (0.5-20µm). In the case of this research instrument, an FEI Quanta 200 ESEM equipped with a Genesis EDAX EDX and GSR-XT software, the instrument detection limit (IDL = 0,8) was calculated in regard to the smallest particle size detected, employing the CRMs, meaning that smaller particles were not detected, except in manual search. The sub-micron detection capability of laboratories from four different proficiency tests using a similar RM were reviewed and found that approximately 50% were considered unsatisfactory for 0.5µm particles. This percentage is steady from 2001 to 2008. These laboratories are recommended to disregard sub-micron GSR during real examinations. Yet, the inability to detect sub-micron particles is critical for Brazilian samples, due to the tendency of CBC primer to generate such smaller particles. Accuracy was tested applying the Z-Score to the results of seven runs and was considered unsatisfactory (the mean z was -9,98, meaning that results were almost 10x below the correct mean number) when the software was installed. At this time, on average 90% of the 2.4µm particles were detected. Satisfactory mean Z-scores were achieved after calibration of magnification using a CRM and of X-ray probe adjust employing a metal CRM, resulting in the detection on average of 90% of all 0.8µm particles. Although a rather acceptable reproducibility was obtained (same sample and parameters over different days and operators), repeatability (same sample and parameters over a short period of time) was not acceptable (*s.d.* = ± 3) against a preferred 1.3 for 0.5µm particles. A great concern resulting from the analysis of Brazilian ammunition generated-GSR is the size of particles. GSR range between 0.5 and 20µm in diameter, but particles generated by CBC ammunition are mostly sub-micron. On one hand, this may increase its potential as a hazardous airborne particle, although it also imposes some difficulties in detection by most SEM systems because of: (1) pixel limitations; and, (2) electron transparency. A minimum 20kV accelerating voltage is required to detect PbL lines, but this may be a problem for sub-µm particles because of the interaction volume and reduced number of BSE. Most systems detect particles >0.5µm, which in reality corresponds to 0.7µm particles. The characteristics arising from CBC-generated GSR probably mean that a smaller beam diameter is needed and associated to a rigorous control of SEM parameters to ensure accurate results.

This research was supported by FINEP grant # Metrofor 01.10.0715.00 and CNPq/Prometro Grant # 563093/2010-2.

Gunshot Residues, Microscopy, Metrology

A154 Analysis of Fatty Acid Amide Hydrolase (FAAH) Inhibitors in the URB Series in Botanical Materials by GC/MS and LC/MS

Anisha Paul, BS, 1507 Juniper Ave, Elkins Park, PA 19027; Jillian K. Yeakel, MS, 105 Revere Dr, Harleysville, PA 19438; Warren Korn, BS, Center for Forensic Science Research and Education, 2300 Stratford Ave, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to evaluate methods for analysis of Fatty Acid Amide Hydrolase (FAAH) inhibitors in the URB series, in botanical materials using Gas Chromatography/Mass Spectrometry (GC/MS), and Liquid Chromatography/Mass Spectrometry (LC/MS).

This presentation will impact the forensic science community by describing a screening process to identify a novel class of synthetic drugs with effects on the endocannabinoid system in botanical materials.

FAAH's compounds inhibit the enzyme Fatty Acid Amide Hydrolase (FAAH), which is believed to be responsible for, among other things, the degradation of the endogenous cannabinoid receptor ligand, anandamide. Anandamide is linked to pathways responsible for mediating anxiolytic, antidepressant, and analgesic effects. In particular, a series of FAAH inhibitors developed at the University of Urbino in Italy, and designated URB, followed by a series number, have been detected in "legal high" products being sold over the Internet. Although these compounds don't act directly on the cannabinoid receptor, they produce similar effects to marijuana by increasing the levels of the endogenous levels of anandamide. In theory, this may result in cannabis-like effects including euphoria and intoxication.

Five compounds from this series, URB-597, URB-602, URB-447, URB-754, and URB-937 were selected for study. The neutral character of URB 602, URB 597, and URB 937 is due to the presence of the carbamate group in their structure, which tends to make them subject to hydrolysis and consequently unstable.

Standards were prepared in methanol and analyzed by GC/MS. Gas Chromatography conditions included the use of a 15m Phenomenex Zebron ZB-5MS, 0.25mm ID column, with a temperature program from 150°C to 325°C at 18 degrees/minute.

URB-602, URB-447, and URB-754 were determined to be stable under these conditions. URB-602 produced major ions at m/z 195, 169, 213, and molecular ion of 295, while URB-447 produced fragments at m/z 400 (molecular ion), 275, 105, and 125. URB-754 had masses as follows; 160, 266 (molecular ion), 104, and 77.

URB-597 and URB-937 showed the presence of degradation products by GC. The peak corresponding to URB-597 showed fragments at m/z 213, 197, 169, and 139, while URB-937 gave fragments with m/z 212, 184, 229, and 128. These degradation products most likely represent hydrolysis of the molecule at its carbamate bridge. URB-597 shares components of its structure with another FAAH inhibitor, JP-104.

Standards were also analyzed by single quadrupole LC/MS. The mobile phase used was 65% Acetonitrile: Isopropanol and 35% 0.1 TFA in water, analyzed on an Eclipse plus 4.6x100mm C-18 column (Agilent). Chromatography was consistent by LC/MS with no evidence of degradation or breakdown.

Extraction procedures were evaluated for URB-602, URB-447, and URB-754. Acid, neutral, and basic extraction procedures were evaluated using pH 7.4 potassium phosphate buffer and 90/10 methylene chloride/ isopropanol. GC data from the analysis of several "legal high" products indicated the presence of URB 754 in products including Kush Hypnotic 20XXX, White Widow 5X, B2 Da Bomb Blueberry Potpourri, Conviction 20XXX, and Dank 15X botanical materials. URB-754 was present in each case with a synthetic cannabinoid compound including AM-2201, JWH-022, and JWH-018 Chloropentyl analog.

URB Compounds, FAAH Inhibitors, Botanical Material

A155 Interpretation Challenges Using the PowerPlex® 16 HS Kit for Forensic Casework

Amy M. Jeanguenat, MFS, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

The goal of this presentation is to educate the forensic DNA community on interpretation challenges faced, especially in mixtures, when amplifying forensic casework samples with PowerPlex® 16 HS.

This presentation will impact the forensic science community by increasing the knowledge of additional common artifacts and anomalies seen in casework samples amplified with PowerPlex® 16 HS that may not be noted in technical manuals or validation studies, which will help during interpretation, comparisons, and reporting.

With the evolution of next generation amplification kits, manufacturers are competing to deliver products that meet the demands of the forensic DNA community. This includes overcoming inhibition, increasing sensitivity, adding discrimination power, and reducing overall amplification time. Although amplification kits undergo developmental

and internal validations, once applied to actual unknown samples they may not behave as predicted. Bode internally validated PowerPlex® 16 HS in a 25µl reaction with 30 total cycles and found it to be reliable, accurate, reproducible, and precise. An examination of mixtures, contamination, and artifact assessment was also performed. During validation, this kit outperformed other amplification kits in its efficiency to overcome inhibition. However, optimization of reagents to increase robustness in the PowerPlex® 16 HS amplification kit has led to an increase in amplification artifacts and anomalies that can make interpretation challenging.

An assessment of artifacts during validation supported an increase in n-4 stutter over the manufacturer's recommendations at D3S1358 (increase from 11.22% to 13.7%) and CSF1PO (increase from 8.15% to 11%). In general, excessive stutter occurred more frequently when amplification reactions generated profiles with alleles greater than 3000 RFU or when n-4 and n+4 peaks were acting on the same stutter artifact. With the exception of the documented dye artifact occurring at 172 base pairs (bp) in the ILS 600, no other dye artifacts were noted.

Once the kit was implemented for use on casework samples, previously unidentified artifacts/anomalies were noted in many samples. This includes a dye artifact at Penta D which ranges from 450bp-500bp and varies in total relative florescent units (RFU) from 300 to 1000 RFU. Other loci displayed uncommon non-specific artifacts including peaks in the n-20 position at TPOX, the n-12 position at TH01, and the n-17 position at Penta D. Occasionally, these peaks fall into sizing bins and can cause confusion in mixture interpretation; however, the most challenging new artifact is an increase in possible bacterial peaks. The addition of a third amplicon of equal or greater height (in RFU) than other alleles present at the same location has been noted in several different casework samples at the following loci: TH01, D18S51, D5S818, D7S820, D16S539, and CSF1PO. These artifacts occurred in sexual assault samples processed within the same year they were collected. The sample types ranged from rectal swabs, tampons, outer labia swabs, peritoneum swabs, and oral swabs. These additional peaks are assumed to be non-human in nature and can be rectified by confirming data with other amplification kits. Finally, discordance between samples has also been noted at Penta E between PowerPlex® 16, PowerPlex® 16 HS, and/or PowerPlex® 18D. Collections of these artifacts led to an internal investigation and discussion ultimately resulting in several interpretation changes needed to effectively interpret samples amplified with this kit.

Case examples, displays of artifacts/anomalies, and changes to interpretation guidelines to accommodate casework processing will be provided.

PowerPlex® 16 HS, Artifacts, Interpretation

A156 The Characterization of Bullet Wipe From Non-Lead Bullets Using Laser Induced Breakdown Spectroscopy

Elizabeth A. Gardner, PhD, UAB, Dept of Justice, UBOB 210, 1530 3rd Ave S, Birmingham, AL 35294-4562; and Brittany Phillips, MSFS, 5709 5th Ct S, Birmingham, AL 35212*

After attending this presentation, attendees will have understanding of how laser-induced breakdown spectroscopy (LIBS) can be used for the presumptive identification of trace evidence, learning how this technology also can be used to detect bullet wipe from non-lead bullets.

This presentation will impact the forensic science community by presenting a new method for the presumptive identification of bullet wipe in bullet holes shot from a distance of over six feet; a distance that gun powder residue is unlikely to travel. Over the years, scientists have developed methods for detecting GSR on a shooter's hands, a victim, or any object that may have been within six feet of the firearm. However, when the weapon is more than six feet from the target, gun powder residue is generally not present. The only residue available for analysis is bullet wipe, material that is transferred from the surface of the bullet as it penetrates the target.

Laser Induced Breakdown Spectroscopy (LIBS) is used to identify the elemental composition of an unknown material. Areas as small as $2mm^2$ can be analyzed, making it an ideal method for the analysis of the minute residues left by a bullet. The advantages of LIBS include minimal sample preparation and short time for analysis. This technique is also relatively non-destructive to most surfaces being tested. Unlike atomic absorption, the composition can be unknown. The primary disadvantage of LIBS is that quantification is not currently possible.

The focus of this project is to apply LIBS as a presumptive test where identifying the composition of the sample is sufficient and quantification can be done as part of the confirmatory analysis, if required. The ease of analysis with LIBS lends itself very well to fast screening of inorganic trace evidence.

Four materials, cotton, wood, drywall, and cement, were shot with three different brands of lead-free cartridges: Extreme Shock: 357 Mag 90 CT2 (ES), Dynamic Research Technologies 9mm (DRT), and Winchester Super Clean NT (WIN). Each material was shot from distances of one, three, six, and twelve-feet. To detect the bullet wipe, the samples were analyzed for copper, lead, and barium. The analysis was performed using addLIBS software and the NIST Atomic Spectra Database.

The manufacturers' information stated that the ES bullets were made of copper-clad tungsten, the DRT bullets had a copper-clad compressed core made from three undisclosed metals, and the WIN had a copper clad tin core. Due to the jacket, copper was the only metal detected in the bullet wipe that could be attributed to the cartridges. Some lead and barium was detected in the bullet wipe, most likely from the barrel of the guns, as these metals were not detected in the casing, bullet, or powder from any of the unfired ammunition used for the controls. Lead and barium were found on the swabs used to clean the barrel of the gun between firing.

Bullet wipe was successfully detected in the cotton, wood, and drywall. Bullet wipe could not be detected in the cement block. Not only did the bullets knock chips off the surface of the block, but cement is a complicated mixture of minerals, including barium oxide.

Gun Powder Residue, LIBS, Bullet Wipe

A157 Compound-Specific Carbon and Hydrogen Isotope Ratios of Paraffin for Forensic Investigations

Gerard J.Q. van der Peijl, PhD, PO Box 24044, The Hague, 2490 AA, NETHERLANDS; and Ines Muegler, PhD, Laan van Ypenburg, Den Haag, 2497GB, NETHERLANDS*

After attending this presentation, attendees will appreciate the forensic isotopic information contained in paraffin and hydrocarbon component mixtures.

This presentation will impact the forensic science community by providing additional discriminating isotopic tools for in-depth paraffin and hydrocarbon investigations.

Paraffins and, in general, hydrocarbon mixtures have a high significance in forensic investigations. Paraffin products are used (e.g., for candles), to impregnate matches or in cosmetics. Hydrocarbons in general are also used as arson accelerants. Remnants of liquid products such as paraffin, petrol, or diesel can often be identified at the crime scene and sometimes on ignition devices, for example, safety matches or candles.

Presently, paraffins and other (volatile) hydrocarbon mixtures are mostly characterized using GC or GC/MS methods. Some successful research has also been done on characterization of paraffin-containing candle waxes as part of an extended arson investigation.[1]

Further discrimination can; however, be obtained by using ^{13}C and ^{2}H isotope information for each single paraffin or hydrocarbon component in the mixture. This will provide a whole new dimension to the characterization of these materials. A GC-IRMS/MS method was developed and validated. Validation results will be shown. The GC-IRMS/MS method was then applied to characterize candle waxes,

paraffin products as used to impregnate safety matches, as well as hydrocarbon mixtures as used for lamp oils.

The additional discrimination of GC-IRMS/MS over the already strong discrimination provided by EA-IRMS will be demonstrated for candle waxes from candles of various brands and shops from the Netherlands that were previously investigated using gas chromatography in combination with bulk carbon and hydrogen isotope ratios.

For the second application, paraffin was extracted from wooden safety matches in the NFI collection of wooden safety matches with burnt and un-burnt samples. Initial compound-specific n-alkane ^{13}C and ^{2}H isotope data from 14 wooden sticks of six different brands of safety matches indicate a wide variation in isotope values from -10‰ to -80‰ VSMOW for hydrogen and -29‰ to -35‰ PDB for carbon. In addition, the effect of burning on the isotope ratios is shown to be negligible for these samples. Further statistical data evaluation using the technique of cluster analysis will be performed to evaluate the potential level of discrimination such as between and within packages of safety matches from one brand.

For the last GC-IRMS/MS application, nine lamp oils from the NFI lamp oils collection were used, nominally representing five different brands. Both for ^{13}C as well as for ^{2}H isotopes, a wide variation is observed. Single brand lamp oils as bought in various shops could easily be discriminated in this way.

The above investigations are only a first step in applying GC-IRMS/MS to hydrocarbon mixtures in a forensic context. For some applications (candles, cosmetics), method application appears to be straightforward. For other applications, further investigations will be required. For example, in arson investigations, remnants of hydrocarbon mixtures as used for accelerants will normally be strongly evaporated, skewing the isotope ratios of the components. Furthermore, pyrolysis products from other materials may be present in a fire residue sample, potentially resulting in complex chromatograms where the hydrocarbon components to be investigated cannot be separated from other components.

A158 Identification of an Impurity in Methamphetamine Synthesized Via Reductive Amination

Jennifer B. Thuor, MS, 22624 Dulles Summit Ct, Dulles, VA 20166*

After attending this presentation, attendees will better understand the importance of classifying methamphetamine based on synthetic route and one specific way in which that task is accomplished. Classifying methamphetamine based on synthetic route provides valuable intelligence concerning current manufacturing trends, which in turn leads to the effective monitoring of precursor and essential chemicals. Even in high-purity products, trace amounts of such route-specific impurities remain. Since manufacturing methods are ever-changing, it is imperative to keep abreast of these key "marker" impurities by isolating and identifying them, and determining their significance in any given sample.

This presentation will impact the forensic science community by making synthetic route identification of methamphetamine a little easier, therefore enhancing the communitys ability to track synthesis trends and movement of the drug.

In this study, one previously unidentified impurity was targeted for isolation and structural elucidation because of its presence in roughly 26% of seized methamphetamine samples produced via reductive amination that were analyzed at the DEA Special Testing and Research Laboratory in the past year. The samples were seized from various locations throughout the United States and port of entry locations at the Mexican border. A majority of the methamphetamine seized in the United States has been smuggled from Mexico where it is synthesized using one of two common reductive amination methods: the Mercury-Amalgam method and the Leuckart method. Both methods use phenyl-2-propanone (P2P) as the precursor, but subsequently use different essential chemicals. Very few reliable impurities have been identified that are specific to the Mercury-Amalgam (also known as the "Biker Method") versus the Leuckart methods, making classification difficult. The targeted impurity in this study is theorized to be synthesized by the Leuckart method.

Isolation and elucidation were carried out using a methamphetamine hydrochloride exhibit that contained approximately 1% of the target impurity. The sample was extracted in a phosphate buffer designed to remove most of the methamphetamine from the impurity. Preparative high performance liquid chromatography was then performed on the extract to isolate the target compound from the remaining methamphetamine and any other minor impurities still present. Once completely isolated, carbon and proton nuclear magnetic resonance spectroscopy were performed to elucidate the structure of the impurity. With the structure known, the mechanism of its formation can be identified, and its value as a route-specific marker compound established.

In regards to the forensic community, this study will improve the classification of the synthetic route used to manufacture the methamphetamine, ultimately aiding the intelligence community with the monitoring of methamphetamine manufacturing trends as well as the trafficking of the drug and its precursors. The identification of another potential route-specific marker adds an additional distinguishing factor between exhibits. Since methamphetamine is completely synthetic, the place of manufacture cannot be determined by simply looking at the chemical analysis of the exhibit. Instead, methamphetamine exhibits are analyzed, classified by synthesis route, and then compared to one another by looking at several characteristics identified during analysis, especially impurities left behind from synthesis. The results of these comparisons are used to update methamphetamine manufacturing trends which in turn support the intelligence and law enforcement communities with the monitoring of precursors and essential chemicals.

Methamphetamine, Synthesis, Impurity

A159 Multivariate Empirical Bayes Methods Applied to the Identification of Impression Evidence

Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Rd, West Haven, CT 06516; Frani Kammerman, MS, John Jay College of Criminal Justice, 454 West 59th St, New York, NY 10019; Loretta Kuo, BS, 899 10th Ave, New York, NY 10019; Peter J. Diaczuk, BS, 445 W 59th St, New York, NY 10019-2925; Patrick McLaughlin, BS, John Jay College of Criminal Justice, 454 West 59th St, New York, NY 10019; Elizabeth W. Phelps, MFS, Boston, MA; James E. Hamby, PhD, Int'l Forensic Science Lab, 410 Crosby Dr, Indianapolis, IN 46227; and Nicholas D. Petraco, PhD, John Jay College of Criminal Justice, 454 West 59th St, New York, NY 10019*

After attending this presentation, attendees will better understand how to apply empirical Bayes multivariate statistical methods to the identification of impression evidence, specifically firearm and tool markcomparisons.

This presentation will impact the forensic science community by presenting examples and explanations of empirical Bayes methods for the identification of impression evidence.

For several decades, and especially since the National Academy of Sciences' 2009 Report *Strengthening Forensic Science in the United States*: *A Path Forward*, forensic firearm and tool mark comparisons have been under increased scrutiny. A significant criticism of the analysis of pattern and impression evidence is that there is no accepted

methodology to generate numerical proof that independently corroborates morphological conclusions. This research critically evaluates the use of empirical Bayes methods for the analysis of firearm and tool mark impression evidence.

For more than half a century, empirical Bayes methods have been applied to many types of problems in a plethora of disciplines including, but not limited to, genomics, economics, epidemiology, safety engineering, and quality assurance. Its rise in popularity can be attributed to the increase in data set sizes, computing power, and because of the straightforward nature of inference based on Bayes' rule. However, empirical Bayes methods have not yet been applied to the statistical analysis of forensic evidence.

The appeal of empirical Bayes methods is that it blends objective frequentist and subjective Bayesian approaches which lead to a falsifiable inference method consistent with the Popperian philosophy of science. Empirical Bayes methods can be interpreted as an approximation to a "fully Bayesian treatment" of a hierarchical model in which the parameters at the highest level of the hierarchy are set to their most likely values, rather than being integrated out. From a forensic science perspective, the most significant advantage of empirical Bayes methods is their ability to formulate clear statistical inferences in which the prior probability is estimated objectively from the data rather than subjectively before the data is observed.

In this research, 3D quantitative surface topographies of firearm and tool markstriated impressions were collected using confocal microscopy. A reasonably complete striation pattern was then summarized as multivariate feature vectors in the form of mean profiles. Next, principal component analysis (PCA) was used to reduce correlation within each profile while maintaining the essential information and a support vector machine (SVM) learning algorithm was used for identification. Last, empirical Bayes methods were used to estimate local false discovery rates (FDR), also known as posterior error probabilities, which quantitatively assesses whether an identification *really is correct*. In order to alleviate the concerns of data reuse, common in empirical Bayes based schemes, we adopted the standard multivariate model fitting practice of first splitting the data into separate training, validation and test sets. The training set was used to generate estimates of a null likelihood and null prior. The validation set was then used to find FDR estimates based on the training set null estimates. This approach has the added advantage that estimates of standard errors for fdrs are available. At each step in the process, goodness-of-fit diagnostics were applied and independence assumptions on the fit *z*-values (required for the standard error formulas) were tested. The FDR estimates can ultimately be used to accompany each identification of an unknown with an output by a machine learning algorithm, providing statistical support for impression evidence conclusions.

Empirical Bayes, Impression Evidence, Statistics

A160 Whole Mitochondrial Genome Sequencing Using Probe Capture and 454 Sequencing Technology

Valerie McClain, MS, 6534 1st Ave NE, Seattle, WA 98115; Cassandra Calloway, PhD, 5700 MLK Jr Way, Oakland, CA 94609; Daniela Cuenca, MS, 1 Shields Ave, Davis, CA 95616; and George Sensabaugh, DCrim, Univ of California, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720*

After attending this presentation, attendees will gain deeper knowledge of sequence capture for enriching mitochondrial DNA and next generation sequencing using 454.

This presentation will impact the forensic science community by introducing a novel capture method for sequencing the entire mitochondrial genome of degraded or limiting samples.

Mitochondrial DNA (mtDNA) analysis is most useful in forensic cases when samples are degraded and nuclear STR testing cannot produce a complete discriminating profile. The most widely used approach for mtDNA analysis is sequencing the hypervariable regions (HVI/HVII) by Sanger sequencing. The maternal inheritance pattern of mtDNA and sequencing information from only the HV regions provides limited discrimination power, particularly in the Caucasian population due to a few common types. Sanger sequencing is also limiting in that it often fails to detect and resolve low level mixtures, as well as low level heteroplasmy; both common observations in forensic mitochondrial samples. The development of a method for whole mitochondrial genome sequencing using a liquid phase hybridization probe capture strategy followed by sequencing using 454 Next Generation Sequencing (NGS) to overcome these limitations will be described. The hybridization probe capture technique allows the entire mitochondrial sequence to be captured for analysis regardless of fragment size by exploiting a very large number of capture probes designed directly from the mitochondrial genome. Utilizing 454 NGS after capture yields tens to hundreds of thousands of sequence reads making it possible to detect mixtures, including heteroplasmy at lower levels, than current Sanger sequencing methods. Moreover, highly degraded DNA samples already consist of small DNA fragments and can be directly subjected to the capture and sequencing analysis.

The Nimblegen SeqCap EZ platform was chosen as the capture platform due to its extensive tiling design and ability to efficiently incorporate hundreds of thousands of capture probes. To increase the specificity of the probes, the circular nature of mtDNA, and the high density and distribution of polymorphisms was considered in the design strategy. The probes were also designed to exclude the capture of known nuclear pseudogenes. The final design directly targets 99.99% of the mitochondrial genome with unique probes.

Results show that 100% of the mitochondrial genome of all samples was captured with coverage adequate to yield unambiguous sequence assignments with an average on target capture rate of 75%. All SNPs previously detected by Sanger sequencing were also detected by 454 sequencing in all samples. Multiple samples have been tested to evaluate the specificity of the assay. The sensitivity of the method was tested by reducing the starting amount of DNA to forensically relevant DNA levels (<1ng sample DNA) with no loss in sequencing accuracy. The method also achieved resolution of mixtures below the limits of Sanger sequencing (<10%). To improve efficiency, the probe capture hybridization time was reduced from the manufacturer's recommendation of three days to one day. This greatly improves the throughput of the capture method, without affecting the on target capture rate, or accuracy of the capture probes.

Current studies focus on improving the sensitivity and robustness of the method. To analyze samples from more diverse populations and then investigate forensically relevant samples is propsed in this study. These samples include ones with even more limited total DNA, and samples which have degraded beyond the limit of conventional STR analysis. In conclusion, a method for whole mitochondrial genome capture followed by NGS which can be applied to the field of forensic science has been successfully developed.

Mitochondrial DNA, 454, Sequence Capture

A161 Mitochondrial DNA Recovery and Analysis From Spent Cartridge Casings

Michelle Metchikian, BS, 5408 Pineridge Dr, La Crescenta, CA 91214; Alicya E. Orlando, BS, 1842 Hamilton Rd, B16, Okemos, MI 48864; and David R. Foran, PhD, Michigan State Univ, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will learn about the utility of mitochondrial DNA (mtDNA) analysis of epithelial cells from spent cartridge casings and the optimal DNA recovery method from such evidence.

This presentation will impact the forensic science community by detailing a highly sensitive DNA analysis method that allows for the identification of a weapon's handler using mtDNA recovered from spent cartridge casings.

It is not uncommon that the only evidence remaining at the scene of a shooting is spent cartridge casings. Because cartridges are usually loaded into a firearm by hand, forensic scientists have long attempted

obtaining fingerprints from spent cartridge casings, but these efforts are almost never successful. An alternative method for identifying the person who loaded bullets into a clip or chamber of a firearm comes from the epithelial cells that may be deposited onto handled cartridges. Previously, scientists have examined the feasibility of STR typing of DNA from spent cartridge casings, but have had limited success, most likely due to a combination of low copy number DNA, DNA degradation caused by temperatures reaching 1800°C during firing, and PCR inhibition resulting from the metal and/or primers in the gunshot residue.

While obtaining even a partial STR profile from spent cartridge casings can be beneficial, in most cases not enough DNA data is recovered to link a suspect to the scene. In this regard, there is a greater likelihood of obtaining DNA typing results by focusing on mtDNA due to its higher copy number and protection in the mitochondrion. In spite of this, however, researchers have not looked into the inherently promising mtDNA analysis as a tool for identifying the handler of cartridges.

In this study, volunteers loaded ten 40-caliber cartridges each into the magazine of a gun. The cartridges were then fired and DNA was recovered from five of the ten fired casings individually using a double swab method—a wet swab followed by a dry swab—for each casing. For the remaining five casings, one pair of swabs was used to swab them all, resulting in a "cumulative swab." A standard organic extraction, followed by the use of spin columns for removal of PCR inhibitors, was used to purify the DNA. Yields were determined, and no statistical difference between the recovery methods was found.

Next, STR and mtDNA assays were investigated. STRs were amplified and the number of alleles consistent with the handler was compared among the double swab method, cumulative swab method, and a consensus profile method that considered the five STR results from the individual casings in combination, to help distinguish real peaks from drop-in. For mtDNA, amplification parameters were optimized, segments between 220 and 270 base pairs in hypervariable regions I and II (HVI and HVII) were amplified, and the products underwent Sanger (dideoxy) sequencing. The mtDNA haplotypes produced were compared to those of the handlers in order to determine the utility of mtDNA analysis, and processing the spent cartridge casings individually and cumulatively.

Almost all of the samples, regardless of the swabbing method, produced few or no STR alleles, which was consistent with previous studies. In contrast, mtDNA was successfully amplified and sequenced from the vast majority of both individually and cumulatively swabbed spent cartridges, including those for which STR testing was negative. Given the increased sensitivity of mtDNA testing, contamination represents a particular problem, and extreme care is required to avoid it during evidence collection and processing. In spite of this caveat; however, mtDNA analysis from spent cartridge casings was quite successful, proving to be a more viable technique than STR typing of these samples.

Mitochondrial DNA, Cartridge Casings, DNA Collection

A162 Validation of a New Robotic System to Automate High Throughput mtDNA Sequencing in a Forensic Laboratory

Alexandra J. Mattioli, BS, Robert S. Oliver, MSc, and Kimberly S. Andreaggi, MFS, Dover AFB, 115 Purple Heart Dr, Dover, DE 19902*

After attending this presentation, attendees will understand the benefits and challenges encountered when validating a new robotic platform in a forensic laboratory for the mtDNA sequencing of high-quality reference samples.

This presentation will impact the forensic science community by providing information on how a robotic instrument can be successfully introduced into the laboratory and demonstrate how it can improve the high throughput processing workflow within the laboratory.

Currently, a number of forensic laboratories, including the Armed Forces DNA Identification Laboratory (AFDIL), are working toward developing novel automated solutions that allow cost effective, reproducible, and error-free processing of a high quantity of samples. Each year, the mitochondrial DNA (mtDNA) section receives and processes approximately 3,000 buccal swabs from maternal family members that are used for comparison to unknown samples from past U.S. military conflicts. Applying a high throughput approach toward reference processing is desired for increased efficiency and accuracy. For the last 12 years, AFDIL has used the Tecan Genesis® Workstation 200 to semi-automate all post-amplification mtDNA control region sequencing steps. This process, although accurate, required some user intervention due to a lack of fully integrated peripherals. In December of 2011, Tecan stopped supporting the older Genesis platforms. In preparation for this loss, AFDIL began the process to procure a new liquid handling instrument or face having to manually process family reference samples (FRS). It was vital that the new system continue to provide the necessary robotic capabilities while also incorporating enhancements that could further improve the workflow, increase overall sample throughput, and decrease user interactions.

Research and planning resulted in AFDIL acquiring and customizing the Hamilton's MICROLAB® STARplus liquid handling platform to allow for increased sample throughput and reduced user interactions during the automated mtDNA sequencing of FRS. The system includes eight independent pipetting channels, a 96-probe head, and two different gripper tools, as well as an external arm to integrate a plate sealer and eight thermal cyclers. Method development was an intensive process that included definition of labware, liquid class optimization, and the creation of a user-friendly workflow that allows parameters such as the number of samples or sequencing primers used to be easily changed. This flexibility ensures that the method can be utilized in a wide range of circumstances and by multiple sections at AFDIL without revisions. During method development, if any aspect of the automated post-amplification processing was unacceptable, the necessary modifications were made to the method or materials prior to the start of the validation. The development of a robust and reliable automated method was imperative to ensure efficient and accurate sample processing while meeting throughput requirements.

After five months of method development and optimization, an internal validation was performed to demonstrate that the Hamilton STARplus would produce sequencing products that were comparable to the results obtained when processed manually or on the Tecan. The validation included three experiments which were designed to meet applicable Quality Assurance Standards guidelines. Once the validation was complete, AFDIL's laboratory information management system and Standard Operating Procedures were updated for the integration of the new Hamilton robotic workflow. This post-amplification robotic system will enhance the high-throughput processing capabilities of reference samples and allow AFDIL to process at least 400 FRS per month, equating to over 6,000 sequencing reactions covering a 1,200-base pair region of the mtDNA genome. The implementation of the customized Hamilton STARPlus system into casework will decrease both processing time and required user interactions, greatly improving AFDIL's ability to process reference samples in real-time and ensure that the most up-to-date database is available for comparisons in missing persons cases.

The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of the Army, the Department of Defense, or the U.S. Government.

Mitochondrial DNA, Automation, Validation

A163 Detection of Low-Level DNA Sequences Associated With Nuclear Mitochondrial Pseudogenes (NumtS) From Human Mitochondrial Control Region Amplicons Using Massively Parallel 454 Pyrosequencing

Brittania J. Bintz, MSc, Groves B. Dixon, BS, and Erin S. Burnside, MSc, Western Carolina Univ, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; and Mark R. Wilson, PhD, Western Carolina Univ, Dept of Chemistry/Physics, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will have a better understanding of next-generation sequencing (NGS) as applied to mitochondrial DNA control region analysis. Approaches to quantify minor variant detection thresholds of the Roche GS Junior 454 pyrosequencing instrument will be described. Additionally, the detection of nuclear pseudogenes during mixture study deep sequencing runs, and steps taken to confirm the presence of these pseudogenes in our donor population, will be discussed. Finally, detection of inconsistent, non-NumtS affiliated minor variants in hair shaft tissues will be discussed, and research approaches taken to elucidate causes of these variants.

This presentation will impact the forensic science community by outlining foundational research being performed in the area of Next-Generation Sequencing (NGS) of the human mtDNA control region. Preliminary suggestions for streamlined NGS sample preparation, use of Roche Amplicon Variant Analyzer (AVA) software, and data analysis considerations will be offered. Reasonable expectations for instrument detection threshold, pyrosequencing-specific sequencing errors, and tissue dependent differences in sequence data will be described. A per-run cost analysis using the Roche GS Junior platform will be presented.

Massively parallel pyrosequencing on the Roche GS Junior provides thousands of independent reads per sequencing run, and thus has the potential to detect and quantify minor variants with vastly greater sensitivity and precision than traditional Sanger sequencing. The minor variant detection threshold was determined for the Roche GS Junior instrument using mixtures of mtDNA hypervariable (HV) region amplicons with known sequences. In addition to the expected variants originally obtained using dideoxy terminator sequencing, a set of nineteen unexpected variants in HV1b reads (corresponding to base pairs 16159 – 16391 in the mitochondrial control region) at a level of approximately 1% were detected. These variants are reproducible and are always detected as a set within individual reads of HV1b amplicons. The total depth of coverage did not appear to affect the level at which the unexpected variants were detected. A standard nucleotide BLAST search of the variant sequence was performed which showed 100% sequence similarity to a segment of a 611bp nuclear mitochondrial pseudogene (NumtS) originally reported in 1995 by Zischler *et al*.[1] This NumtS is an insertion of the mitochondrial control region (bases 16,089 – 59) on the short arm of chromosome 11, spanning the primer binding sites of the targeted HV1b region.[2] Nuclear DNA specific primers flanking the insertion were used to amplify the pseudogene from buccal extracts without amplifying DNA from the mitochondrial control region.[3] This amplification strategy confirmed the presence of the NumtS in 19 out of 20 donors, with one donor being homozygous-negative for the insertion. Dideoxy terminator sequencing was used to successfully confirm the presence of the variant sequence in the amplified NumtS from donors positive for the insertion. This identification furthers the understanding of human mtDNA variants and is expected to have a positive effect on the interpretation of mtDNA profiles using deep sequencing methods in forensic casework. This work will ultimately allow expansion in the analysis of mtDNA beyond the control region using a whole genome amplification (WGA) technique to increase starting concentrations of extract from compromised samples.

Mitochondrial DNA, Pyrosequencing, Variants

A164 Next Generation Sequencing Applications for SNPs and Mitochondrial DNA in Human Identification

Reina Langit, MS, Robert Lagace, BS, Sharon Wootton, PhD, and Lori K. Hennessy, PhD, Life Technologies, 850 Lincoln Centre Dr, MS404-1, Foster City, CA 94404*

After attending this presentation, attendees will gain an understanding of comprehensive laboratory and bioinformatic workflows for obtaining mitochondrial and SNP genotypes using next-generation sequencing technology.

This presentation will impact the forensic science community by giving an understanding of the potential use of next generation sequencing for human identification applications.

Next-generation sequencing technology is a subject area in which the forensic community has previously done little research. However, this presentation shows that using genomic DNA or mitochondrial DNA extracted from bone, blood, buccal swab, or other forensic samples, one can obtain mitochondrial and/or SNP genotypes for up to 96 individuals in a single next-generation sequencing run.

The field of human identification has been dominated by capillary electrophoresis-based (CE) STR fragment analysis. There has also been a minor effort to sequence the hypervariable regions I/II of the mitochondrial genome by CE. The low throughput of CE sequencing makes it difficult to incorporate complex DNA testing into routine procedure for criminal labs. Next-generation DNA sequencing technologies have advanced dramatically in recent years, and the costs have been reduced enough to make adoption of next-generation sequencing more attractive to the forensic community and criminal labs. Laboratories that adopt a next-generation sequencing approach are capable of generating data that can be used to produce a more detailed genomic and phenotypic profile than the current STR approach at less cost than traditional sequencing or SNP assays.

The whole 16kb mitochondrial genome can be sequenced in one next-generation sequencing run. If sequenced on CE, 64 separate reactions would be necessary (assuming 500bp amplicons and forward/reverse sequences). In fact, the new higher throughput capacities enable whole mitochondrial genome sequencing of up to 96 individuals in a single sequencing run.

To test the feasibility of this idea, an assay system containing 32 fusion adaptors with a short sequence tag made of different combinations of nucleotides attached to an adaptor (barcode) was developed. The whole mitochondrial genome was amplified with 2 PCRs each yielding overlapping 8-9kb amplicons. The two PCR products were then combined, sheared, and ligated to an adapter and a fusion barcoded adaptor. The PCR products from each individual can then be pooled and sequenced in a single sequencing run. Additionally, for sequencing more compromised samples, a 2 PCR mitochondrial mini amplicon system consisting of two multiplexes of five primer sets spanning the mitochondrial control region was tested.

To demonstrate feasibilty for an SNP assay, a panel of 106 autosomal and 33 Y chromosome SNPs selected from publically available datasets was constructed. A single PCR multiplex for ~200bp amplicons covering the 139 SNP loci was generated. The PCR products were ligated to adaptors, and barcoded libraries from 32 individuals were pooled and sequenced in one sequencing run and compared to reference genotypes.

The high capacity of the next-generation sequencing technologies makes combining many of the currently used human identification methods possible. Multiplexes of any combination of STRs, phenotypic SNPs, autosomal identification SNPs, lineage SNPs, Y SNPs, Indels,

mitochondrial sequences, or SNPs are possible in one reaction. Inclusion of historical markers would allow for a gradual shift to other markers while at the same time keeping continuity with current forensic data sets.

Sequencing, Mitochondrial, SNP

A165 Estimating Genetic Ancestry Using SNP Analysis

Camilla Green, BS, and Daniel Hellwig, MSFS, Sorenson Forensics, 2495 SW Temple, Salt Lake City, UT 84115*

After attending this presentation, attendees will understand how utilizing SNP technology in a specific assay can be applied to crime scene evidence to obtain genetic ancestral information.

This presentation will impact the forensic science community by discovering new forensic DNA applications available for criminal investigations in helping to reduce the number of potential suspects in an unsolved or cold case.

The utilization of many worldwide DNA databases, such as CODIS, can be an essential tool in modern criminal investigations. Unfortunately, when an evidentiary DNA profile does not provide a viable suspect subsequent to a database search, the investigator may be left with little forensic direction. The use of ancestral testing can be a potential option to obtain additional information regarding the donor of DNA left at a crime scene. However, there are limitations to ancestry testing due to the potential that a person's overall ancestry may be wrongly assumed with the use of haplogroups. The mtDNA or YSTR testing methods are only evaluating a small, selected portion of a person's genomic ancestry. To assist in these critical situations, Sorenson Forensics developed Investigative LEAD™; a Single Nucleotide Polymorphism (SNP) based DNA test designed to estimate genetic ancestry against a model of five genetically distinct, putative parental populations. The populations and the reference samples representing them are as follows: Western European (HapMap CEU, Northwest European descent residing in Utah), West Sub-Saharan African (HapMap YRI, Yoruba from Ibadan, Nigeria), East Asian (HapMap CHB from Beijing, China), Indigenous American (compilation of samples identified as being from populations indigenous to North, Central, and South America including Maya, Pima, Karitiana, Surui, and Arawak descent), and the India Subcontinent (HapMap GIH, Gujarati Indian descent residing in Houston, TX). In addition, the Investigative LEAD assay covers all autosomal chromosomes and the test markers are associated with ancestral informativeness so that an accurate representation of the human genetic anthropology is obtained. Our method uses 190 SNP Ancestry Informative Markers (AIMs) chosen from their scored ability to specifically differentiate between the five reference populations using Principal Component Analysis (PCA) as the comparative analysis tool and includes some markers identified as informative in previous genetic ancestry estimation publications. The method uses fluorescence-based polymerase chain reaction reagents to provide qualitative detection of targets using post-PCR endpoint analysis. As a modified approach to standard genotyping, this system miniaturizes the reactions down to 33 nanoliters for cost efficiency and high throughput. The data analysis uses a Principal Component Analysis (PCA) and a proprietary algorithm based on the program FRAPPE. The method calculates affinity levels of an individual DNA sample and then compares that to at least a hundred randomly selected subsets of individuals from the reference populations. Background interference is calculated simultaneously and is used to estimate confidence intervals based on a calibration that was effected using thousands of worldwide individuals. The effects of inhibitors, species specificity, sensitivity, non-probative casework samples, and a comparison of extraction methods from the developmental validation will be presented to demonstrate that the test is robust and viable for the forensic sample types frequently encountered in criminal investigations. The test is capable of providing valuable information regarding the genetic ancestry of the donor of crime scene DNA evidence, which can subsequently aid in reducing a pool of suspects in the investigation. Another application for this technology will be to assist in the determination of the possible contributor of skeletal remains.

SNP, Analysis, DNA

A166 Implementing SNPs Into Forensic Casework: An Assay and Interpretation Models to Predict Ancestry and Eye Color

Katherine B. Gettings, MS, and Daniele S. Podini, PhD, George Washington Univ, Dept of Forensic Sciences, 2100 Foxhall Rd NW, Washington, DC 20007*

After attending this presentation, attendees will be informed of a new Single Nucleotide Polymorphism (SNP) assay that can be used to predict ancestry and eye color of an unknown individual, also covering developmental validation, steps of individual lab implementation, and interpretation of results.

This presentation will impact the forensic science community by understanding that when an STR DNA profile obtained from crime scene evidence is not consistent with known or database profiles, no further information is available from genetic evidence. If forensic laboratories were to implement this assay, then further analysis targeted at inferring the ancestral origin and phenotypic characteristics of the perpetrator could provide valuable investigative information. Results of this analysis would aid in prioritizing suspect processing, corroborating witness testimony, determining the relevance of evidence to a crime, and ultimately increase the ability to identify individuals related to the crime scene.

The existence of population-specific SNP variation found throughout the world can be used to predict the ancestry of an unknown individual, and, in some cases, can also predict externally visible characteristics (EVC). A panel of 50 SNPs showing strong association to pigmentation phenotypes and/or ancestry has recently been determined and an assay with which to type these SNPs using the single base extension (SBE) technology has been developed. Evaluation of this panel found it to be sensitive and robust, similar to current STR typing methods. All the primer sequences, protocols, and analysis parameters (including GeneMapper ID and GeneMarker panels/bins) are publicly available. This panel can be implemented with minimal investment, as it uses the same equipment and similar methods already in use in forensic DNA casework laboratories.

Also to aid in implementation, an ancestry interpretation method has been made available, using a U.S. sample set and the open source web-based application Snipper. By adding the genotypes from an unknown sample and running Snipper with the known sample set, users will receive likelihood ratio results, which have been shown to reliably predict the ancestry of an unknown individual. Further, if the individual is determined to be of European ancestry, results of this evaluation show that a freely available excel-based prediction model can be used to indicate eye color. The 50 SNPs selected were also based on their ability to provide information on hair color and skin melanin content; however, at this time the number of individuals with known phenotype and corresponding genotype data for these SNPs is insufficient to generate reliable prediction models. Funding to increase the size of this U.S. sample database is being sought.

Lastly, evaluations are ongoing to determine if other forensic DNA results (STR, YSTR, mtDNA) can be integrated to increase the ancestry prediction ability. Using the free, excel-based Omnipop, a method of evaluating the random match probabilities of an individual's STR profile in different populations that could be used to predict ancestry has been developed. Also under development is the incorporation of the YSTR haplotype worldwide distribution using a web-based haplogroup predictor. These methods have been tested on a U.S. sample set to determine if combining results from other markers strengthens or weakens the SNP ancestry prediction. Overall, such a model could be incorporated into forensic casework to maximize the information obtained from an unknown sample.

SNP, Ancestry, Phenotype

A167 Validation of IrisPlex in the United States: A DNA-Based Tool for the Prediction of Eye Color

Gina Dembinski, BS, 4928 Sunscape Circle, Apt 1506, Indianapolis, IN 46237; and Christine J. Picard, PhD, 723 W Michigan St, SL 306, Indianapolis, IN 46202*

After attending this presentation, attendees will understand the concept of DNA phenotyping, especially relating to iris color, the application of the IrisPlex system and its prediction model component, alternative approaches for quantifying iris color, and other possible prediction methods.

This presentation will impact the forensic science community by providing information regarding casework where DNA from biological evidence is limited in providing probative information for the investigation. Physical characteristics of the donor such as hair, skin, or eye color, may present investigational leads when the conventional STR profile of the unknown DNA sample does not match any suspects or victims nor hits in a DNA database. It may also be useful for the identification of missing persons or victims of mass disasters to provide investigators with the most likely appearance of the unknown individual. S DNA phenotyping is the ability to determine physical external characteristics solely based on genotype analysis. Iris color is a complex genetic trait determined by several different genes resulting in highly polymorphic phenotypes. The IrisPlex system was developed in the Netherlands and is a multiplex SNP genotyping assay combined with a statistical model for predicting eye color. The system targets six eye color-informative, Single Nucleotide Polymorphisms (SNP) and using the genotype data, a multinomial logistic regression model was developed based on minor allele frequencies and is used for predicting the probability of eye color into three categories: brown, blue, and intermediate.

This work focuses on the developmental validation of the IrisPlex system and to evaluate the accuracy of the system's prediction component on a North American population. Validation of this work was done amplifying the same SNPs using the SNaPshot chemistry single base extension method. Capillary electrophoresis was performed on the ABI 3500 genetic analyzer.

The results of the IrisPlex study indicated predictions with greater than 90% accuracy of blue and brown eye color based on a European (Dutch) population. The prediction results based on the North American sample population so far, using the same parameters in the IrisPlex model, do not have the same level of accuracy or prediction power, especially with the blue color. All but one sample tested from the North American population so far is heterozygous at the rs12913832 SNP locus, which has been found to have the highest association with blue and brown eye color predictions when in the homozygous state. The highest probability predicted with the North American samples collected so far is 56% for blue eye color. These results are reasonably expected as North America is a highly admixed population compared to the European populations previously studied, which is where most eye color variation originates.

The parameters of the statistical regression model need to be adjusted for the differences in the allelic and genotypic frequencies between the two populations, and this is one of the goals of this work as a way of improving the prediction accuracy. In addition to validating the method using a North American population, other methods for prediction and quantitation of iris color, possibly to achieve more accuracy with the intermediate color category, are considered and evaluated. One such method for eye color classification is quantification based on separation of the iris color into red, green, and blue (RGB) and luminosity values to create a numerical color scale. Association of that value with the genotype data may be used for prediction purposes.

Iris Color, SNPs, IrisPlex

A168 Alternative Methods for Human Identification: DNA Base Composition Profiling by Electrospray Ionization Time-of-Flight Mass Spectrometry

Kevin M. Kiesler, MS, NIST, 100 Bureau Dr, MS 8314, Gaithersburg, MD 20899; Eric G. Pokorak, BS, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135; Thomas F. Callaghan, PhD, FBI, 935 Pennsylvania Ave NW, Washington, DC 20535; and Peter M. Vallone, PhD, NIST, 100 Bureau Dr, MS 8314, Gaithersburg, MD 20899-8311*

After attending this presentation, attendees will be familiar with the methods used for forensic identification of mitochondrial DNA (mtDNA) by electrospray ionization time-of-flight mass spectrometry (ESI-TOF-MS) and the capabilities of the Plex-ID instrument designed for this purpose. The research findings can guide forensic experts in practical aspects of adopting mass spectrometry as a technique for use in human identification by analysis of the mtDNA control region.

This presentation will impact the forensics science community by delineating the performance capabilities of mass spectrometry-based mitochondrial DNA base composition profiling. A full understanding of the capabilities of ESI-TOF MS instrumentation is critical to the adoption of the technology in the forensic sciences so that cost and labor advantages can be gained without exceeding expectations of performance in routine casework.

Mass spectrometry base composition profiling represents an alternative technology for forensic identification of biological material via mtDNA with improvements over the current method of DNA sequencing through reductions in cost, labor, and time required to generate a result. Mass spectrometry-based detection of DNA is not hindered by length heteroplasmy or mixed contributor samples, both of which are challenging to analyze by DNA sequencing.

In order to investigate the suitability of the Plex-ID ESI-TOF MS for use in forensic identification, experiments have been performed at NIST to assess the operational characteristics of the system when used for base composition profiling of mtDNA. Research aimed to assess the function of the Plex-ID ESI-TOF MS in the areas of: (1) concordance with Sanger sequencing data; (2) limits of detection; (3) monitoring for contamination; and, (4) ability to detect mixtures. Concordance studies evaluated results from the Plex-ID against Sanger sequencing data for DNA templates originating from four major population segments in the United States: Caucasian, African American, Hispanic American, and Asian American. PCR sensitivity was assessed through serial dilution of three unique DNA templates. Sensitivity was monitored over time to ascertain whether there may be changes in sensitivity levels of the PCR reagents or the instrument. Contamination was assessed through an experiment designed to evaluate multiple potential sources of contaminants. The ability to detect and successfully identify mixtures of DNA templates was gauged by mixing two templates together at ratios of 99:1, 19:1, 9:1, 3:1, 1:1, 1:3, 1:9, 1:19, and 1:99 and co-amplifying the templates for subsequent detection on the mass spectrometer.

Concordance study results from 669 samples identified four samples which did not generate full profiles of 24 amplicons, with a single amplicon failing to be detected. This yields a concordance rate of 99.4% (665/669) when using the criteria that a full profile is necessary for registration with the instrument database. When comparing the number of successfully measured amplicon masses, the concordance rate is 99.9% (16,052/16,056). Importantly, the discordances were limited to incomplete profiles rather than incorrect measurements. The limit of detection of template DNA was found to be well below the manufacturer's suggested minimum quantity of 200pg per sample, divided into eight multiplex PCR reactions. Full mtDNA profiles were generated over the range of 8 to 40pg of nuclear DNA template. Sensitivity levels remained within acceptable limits with slight fluctuations during four months of monitoring. Samples were variable in their mtDNA copy number, as expected. To monitor for contamination, 18 experiments were run over the course of eight months. No contamination was detected. Mixtures could be consistently detected when the two components were present at 3:1, 1:1, or 1:3 ratios.

However, complete profiles for both mixture components could not reliably be generated due to limitations in the instrument's ability to resolve two masses that are within 11 Daltons of each other.

Savings in cost and labor inputs, combined with high levels of sensitivity and accuracy make, the ESI-TOF mass spectrometry technique well suited to the forensic human identification laboratory.

A full understanding of the capabilities of ESI-TOF MS instrumentation is critical to the adoption of the technology in the forensic sciences so that cost and labor advantages can be gained without exceeding expectations of performance in routine casework. This presentation will impact the forensic science community by delineating the performance capabilities of mass spectrometry-based mitochondrial DNA base composition profiling.

Mass Spectrometry, Base Composition, Mitochondrial DNA

A169 Evaluation of Pressure Cycling Treatment on Barocycler® NEP3229 for Extraction of Low Template Forensic DNA Samples

Rebecca S. Mikulasovich, MS, Mark Powell, MS, Michael A. Donley, MS, and Roger Kahn, PhD, Harris County IFS, 1885 Old Spanish Tr, Houston, TX 77054*

After attending this presentation, attendees will understand the efforts to increase recovery of DNA from low template samples through the use of Pressure Cycle Treatment (PCT) with the Barocycler® NEP3229 (Pressure BioSciences). Specific goals were addressed, including simultaneous incubation of samples, maximization of DNA yield, and evaluation of instrument parameters and consumables for the target sample. An existing QIAGEN protocol was compared to a modified version incorporating pressure cycling pretreatment.

This presentation will impact the forensic science community by providing laboratories with additional knowledge to make informed decisions when evaluating pressure cycling strategies for challenging samples, such as those collected from touched items, hair, bone, and teeth.

Technological advancements have greatly increased the sensitivity of DNA testing in recent years. Techniques for low template autosomal DNA testing focus, primarily, on extending amplification cycles or increasing detection of the amplified products on capillary electrophoresis via reduction of salts and unincorporated primers. The class of low template samples initially targeted for this study, those recovered from touched items, are generally collected on a cotton swab substrate. Labs have long been challenged with more efficient removal of DNA sample from this substrate. Swabbing solutions, substrate material, and incubation methods have been examined in efforts to improve recovery.

Pressure cycling has recently emerged as a technique with the potential to improve DNA yield prior to amplification, with or without adjustments to amplification or clean-up of amplification products. High pressure treatment of samples prior to extraction has been hypothesized to compromise plasma membranes leading to an increase in permeability of extraction reagents and to more efficient cell lysis. In addition, cyclical exposure of samples to alternating high and ambient pressures may improve the removal of cells and cell-free DNA from the substrate. Within the FT-500ND PULSE tubes, a ram generates a pressure differential inside a tube, forcing the buffer through the swab substrate. This action may improve DNA release from the substrate and/or cell lysis in some fashion.

The present study was undertaken to evaluate a pre-amplification technique with the potential to improve recovery of DNA from a commonly used swab substrate and subsequent extraction. Various parameters were evaluated including incubation method, cycle number, and time at maximum pressure. Samples were prepared by adding 1,000pg, 500pg, 250pg, and 100pg of DNA from a calibrated solution of diluted human saliva to one-half of a cotton swab and drying overnight. Incubation was performed in PULSE tubes at 56°C within the Barocycler® NEP3229 chamber and under a series of experimental conditions including 20, 40, 60, or 80 cycles alternating between 20, 40, 60, or 80 seconds at 35k psi and 10 seconds at ambient pressure. Samples were quantified using Quantifiler® Duo (Applied BioSystems) and amplified using AmpFℓSTR® Identifiler® Plus (Applied BioSystems) reagents at 28 cycles. The amplicons were then injected onto a 3130*xl* genetic analyzer (Applied BioSystems).

Results from the various Barocycler® NEP3229 run parameters tested were varied depending on the specific target amount of DNA in the sample. Optimal run parameters were selected based on an improvement in performance across all low template DNA targets. For the DNA amounts tested, 1,000pg, 500pg, 250pg, and 100pg, runs of 20 cycles with 20 second intervals at maximum pressure recovered more DNA than the existing method across all four DNA target amounts with 22.8% (1,000pg), 50.5% (500pg), 59.3% (250pg), and 56.2% (100pg) improvements. At 1,000pg and 500pg amounts of target DNA, the 80-cycle 20 second method performed slightly better, with additional 23.0% (1,000pg) and 16.8% (500pg) increases. However, this method did not have the same affect at the 250 pg and 100 pg target amounts of DNA, recovering 45.8% (250pg) and 79.8% (100pg) less DNA than the 20-cycle 20 second method. These data agree with recoveries from 1uL of human saliva. Samples with higher amounts of DNA do benefit from increasing the number of PCT cycles; however, samples containing lower amounts of DNA appear to require fewer cycles to remove the sample from the substrate, perhaps preventing re-adherence to fibers of the cotton swab.

Findings from additional validation studies performed using pressure cycling pretreatment as well as its affect on DNA recovery from bone, hair, and tooth samples will be shared.

Pressure Cycling, Low Template, Extraction

A170 A 27-Locus STR Assay to Meet All United States and European Law Enforcement Agency Standards

James W. Schumm, PhD, 13315 Palmers Creek Ter, Lakewood Ranch, FL 34202-5005; and Cristina Gutierrez, PhD, Eugene Tan, PhD, and Richard Selden, MD, PhD, NetBio, 830 Winter St, Waltham, MA 02451*

After attending this presentation, attendees will become familiar with a 27-locus, six-dye multiplex containing all STR loci recommended or proposed for use in national databases in the United States, Europe, and Asia, and with advanced instrumentation that permits separation and detection of up to eight separate dyes to support even more highly multiplexed assays.

This presentation will impact the forensic science community by introducing an STR multiplex containing all existing and proposed standard loci for database searches in United States, Europe, and Asia that will support cross-border searching of all existing and proposed databases.

Investigative and judicial agencies worldwide have developed DNA databases to store short tandem repeat (STR) profiles. These databases provide capabilities to match DNA profiles from crime scene samples to database entries, provide investigative leads, and permit familial searching. Recently the FBI proposed expansion of the CODIS core loci to include amelogenin plus 19 required STR loci and three recommended STR loci. This approach retains the current 13 CODIS core STR loci (with transfer of the locus TPOX from required to recommended status), while expanding the set to include STR loci popular in other parts of the world, notably Europe. Increasing the number of loci in multiplex sets will not only permit compatibility across borders, but will also diminish the chances of obtaining false hits in databases, and will enhance the ability to perform familial searching. It will also improve kinship analysis in support of immigration requests.

In this presentation, attendees will become familiar with the development of a multiplex STR set permitting co-amplification of 26 STR loci plus amelogenin to supporting expansion of database compatibility across national and international borders. The 27plex set includes all 15 loci in common between the proposed CODIS required

core and the European standard, i.e., amelogenin, D1S1656, D2S441, D2S1338, D3S1358, D8S1179, D10S1248, D12S391, D16S539, D18S51, D19S433, D21S11, FGA, TH01, and vWA. In addition, the 27plex includes locus D22S1045 that is part of the European standard and is recommended in the proposed expanded CODIS core. It includes the proposed five additional required CODIS core loci CSF1PO, D5S818, D7S820, D13S317, and DYS391, and the remaining two proposed CODIS recommended loci SE33, and TPOX. Beyond these, the multiplex contains an additional locus commonly employed in Asia, D6S1043, and three other loci, Penta C, Penta D, and Penta E, respectively, that are commercially available and are used in many database searches.

To maintain the forensic preference for amplification products of less than 500 bases while incorporating so many highly polymorphic loci required expansion of previously described dye panels to six fluorescent dyes and modification of the existing NetBio GeneBench electrophoresis instrument to permit detection, separation, and display of amplified products containing each individual dye. In addition, the multiplex design generates amplified products of all alleles smaller than 400 bases except for the least commonly employed loci D6S1043, SE33, Penta C, Penta D, and Penta E. The authors propose the use of the 27-locus multiplex to permit laboratories in any jurisdiction to employ an expanded common global STR profiling set to permit full application of all data currently available in any of the national or international databases.

The multiplex has been optimized to generate all products in a 19.5 minute amplification reaction. The modified instrument used to evaluate the amplified products can simultaneously detect and employ software to separate eight or more different fluorescent dyes. These additional advances provide opportunity for adaptations to Rapid DNA Analysis and to multiple instrument platforms, and for the creation of a variety of amplification formats from higher order multiplexes to highly discriminating miniplexes.

Multiplex, CODIS, Database

A171 Detection of Deletion/Insertion Polymorphisms From Challenged Samples

Rebecca Klein, BS, Penn State Univ, Forensic Science Program, 107 Whitmore Laboratory, Unviersity Park, PA 16802; and Reena Roy, PhD, Penn State Univ, Forensic Science Program, 325 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will learn an alternate method of detecting polymorphism from environmentally insulted evidence samples.

This presentation will impact the forensic science community by allowing the scientist to generate insertion/deletion polymorphism profiles from samples where complete Short Tandem Repeat (STR) DNA profiles may not be possible to obtain.

Analysis of Short Tandem Repeats (STRs) is currently the most commonly used method for human identification. However, DNA extracted from evidence samples exposed to environmental insults does not always yield complete STR profiles. Light, humidity, elevated temperatures, and bacterial or fungal contaminants all degrade DNA, which in turn can lead to the loss of genetic information. Also, the efficiency of the PCR amplification process is reduced when inhibitors such as salts, heme in blood, indigo dye found in denim, phenolic compounds, melanin found in skin and hair, humic acid from soil, and collagen and calcium in bone are present in the extracted DNA. Degradation and inhibition can lead to loss of signal, peak imbalance, and allelic dropout with current STR technology. In situations where DNA is highly degraded, the molecule becomes fragmented and the chances of obtaining complete profiles are reduced. Typically, the larger amplicons are the first to fall below the detection limit. This problem has prompted research in the area of extraction and amplification methods to obtain complete DNA profiles from these types of compromised samples.

The Investigator DIPplex® Kit from Qiagen combines 30 insertions and deletions (InDels) markers as well as Amelogenin in a single PCR reaction. These unlinked markers are distributed across 19 chromosomes. One significant advantage of this kit is that stutter peaks commonly seen as artifacts of STR analysis do not appear in DIPplex® profiles. The PCR products generated by the primers are no larger than 150 base pairs. Due to the small amplicon size, the assay is highly sensitive and the manufacturer claims it can create a full DNA profile from as little as 63pg of DNA.

The current study focuses on the detection of insertion/deletion polymorphisms from challenged samples using the Investigator DIPplex® kit from Qiagen. Unlike the PCR amplification kits currently available in the forensic community that amplify 15 or more STR loci, the DIPplex® kit allows for multiplex amplification of 30 bi-allelic areas of known InDels plus the Amelogenin locus. This PCR amplification kit uses reduced amplicon sizes (maximum of 150bp), similar to SNPs, improving the amplification of degraded samples. The combination of current STR analysis procedures and small amplicon sizes makes InDels suitable for pristine as well as degraded DNA evidence samples.

This research included analyzing different types of body fluids from humans, some of which have also been subjected to environmental insults. Body fluids such as saliva, blood, semen, and nasal secretions, etc. from male and female human donors were analyzed to determine if they yield consistent profiles from the same donor. Another goal of this research was to assess the DIPplex® kit's capacity for samples that closely resemble forensic casework evidence. For the purpose of validating the kit, samples from various animals were also included to determine if the kit is species specific.

The experiments indicated that complete DIPplex® profiles can be obtained from degraded samples which yielded either partial or no STR profiles. These samples included washed bloodstains deposited on various types of fabrics, such as denim.

Reducing the primer concentration as well as the total reaction volume gave results comparable to profiles obtained when following the manufacturer's recommended protocol. Increasing the cycle number from the recommended protocol also improved the yield of profiles from DNA extracts which were degraded and below optimum quantity.

Direct amplification with 1.2mm blood and saliva punches from various substrates yielded complete profiles when using less than the recommended cycle number.

DNA extracted from several animals yielded either no profile or profiles dissimilar to humans. The results indicate that analysis of bi-allelic insertion/deletion polymorphisms can be useful in supplementing data obtained with STR profiles.

InDels, DNA Polymorphism, STR

A172 Determination and Use of Optimized Techniques to Analyze Trace DNA From Fingernails

Ashley Doran, BA, Lisa M. Hebda, BS, and David R. Foran, PhD, Michigan State Univ, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will recognize optimal methods for collection and processing of fingernail evidence and learn the importance these methods have for forensic practitioners.

This presentation will impact the forensic science community by introducing the best ways to collect and process trace evidence from fingernails in order to obtain the highest yields of exogenous DNA, along with the most genetic data. The results of this research have the potential to change the way forensic nurses, pathologists, and forensic biologists collect and process trace evidence from fingernails.

When two or more individuals come into contact with one another during a physical assault, a victim may fight back against the assailant, potentially resulting in the transfer of biological material, which has the potential to act as important evidence. In particular, a person struggling to free themselves from an assailant may grab and scratch that person,

resulting in the deposition of cells beneath their fingernails. Given this, medical examiners, sexual assault nurse examiners, and others regularly collect fingernail evidence following assault, however, the manner in which they do so is highly variable, and the success in obtaining probative evidence is unknown.

Currently, various procedures are used for collecting biological evide nce from nails, including clipping the nail itself, scraping beneath the nail using a wooden applicator, and swabbing underneath the nail. In the first portion of this research, female volunteers donated fingernails, on which one microliter of blood from a male volunteer was deposited. DNA was isolated using an organic extraction, and male specific DNA was quantified using real-time PCR. Soaking the nails directly in digestion buffer yielded the highest levels of male DNA, while scraping recovered the least.

Next, different extraction methods were compared in order to optimize yields; a silica-based kit extraction was compared to the organic extraction, with the former yielding more DNA. Several aspects of the kit extraction were then optimized, including incorporating more than one elution and the volume used for elution.

Genetic analyses included comparing autosomal STRs and Y chromosome STRs. The soaking and swabbing procedures resulted in mixtures of nail and blood profiles, while the scraping procedure generally showed only male DNA, although allelic dropout often occurred. Assaying Y chromosome STRs produced clean, complete profiles from both soaked and swabbed nails, while scrapings again displayed dropout.

Crime laboratories often receive nails as a set, and process them together using a cumulative swab, in order to save time and resources. This has the potential to transfer material from a nail that harbors exogenous DNA to ones that do not, resulting in cross contamination and/or loss of valuable evidence. Male blood was placed on one or two female nails, which were then swabbed intermittent with nails without blood deposition. This cumulative swabbing led to cross contamination between nails, including full Y chromosome STR profiles from the nails without blood. In contrast, when nails with and without blood were transported together and then processed individually, no cross contamination occurred, although a substantial amount of male DNA was lost through transportation.

Finally, the fully optimized procedure was tested on actual scratchings. Female volunteers scratched male volunteers on the underside of the forearm, using the middle three fingers. The scale was tared with the forearm relaxed on the center, and the set amount of force was applied before scratching commenced. The nails were clipped or swabbed, and the resultant nail or swab head was soaked in the kit's digestion buffer overnight. Multiple elutions were used to recover DNA from the kit columns. Male DNA was quantified, and DNAs were assayed for both autosomal STRs and Y chromosome STRs.

Fingernails, DNA Analysis, Y-STRs

A173 Development of a Highly Sensitive Quantification System for Assessing DNA Quality in Forensic Samples

Sudhir K. Sinha, PhD, and Anne H. Montgomery, MS, InnoGenomics Technologies, LLC, 1441 Canal St, Ste 307, New Orleans, LA 70112; Gina M. Pineda, MS, PO Box 113006, Metairie, LA 70011-3006; and Robyn Thompson, MS, and Lauren Klaskala, BS, InnoGenomics Technologies, LLC, 1441 Canal St, Ste 307, New Orleans, LA 70112*

After attending this presentation, attendees will understand the scientific basis for primer and probe design of a human DNA test method that can simultaneously estimate the quantity and quality of DNA in a potentially degraded forensic sample.

The presentation will impact the forensic science community by providing forensic DNA analysts with information regarding a new DNA quality and quantity assessment method, a highly sensitive system and valuable tool when making decisions regarding the appropriate test kit to analyze potentially degraded forensic DNA samples.

Real-time PCR provides reliable results which are essential for determining the amount of amplifiable DNA in a biological sample. The recent advances in mini STR analysis systems have now made it possible to analyze highly compromised samples. A system which can assess the extent of degradation in a forensic sample will be a useful tool for DNA analysts. Recent scientific literature reports the evaluation of the quality assessment of degraded DNA samples using Ya5-lineage Alu genetic element.[1] This presentation utilizes two independent genomic targets to obtain quantification of an 80bp short DNA fragment and a 250bp long DNA fragment in a degraded DNA sample. A multi-copy intra *Alu* based approach, to quantify human specific DNA in an evidence sample, has been successfully used to obtain DNA quantification with high sensitivity.[2] *Alu* are Short Interspersed Elements (SINE), approximately 300bp insertions which are distributed throughout the human genome in large copy number. The use of an internal primer to amplify a segment of an *Alu* element allows for human specificity as well as high sensitivity when compared to a single copy target. In this study, primers and probes were designed using two independent intra *Alu* insertions targets. The 80bp target sequence is from aYb8-lineage specific *Alu* insertion, whereas the 250bp target sequence is from Ya5-lineage *Alu* insertion. Use of a multi-copy target, two different size Alu markers along with a synthetic target, as an Internal Positive Control (IPC), provides an additional assessment for the presence of PCR inhibitors in the test sample.

The average age of Yb – lineage subfamily is estimated as 2.39 million years. It is estimated that the human genome contains over 1800 *Alu* Yb family elements and, out of those, approximately 50% are from the Yb8 subfamily. Another advantage of the *Alu* Yb 8 system is the presence of a large number of fixed insertions. It has been reported that only 20% of the Yb-lineage *Alu* elements are polymorphic for insertion presence or absence in the human genome.[3] Because a large number of these fixed elements are present in every human genome, this minimizes the individual specific variation possible when using a multi-copy target quantification system.

The precision and sensitivity studies indicated that this system has a sensitivity threshold in the range of 3-4pg, similar to those reported for other *Alu* based quantification systems. The slope of the standard curve ranged between -3.53 and -3.3. The amount of synthetic IPC target was adjusted to provide reproducible Ct values between 12-14 cycles for samples with no inhibition. A correlation study of estimated quantification for both 80bp and 250bp fragments with the STR analysis results obtained from DNAse I degraded DNA samples will be presented.

In conclusion, a DNA-based qualitative/quantitative/inhibition assessment system, that accurately predicts the status of a biological sample, will be a valuable tool for deciding which DNA test kit to utilize when processing forensically compromised samples for DNA testing.

DNA Degradation, DNA Quantification, DNA Quality

A174 Recertification of Standard Reference Material 2372 – the Human DNA Quantitation Standard: The What, the Why, and the How

Margaret C. Kline, MS, Erica Butts, MFS, and David L. Duewer, PhD, NIST, 100 Bureau Dr, MS 8314, Gaithersburg, MD 20899-8314*

After attending this presentation, attendees will understand why the National Institute of Standards and Technology (NIST) has recertified the standard reference material 2372 (SRM 2372) human DNA quantitation standard, and how that recertification has been performed to achieve traceability to SI units.

This presentation will impact the forensic science community by assuring the understanding of procedures and policies followed by NIST to assure the quality and fitness-for-purpose of the standard reference materials that the community uses to assure the quality of their measurements and to demonstrate that quality to their accrediting bodies.

SRM 2372 is intended primarily for use in the value assignment of human genomic deoxyribonucleic acid (DNA) forensic quantitation materials. SRM 2372 consists of three materials: one single-source male, one multi-source female, and one multi-source male/female mixture, all solubilized in TE^{-4} buffer. SRM 2372 was originally certified for spectroscopic traceability in units of decadic attenuance, D_{10}. The D_{10} scale is a measure of absorbance and is traceable to the unit 1. The certified values of all three SRM 2372 components had D_{10} values of approximately one. The conventional conversion factor for aqueous solutions of double stranded DNA (dsDNA) is: 1.0 D_{10} at 260nm = 50ng/µL DNA. Data on the performance of the SRM 2372 components with three qPCR methods is supplied at http://www.cstl.nist.gov/biotech/strbase/srm2372.htm.

The genomic DNA in all three of the SRM 2372 components was prepared to be dsDNA; however, five years after production these dsDNA solutions transformed into mixtures of dsDNA and single stranded DNA (ssDNA). The conventional conversion factor for aqueous solutions of ssDNA is: 1.0 D_{10} at 260 nm = 40ng/µL DNA. Therefore, this partial conformational change increased D_{10} at 260nm but did not change the DNA mass concentrations or the behavior of the materials in qPCR assays. However, recall that the SRM 2372 components were certified for their spectroscopic properties and not for the conventional conversion to mass concentration. Sales of SRM 2372 were therefore suspended as soon as the spectroscopic instability was recognized.

After determining that the solution volumes of the SRM 2372 components were unchanged and there had been no appreciable degradation of the DNA, it was decided to recertify the remaining units for the spectroscopic properties of ssDNA. Since the conversion between dsDNA and ssDNA was incomplete and somewhat variable among units, methods for users of these materials to force complete conversion to ssDNA are required. Two methods have been developed: heat treatment at 98°C and strand disassociation by sodium hydroxide (NaOH). The recertified values incorporate the variability of this conversion and, as such, the uncertainty intervals for the new values are larger than the original ones. The re-certified spectroscopic values remain traceable to the unit 1.

In addition, the SRM 2372 components are now certified for "copy number," that is, the total number of genome-equivalents present in the solution based on results from numerous digital PCR assays. qPCR assays associated with chromosomes 1, 4, 5, 6, 9, and 14 were developed in-house to be able to assess possible copy number variability issues associated with the three SRM components. Once the qPCR assays were optimized using an AB7500, they were then transposed onto the digital PCR platforms for analysis of copy number. Historically, component C of SRM 2372 has shown variability in some commercial qPCR assays. Developing qPCR assays that cover areas of six different chromosomes was done to try and understand the variability associated with these past results.

SRM 2372 components have also been checked for their performance with commercially available qPCR assays that may be of interest to the forensic DNA community.

DNA Quantitation, Digital PCR, Decadic Attenuance

A175 Expansion of the ILRC Database: Addition of Weathered and Biologically Degraded Liquids

Mary R. Williams, MS, National Center for Forensic Science, University of Central Florida, PO Box 162367, Orlando, FL 32816-2367; Michael E. Sigman, PhD, Univ of Central Florida, PO Box 162367, Orlando, FL 32816-2367; Dee A. Turner, BS, IUPUI, Dept of Chemistry and Chem Biology, 402 N Blackford St, LD326, Indianapolis, IN 46202; and John V. Goodpaster, PhD, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202*

The goal of this presentation is to inform attendees of the addition of degraded ignitable liquids to the Ignitable Liquids Reference Collection (ILRC) database.

This presentation will impact the forensic science community by providing information on the degradation of ignitable liquids through evaporation (weathering) and biological degradation. The ILRC database will be modified to incorporate degradation data of fifty ignitable liquids.

In 2000, the Ignitable Liquids Reference Collection (ILRC) and Database were established as a joint project between the National Center for Forensic Science (NCFS) and the Technical Working Group for Fire and Explosions (TWGFEX). The need for a collection of reference ignitable liquids with associated GC/MS analysis data was confirmed by fire debris analysts in a 1998 national survey of forensic laboratories.[1] In 2002, the ILRC database became accessible to the public. The collection of reference ignitable liquids and the database of GC-MS analysis data are housed at NCFS. The ILRC committee, a committee within TWGFEX, reviews all of the data and classifies each reference ignitable liquid based on the American Society for Testing and Materials (ASTM) E1618 classification scheme.[2] The ILRC database contains product information, classification information, and GC/MS data.

In 2007, the ILRC database software was upgraded to provide the user enhanced searching capabilities. In 2010, NCFS and TWGFEX developed a substrate database containing a compilation of headspace GC/MS data from burned and unburned materials that are common to fire scenes. Substrates are materials which undergo pyrolysis and combustion processes during a fire and are constituents in fire debris collected at a fire scene. These materials may produce compounds that can interfere with the identification of ignitable liquids in fire debris. The database can assist fire debris analysts by demonstrating the types of compounds and chromatographic patterns that may be produced by these commonly encountered materials.

Processes that complicate the analysis of ignitable liquid residues in fire debris, besides the interfering products from the pyrolysis and combustion of substrate materials, is evaporation and biological degradation. Weathering is the evaporation of the more volatile compounds of an ignitable liquid resulting in a greater concentration of the less volatile compounds.[3] Ignitable liquid residues recovered from soils or other organic matter are known to lack target compounds that are associated with common types of ignitable liquids due to the consumption of the ignitable liquid residue by microorganisms.[4] While evaporation affects the chromatographic profile, primarily through loss of the "front end" of the chromatographic profile by evaporation of the most volatile components, biological degradation tends to selectively remove certain types of hydrocarbons.

The National Center for Forensic Science (NCFS), Indiana University – Purdue University Indianapolis (IUPUI) and the ILRC committee of the Technical Working Group for Fire and Explosions are collaborating to integrate weathered and biologically degraded ignitable liquids into the database. Ignitable liquids will be weathered to 25%, 50%, 75%, 90%, and 95% and biologically degraded at zero, seven, fourteen, and twenty-one day time periods. The database software will be modified to enable the user to search for the additional ignitable liquids.

Fire Debris, Ignitable Liquids, Database

A176 Comparison of SIMCA With LDA and QDA for the Identification and Classification of Ignitable Liquid Residues

Erin E. Waddell, BS, Mary R. Williams, BS, and Michael E. Sigman, PhD, Univ of Central Florida, NCFS, PO Box 162367, Orlando, FL 32816*

The goal of this presentation is to establish a methodology with known error rates for identification and classification of ignitable liquids in fire debris samples.

This presentation will impact the forensic science community by discussing the benefits of each method when applied to ignitable liquid and pyrolysis product classification in fire debris analysis. The methods investigated are intended to provide statistical support for current laboratory practices.

This research compared chemometric methods for classifying ignitable liquids and ignitable liquid residues in fire debris samples. The methods emphasized identifying samples that contain ignitable liquid residues and assigning ignitable liquid residues to classes as defined by the American Society for Testing and Materials (ASTM) E1618 standard. ASTM classes include: aromatic, gasoline, petroleum distillates, isoparaffinics, naphthenic paraffinics, normal alkanes, miscellaneous, and oxygenates. This presentation will impact the forensic science community by discussing the benefits of each method when applied to ignitable liquid and pyrolysis product classification in fire debris analysis. The methods investigated are intended to provide statistical support for current laboratory practices. The goal of this research is to establish a methodology with known error rates for the identification and classification of ignitable liquids in fire debris samples.

Results using Soft Independent Modeling Of Class Analogies (SIMCA) will be compared to those obtained using Linear Discriminant Analysis (LDA) and Quadratic Discriminant Analysis (QDA). SIMCA is a soft classification technique which allows a sample to be classified into a single class, multiple classes, or to be unassigned. The option of classifying into multiple classes could be beneficial for fire debris samples since the ratio of ignitable liquid residue-to-substrate pyrolysis is unknown. Discriminant analysis is a hard classification technique which means that each sample must be assigned to a single class and failure to assign to a class is not an option. For both techniques, models were developed from libraries of Gas Chromatography-Mass Spectrometry (GC/MS) data for ignitable liquids and pyrolysis products. Models for assigning samples to the ASTM classes were based on the Total Ion Spectrum (TIS). Cross-validation techniques were also used for each chemometric method. A test set was created by randomly selecting 20% of the samples from each class, with the remaining 80% developing a model data set. The samples in the test set were then classified using the respective chemometric method. Cross-validation steps were repeated 100 times with a new test set being selected and classified each time. Total correct classification percentages were calculated as the sum of the cross-validation tests. All models developed for ignitable liquid and substrate library data were applied to fire debris samples.

Outlier samples within each class were first removed based on their orthogonal and score distances before the SIMCA model was developed. For each class, Principal Components Analysis (PCA) was performed and the cutoff distances for the orthogonal and score distances were calculated from the model data. The test data set was projected into the model PCA space for the respective classes and orthogonal and score distances were calculated. A sample was assigned to the given class if the calculated score value was less than or equal to one. If the value exceeded one, the sample was not assigned to that class. A sample was considered to be correct if it only assigned to the known class and partially correct if it assigned to multiple classes that included the correct class.

Preliminary results show that when using all ASTM classes, other than miscellaneous and oxygenate classes, most of the samples classified using SIMCA were correct, or partially correct, with very few samples being incorrectly assigned. A partially correct sample was assigned to multiple classes that included the correct class, but also included incorrect assignment(s). For discriminant analysis methods, a two-class multi-step classification scheme was used.[1] The optimal QDA model gave correct classification rates greater than 90% for all steps; the optimal LDA model's correct classification rates were greater than 75% for all steps.

Fire Debris, Chemometrics, Error Rates

A177 Utilizing GCxGC/TOF-MS to Improve the Data Quality for the Analysis of Fire Debris

Jessica L. Westland, MPS, Kari L. Organtini, MSc and Frank Dorman, PhD, Penn State Univ, 107 Whitmore Lab, State College, PA 16802*

After attending this presentation, attendees will understand the ability of Comprehensive Gas Chromatography – Time-of-Flight Mass Spectrometry (GCxGC – TOFMS) to differentiate between gasoline samples as well as identify marker compounds that can help aid in arson investigations. The attendees will also recognize the difficulties associated with an arson investigation, the current extraction methodologies, and the reason a more sensitive and selective technique may be beneficial. The attendees will also be introduced to the use of Principal Component Analysis (PCA) for the evaluation of the site samples.

This presentation will impact the forensic science community by developing a technique that can allow for the differentiation of fresh and burnt gas samples and identifying marker compounds that indicate combusted gasoline versus gasoline that has been environmentally weathered.

Arsons can be particularly difficult crimes to investigate, due to the nature of the fire, which generally destroys most of the material evidence. Due to the lack of material evidence at the scene, the analysis of volatiles that may still be present from the use of common materials for fire initiation is typically evaluated. These volatiles, left from the fuel source used at the scene, may provide the evidence needed to connect an arsonist with their crime, and also determine the type of accelerant used. Historically, specific sources of accelerant were not able to be determined, in part due to the lack of selectivity of the analytical methods which have been previously employed.

The extraction methods utilized for these volatiles include gas headspace (under static or dynamic conditions), Solid Phase Micro-

extraction (SPME), and activated carbon strips with carbon disulfide. The most common extraction method, accepted for fire debris analysis and arson investigations, is headspace extraction of the fire debris with carbon strips followed by the extraction of the carbon strip with carbon disulfide. Appropriate instrumental techniques for the analysis of fire debris and ignitable liquid residues include GC/FID, GC/MS and/or GC/MS (SIM), and GCxGC/TOF-MS. The lack of selectivity of GC/FID has resulted in the more common use of GC/MS and/or GC/MS (SIM) because of the ability to evaluate the chromatogram for specific mass-to-charge ions, allowing for interpretation based upon compound classes. More recently, GCxGC has been considered for use in this application because of its ability to further separate compounds prior to detection. The resulting ability of the chromatograph to separate a hydrocarbon mixture based upon its compound classes (aliphatic, branched aliphatic, aromatic, etc.) enables the user of the data to quickly determine and describe the composition of the potential accelerant. Additionally this technique, due to its ability to provide higher data density, may allow for the identification of marker compounds to link the fuel with specific sources, and differentiate between gasoline used as an accelerant versus gasoline that has merely evaporated (weathered) as a result of normal degradation.

A case study from an active arson investigation of a forest fire utilized GCxGC/TOF-MS will be presented The technique's ability to identify the differences between un-weathered and weathered samples as well as pre- versus post-burn samples will be highlighted. Due to the environmental location of the fire, the differentiation between combusted gasoline and environmentally-weathered gasoline will also be noted. Statistical analysis was used to assist with the data sets and provide a convenient way to observe the similarities and differences between the samples.

GCxGC/TOF-MS, Fire Debris, Investigation

A178 A Comprehensive Study of Weathering and Microbial Degradation of Ignitable Liquids

Dee A. Turner, BS, IUPUI, Dept of Chemistry and Chemical Biology, 402 North Blackford St, LD 326, Indianapolis, IN 46237; John V. Goodpaster, PhD, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202; and Mary R. Williams, BS, and Michael E. Sigman, PhD, Univ of Central Florida, NCFS, PO Box 162367, Orlando, FL 32816-2367*

After attending this presentation, attendees will understand the concepts of weathering and microbial degradation of ignitable liquids from all ASTM classes.

This presentation will impact the forensic science community by highlighting the major trends in bacterial degradation of various examples of ignitable liquids from each ASTM class.

An organic-rich substrate such as soil is an excellent source of carbon for bacteria. Since ignitable liquids are comprised of various hydrocarbons, soil bacteria can also utilize these fuels as a carbon source. Previous work completed in our laboratory on the biodegradation of ignitable liquids has shown a significant loss of normal alkanes in the range of C_9 to C_{16} as well as lower substituted aromatic compounds. Branched alkanes appear to be more resistant to degradation than normal alkanes. In addition, the degree of degradation was positively correlated to the length of the alkyl chain on the mono-substituted alkylbenzenes. Also, the position of the alkyl branches plays a significant role in the ability of the bacteria to metabolize the alkylbenzenes. This can be problematic for fire debris analysis as samples may sit for many weeks before they are analyzed due to case backlog. As a result, selective loss of key components due to bacterial metabolism can make identifying and classifying ignitable liquid residues by their chemical composition and boiling point range very difficult. Of particular interest in this study is the monitoring weathering and degradation of various ignitable liquids in all ASTM classes in order to expand an existing database that can be used by fire debris analysts as a tool in the identification of ignitable liquids.

Weathering is the evaporation of the more volatile compounds of an ignitable liquid resulting in a greater concentration of the less volatile compounds. Weathering of the ignitable liquid is typical in fire debris due to the heat of the fire. The effect of ignitable liquid weathering on the chromatographic profile is the loss or reduction in intensity of the peaks at earlier retention times and an increase in intensity of the peaks at later retention times. The altered chromatographic profile of the weathered ignitable liquid residue makes comparisons to un-weathered reference ignitable liquids more complicated.

For degradation experiments, 20µL of the ignitable liquid was spiked onto 100g of potting soil and allowed to age for zero, seven, fourteen, and twenty-one days. The samples were then analyzed using passive headspace adsorption followed by solvent desorption, and then analyzed by GC/MS. Weathering of the ignitable liquids was performed by volume reduction of 10mL of ignitable liquid to 7.5, 5.0, 2.5, 1.0, and 0.5 ml corresponding to 25%, 50%, 75%, 90%, and 95% weathered, respectively. The ignitable liquids were heated in a dry bath under a gentle flow of nitrogen. At each evaporation point, a 20µL aliquot of the ignitable liquid was diluted into 1mL of carbon disulfide for GC/MS analysis.

This study will show that gasoline and petroleum distillates, which predominantly contain aromatic and n-alkane hydrocarbons respectively, suffer significantly from microbial degradation in just a few days while naphthenic-paraffinic liquids, which contain branched and cyclic alkanes, generally suffer the least microbial degradation. Oxygenated liquids also are significantly degraded; however, recovery of the oxygen-containing compounds in these liquids may present a challenge. Isoparaffinic liquids also suffer from microbial degradation. When comparing branched alkanes, long chained alkanes with one alkyl substituent are less resistant to microbial degradation than alkanes with multiple alkyl substituents. The changes in the chromatographic profile of various ignitable liquids described herein are a result of the selectivity of the bacteria to metabolize the hydrocarbons found in these liquids, which is solely based on the chemical structure of the compound. Weathering is a process that is based on the boiling point of the compound. In weathering, compounds with a lower boiling point will be lost preferentially; whereas, in microbial degradation, longer chain and less branched compounds are lost preferentially.

Fire Debris, Ignitable Liquid, Degradation

A179 Principal Components Analysis and Hierarchical Cluster Analysis for the Identification of Ignitable Liquids in Simulated Fire Debris

Andrew T. DeJarnette, BS, 2331 Knob Hill Dr, Apt 10, Okemos, MI 48864; Ruth Waddell Smith, PhD, Michigan State Univ, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824; and Victoria L. McGuffin, PhD, Michigan State Univ, Dept of Chemistry, East Lansing, MI 48824-1322*

After attending this presentation, attendees will have an understanding of how multivariate statistical procedures can be used to aid the identification of ignitable liquids in fire debris, demonstrating the use of Principal Components Analysis (PCA) and Hierarchical Cluster Analysis (HCA) for the association of simulated fire debris samples to appropriate ignitable liquid standards.

This presentation will impact the forensic science community by presenting a more objective method for the analysis of fire debris samples. The application of PCA and HCA in this manner provides a statistical basis for the comparison of forensic evidence addressing concerns regarding the subjectivity of evidence comparisons that were raised in the 2009 Report published by the National Academy of Sciences.

Following analysis by gas chromatography-mass spectrometry (GC/MS), chromatograms obtained from fire debris samples are

compared to chromatograms of ignitable liquid standards to identify the presence of any ignitable liquid in the debris; however, several factors can complicate the chromatogram from the debris, making this comparison more challenging. Examples include the loss of volatile compounds, as well as the introduction of compounds that can be inherent to the debris itself or products of thermal degradation. As a result of these factors, the chromatogram from the fire debris sample may be visually dissimilar from the chromatogram of the corresponding liquid standard.

The purpose of this research was to investigate the use of multivariate statistical procedures to compare chromatograms from simulated fire debris to appropriate liquid standards, despite evaporation and the presence of matrix interference compounds and thermal degradation products. Three liquids were selected from each of three classes (naphthenic paraffinic, isoparaffinic, and alkane) as defined by ASTM International. Each liquid was evaporated to 0% and 50% by volume, then spiked onto a Kimwipe and extracted using a passive headspace procedure. A nylon carpet/carpet padding matrix was used in this research to represent a common household material. Samples of the matrix were initially burned for predefined times to determine an appropriate burn time that generated significant matrix interference compounds. To simulate fire debris, each liquid standard was spiked onto separate samples of the unburned matrix, which was subsequently burned for the appropriate time. These samples were then extracted using the passive headspace procedure, then analyzed by GC/MS.

Before analysis of the resulting chromatograms, it was necessary to perform data pretreatment procedures to minimize non-chemical sources of variance. Total ion chromatograms of the standards and debris samples were first smoothed to minimize instrument noise, thereby improving the signal-to-noise ratio. The chromatograms were then aligned to account for shifts in retention time, and finally normalized to account for slight differences in the injection volume.

The association of the simulated fire debris samples to their respective liquid standards was first evaluated using PCA. This statistical procedure is used to reduce the dimensionality of the data and identify sources of variance with the dataset. Results from PCA are shown in the form of scores plots and loadings plots. In the scores plot, chemically similar samples are positioned closely and distinctly from chemically different samples. The loadings plots are used to identify those compounds within the liquids contributing most to the variance described by the principal components. Principal components analysis was performed only on chromatograms of the liquid standards to demonstrate that the liquids could be differentiated based on liquid type and evaporation level. Then, the fire debris samples were projected onto the scores plot to investigate association to the corresponding liquid standard.

Hierarchical cluster analysis is used to assess the similarity of samples within a dataset, displaying results graphically in the form of a dendrogram. Samples that are clustered closely in the dendrogram are considered more similar. In this research, HCA was performed on the full dataset to investigate clustering, or association, of the fire debris samples with the appropriate liquid.

Using both PCA and HCA, it was possible to associate the debris to the type of liquid, despite evaporation and the presence of matrix interference compounds and thermal degradation products, from the carpet/carpet padding matrix. These procedures may provide an objective method that can be applied for the analysis of fire debris.

Fire Debris Analysis, Multivariate Stats, Chemometrics

A180 Professional Ethics and the Introduction of New or Novel Methodology

Douglas M. Lucas, DSc, 5280 Lakeshore Rd, No. 1111, Burlington, ON L7L 5R1, CANADA*

After attending this presentation, attendees will have a better understanding of the ethical and scientific obligations in the introduction of evidence based on new or novel methodology.

This presentation will impact the forensic science community by providing a description of the differing ethical responsibilities of the various participants based upon differences in their professional duties.

The word "ethics" is derived from the Latin "*ethos*" which translates as "customary behavior." Webster defines ethics as: "the moral principles which determine the rightness or wrongness of particular acts or activities." Simply put, ethics deal with the commitment to do what is right, good, and proper.

The definition of ethics used for this presentation is from Oxford: "the science of human duty in its widest context." If "human" is replaced with "professional" this definition may be applied to any profession. By linking "ethics" with "duty" in a professional context, a basis is established for understanding how a specific conduct may be considered quite ethical for one profession yet patently unethical for another—their duties are different. Nowhere is this more apparent than with forensic science because of its close association with three professions—science, law and law enforcement.

For example, forensic science and law enforcement are distinct professions with complementary but differing duties. During an investigation, it is quite acceptable for the police investigator to rely on information obtained from a variety of sources and in myriad ways. Conversely, the conclusions of the forensic scientist must be based solely on the demonstrable scientific evidence developed. For science and law, the differences in duties are even more distinct. Scientists are expected to be totally objective, completely impartial, technically competent, and openly communicative; however, it is the duty of the attorney to aggressively represent the interests of his client whether it be "the people" or a defendant. It is the scientist's duty to describe the evidence as it actually is; it is the lawyers duty to describe it in the light most favourable to his client.

The attempt to introduce new or novel methodology can produce ethical challenges for each of the professions. These will vary depending on whether the evidence relates to a totally new form of evidence or whether it is simply a new application of an existing science. They also may be different at the investigative stage and at trial. The "one off" type of case will also be distinct from a new application to "regular" types of cases.

The onus is always on the forensic scientist to ensure that a new method is based on sound scientific principles, is well documented, produces reliable results, has its limitations and sample requirements clearly established, and has been peer reviewed. If it is intended to go beyond the "one off" case or the investigative stage, it should also have been published for appropriate broad professional review. In the absence of any of these, the scientist has not fulfilled his professional duty.

The law enforcement officer is required to ensure that the information developed by the scientist is relevant to the investigation, is based upon proper contextual information, and, if the information is to be used in decision-making, that it is used as intended and not distorted in any way.

The prosecutor has a duty to ensure that the method produces information that is relevant to the issue(s), that it meets the requirements for admission into evidence, and that it is presented thoroughly and effectively. The defense attorney has the duty to understand the method sufficiently that appropriate challenges may be made in the best interest of the defendant.

When new/novel methods are to be used, all the participants have specific duties and, thus, related professional ethical obligations.

Ethics, New Methodology, Professional Duty

A181 Enhancing Canine Performance Through Improved Training Materials and Adoption of International Best Practices (SWGDOG and ICODD)

Kenneth G. Furton, PhD, Florida Int'l Univ, Int'l Forensic Research Inst, University Park, Miami, FL 33199; and Jessie Greb, MBA, 11200 SW 8th St, CP 330, Miami, FL 33199*

After attending this presentation, attendees will understand how improved training materials and the establishment of best practices for detection teams is improving interdiction efforts and courtroom

acceptance of dog alert evidence as well as the importance of creating an accreditation commission, the International Commission on Detector Dogs (ICODD). This presentation will impact the forensic science community by providing a better understanding of how the Scientific Working Group on Dogs and Orthogonal Detector Guidelines (SWGDOG) and accreditation through ICODD are improving the consistency and performance of deployed detector dog teams and their optimized combination with emerging electronic detectors.

This presentation will impact the forensic science community by providing the results of the latest studies identifying and quantifying odorants used by certified law enforcement and military detection canines and the development of odor mimics for use as field calibrants. A variety of factors can influence the measured performance of canine teams including the source of training materials, the containment system used, how the training materials are presented to detection teams, and how the teams were trained and maintained. The presentation will also describe the implementation of best practices developed by SWGDOG through the formation of ICODD. SWGDOG best practices have been developed by a membership of respected scientists, practitioners, and policy makers representing diverse backgrounds. SWGDOG has been cooperatively funded by the NIJ, FBI, DHS, and TWSG since 2005. This project was undertaken as a response to concerns coming from a variety of sectors, including law enforcement and homeland security, regarding the need to improve the performance, reliability, and courtroom defensibility of detector dog teams and their optimized combination with electronic detection devices.

The approval of each subcommittee best practice document takes a minimum of six months to complete including a two-month period of public comments. The 10 SWGDOG subcommittees are as follows: (1) unification of terminology; (2) general guidelines for training, certification, maintenance, and documentation; (3) selection of serviceable dogs and replacement systems; (4) kenneling, keeping, and health care; (5) selection and training of handlers and instructors; (6) procedures on presenting evidence in court; (7) research and technology; (8) substance dogs: agriculture, arson, drugs, explosives, human remains, contraband, pest, currency, and firearms; (9) scent dogs: non-specific human scent wilderness area search, location checks, article search, scent identification line-ups, live people in disaster environments, track trail people based on last known position, pre-scented canines aged trail, and live people in avalanche; and, (10) outreach and education.

The success of SWGDOG is dependent on the 55 SWGDOG members as well as the numerous external members within the working dog community who take the time to provide detailed commentary during the public comment stages. To date, there are *thirty-nine* approved guidelines within 436 pages of resources. SWGDOG is a catalyst in prioritizing research and development in both canine and orthogonal detector areas, in direct support of local law enforcement activities. The current success of SWGDOG is being manifested by a shift of some national canine organizations to adopt the approved SWGDOG best practice guidelines. Furthermore, the documents prepared thus far by SWGDOG members have been used to support the requirements of Homeland Security Presidential Directive -19 (HSPD-19), Combating Terrorist Use of Explosives within the United States.

Detector Dogs, Best Practices, SWGDOG

A182 Admissibility of Unconfirmed Accelerant-Detection Canine Alert

Colin C. Murphy, JD, 107 S 4th St, Clear Lake, IA 50428*

After attending this presentation, attendees will understand current legal issues surrounding the admissibility of Accelerant-Detection Canine (ADC) alerts without laboratory analysis confirming the presence of ignitable liquids.

This presentation will impact the forensic science community by detailing how while a number of courts have followed the recommendations of the IAAI Forensic Science Committee and the NFPA Technical Committee on Fire Investigation and rejected the admissibility of expert testimony regarding unconfirmed alerts, others have nevertheless admitted this type of opinion evidence either as proof that an accelerant was present near the origin of the fire or that arson was the cause of the blaze. In arson cases, where the ultimate issue is whether a fire started accidentally or purposely, the jury could easily disregard the lack of laboratory confirmation and equate an uncorroborated alert with proof that the fire was aided by an accelerant. The probability of a wrongful conviction under those circumstances is not insignificant.

While the utility of ADCs in securing samples with a higher probability of laboratory confirmation may be generally accepted in the field of fire science investigation, the body of scholarly literature to date confirms that even the best-trained ADC cannot discriminate between accelerants and all possible background contaminants or byproducts of pyrolysis. As a result, the mere detection of traceable quantities of these substances has limited evidential value. Also, studies have shown they can falsely alert to areas of a fire scene that contain no trace evidence of ignitable liquids.

There is scant support for the proposition that a canine's olfactory sensitivity and specificity is more accurate than state-of-the-art GC/MS instruments employed in crime labs. This is why most scientists in the field conclude that an unconfirmed alert should be considered invalid, unreliable, and entitled to no weight. However, courts are not uniform in their approach to the question of whether these alerts are reliable.

The presentation will focus on the legal analysis on which courts rely in either admitting or rejecting expert testimony on unconfirmed alerts. This necessarily involves an examination of the issues of relevance, the prejudicial effect of this type of testimony and the tendency to confuse and mislead the jury, and foundation for expert opinions under the rules of evidence. Particular emphasis will be placed on the question of admissibility of such unconfirmed alerts under both *Frye*, *Daubert,* and *Kumho Tire* standards.

Canine, Accelerant, Arson

A183 Dog Scent Lineups: A Junk Science Injustice

Jeff Blackburn, JD, Innocence Project of Texas, 1511 Texas Ave, Lubbock, TX 79401*

After attending this presentation, attendees will understand the misuse of dog scent lineups in criminal cases.

This presentation will impact the forensic science community by pointing out the dangers in relying on unvalidated methodologies, often referred to as "junk science."

It is well known that dogs possess superior olfactory abilities compared to humans. Their ability to follow trails is well documented and accepted as an investigative tool. The use of dog scent lineups to associate a particular individual with a particular location is a more recent use of this tool — one which has found its way into criminal trials and resulted in wrongful convictions.

Under perfect conditions, with the careful application of controls to prevent undue influence on the canine by its handler, scent lineups may achieve an accuracy of 85%.[1] This presentation will focus on an individual who, without the benefit of any protocols or controls, claimed under oath that his canines were accurate more than 99% of the time.

Fort Bend County Sheriff's Deputy Sergeant Keith Pikett became very popular among Texas prosecutors because of his unique "ability" to associate defendants with crime scenes. He developed a down-home, folksy testimonial style and appeared at trials throughout Texas. Even after the prosecution bar became generally aware of some of Sgt. Pikett's shortcomings, they continued to call on him to help "solve" their cases.

Some of the testimony that prosecutors presented and judges allowed included the amazing claim that even though he did not keep detailed records, his dog "Clue" had only been wrong in one out of 1,659 lineups.[2] His dog "James Bond" had been wrong once out of 2,266 lineups, and his dog "Quincy" had only been proven wrong in three out of 2,831 lineups.[3,4] Pickett denied that he had any need of any formal training in scent lineups, he denied that he needed to follow any formal protocols, and he rejected the results of scientific studies.[5] Pickett

claimed his dogs could identify scent more than 10 years old, and could also identify scents from vehicles.[6,7]

In 2002, the case of *State vs. Winston* cemented Sgt. Pickett's status as the leading scent lineup expert in Texas. In this case, the 14th Court of Appeals held that Winston was a qualified expert.[8] Thereafter, Pickett was allowed to present his lineup testimony in Texas as "scientific evidence."

As is the case with many charlatans, Sgt. Pikett attempted to enhance his credibility by falsifying his credentials. Sgt. Pikett earned a Bachelor of Science degree in chemistry from the University of South Alabama in 1977 and a "Master of Sport Science" degree from the United States Sports Academy in 1984; however, at various times, he testified under oath that he held a Bachelor of Science degree in chemistry from Syracuse University and a Masters degree in chemistry from the University of Houston. Both institutions' registrars stated that they had never heard of the man.

As is the case with many instances of "expert" witness misconduct, there were no serious consequences for Sgt. Pickett. He was never reprimanded, never disciplined, and certainly never charged with perjury. After the Innocence Project released a report detailing Sgt. Pickett's career, he "retired" in January 2010. Meanwhile, prosecutors and police continue to use scent lineups.

A184 Who Let the Dogs In? The Admissibility and Scope of Testimony of Dog Handlers

Joseph J. Maltese, JD, New York Supreme Court, 130 Stuyvesant Pl, 3rd Fl, Staten Island, NY 10301; and Stephanie Domitrovich, JD, PhD*, Sixth Judicial District, Erie County Court House, 140 W 6th St, Rm 223, Erie, PA 16501*

The goal of this presentation is to explore the mistakes made in *U.S. vs. Hebshie* as examples of what defense counsel, law enforcement, and prosecutors can do in the future to avoid misuse of this valuable tool, also addressing these issues by reviewing both federal and state cases.

This presentation will impact the forensic science community by outlining the foundational requirements for allowing dog handlers to testify in court about the reactions of trained accelerant-detection dogs in detecting the presence of a fire accelerant in a criminal or civil arson cases, as well as the reactions of drug detection dogs.[1-3]

In 2006, James Hebshie was convicted and sentenced to 15 years in prison for arson and mail fraud for setting a fire in a commercial building where he worked.[4] In order to prove that the fire was arson, the Government elicited testimony from an accelerant-detection dog handler and a laboratory technician, who testified about the incendiary nature of the fire. Notwithstanding, the trial judges repeated suggestions to defense counsel to take time to consider the admissibility of this testimony, the defense counsel did not request a pre-trial hearing nor mount any meaningful challenge to the evidence at trial. In 2010, a motion was brought to vacate Mr. Hebshie's conviction, claiming that defense counsel's failure to mount a challenge to the "accelerant-detection dog" testimony constituted ineffective assistance of counsel.

Few people would challenge the principle that dogs generally possess an enhanced ability to detect certain oders such as food or specific sustances such as marijuana, heroin, cocaine, methamphetamines, and, perhaps, even fire accellerants. However, utilizing that ability to assist law enforcement personnel to uncover such substances requires specialized training in order to alert their handlers when they have detected such a substance. The alert may be a bark or scratching at the location, or it may be an obvious turn of the head or tail movment, or by just passively sitting at the location. Since all of these actions are part of a dogs usual activities, training the dog to perform in a specific manner to alert the handler that it has detected the specific substance for which it is trained differs with each dog. But without maintaining acurate data on how proficient a particular dog is in making positive alerts as opposed to false positive alerts to drugs or fire accelerants, there is no objective way to judge the reliability of that particular dog.

While certificates attesting to the dogs training should be an initial factor, continuous proficiency testing should be maintained and documented to ascertain a particular dogs error rate in order to determine the reliability of any particular dog. The use of dogs as an investigative tool should be used appropriately. When the government seeks to introduce evidence regarding a dog's role in the investigation, the question is not whether dogs can generally detect certain odors, but how acurate and proficient that specific dog is in detecting that specific odor. Courts as "gatekeepers" of evidence have an obligation not only to consider the admissibility of the evidence, but what limitations, if any, should be placed on the testimony of dog handlers.[5] Judge Nancy Gertner in the *Hebshie* case, stated "a certain patina attaches to an expert's testimony unlike any other witness; this is "science," a professionals judgment, the jury may think, and give more credence to the testimony than it may deserve."

This presentation will look at what judges and counsel should review in addressing the use of drug detection alert dogs and accelerant alert dogs as evidence in a trial and whether there are any differences. What are the parameters for the admissibility of this type of evidence? What underlying data should be required in order to allow the testimony of a dog handler in court? What can law enforcement do to improve the admissibility of such testimony? Finally, what obligation do the various participants in the criminal justice system have to assure that only reliable evidence is presented to the trier of fact?

While the judiciary has continued to struggle with how to address emerging technologies, courts are looking with a more critical eye toward the underlying principles, procedures, and methods employed by forensic specialists that were once assumed to be reliable and pondering whether to continue to admit such evidence into a trial without first knowing about its underlying validity.[6]

A185 Forensic Attribution of Matchsticks Using Integrated Analysis With Morphological Examination, Fourier Transform Infrared Spectroscopy (FTIR), Scanning Electron Microscopy-Energy Dispersive X-Ray Spectroscopy (SEM-EDS), and Inductively Coupled Plasma-Mass Spectrometry (ICP-MS)

Ciaran F. Phillip, BS, and Christopher J. Ehrhardt, PhD, Virginia Commonwealth Univ, Dept of Forensic Science, 1015 Floyd Ave, Richmond, VA 23284*

After this presentation, attendees will be able to recognize the unique physical and chemical features present in match heads with different functions and match heads with the same function but originating from different manufacturers; also learning how these features can be incorporated into a multivariate signature that can be used to identify the specific type and commercial brand of an unknown match.

This presentation will impact the forensic science community by introducing a scientifically and statistically robust analytical scheme for collecting forensically relevant information from question matchsticks. Such forensic signatures can provide investigative leads in criminal cases and better illustrate the association between question and known matches to a jury.

Because matches are designed for quick fire starting, they are quite amenable to criminal activity and are often encountered in arson and bombing cases. Different functional types of matches display physical and chemical differences in both burned and unburned match heads that are specific to that match type. Furthermore, previous research has shown that there are chemical features in match heads that are not shared by matches from different brands; however, no project before this has attempted to combine the physical and chemical characteristics of both spent and unspent match heads in order to create multivariate signatures to be used for functional and commercial brand classifications.

There are three main functional classes of matchsticks: safety, strike-anywhere, and waterproof. Safety matches are the most pervasive and widely used type of match. They often find use in kitchens, places of worship, and most other instances where safe fire starting is required. The components for igniting these matches are separated into a match head and a specially designed striking surface. In contrast, strike-anywhere matches are not common and are generally used by outdoor enthusiasts as a reliable method for starting fire. They have all ignition components in the match head and can be lit on any suitably rough surface. Waterproof matches are safety matches (can only be lit when struck on a specially designed surface) that have been coated with a water-resistant, yet flammable, polymer binder. Like strike-anywhere matches, waterproof matches are used as outdoor survival tools by campers, hikers, and even the military.

For this project, four brands of safety, two brands of strike-anywhere, and four brands of waterproof matches were used. Safety match brands included: Diamond™ Strike On Box, Diamond™ Deluxe Matchbooks, Industrial Revolution/UCO Long-Burn, and HomArt® Fancy Fish Superior Quality. Diamond™ and Redbird were the strike-anywhere match brands, and Coleman®, REI® Stormproof, Proforce Equipment, and Coghlan were the brands of waterproof match. Matches were analyzed using an analytical scheme of stereomicroscopy for documenting visual characteristics, Fourier Transform Infrared Spectroscopy (FTIR) to identify any binder coating present, scanning electron Microscopy-Energy Dispersive X-ray Spectroscopy (SEM-EDS) to determine elemental composition, and Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) to measure multi-elemental concentration profiles.

Results showed that matches do have distinct physical characteristics that are unique for particular commercial brands and types. Match head color, texture, structure, and metrics were particularly excellent markers for indicating a match's functionality and commercial brand. Chemical analyses revealed that different commercial brands of waterproof match have different polymer binders including nitrocellulose (Coleman® and Coghlan), alkyd (REI Stromproof), and shellac (Proforce Equipment). No polymer binder was identified in safety or strike-anywhere matches. Elemental composition was found to be similar among all match types and brands with the majority of the samples containing silicon, potassium, chlorine, magnesium, titanium, iron, zinc, chromium, lead, thorium, and uranium. However, concentrations vary significantly between brands. For example, average ^{70}Zn concentration was 247.7ng·mL^{-1} and 60.2ng·mL^{-1} in Diamond and Redbird strike-anywhere matches respectively. Similar differences were seen for ^{24}Mg, ^{57}Fe, Pb (all isotopes), ^{232}Th, and ^{238}U. Principal component analysis (PCA) and hierarchical clustering analysis (HCA) performed on the multivariate data set produced distinct clades for waterproof match brands, while safety and strike-anywhere match brands were distributed throughout the cladogram. Taken together, these results indicate that robust signatures exist for functional classes of matchsticks and individual commercial brands. Implementation of this analytical scheme with multivariate statistical analysis will increase the evidential value of question matches providing leads for investigators and strengthening conclusions of consistency between question and known evidence.

Matchstick Typing, ICP-MS, Multivariate

A186 Evaluation of Lip Cosmetics Using Raman Spectroscopy

Paige Gardner, BS, 1102 W Grace St, Apt 10, Richmond, VA 23220; and Massimo F. Bertino, PhD, Dept of Physics, 701 W Grace St, Richmond, VA 23284-3079*

After attending this presentation, attendees will be informed about the possibility of using Raman spectroscopy in the analytical scheme for lip cosmetics.

This presentation will impact the forensic science community by suggesting a non-destructive, rapid method for evaluation of lip cosmetics that can provide significant discriminatory information for comparisons.

Because of the ease of transfer and prevalence of use, lip cosmetics are often encountered on crime scenes. The vast array of different manufacturers, product types, and colors make them a potentially powerful source of associative evidence. However, many current analytical schemes need components of lip cosmetics to be extracted and analyzed separately. For example, dye components may be extracted and analyzed with High Performance Liquid Chromatography (HPLC) or Thin Layer Chromatography (TLC), while oils and waxes may be analyzed using Gas Chromatograph/Mass Spectrometry (GC/MS). Raman spectroscopy can give a more complete look at chemical composition without need for extraction procedure, which reduces both handling time for the sample and risk of contamination.

In this study 80 lipsticks, 34 lip glosses, and 17 lip balms were obtained from donations and evaluated using Raman spectroscopy at an excitation of both 532 and 780nm. Pure samples were analyzed as smears on aluminum foil. Intra-product studies were first conducted to determine the effect of dye combinations when the base composition was unchanged. Four common colors, red, brown, purple, and purple-brown were selected from the lipsticks and grouped with ten similarly colored products from different manufacturers for comparison. Any two lipsticks outside these groupings with visually identical colors were also compared. The possibility of examining cosmetic samples directly from a substrate (such as cotton swabs, colored fabrics, and automobile panels) was also evaluated. For substrate studies, two identically colored lipsticks were selected and applied to the desired surface and examined without extraction. The ability to distinguish the lipstick from the substrate as well as the ability to differentiate between lipstick samples was assessed. Spectra were compared using visual overlays.

While fluorescence severely limited the analysis by the 532nm source, the 780nm source provided useful spectra from all analyzed samples. Within a brand, colors from the same product line could be distinguished from one another using Raman spectroscopy alone. This

was true even for colors that were very close to one another, indicating that dye components contribute significantly to the Raman spectra. It was also possible to distinguish between the same colors from different products within the same manufacturer.

In inter-brand comparison of similarly colored samples, the lipstick samples could all be discriminated using only the Raman spectra. Many similarities were attributed to dyes used, but there was enough variation between dye formulations and other chemical components to provide unique spectra. Lip glosses and lip balms showed less variation within the same product, mostly likely due to less contribution from pigmentation. It was also possible to distinguish the lipstick signal from the substrates examined. However, there was detail lost from the pure spectra. Despite this, it was still possible to use the spectra as a source of discriminatory information.

Instances where spectra could not be differentiated were limited to lip glosses and lip balms of different colors from the same product type and manufacturer. No lip glosses or lip balms had the same spectra as a lipstick. Variation in chemical composition of lip cosmetics provides significant discriminatory power and opens the possibility of creating a database that catalogues Raman spectra of lip cosmetics.

Lip Cosmetics, Lipstick, Raman Spectroscopy

A187 Differentiation of Color Toners on Paper Using Raman Analysis and Chemometrics

Jeanna M. Feldmann, BS, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202; Jay A. Siegel, PhD, 8334 Tilly Mill Ln, Indianapolis, IN 46278; and John V. Goodpaster, PhD, IUPUI, FIS Program, 402 N Blackford St, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will understand the advantages of using Raman spectroscopy in questioned document casework to further differentiate photocopier and laser printer toner cartridges. In addition, attendees will gain an understanding of multivariate statistics as they apply to this particular type of evidence.

This presentation will impact the forensic community by demonstrating a spectroscopic method of analysis that is not only quick and non-destructive with no sample preparation, but is not plagued by the interference of paper, also addressing the recommendations set forth in the National Academy of Sciences' report. For example, there is a need for continued research in many areas of forensic science that could contain a statistical component. In particular, visual examination and comparison of two spectra cannot always detect subtle differences. However, the same spectra could be objectively compared through the application of multivariate statistical analysis.

Toner analysis has become an area of increased interest due to the wide availability of laser printers and photocopiers. Toners contain a number of components, including, but not limited to, polymer resins, dyes/pigments, surfactants, and charge control agents. The formulation of these toners, granule size, and melting point can vary between manufactures and machines. In addition, toner is most often encountered on paper in questioned document analysis. Because of this, it is important to develop methods that limit the interference of paper without damaging or destroying the document. Previous research using Fourier Transform Infrared Spectroscopy (FTIR) has differentiated toners based on their polymer resin components. Developing a method to differentiate toners based on their other components is important for increasing the discriminating power of toner analysis.

Raman spectroscopy is a popular tool for the chemical analysis of pigmented samples. The technique involves measuring the vibrational modes of a molecule in the form of inelastic scattering of light after being subjected to a monochromatic light source, such as a laser. The use of a microscope provides a very high level of spatial resolution and depth discrimination. However, the interference from carbon black and iron oxide contained within black toner make it a problematic sample for analysis. As a result, cyan, yellow, and magenta toners were the focus for this study. Analyses were performed using a dispersive micro-Raman spectrometer equipped with a 785nm diode laser, a CCD detector, and an objective at 20X magnification. Three different methods were developed for cyan, yellow, and magenta toners on paper, respectively, to optimize results. One hundred samples of each color toner were collected. Cyan toner samples were subjected to 10% laser power with an exposure time of nine seconds for 15 scans. Yellow toner samples were subjected to 100% laser power with an exposure time of 10 seconds for 15 scans. Magenta toner samples were subjected to 25% laser power with an exposure time of 10 seconds for 30 scans. Due to the increased paper interference in the yellow and magenta toner samples, spectra of the paper for each sample were collected and spectral subtraction was performed. The data collected from these analyses was then processed using a combination of statistical procedures, including Principal Component Analysis (PCA), Agglomerative Hierarchal Clustering (AHC), and Discriminative Analysis (DA). The conclusions drawn from this study were used to form a classification scheme for each colored toner.

Raman Spectroscopy, Color Toners, Chemometrics

A188 Forensic Examination of Artificial Sweeteners

Vincent J. Desiderio, MS, Andrew M. Bowen, MS*, and Robert B. Moberley, MS, U.S. Postal Inspection Service, National Forensic Laboratory, 22433 Randolph Dr, Dulles, VA 20104-1000*

After attending this presentation, attendees will: (1) become aware of the analytical challenges posed by the forensic examination of artificial sweeteners, occasionally submitted to the laboratory as unknown materials in "white powder" cases; and, (2) understand the advantages and disadvantages of various instrumental approaches to characterizing and identifying these products when they are encountered as evidence.

This presentation will impact the forensic science community by providing recommended analytical approaches for the most effective characterization and identification of artificial sweeteners. This will improve their ability to examine this type of evidence in the event that they encounter it in their laboratories.

After the 2001 Amerithrax case that involved mailed letters containing anthrax spores, "white powder" incidents became relatively common events in the news. Law enforcement officials focused significant resources on the development of capabilities for responding to and identifying suspicious white powders encountered in public spaces. These efforts resulted in the creation of a variety of first-response teams affiliated with police departments, firefighters, National Guard, and other federal law enforcement groups. After an initial assessment of the threat posed by the white powder (often utilizing portable instrumentation or mobile laboratories designed to rule out specific weapons of mass destruction), the material is typically collected for submission to a laboratory for more specific identification. These powders, therefore, have the potential to end up in forensic laboratories as evidence. Another result of the widely publicized anthrax case is the relatively common occurrence of copycat individuals who include white powders in threatening communications often mailed to victims. Many of these letters are submitted as evidence to the National Forensic Laboratory of the U.S. Postal Inspection Service, or to other forensic laboratories around the country. As a result, there is a continuing need for forensic laboratories to be well prepared to identify unknown materials in general, and white powders in particular.

Although some of these powders are hazardous materials, the vast majority end up being common household products or commercially available chemicals. It is the job of the laboratory to identify these materials and, in many cases, to subsequently compare them with products obtained from the residence or workplace of a suspect. The majority of these commercial products are fairly straightforward to characterize and identify; however, some materials pose analytical challenges for the typical forensic laboratory. Several of the commonly used artificial sweeteners are so sweet that they are used in very small quantities in the final consumer product. The vast majority of the powder in these products consists of fillers (typically D-glucose). The fact that the sweetening agent is present in such small quantities can make it

challenging to unambiguously determine the identity of the product or compare it to similar products submitted to the laboratory. The National Forensic Laboratory has received artificial sweeteners as evidence associated with threatening letters in the past, prompting the laboratory to acquire and characterize standard artificial sweeteners using a wide variety of analytical techniques, including stereomicroscopy, polarized light microscopy, Fourier Transform-infrared spectroscopy, scanning electron microscopy, energy dispersive spectroscopy, X-ray diffraction, Raman spectroscopy, and gas chromatography-mass spectrometry.

This presentation will introduce the audience to the commonly encountered sweetening agents and discuss their occurrence in commercial products. The results obtained during characterization of several of the most common artificial sweeteners will also be discussed. The advantages and disadvantages of the various instrumental techniques for the purpose of identifying these sweetening agents will be considered. Suggestions will be made to the audience related to appropriate analytical approaches to the examination of suspected artificial sweeteners. The work presented here will provide the foundation for the future development of an analytical scheme for characterizing and identifying all of the common artificial sweetening agents.

Sweeteners, White Powders, Chemical Unknowns

A189 The Microscopic Study of the Statistical Significance of Household Dust Specimens

Mary Eng, BS, New York City Police Lab, 150-14 Jamaica Ave, Jamaica, NY 11432; Nicholas D. Petraco, PhD, 899 10th Ave, New York, NY 10019; Nicholas Petraco, MS, 73 Ireland Pl, Amityville, NY 11701; and Anna S. Duggar, MS, Loyola Univ, Forensic Chemistry, 6363 St Charles Ave, New Orleans, LA 70118*

After attending this presentation, attendees will understand some of the tenets behind principal component analysis, support vector machines, and partial least squares discriminant analysis in order to build statistical models of the composition profiles in the study of household dust specimens.

This presentation will impact the forensic science community by establishing the statistical significance of household dust specimens in trace evidence casework; its high confidence level of 99% and error rate of less than 1% reported will go a long way in re-establishing trace evidential materials as a powerful form of scientific evidence.

This paper continues the discussion and study of the statistical significance of household dust specimens presented at the 2011 AAFS Annual Scientific Meeting in Chicago. Additional results of the original household dust specimens, as well as new results for household dust specimens obtained from homes, businesses, and apartments encompassing the New York City Tri-State region, and from other areas in the United States are presented.

The original procedure which began with a preliminary visual and stereomicroscopic examination of each dust specimen has been expanded in order to include a more diverse array of particulate materials. The contents of each new dust specimen are sorted with the aid of a stereoscopic microscope into groups of similar-looking: hairs, fibers, and particulate materials depending on the composition of each dust specimen's composition. In addition, aggregate groupings of fibrous and particulate materials are teased out of each dust specimen and examined. Each aggregate group is further subdivided into smaller subsets based on their macroscopic physical appearance, primarily color and morphology. Each fibrous and/or particulate subset is mounted on a 7.5cm x 5cm microscope slide in Cargille® 1.540 High Dispersion (HD) refractive index oil. Finally, each fibrous and/or particulate subset aliquot is characterized and identified utilizing stereo and polarized light microscopy. Three aliquots were examined from each household dust specimen. Particulates too large to be mounted for PLM examination were studied with other forms of analytical instrumentation, i.e., Fourier Transform Infrared Spectroscopy, X-ray Fluorescence, and X-ray Diffraction.

The resulting information for each new specimen and its mounted subset was collected on a revised dust tabulation data sheet specifically designed for this study. The newly acquired data and the data collected in the prior study were combined and resubjected to principal component analysis, support vector machines, and partial least squares discriminant analysis in order to build statistical models of the composition profiles. These statistical models were then subjected to a test set of randomly selected unlabeled dust samples in order to compute estimates of misidentification rates (error rates). The methods used to compute these error rates were hold-one-out cross validation and bootstrapping.

A number of interesting trends, such as the ubiquitous occurrence of certain types of natural fibers, the recent occurrence of a wider range of species of natural fibers, the appearance of microfibers, the appearance of faux fibers, the proliferation of green fibers, and the expansion of more diverse mixtures of synthetic fiber types as well as the frequent occurrence of several classes of biological and particulate materials, are extensively discussed. Recommendations regarding the use and value of these ubiquitous materials in establishing whether a contact transfer occurred based on their presence are statistically evaluated and discussed at length.

In particular, the building of sound scientifically acceptable statistical models that meet the challenges of the NAS Report on Forensic Sciences, and establish high confidences, levels and accurate error rates for the microscopic examination of forensic dust specimens were primary goals in this study.

Statistical Significance, Household Dust, Trace Evidence

A190 Forensic Discrimination of Copper Items Using Trace Element Concentrations

Joshua Dettman, PhD, and Alyssa Cassabaum, BS, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; and JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, FBI Academy, Bldg 12, Quantico, VA 22135*

After attending this presentation, attendees will understand the general principles of source discrimination, method development for determination of trace element concentrations using Inductively Coupled Plasma-Mass Spectrometry (ICP-MS), and the statistical comparison of trace element concentrations in copper from different sources for discrimination among and association between sources.

This presentation will impact the forensic science community by potentially providing a new means to associate crime scene and suspect-linked copper items based on their trace element concentration profiles.

Copper can be encountered in criminal cases such as theft (as raw material from mines and as wiring or piping from construction sites and homes) and bombings (wiring in explosive devices). At present, the only means of reliably associating copper items is on the basis of fabrication marks, which may not be possible in all cases depending on the copper item. The goal of this research is to assess the potential of using the trace element concentrations of a copper item from a crime scene to either associate or eliminate as a source a copper item associated with a suspect.

The conductivity of copper is dependent on its purity (i.e., concentration of trace element contaminants). Rapid techniques such as spark source optical emission spectroscopy and X-ray fluorescence spectroscopy are commonly used in production laboratories to determine trace element impurities in copper. However, quantitation limits for these techniques are close to or higher than the analyte concentrations in high purity copper. Due to the requirement of lower detection limits, an alternative method based on ICP-MS instrumentation was explored.

Concentrations of trace elements in copper were initially determined using solution ICP-MS in NIST standard reference materials for method validation. It was determined that a microwave digestion step after initial dissolution of the copper samples in concentrated nitric acid was required to achieve quantitative recovery of all analyte elements. The standard reference materials were also used to construct a matrix-matched calibration curve, which was compared with non-matrix-matched calibration. To increase the number of elements available for source discrimination, noncertified elements present in the

standard reference materials were identified as present using solution and laser ablation ICP-MS, although the accuracy of the method for these elements cannot be confirmed. Relevant figures of merit determined include method detection limits based on 10 replicate blanks that were carried through the sample preparation process, matrix effects due to high concentrations of copper, method accuracy by comparison of measured and certified analyte element concentrations, and reproducibility of the sample preparation and measured concentrations.

To discriminate between copper items, the variation in trace element concentrations within a "source" (e.g., from different parts of the copper item and/or from the same production batch) must be small compared to the variability in trace element concentrations between production batches from the same manufacturer, items produced by different manufacturers, and geographic location of raw material mining. Samples were collected to represent copper from different geographic regions, refining operations, and production procedures used to produce specific types of copper items. Statistical techniques are used to identify elements that contribute significantly to the variation within and between samples, and to group samples based on their trace element concentration profiles. Statistical analysis of the trace element concentration profiles could potentially provide a link between the copper item recovered from the crime scene and an item associated with a suspect, or exclude a suspect from further investigation.

Source Discriminatio, Trace Elements, Copper

A191 Duct Tape Sourcing Examinations: Developing Investigative Leads Using Multiple Resources

Diana M. Wright, PhD, and Andria H. Mehltretter, MSFS, FBI, Laboratory Division, Chemistry Unit, Rm 4220, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will have knowledge of the methodology used to source duct tape bindings using a combination of factors that can provide highly discriminating investigative lead information. These factors include physical characteristics, instrumental analyses such as X-ray Diffraction (XRD) and Pyrolysis-Gas Chromatography/Mass Spectrometry (Py/GC/MS), a duct tape reference collection and database, and industry contacts. Results demonstrate that the combination of these factors can provide highly discriminating investigative lead information.

This presentation will impact the forensic science community by disseminating knowledge regarding discrimination achieved through XRD and Py/GC/MS analyses, two techniques not commonly associated with duct tape analyses. Further, the use of a reference collection and searchable database provided an efficient means of culling large-scale manufacturers and distributors from the list of possible tape brands.

The case example presented will describe how the FBI Laboratory was able to develop investigative lead information in a homicide case. When investigators arrived at the crime scene, they observed a deceased victim and a witness loosely bound with duct tape. The witness stated that both persons were victims of a robbery. Local law enforcement requested forensic examinations to further their investigation, including sourcing of the tape.

The bindings were examined in order to document physical characteristics such as the backing construction, adhesive color, width, scrim count and construction, and the backing and overall tape thicknesses. Chemical analyses of the adhesive and backing components of the duct tape were conducted via Fourier Transform Infrared Spectroscopy (FTIR), Scanning Electron Microscopy/Energy Dispersive Spectroscopy (SEM/EDS), XRD, and Py-GC/MS. From the FTIR results of the adhesive, talc was readily observed, but the rubber and tackifying resin composition were difficult to interpret. XRD results revealed contaminants, tremolite and phlogopite, not previously identified in duct tape adhesives analyzed in the FBI Laboratory, suggesting the tape was not a commonly available product. Tremolite is a form of asbestos and phlogopite is a sheet aluminosilicate that falls into the mica class; both can be found as contaminants in common filler and extender pigments such as talc and dolomite. Py-GC/MS was used to elucidate that the adhesive formulation was styrene-butadiene-styrene (SBS) when FTIR results did not adequately distinguish between SBS or the use of a tackifying resin in a styrene-isoprene-styrene (SIS) formulation. The distinction was important for sourcing purposes given that most manufacturers use SIS or isoprene alone.

Using the National Forensic Tape File (NFTF) reference collection and database, industry contacts, and the Internet, a single manufacturer was able to be identified, and from it, a specific tape product was targeted as the source of the bindings. When sales data for this product was evaluated for the state where the crime occurred as well as its three neighboring states, it was found that only one distributor bought the product and in turn sold it to eight industries: mostly mid-size manufacturers of consumables (e.g., paper products), durable goods (e.g., furniture, storage tankers, food services), and two locations of a funeral service provider.

This case highlights the utility of employing a variety of analytical and reference-based resources to source manmade, mass-produced materials. It is also unusual in that the chemical analyses proved to be more discriminating than the totality of the physical characteristics of the tape due to the raw material choices of the manufacturer, both the specified choice of SBS and the filler with the readily observed impurities. Compelling investigative lead information was reported to the contributor using the described resources, most of which are readily available or can be developed by any laboratory system interested in conducting duct tape sourcing examinations.

Duct Tape Sourcing, Instrumental Analysis, Reference Collection

A192 Operation Invisible Dead: A Blind Study of Soil Identification Using a Microbiological Database

Sabreena Larson, MS, 1901 Vine St, Lincoln, NE 68588; Niraj Patel, BS, Univ of Nebraska, Lincoln, NE 68588-0664; Victoria Freeman, 1901 Vine St, Lincoln, NE 68588; Cheryl P. Bailey, PhD, Univ of Nebraska, Lincoln, NE 68588-0664; and David O. Carter, PhD, Chaminade Univ, Div of Natural Sci and Math, 3140 Waialae Ave, Honolulu, HI 96816*

After attending this presentation, attendees will understand more thoroughly the application of soil microbial community profiling and the potential use of a soil database to identify microbiological soil evidence.

This presentation will impact the forensic science community by exploring the use of Capillary Electrophoresis-Single Strand Conformation Polymorphism (CE-SSCP) to identify soil samples using a soil microbiological database.

Soils have been used as trace evidence for well over a century. As technology has advanced, so has the value of soil evidence. Most recently, soil microbial community profiles have been used to provide an accurate discriminating factor between soil samples of known and unknown origin. The use of microbiological physical evidence can detect the uniqueness or similarity of the soil evidence when compared to the collected reference soil samples from the crime scene. The current literature contains several papers that test the accuracy and limitations of these methods; however, no one has yet done a case study on how well soil microbial community identification works with a database. Thus, a blind study was set up with a database to test the sensitivity and reliability of the soil microbial evidence.

The blind study was set up where a "criminal" dug a shallow grave using a shovel. Upon completion of the shallow grave, the "criminal" then placed the shovel and one shoe into individual paper bags for evidence collection. The other shoe was worn back to a place of residence, and then placed in a paper evidence bag. The shovel and two shoes were allowed to air dry at room temperature for 48 hours. The soil was collected from these objects by a different undergraduate researcher. This analyst conducted all sampling and handling without knowledge of the location of the grave. DNA from the soil was extracted

using a commercially available DNA extraction kit. Amplification of the extracted DNA was done with fluorescently labeled primers and a proofreading enzyme for the V3 region of the 16S ribosomal DNA. Using CE-SSCP the soil microbial community was characterized. This method yields electropherograms of the microbial community DNA specific to the bacteria present in the soil sample. The profiles of the soil microbial community were compared to a database of four soil plots in southeastern Nebraska over three different seasons. The database was made from a previous research project and holds 72 profiles. The samples in the database were processed with DNA extracted within 24 hours of removal of soil from the ground at a depth of 0cm to 5cm. DNA extraction, Polymerase Chain Reaction, and CE-SSCP for the samples in the database were all processed the same way as the samples from this study. It is understood that this is a relatively small database, but it can help to initiate the usefulness of a soil microbiological database.

The database has been made and the samples have been processed via CE-SSCP. The results of the study are two-fold. When visually examining the soil microbial electropherograms from CE-SSCP, the location of the grave was correctly identified. However, to ensure a reliable outcome is obtained, statistical analysis must be conducted. R software will be used to statistically compare and contrast the samples of interest to the database.

Soil, CE-SSCP, Microbial DNA

A193 An Unusual Tool/Fracture Mark Case to a Smokestack From a 19th-Century Steam Engine

Gregory E. Laskowski, MPA, 8021 Dottie Ct, Bakersfield, CA 93308*

The goals of this presentation are to educate about examination of tool marks and the use of fracture matches to determine the common origin of a portion of a 19th-century cast-iron smokestack and also learn about the theft of antiquities from federally protected archeological sites and how the Antiquities Act of 1906 and the Archaeological Resources Protection Act of 1979 apply to persons accused of theft, and also to educate the participants on the history and processes of gold mining in Kern County, California.

This presentation will impact the forensic science community by helping them understand the process of forensic examinations of antiquities illegally harvested from archaeological sites.

The theft of antiquities from federally designated archeological sites is a growing problem in the United States. The price of iron as well as other metals such as copper, silver, and gold in the recycled metals market has steadily increased, thus making the harvesting of metal-bearing materials from abandoned sites economically attractive. The unfortunate effect of this phenomenon is the vandalism, destruction, and theft of antiquities from unprotected federal lands. The Antiquities Act of 1906 signed by President Theodore Roosevelt and the Archeological Resources Protection Act (ARPA) of 1979 were enacted to protect antiquities from being obliterated, removed, or destroyed from federal and Native American lands.

In the summer of 2011, the Bureau of Land Management (BLM) submitted evidence to the Kern Regional Crime Laboratory (KRCL) items that had been illegally harvested from an abandoned gold mine designated as an archeological protected site. These evidence items included the following: a flattened riveted cast-iron section of 19th-century smokestack seized from the suspect, a concrete cutting saw with circular metal cutting wheel seized from the suspect, a rounded section of a cast-iron 19th-century smokestack recovered from the mine site, and a circular metal cutting wheel recovered from the mine site. BLM requested the laboratory to determine if the flattened smokestack seized from the suspect's vehicle was at one time part of the smokestack remnant recovered from the mine site.

An examination of the flattened section seized from the suspect and the remnant from the mine site was conducted using standard comparison methodology and recorded using digital photography. The process of restoring the flattened section of smokestack, the comparison of cut marks and fracture mark analysis, the legal implications of ARPA, and a brief history of gold mining and its processes in Kern County California will be discussed.

The process of examination included:

1. Visually determining if the two items are compatible.
2. Reshaping and reforming the unknown items that an attempted alignment could be accomplished.
3. Aligning the items to determine where common tool marks could be compared.
4. Searching for fracture matches when conventional tool marks comparisons were not feasible.
5. Identifying fracture matches to establish common source.

Conventional tool mark techniques were not used due to the nature of the cutting instrument, which was determined to be a worn-down grinding wheel on a gas-powered concrete saw. However, a fracture match was identified in an area were the grind cuts were incomplete. The fracture match was difficult because of the brittleness of the metal caused from years of oxidation and corrosion in the open-air environment.

In conclusion, fracture mark comparison is possible when conventional tool mark examination and identification techniques fail, working with decomposing and corroded metal has its challenges when attempting common source identifications, and 19th-century manufacturing techniques do allow for individualization.

Fracture Match, Tool Mark, ARPA

A194 Virtual Tool Mark Generation for Efficient Tool Mark Analysis

Laura D. Ekstrand, BS, Iowa State Univ, 2624 Howe Hall, Ames, IA 50011; Song Zhang, PhD, Iowa State Univ, 2096 Black Engineering, Ames, IA 50011; L. Scott Chumbley, PhD, Iowa State Univ, 214 Wilhelm, Ames, IA 50011; Taylor Grieve, BS, Iowa State Univ, 206 Wilhelm, Ames, IA 50011; and David J. Eisenmann, BS, Iowa State Univ, 183 ASC II, Ames, IA 50011*

After attending this presentation, attendees will be informed about ongoing research into a computer-aided method for tool markanalysis that uses virtual tool marks to predict the angle of a real tool mark. Attendees will learn about the basic procedure, scientific principles, and potential advantages of this new technique and see a preview of the current state of the software development. They will also have the opportunity to provide input on the direction and quality of the research and suggestions for future methods that could be developed.

This presentation will impact the forensic science community by demonstrating a statistical method that can not only strengthen the rigor of impression evidence analysis, but also increase its efficiency. In particular, the presentation will focus on an application of the statistical algorithm to estimate the tool-marking angle and twist of a real mark. This knowledge could prevent examiners from generating extra marks at unprofitable angles, saving time and reducing possible damage to evidence.

In 2009, a National Academy of Sciences Report called for investigation into the scientific basis behind tool mark comparisons.[1] Answering this call, the authors have attempted to prove or disprove the hypothesis that tool marks are unique to a single tool. Recently, it was demonstrated that a statistical algorithm could, in most cases, discern matching and non-matching tool marks made at different angles by sequentially numbered screwdriver tips.[2] Moreover, in the cases where the algorithm misinterpreted a pair of marks, an experienced forensics examiner could discern the correct outcome. While this research serves to confirm the basic assumptions behind tool markanalysis, it also suggests that statistical analysis software could help to reduce the examiners workload.

This led to a new analysis approach that relies on 3D scans of screwdriver tip surfaces at the micrometer scale from an optical microscope. These scans are carefully cleaned to remove noise from the data acquisition process, and then they are assigned a coordinate system that mathematically defines angles and twists in a natural way.

The marking process is then simulated by using a 3D graphics software package to impart rotations to the tip and take the projection of the tips geometry in the direction of tool travel. The edge of this projection, retrieved from the 3D graphics software, becomes the virtual tool mark. Using this method, virtual marks are made at increments of 10 degrees and compared to a scan of the real tool mark. The previously developed statistical package performs the comparison, comparing the similarity of the geometry of both marks to the similarity that would occur due to random chance.[2] Finally, the method informs the forensics examiner of the angle(s) of the best matching virtual mark, allowing the examiner to focus his/her mark analysis on a smaller range of angles and twists.

The preliminary results seem promising. The virtual marking software is capable of importing and cleaning a 3D tool tip in about a minute and producing a virtual mark profile in a matter of seconds. The statistical mark-to-mark comparison can also be performed in seconds. These time estimates are from a standard desktop computer with a 3.20 GHz processor and an inexpensive graphics card. Therefore, the proposed method is capable of making comparisons at several angles in a reasonable amount of time.

Tool Marks, Impression Evidence, Software Development

A195 The Examination, Evaluation, and Identification of Fired 9mm Cartridge Cases Fired from 1,500+ Different GLOCK® 9mm Semiautomatic Pistols Manufactured Over a 20-Year Period

James E. Hamby, PhD, Int'l Forensic Science Lab, 410 Crosby Dr, Indianapolis, IN 46227; and Steven A. Norris, BS, 208 S College, Cheyenne, WY 82002*

After attending this presentation, attendees will understand some principals of utilizing both optical, confocal microscopy and computational pattern recognition in the examination and identification of fired GLOCK® 9mm cartridge cases to include fired cases that were obtained from recently manufactured consecutive firearms slides.

This presentation will impact the forensic science community by demonstrating the ability to identify fired cartridge cases to specific firearms.

Over the last several decades, forensic examiners have struggled with the fact that there is no accepted methodology to generate numerical proof that would independently corroborate morphological conclusions regarding impression evidence such as tool marks. The purpose of this research is to take a step toward developing standardized methodologies that can objectively evaluate tool markcomparison and identification. This presentation will impact the forensic and legal community by presenting the results of research conducted over a 20-year period that involved the identification and inter comparison of over 1,500 fired cartridge cases.

In this research, 617 GLOCK® Model 17 & 19 9mm semiautomatic pistols were obtained from the then Indianapolis Police Department (IPD) and test fired to obtain four fired cases from each pistol. The test fired cases were microscopically examined, evaluated, and intercompared using forensic optical comparison microscopy to determine if the casings could be individualized. Subsequentially, 700 additional cartridge cases—recently manufactured over a five-year period—were added to the research. Using forensic optical comparison microscopy, the combined 1,275 test fired cases were microscopically examined, evaluated, and compared if the fired cases could be individualized. A report of this research experiment was presented at the 2011 annual training seminar of the Association of Firearm and Tool Mark Examiner (AFTE). An additional 225+ fired cases have been added to the existing research cases and examined to determine if they are identifiable to themselves and to the exclusion of the other cases.

Additionally, this research is to take a step toward developing standardized methodologies that can objectively evaluate tool markcomparison and identification. Fifty-eight primer shear marks on 9mm cartridge cases, fired from four GLOCK® Model 19 pistols, and a series of 9mm cases test fired from recently manufactured consecutive GLOCK slides were collected using high-resolution, white light confocal microscopy. The resulting three-dimensional surface topographies were processed with outlier and form removal before a cubic spline filter was used to extract all "waviness surfaces"—the essential "line" information familiar to firearm and tool mark examiners. Taking the mean of all profiles that made up each surface summarized the primer shear waviness topographies. The mean profiles were then subjected to Principal Component Analysis (PCA) for dimensional reduction and Support Vector Machines (SVM) for profile-gun associations. Using 10,000 bootstrap resampling iterations, PCA-SVM required only six "synthetic" features (6D) to produce an estimated identification error rate of 0% on a larger data set of assumed similar statistical properties. At the 95% level of confidence, Conformal Prediction Theory (CPT) coupled with SVM showed an empirical error rate of 7%, slightly higher than the long run guarantee of 5%. With these results, suggestions are made for practical courtroom application of CPT for assigning levels of confidence for SVM identifications of tool marks recorded with confocal microscopy.

Forensic firearms examiners have routinely identified fired bullets and cartridge cases with suspect firearms over the past 100+ years, including numerous studies involving consecutively manufactured components. Conversely, firearms examiners have routinely excluded fired components (bullets and/or cartridge cases) during this same time period. In this research project, examination of the fired cartridge cases against each other, validated that each was identifiable and unique. Additionally, the utilization of confocal microscopy and computational pattern recognition in examining some of these fired cases—including several from consecutive manufactured slides—further validates the ability of a trained examiner to differentiate between various fired components.

This presentation will impact the forensic and legal communities by demonstrating the ability of qualified examiners to evaluate and inter compare a significant number of fired cartridge cases (over 2,250,000 examinations) using conventional optical microscopy. Additionally, the research to take a step towards developing standardized methodologies that can objectively evaluate tool mark comparison and identification with the addition of confocal microscopy will be of great value to the forensic and legal community.

Firearms ID, Manufacturing, Legal Issues

A196 Ballistics Evidence in the JFK Assassination: Just the Facts!

Douglas K. Shaffer, MS, ICE HSI Forensic Laboratory, 8000 Westpark Dr, Ste 325, OI FDL Stop 5116, McLean, VA 20598-5116*

After attending this presentation, attendees will learn about the documented ballistics evidence in the JFK assassination, and how modern forensic science techniques have impacted the understanding of the case. Attendees can implement the forensic information learned into their research studies and investigation of the assassination.

This presentation will impact the forensic science community by providing attendees with a comprehensive knowledge of the ballistics evidence in the JFK assassination. New information reported by respected investigators from the academic, forensic scientific, legal, and medical communities will impact attendees in terms of their knowledge and competence pertaining to this case.

After nearly fifty years of study, the assassination of President John F. Kennedy remains an unsolved case in the eyes of many forensic experts and the general public. Within months of the 1963 assassination, and, in particular, after the release of the Warren Commission Report in September 1964, doubts began to emerge as to the veracity of some of the conclusions in the Report. The Commission's

findings concluded that Lee Harvey Oswald had acted alone in assassinating the President and assured the public that there had been no conspiracy.[1]

By the mid-1960s, several books and media articles raised legitimate questions regarding the lone assassin theory.[2,3,4] Following a high-profile investigation and trial led by New Orleans District Attorney Jim Garrison (1969) and several Congressional investigations related to the assassination, including the Rockefeller Commission (1974), the Church Committee hearings (1975-76), and the House Select Committee on Assassinations (HSCA, 1977-79), much new forensic evidence was brought to light. The last official verdict, released by the HSCA in 1979, concluded "on the basis of the evidence available, that President John F. Kennedy was probably assassinated as a result of a conspiracy."[5]

With the founding of the Assassination Archives and Research Center (1984) and the Coalition on Political Assassinations (1994), which served as national networks for serious researchers into the JFK (and other) political assassinations, and augmented by materials being obtained under the Freedom of Information Act (FOIA), a growing demand for the release of assassination records led to the creation and subsequent extension of the Assassination Records Review Board (AARB), which held the power to order Federal agencies to supply all materials considered to be Kennedy assassination records to the National Archives and Records Administration (NARA) by a specified date. During its tenure, the AARB oversaw the release of more than four million pages, the largest release of classified documents in U.S. history.[6]

The newly released AARB files provided JFK assassination researchers with a windfall of new forensic information, including pertinent medical, ballistics, photographic, acoustics, and trace evidence. This presentation will report and discuss much of that evidence, including X-ray images of the President's skull, bullet fragments recovered from the limousine, and the state-of-the-art digital replication of the Zapruder film original. A discussion focused on the ballistics evidence, which interconnects with the aforementioned forensic information, will be presented in a logical manner based on reliable factual evidence. The Hon. John Tunheim, Chairman of the Assassination Records Review Board, described the JFK assassination as "a giant jigsaw puzzle with a lot of missing pieces."[7] It is hoped that after hearing this presentation, attendees will be able to put some of those pieces back in the puzzle.

Ballistics, JFK Assassination, Forensic

A197 Assessing the Degree of Similarity Between Accidental Patterns on Shoeprints Associated With Wearers That Participate in Shared and Independent Activities

Manal R. Khalil, BS, 5323 Fox Cove Ln, Greensboro, NC 27407; Jacqueline A. Speir, PhD, 100 College Dr, Allentown, PA 18104; and Nicholas D. Petraco, PhD, John Jay College, 454 W 59th St, New York, NY 10019*

After attending this presentation, attendees will understand the degree of similarity between accidental characteristics based on the context in which footwear is used, how accidental characteristics change with wear over time, and how imaging science and semi-automated numerical methods can assist with comparisons.

This presentation will impact the forensic science community in many ways, from the determination of false positives and false negatives, assessing the divergence of an accidental pattern with continued wear, and gauging the reliability of using imaging science and semi-automated numerical methods to quantify the similarity in accidental patterns that vary with continued use and wearer-context.

The goal of this research is to address the similarity and change in correlation between accidental patterns that develop on the outsoles of shoes worn by individuals that participate in shared versus independent activities. To carry out this research, two groups of volunteers were solicited and provided with new/approved footwear. The first group was asked to wear the footwear while repeatedly participating in shared group activities over a seven-month period of time, while the second group was permitted to wear the approved footwear while carrying out daily independent activities. At predetermined step-intervals participants submitted their footwear for analysis, which consisted of the following data: (1) acquisition; (2) registration; (3) segmentation; (4) processing; and finally, (5) comparison. Steps 1 – 5 resulted in a 731-dimensional feature vector (per scan) that described the accidental pattern associated with each outsole. In total, 1,018 feature vectors were created, generating 34,218 pair-wise comparisons, wherein the similarity between each pattern was defined using the correlation metric. The pairwise comparisons generated six major probability density functions that describe the correlation of Known-Matches (KM), Known Non-Matches (KNM), and known-matches between feature vectors separated by continued wear.

Data analysis consisted of three phases. The first phase compared the density of similarity scores for known-matches across groups. In theory, this was a quality assurance measure since group-differences between known-matches was not anticipated. However, the results indicate that the correlation metric is sensitive to the total number and size of accidentals populating the feature vectors, which can be related to the physical size of the shoe, and the types of activities participated in while wearing the footwear. As such, it is reported that the differences in the correlation of KM comparisons across groups can be explained by the variation in shoe size, and the fact that the shared group performed restricted activities.

The second phase of data analysis compared the density of correlation scores for known-matches that differ with usage, in an effort to determine the degree to which continued wear decreases measured similarity. This question is of interest to the forensic community since exemplars worn for days or weeks after the commission of a crime may show loss and acquisition of accidentals not present on the questioned print deposited at the crime scene. The results of this study indicate that if willing to accept the chance of 1 false positive out of every 100 comparisons, then 0 miles of additional wear will lead to 99 out of 100 true positives. However, if the questioned and exemplar known-matches differ by just 10 miles of wear, the additional wear decreases the chance of obtaining a true positive to 23 in 50 for the shared group, and 43 in 50 for the independent group.

The third phase of data analysis compared the density of correlation scores for KNMs across groups. The goal was to determine if participation in a shared activity increases the similarity of accidental patterns on the outsoles of shoes worn by different individuals (and at

the extreme, a rise in the number of false positive associations). The results indicate that it is likely to encounter a negative correlation 58% of the time when comparing KNMs between individuals that participate in random activities, and 64% of the time when comparing KNMs between individuals that participate in shared activities. However, when a positive correlation is computed, it is more likely to be greater in magnitude for KNMs in the shared group.

Footwear, Shared Activity, Accidentals

A198 A 3D Imaging Device for Tire and Footwear Impressions

Ruwan E. Gamage, BSc, IUPUI, 723 W Michigan St, SL 280, Indianapolis, IN 46202; Abhishek Joshi, MS, 318 N West St, Apt 225, Indianapolis, IN 46202; and Jiang Yu Zheng, PhD, and Mihran Tuceryan, PhD, IUPUI, 723 W Michigan St, SL 280, Indianapolis, IN 46202*

After attending this presentation, attendees will see a description of a new prototype device to capture three-dimensional (3D) height images as well as two-dimensional (2D) color images of tire and footwear impressions.

This presentation will impact the forensic science community by introducing a new device and a new method for non-destructively capturing the details of impression evidence by producing high-resolution 3D depth images with metric measurements co-registered with high-resolution color images.

The anticipated manner of using this device will be to take the device to the field and scan impression evidence. The result of this is an HD video on an SD card that is then processed in the crime lab in order to generate the 3D impression image and the 2D color image of the evidence. The resulting 3D impression evidence can be used to match suspect footwear or tires. Through the use of automated matching algorithms that utilize the 3D impression image, a goodness-of-fit measure can also be calculated.

The design of the device is based on a class of methods known as "shape from structured light." It uses a camera/line laser assembly that can estimate the surface depth values along a single laser line in the image based on the deformations of the laser line caused by the surface shape. This results in a one-dimensional (1D) depth image in one frame of the video along the laser line. The depth image of the entire impression is generated by moving this camera/line laser assembly along a motorized rail at a precisely controlled and constant speed and estimating the depth values along successive laser lines. The desired 3D image of the impression is obtained by stacking these one-dimensional depth values along the axis aligned with the rail movement direction.

The camera used in the camera/laser assembly is a high definition (HD) video camera. Scanning of the surface consists of recording the video at 30 frames per second (fps) as the camera/laser assembly moves along the rail. This video is later processed in the crime lab to compute the impression depth image. The HD video camera is oriented such that the highest resolution of the camera image is perpendicular to the rail motion, thus increasing the resolution in this perpendicular direction. The image formation model along this direction is perspective projection. The resolution of the image along the rail motion depends on the speed with which the camera assembly is moved—the slower the motion, the higher the resolution of the depth image in this direction. Moreover, the image formation model in the direction of the rail movement is orthographic projection. This allows long span impression evidence such as tire track impressions to be scanned in a single attempt without the need to consider camera models and the necessity to stitch together multiple 2D images.

In order to obtain the proper metric scale of the impression evidence, a calibration object is placed next to the impression and this object is scanned as part of the data. This eliminates the need for pre-calibration of the system. Instead, the calibration object in the captured video and the object's true dimensions are used in order to compute the impression surface shape with true scale information.

The resulting device is portable, easy to use, is non-destructive of the evidence, saves time at crime scenes compared to current methods, and provides metric information about the surface shape. The device is designed to be able to digitize long tire track impressions (up to 1.75m) in a single scan without the need to capture multiple images and stitch them together. The 3D images produced by the device can have a resolution in depth of 1mm to 0.5mm, capturing fine details. The image resolution along the rail motion can be as little as 0.0438mm. The image resolution perpendicular to the rail motion at a distance of 500mm is about 0.2369mm. The basics of the design, how the device works, and some impression digitization results using it will be presented.

This project was supported by Award No. 2010-DN-BX-K145, awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication/program/exhibition are those of the author(s) and do not necessarily reflect those of the Department of Justice.

Impression Evidence, 3D Image, Depth Image

A199 Quantitative Algorithm for Digital Comparison of Torn Duct Tape

Jessica Mally, BS, and Frederic A. Tulleners, MA, UC Davis, Forensic Science Graduate Prog, 1909 Galileo Ct, Ste B, Davis, CA 9561; and William Ristenpart, PhD, UC Davis, Chemical Engineering & Materials Science, One Shields Ave, Davis, CA 95616*

After attending this presentation, attendees will understand some of the principles of objective, quantitative methods. These mathematical methods are currently in use by the academic engineering community, and can be applied to the area of physical matching in regards to duct tape examinations. The attendees will have greater appreciation for some of the complex tasks that can be conducted with modern digital imaging software.

This presentation will impact the forensic science community by establishing the first objective numerical methodology that can be successfully applied to physical matching of duct tape, its results meeting one of the key tenants of the NAS Report "*Strengthening Forensic Science in the United States: A Path Forward*."

The National Academy of Sciences (NAS) cited the need to establish the scientific basis demonstrating the validity of forensic science methods. In support of this, we have developed a quantitative algorithm for the digital comparison of torn and cut duct tape ends to evaluate their end match. This algorithm is programmed to perform a series of software routines that will result with each torn duct tape end profile displayed in a graphical format and then the profile of the torn duct tape end is compared to all the other duct tape specimens using residual analysis. The key idea of this research is that the true match will have a statistically significant lower sum of the squared residuals than all the other test specimens that do not match; the associated non-matching specimens will have much larger residual values. Having numerical results will enable us to derive meaningful statistical information that can describe significant differences between the matching and non-matching duct tape ends. This research involves the inter-comparison of samples from a set of 100 pairs of torn duct tape specimens. Inter-comparison of this set of 100 pairs resulted in 10,000 inter-comparisons. These torn duct tape specimens are also unique in that each of these specimens has been used in a previous statistical research study to look at end matches by four experienced Graduate Student Researchers (GSRs); these GSRs were required to inter-compare duct tape specimens as part of a training protocol. The GSRs had to identify those that matched and those that did not match within the set of 100 pairs of duct tape, which all four GSRs were able to do correctly. Using the quantitative mathematical algorithm, it is expected to provide numerical data correlating matching and non-matching specimens which can be related to the findings of the analyst. The end product of this research will be a quantitative and statistically rigorous guideline for end match comparison.

In this analysis, the left side of a torn tape specimen was called the "Exemplar" tape and it was compared to the right side of a torn tape specimen which was called the "Sample" tape. The procedure for

processing each tape specimen consists of a series of steps beginning with scanning the specimens into the computer at 1,200 DPI. Next, using MATLAB®, the North and South boundaries of each tape are selected, followed by defining the torn area of interest. The algorithm then performs a series of image manipulation and provides a graphical profile of the torn ends. Due to minute thread fragments extending from the tape that can interfere with residual analysis, the algorithm performs a series of extraction and dilation routines on the torn profile. The Exemplar profiles are then compared to the 100 Sample profiles in the database using residual analysis. The hypothesis is that the pair of tapes with the lowest residual value (in pixel^2 x 10^6) should be a matching pair in the set of 100 pairs of tapes. Research supported this hypothesis, in that a pair with the lowest residual values for the set was determined to be the matching pair. There are still many issues that could enhance future research in this area such as the "entropy of the torn specimen." The current algorithm treats each tear or cut in the same manner, but in reality a tape with a complex tear pattern is much more significant. This type of tape, because of its randomness, should be given a more unique residual value than a tape with a very simple tear pattern, even though the residual value for the two tapes could be similar. Although this development work used the engineering software MATLAB®, the end product will be an executable program that does not necessarily require the use of MATLAB®.

Duct Tape, Physical Matching, Image Analysis

A200 Taiwan Banknote Drug Contamination

Chun-Yu Chen, MS, and Frederick P. Smith, PhD, Univ of New Haven, Forensic Science Program, 300 Boston Post Rd, West Haven, CT 06516*

After attending this presentation, attendees will understand some potential forensic implications of banknote drug contamination focusing on specific results from the analyses of New Taiwan Dollar (NTD) banknotes, comparing these data with drug-use demographics and drug seizures in Taiwan, as well as published reports concerning currency from the U.S. and other countries.

This presentation will impact the forensic science community by furthering the understanding of external contamination issues, which may be germane to medico-legal investigators who evaluate the significance of drug test results in: (1) questioned deaths; (2) public health concerns/forensic epidemiology; (3) drug crimes; and, (4) drug-use toxicological tests where reliability is based on assumptions about external contamination, particularly when forensic investigators rely on examinations of surfaces in the workplace and elsewhere to interpret the significance of the presence of drugs on these surfaces.

New Taiwan dollars (n = 200, $100 denomination) were collected from five major metropolitan areas representing a geographical distribution within the Republic of China (Taipei, Taipei County, Tauyuan, Taichung City, and Kaohsiung), taking precautions to insure the integrity of collection procedures. From each general location, multiple bills were retrieved from actual transactions in commercial locations including outdoor markets near temples, food stands, betel nut outdoor stands, convenience stores, hotels (including in red-light district), fuel stations, private karaoke and movie booth rentals, entertainment, and gaming locations (slot machines).

Initial presumptive testing of banknotes was conducted using disposable Drugwipe II immunoassay devices (formerly Securetec, now Affiniton LLC) for the following classes of controlled substances/metabolites: cannabis, amphetamines, cocaine, and opiates. Further extraction followed for instrumental confirmation. Negative and positive controls were included as additional tests to exclude false-positive results from laboratory contamination. Deuterated internal standards (d_3-cocaine, d_5-amphetamine, d_5-methamphetamine, d_5-methylenedioxymethamphetamine, d_4-ketamine, d_3-morphine, and d_3-Δ^9-tetrahydrocannabinol) were added to the banknotes, and they were air dried. Analytes were removed from specimens using 10mL 0.1 N hydrochloric acid, and then separated using solid phase (SPE) columns, derivatized using pentafluoropropionic anhydride, and analyzed by ion trap CI-GC/MS.

When extracted and screened with Drugwipe II, a significant number of bills showed positive results for cannabis (69.6%), amphetamines (65.2%), opiates (26.1%), and cocaine (8.7%). Since Taiwan is an island-nation located on the edge of Southeast Asia and Northeast Asia, with a well-developed shipping system (both maritime and air transport) and extensive movement of goods within these regions and worldwide, there is ample opportunity for drug trafficking. The relationship between illicit drug seizures and drug-use demographics within Taiwan provide insight into NTD banknote analyses reported in this research. These data show quantities of controlled substances (ng/banknote) which exceed the limits of detection and limits of quantification for analyses of other external surface matrices such as hair (expressed in ng/mg) and sweat (expressed in ng/mL extract), as well as inanimate objects, for which there is no mandated standard practice or cutoff for reporting a surface as "positive" for a drug. These results suggest caution when ascribing drug use conclusions based on surface testing when contamination cannot be excluded.

Drugs, Contamination, Currency

A201 Statistical Comparison of Mass Spectral Data in the Identification of Amphetamine-Type Stimulants

Melissa A. Bodnar Willard, BS, and Victoria McGuffin, PhD, Michigan State Univ, Dept of Chemistry, 320 Chemistry Bldg, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State Univ, School of Criminal Justice, Forensic Science Program, East Lansing, MI 48824*

After attending this presentation, attendees will be familiar with a statistical procedure that has been developed for the comparison of mass spectral data.

This presentation will impact the forensic science community by providing a method to assign statistical confidence to the comparison of mass spectra. Specifically, application of the statistical procedure in the comparison of mass spectral data generated for standards and case samples containing amphetamine-type stimulants will be presented.

Gas chromatography-mass spectrometry is commonly used for the analysis of controlled substance samples. While this technique provides both retention time and mass spectral data for the comparison of the submitted sample to a suitable reference standard, the identification of amphetamine-type stimulants can be challenging. Firstly, since many of these compounds have the same phenethylamine base structure, the resulting mass spectra are very similar, especially in the lower mass region. Additionally, these compounds readily fragment under typical electron ionization conditions and, oftentimes, the molecular ion is not present in the spectrum, making identification based on molecular mass difficult. These challenges can be overcome by derivatizing the sample or by using alternative ionization procedures; however, both of these options increase the time necessary for sample analysis, which is not desirable in a forensic laboratory. As a result, amphetamine-type stimulants are typically analyzed in the underivatized form and under electron ionization conditions.

The resulting mass spectrum of the controlled substance in the submitted sample is then compared visually to the spectrum of a known reference standard, either analyzed by the laboratory or obtained from a mass spectral database. However, since the publication of the National Academy of Sciences Report in 2009, there has been a trend toward a more statistical evaluation of forensic evidence, which is not commonplace in controlled substance analysis and identification. The aim of this research was to develop a suitable procedure that provides such a statistical basis for the comparison of mass spectral data, thereby addressing the current limitations.

The developed procedure uses Student's t-tests and classical probability theory to compare two mass spectral fragmentation patterns. Briefly, the Student's t-test is used to compare the two spectra at every mass-to-charge ratio (m/z) in the scan range. The calculated t-statistic (t_{calc}) is then compared to the critical t-value (t_{crit}) at the required confidence level. If, at any m/z in the range, t_{calc} is greater than t_{crit}, then

the two spectra are considered to be statistically distinguishable. If t_{calc} is less than t_{crit} at all m/z, the two spectra are considered to be statistically indistinguishable. In these cases, classical probability theory is used to determine the random match probability, which is the probability that the spectral pattern occurs by chance.

In this presentation, the procedure is applied for the comparison of mass spectra of amphetamine-type stimulants. Spectra of case samples containing amphetamine, methamphetamine, 3,4-methylenedioxyamphetamine, 3,4-methylenedioxymethamphetamine, and phentermine were obtained from an accredited forensic laboratory and compared to spectra of appropriate reference standards. Each case sample spectrum was statistically associated to the corresponding reference standard at the 99.9% confidence level. Random match probabilities were also calculated and, in each case, the probability of the spectral pattern occurring by chance was infinitesimally small (e.g., 1.7×10^{-39} for the comparison of a case sample containing amphetamine to an amphetamine reference standard).

Mass spectra of the case samples were also compared to all other reference standards, using the same procedure. In general, statistical discrimination of the samples from unrelated standards was observed at the 99.9% confidence level, which is the most rigorous confidence level for discrimination. However, a case sample containing methamphetamine was discriminated from the phentermine reference standard at the slightly lower confidence level of 99.0%. These two substances have the same molecular mass and, since they are structural isomers, distinction of the two based on mass spectral data is challenging. Despite the similar fragmentation patterns, methamphetamine and phentermine were distinguished with high confidence.

While demonstrated for the comparison of controlled substances data, the statistical procedure developed can be readily applied to other types of forensic evidence in which the comparison of mass spectral data is necessary.

Mass Spectral Data, Statistics, Amphetamines

A202 Pharmaceutical Identifier Confirmation Via AccuTOF™ DART®

Jacob Easter, BS, 2020 Monument Ave, Apt 2, Richmond, VA 23220; and Robert Steiner, BS, Virginia Division of Forensic Sciences, 700 N 5th St, Richmond, VA 23219*

The goal of the presentation is to show how pharmaceutical identity can be confirmed using tablet physical identifiers and mass spectrum from an Accurate Mass Time-Of Flight Mass Spectrometer, coupled with the Direct Analysis In Real Time ion source (AccuTOF™ DART®).

This presentation will impact the forensic science community by using physical identifiers and the AccuTOF™ DART® to confirm pharmaceutical identity that will eliminate the use of GC/MS and effectively reduce analysis time. This will prove helpful in laboratories with large backlogs and will simplify the confirmation process.

Pharmaceutical tablets are analyzed in a forensic-controlled substances laboratory on a daily basis and comprise a large amount of the casework. The current method for identifying pharmaceuticals at the Virginia Department of Forensic Science (VaDFS) begins with physical identification, using sources such as Ident-A-Drug, The Drug Identification Bible, and RxID software. Thin Layer Chromatography (TLC) is then utilized to screen for the presumptive identity of the pharmaceutical. Alternatively, the AccuTOF™ DART® is utilized for pharmaceutical screening at DFS and is the most definitive screening test. Finally, the tablet is analyzed using a Gas Chromatograph and Mass Spectrometer (GC/MS) to confirm the identity.

The AccuTOF™ DART® is composed of an ambient ion source coupled with an accurate mass time-of flight mass analyzer. The ambient ion source allows samples to be analyzed at atmospheric pressure requiring minimal sample preparation without extraction. The sample molecule is protonated via the DART® and enters the TOF mass analyzer. The mass of the protonated molecule is accurate to ± 5.0 mDa with a much higher resolving power than the nominal mass produced in a quadrupole MS. Higher ion source voltages cause fragmentation through collision-induced dissociation (CID), producing a spectrum similar to an electron ionization source.

This project seeks to investigate the confirmation of pharmaceuticals using the AccuTOF™ DART® after preliminary identification through tablet and capsule markings. The Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) advises confirming the identity of pharmaceutical tablets through a Category B technique, such as physical identification, and a Category A technique, such as mass spectrometry. Differentiating between pharmaceuticals with the same molecular mass can be difficult when using the AccuTOF™ DART® because the same protonated molecule is produced. For example, codeine and hydrocodone have a molecular mass of 299 Da and will produce a protonated molecule with a mass of 300.160 Da on the AccuTOF™ DART®. By increasing the source voltage, unique ion fragments are expected to appear in the spectrum and will aid in distinguishing between drugs with identical protonated molecules. Cocaine and scopolamine have a molecular mass of 303 Da; when fragmented, cocaine will produce an ion with a mass of 182 Da and scopolamine will produce an ion with a mass of 138 Da. These unique fragments, along with others, differentiate cocaine and scopolamine. Reproducibility of spectra from one data file to another were experimentally determined and statistically evaluated to ensure accurate identification. For pharmaceuticals that do not have an obvious difference in ion fragments, Principal Components Analysis (PCA) was used for differentiation. PCA is a statistical analysis used to discriminate between similar data values. Linear Discriminant Analysis (LDA) was performed on the PCA plot to determine differences between data values. LDA models categorical data through linear combinations to determine differences. It provides an objective, measurable value to the PCA plot.

Results were obtained using DART® parameters of 275°C gas stream temperature, and Orifice one voltages of 30V and 90V. The 90V spectra provided different fragment ions and abundance values for pharmaceuticals with the same molecular mass, thus making it possible to differentiate between hydrocodone and codeine and, similarly, morphine and hydromorphone. A separate analysis was performed on the isomers of codeine: heterocodeine, hydrocodone, neopine, and pseudocodeine. All five were differentiated using PCA and LDA. Over 500 pharmaceutical tablets and capsules, collected from VaDFS casework, were analyzed and their pharmaceutical identifiers were accurately confirmed in this experiment. If the AccuTOF™ DART® spectrum identifies a different drug than what was indicated by the pharmaceutical identifiers, then the sample would be confirmed using the original analysis scheme with the use of GC/MS.

Using physical identifiers and the AccuTOF™ DART® to confirm pharmaceutical identity will eliminate the use of GC/MS and effectively reduce analysis time. This will prove helpful in laboratories with large backlogs and will simplify the confirmation process.

Pharmaceutical, DART®, Mass Spectrometry

A203 HPLC-UV Determination of Synthetic Cannabinoids in Herbal Products

Laura A. Ciolino, PhD, FDA, Forensic Chemistry Center, 6751 Steger Dr, Cincinnati, OH 45237*

After attending this presentation, attendees will learn about a validated HPLC-UV method for the determination of synthetic cannabinoids in various sample matrices including bulk plant materials and powders will be fully described. Suitability of the HPLC-UV method has been demonstrated for compounds representing several structural classes of synthetic cannabinoids, including the naphthoylindoles (JWH-018, JWH-073, JWH-200, AM-2201, JWH-122), cyclohexylphenols (CP 47,497 and CP 47, 497-C8 homolog), benzoylindoles (RCS-4), phenylacetylindoles (JWH-250), and others (HU210, UR144, XLR11). Quantitative results for a series of herbal product forensic samples will be presented.

This presentation will impact the forensic science community by providing the forensic chemist with an analytical method for determinating synthetic cannabinoids in herbal smoking products.

A validated HPLC-UV method for the determination of synthetic cannabinoids in various sample matrices including bulk plant materials and powders will be fully described. Suitability of the HPLC-UV method has been demonstrated for compounds representing several structural classes of synthetic cannabinoids, including the naphthoylindoles (JWH-018, JWH-073, JWH-200, AM-2201, JWH-122), cyclohexylphenols (CP 47,497 and CP 47, 497-C_8 homolog), benzoylindoles (RCS-4), phenylacetylindoles (JWH-250), and others (HU210, UR144, XLR11). Quantitative results for a series of herbal product forensic samples will be presented.

In 1990, it was discovered that a receptor found in brain cells mediates the CNS effects of Δ^9-tetrahydrocannabinol including mood and cognition, and this cannabinoid receptor was designated CB1.[1,2] In 1993, a second cannabinod receptor (CB2) was identified, with CB2 receptors being associated with immune cells and their modulation.[2,3] Over the last 20 years, hundreds of cannabinoids have been synthesized by various pharmaceutical or university scientists as part of drug development efforts or pharmacological studies involving CB1 and CB2 receptors. From a chemical standpoint, the synthetic cannabinoids comprise several structural classes including naphthoylindoles, cyclohexylphenols, benzoylindoles, phenylacetylindoles, and others.

Herbal smoking products with added synthetic cannabinoids have emerged as common substances of abuse within the last decade. The EMCDDA reported that sales of these products commenced in Europe during the years spanning 2004 – 2006, while CBP reported the first U.S. occurrence in 2008 as a formal import entry.[4,5] Reports from DEA and the UNODC have shown marked increases in the sales and abuse of cannabinoid-laced herbal products in the years which followed.[6,7] The products have been sold via the internet or specialty stores under a variety of names, among which "Spice" and "K2" are two well-known examples. The products are frequently labeled to contain "aromatic potpourri" or "incense," and consist of dried plant leaves loosely packaged in foil packs. Damiana leaf, marshmallow leaf, and mullein leaf are among the plant materials commonly used. Investigation into the product sources indicates that the cannabinoids are deposited onto plant surfaces via spraying, soaking, and/or mixing with cannabinoid solutions, after which the solvent(s) are evaporated. In July 2012, the FDA Safety and Innovation Act was signed into law, making several classes of cannabimimetic agents (with CB1 receptor activity) Schedule 1 substances in the US.[8]

In this work, an HPLC-UV method for determination of synthetic cannabinoids in bulk plant materials and powders was developed and validated. The method uses acetonitrile for extraction/dissolution, followed by separation on a commercial phenylhexyl stationary phase. UV detection provides excellent sensitivity with limits of detection (LODs) less than 10mg/g for many synthetic cannabinoids which possess highly conjugated chromophores. Spike/recovery studies demonstrate good to excellent recovery (75 -110%) for synthetic cannabinoids from damiana leaf, marshmallow leaf, and mullein leaf over a wide range of cannabinoid content (0.1 – 75mg/g). The method has been applied to a series of case-related herbal products with determined amounts ranging from <0.1mg/g to >100mg/g.

A204 Investigation Into Cyclohexanone as a Schiff-Base Derivatizing Agent for the Detection of Cathinones With Gas Chromatography/Mass Spectrometry

Brandi A. Skymba, MS, 162 E Phillips St, Coaldale, PA 18218; Matthew R. Wood, MS, Ocean County Sheriff's Dept, Forensic Science Laboratory, Toms River, NJ 08753; and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Dr, Allentown, PA 18104*

After attending this presentation, attendees will have a better understanding of the use of cyclohexanone as a derivatizing reagent for cathinone compounds.

This presentation will impact the forensic science community by providing a simple method for screening and identification of the target cathinone analogues in illicit samples using cyclohexanone as a Schiff-base derivatizing agent and Gas Chromatography-Mass Spectrometry (GC/MS).

*"*Bath salts*"* have recently become an illicit drug problem across the United States. Originating in the United Kingdom, *"*bath salts*"* have spread nationwide and are currently being classified as illegal substances of abuse by most states. Illicit drug suppliers are trying to circumvent the control of these substances by altering the structural arrangement of the compounds creating new analogues. As a result, forensic scientists are scrambling to develop methods to detect and identify these illicit substances. Consequently, cyclohexanone was investigated as a derivatizing reagent for the detection by GC/MS of thirteen structurally similar *β*-keto-phenethylamine compounds which have evidence of abuse. Cathinone, cathine (norpseudoephedrine), methcathinone (ephedrone), 4'-methylmethcathinone (mephedrone), 4'-fluoromethcathinone (flephedrone), dimethylcathinone (diethylpropion), ephedrine, pseudoephedrine, norephedrine (phenylpropanolamine), methylpseudoephedrine, N-ethylcathinone (ethcathinone), 4'-methoxymethcathinone (methedrone), and 3,4-methylenedioxymethcathinone (methylone) were all examined using GC/MS. Derivatization of the cathinones by cyclohexanone via Schiff-base formation was simple and proved to be an efficient method. Using this method, it is possible to achieve separation and identify many structurally similar cathinone-related compounds in mixtures.

A GC/MS method for screening or confirming 13 cathinone-related compounds using cyclohexanone as Schiff-base derivatizing reagent was developed. The method is capable of separating the 13 cathinone compounds tested with baseline resolution in less than 11 minutes. Primary and secondary amines will react with cyclohexanone via a Schiff-base reaction to form two distinct different types of derivatives. Tertiary amines, such as diethylpropion and methylpseudoephedrine, do not react with cyclohexanone to form a derivative and also do not interfere with the method. Cyclohexanone forms an imine derivative with primary amines and enamine derivatives with secondary amines. Cathinone forms both an imine and enamine when it is derivatized using cyclohexanone. Due to the presence of the *β*-hydroxyl functional group, ephedrine and pseudoephedrine (both being secondary amines) react with cyclohexanone to form oxazolidines. The reactions are all reproducible and show good chromatographic behavior on the gas chromatographic column stationary phase tested.

GC/MS data was acquired using a quadrupole Mass-Selective Detector (MSD). The gas chromatographic oven temperature

parameters were set with an initial temperature of 120 C which then increased 15 C/min to 250 C for a total run time of 10.67 minutes. The column used was a 30m x 0.25mm x 0.25µm phenylmethylsilicone capillary column (Rxi® -5Sil MS) using Helium as a carrier gas with a linear gas velocity of 38cm/sec. Methanol was used as the solvent and a sample volume of 1µL was injected in the split mode with a split ratio of 50:1. A retention time optimization study provided the most advantageous separation conditions.

Using cyclohexanone to form the Schiff-base derivative, a more complicated mass spectrum can be created and used to identify and differentiate similar cathinone compounds. The increased fragmentation also aids in providing more structural information about the compound. This method can be used to screen unknown samples and identify multiple cathinones in one sample.

Forensic Science, Forensic Chemistry, Cathinones

A205 A Retrospective Critical Evaluation of Statistical Techniques Utilized in Clandestine Drug Profiling

Sarah D. Sharratt, MMath, and, Beverley R. Vaughan, PhD, Anglia Ruskin Univ, East Rd, Cambridge, CB1 1PT, UNITED KINGDOM; and Michael D. Cole, PhD, Anglia Ruskin Univ, East Rd, Cambridge, CB6 2UD, UNITED KINGDOM*

After attending this presentation, attendees will recognize the need to consider which statistical techniques are appropriate prior to analysis being carried out and gain awareness of issues relating to some of the statistical methods previously used for drug profiling.

This presentation will impact the forensic science community by encouraging consideration of statistical approaches to data processing prior to analysis, identifying the appropriateness of statistical techniques currently utilized in drug profiling, and questions that need to be answered relating to some of these.

Selection of statistical methods for clandestine drug profiling is often not considered in detail prior to application and where consideration is made, the basis is frequently identification of common practice or testing a variety of approaches against known results. There needs to be reference to the underlying assumptions or distributional requirements when deciding upon the appropriate statistical technique.

Reliable, robust methods for identification of illicit compounds are essential to many involved in law enforcement. This process includes not only direct identification of the compounds but is also coupled with the determination of methods of manufacture and ability to associate seizures. Physical and chemical profiling of illicit drugs aims to establish whether or not there are links between seizures.[1,2,3]

A wide variety of statistical methods have been applied to both the physical and analytical measurements of illicit drug samples in attempts to establish similarity, or lack thereof, between samples.[1,5,6] Approaches to selection of the technique to utilize vary from “what everyone else does” to “what gives the best fit to what we know to be true.”

In fact, many statistical techniques are based upon assumptions relating to the data set being analyzed or rely upon properties of the data set to produce results. Yet these techniques are utilized without consideration of this in drug profiling.

The extent of evaluation of both analytical and statistical approaches varies by drug type — synthetic, semi-synthetic, or natural — and by drug. For synthetic drugs, there has been extensive research into drug profiling, including a harmonized analytical and statistical method for amphetamine profiling.[1] Research relating to semi-synthetic drugs (cocaine and heroin) is less abundant and, for natural drugs such as cannabis, is limited, as identified by Groger *et al.*[4]

This abstract presents a review of the statistical techniques which have been utilized in profiling of clandestine drugs from each of the synthetic, semi-synthetic, and natural drug groupings. The assumptions for each of the approaches followed are identified and evaluated in the context of current understanding of the properties of the drug profiles. Such consideration allows the identification of key issues in selection and evaluation of appropriate statistical methodologies across a wide range of illicit drugs.

For the first time, this research will critically evaluate the use of statistical methods within the context of drug comparison. Foreseeable impact of this is recognition of the need to consider which statistical techniques are appropriate prior to analysis being carried out. This will allow inferences to be correctly drawn by forensic scientists and law enforcement bodies when profiling clandestine drug seizures allowing appropriate and reliable both by the laboratories but also between laboratories and across borders.

Statistics, Drug, Profiling

A206 Development of a Surface-Enhanced Raman Spectroscopy Method for the Detection of Benzodiazepines in Urine

Erika L. Doctor, MS, and Bruce R. McCord, PhD, Florida Int’l Univ, Dept of Chemistry, University Park, Miami, FL 33199*

The goal of this presentation is to show the development of surface-enhanced Raman spectroscopy method for the analysis and detection of trace quantities of benzodiazepines in urine. The optimization of various parameters of this technique as well as the limits of this method will also be discussed.

This presentation will impact the forensic science community by providing information regarding Surface-enhanced Raman spectroscopy (SERS) method and how it has shown the applicability of SERS for the detection of trace quantities of benzodiazepines extracted from toxicological samples and the use of the technique over a wide range of compounds. SERS is more specific than currently used immunoassays as it provides spectral information for the compounds present. Also, this technique has higher sensitivity and permits detection of drugs such as lorazepam, which have poor cross reactivity when using standard immunoassays.

Benzodiazepines are medications for anti-anxiety and anti-depression that are commonly prescribed. These drugs are prominent in the commission of drug-facilitated sexual assaults due to their effects on the central nervous system such as drowsiness, amnesia, confusion, and impaired coordination. Due to their potency, a low dose of these compounds is often administered to victims; therefore, the target detection limit for these compounds in biological samples is 50ng/mL, which is well below therapeutic concentrations.

Surface-enhanced Raman spectroscopy (SERS) has previously been shown to detect trace quantities of compounds, such as nicotine, in aqueous solutions. This technique has the advantage of overcoming

the low sensitivity and quenching the unwanted fluorescence effects seen with conventional Raman spectroscopy. SERS spectra are obtained by applying a compound of interest onto a SERS-active metal substrate such as colloidal metal particles or metal films. In this case, the colloidal particles are spherical gold nanoparticles in aqueous solution. SERS signals can be further increased with the addition of aggregate solutions. These agents are salt solutions which cause the nanoparticles to amass and form hot-spots which increase the signal intensity. Chlorine salts generally provide the greatest enhancement for two reasons. The chlorine ions displace the stabilizing agent to cause aggregation and they affect the ionic strength of the surrounding solution, changing the surface charge of the substrate, therefore increasing the signal intensity.

Spiked urine samples were prepared by adding diluted benzodiazepine and metabolite samples (prepared in 10% methanol) to drug-free urine at a range of benzodiazepine concentrations (1ng/mL – 500ng/mL). A solid phase extraction method specific for benzodiazepines was used. Extraction efficiency was determined by quantitation using direct infusion mass spectrometry. Aqueous colloidal dispersions of gold spherical nanoparticles were prepared using a modified Lee Meisel 1% sodium citrate reduction method. Particle size and shape were confirmed with an average size of approximately 30nm. Previous work has shown that for benzodiazepines, an aggregate solution made of $MgCl_2$ prepared at a concentration of 1.67 M provided the highest signal intensity at the lowest drug concentration and was used in this study. Aggregate solutions were added to colloidal dispersions followed by the addition of extracted benzodiazepine samples and SERS spectra were obtained.

Overall this method allows for the detection of a wide variety of benzodiazepines and their metabolites. The presence of individualizing spectral peaks provides a high degree of specificity for sample determination. The technique is sensitive with a limit of detection of 2.5ng/mL and linear over several orders of magnitude for the drugs chosen.

This method has shown the applicability of SERS for the detection of trace quantities of benzodiazepines extracted from toxicological samples and the use of the technique over a wide range of compounds. SERS is more specific than currently used immunoassays as it provides spectral information for the compounds present. Also, this technique has higher sensitivity and permits detection of drugs such as lorazepam, which have poor cross reactivity when using standard immunoassays.

Benzodiazepin, SERS, Drug Analysis

A207 Extracting and Characterizing Cannabinoids From Cellusose Storage Cards – A Convenient Sampling Method for Marijuana Samples

Howard A. Harris, PhD, JD, Sean M. Pickett, and Ashli Ridolfi, BS, Univ of New Haven, Forensic Science Program, 300 Boston Post Rd, West Haven, CT 06516*

After attending this presentation, attendees will be aware that marijuana vegetable matter can be simply sampled by rubbing on cellulose collection cards, compact and stable for extended periods. Chemical constituents can be recovered from these cards and characterized using GC/MS.

This presentation will impact the forensic science community by affecting the way large marijuana submissions are stored, with cellulose storage cards providing reference samples that can yield useful comparative intellegence data even years after the initial sampling.

Cellulose-based cards are known to serve as compact and stable storage media for many types of biological fluids and plant samples. The utility of such storage has been demonstrated for *Cannabis sativa* by successful recovery and genotyping of DNA from plant material rubbed on such cards.[1] The sampling is done by rubbing the leafy material directly on the card and later recovery can be done by punching small plugs out of the stained cellulose sampling area. The study demonstrates that such plugs could also be used to look at the chemical constituents (cannabinoids) such as tetrahydrocannibinol (THC) that can be recovered from this type of storage. Recovery of THC would indicate that such samples came from material that had some drug potency and qualitative examination of other recoverable cannabis plant components might aid in comparing and sourcing of the sampled plant material.

The study initially concentrated on developing an efficient recovery scheme for cannabinoids from the storage cards. Several difference solvents including petroleum ether, petroleum ether/ethyl acetate, acetonitrile, dimethylformamide (DMF), and tetrahydrofuran were examined.[2] Cards supplied by the National Marijuana Initiative (NMI) of the High Intensity Drug Trafficking Authority were used.[3] These were cards that had been examined for DNA by Dr. Coyle and her students here at the University of New Haven.[1] An extraction scheme was developed that successfully recovered small amounts of cannabinoids from the cards.

Nineteen cards received from National Marijuana Initiative (NMI) that had been used to sample drug grade cannabis vegetable matter were first examined.[3] Peaks in the gas chromatograms at the retention times of THC and cannabinol were observed. These were also examined using Gas Chromatography/Mass Spectrometry (GC/MS) and the peaks were confirmed to be THC and cannabinol. The chromatographic programs on the two instruments were adjusted so that retention times were almost identical on each instrument. Cards sampled at Nebraska Wesleyan using local wild cannabis, assumed to be hemp type, were also tested.[4] These cards showed a significant peak, in most cases, at the retention time of cannabidiol. This peak was too weak to confirm in all cases but did show, in the majority, a mass spectrum consistent with cannabidiol.

It was found that Gas Chromatography (GC) of the card extracts provided chromatograms with better signal to noise ratio than the Total Ion (TI) chromatograms obtained on GC/MS. However, mass spectra that allowed identification of the primary cannabinoid peaks were obtained.

A Single-Ion Monitoring scheme that shows promise to extend the sensitivity of our GC/MS instrument for such samples was developed. This should allow identification of other naturally occurring cannabinoids, the presence of which should allow comparison of plant samples preserved on cards to gain some useful intelligence information. Because many of the samples were at or near detection limits, the researchers are also looking for ways to improve recovery or chromatographic behavior.

A208 2013 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott St, Vista, CA 92081*

After attending this presentation, attendees will be knowledgeable of SWGDRUG activities during 2012, including revisions to SWGDRUG recommendations, new supplemental documents, and other work products in development.

This presentation will impact the forensic science community by providing current recommendations, new developments, and future

projects and direction of SWGDRUG as it relates to the analysis of seized drugs.

The Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) was formed in 1997 in a joint effort between the U.S. Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). The mission of SWGDRUG is to recommend minimum standards for the forensic examination of seized drugs and to seek their international acceptance. This presentation will provide attendees with an update on SWGDRUG activities during the year 2012, including revisions to SWGDRUG recommendations, new Supplemental Documents, and other work products in development.

In January 2012, version 6 of the SWGDRUG Recommendations was current and available to the general public via the group's website (www.swgdrug.org). Currently, the SWGDRUG core committee is working on revising recommendations pertaining to the use of reference materials. Laboratories throughout the world are encountering difficulties obtaining and verifying new reference materials. These tasks have become more overwhelming with the appearance of new designer drugs like synthetic cannabinoids and bath salts. Revisions to the recommendations will include minimum procedures for the verification of these materials, as well as alternative guidance for when newly emerging materials are encountered and verification is limited to structural elucidation procedures.

In 2012, revised versions of the SWGDRUG mass spectral library were made available to the general community. Currently, the library contains more than 1,600 spectra, including many of the recently encountered synthetic cannabinoids, bath salt compounds, and their isomers. Laboratory analysts throughout the world can download this library from the SWGDRUG website and onto their laboratory instruments. Feedback from analysts and library users continues to be highly positive. The library will continue to be updated on a regular basis and contributions from the forensic community are strongly encouraged.

During 2012, the SWGDRUG core committee finalized Supplemental Document SD-4. This document provides three examples of measurement uncertainty calculations for purity determinations. A draft of the document was made available for public comments via the SWGDRUG website during July – September. Comments received from the public will be reviewed and addressed during the next core committee meeting (January 2013). This presentation will include a general summary and discussion of this supplemental document.

Also during 2012, the SWGDRUG core committee finalized, approved, and posted Supplemental Document SD-5. This document contains two examples of laboratory reports showing how minimum SWGDRUG recommendations can be fulfilled. The two report examples included in SD-5 will also be discussed during this presentation.

Presently, members of the SWGDRUG core committee are also working on the following projects:

- Online resource center for drug analysis training
- Assessing the current controlled substance analogue issue

The SWGDRUG core committee is comprised of representatives from federal, state, and local law enforcement agencies in the United States, Canada, Brazil, Great Britain, Germany, Austria, Switzerland, Australia, and Singapore. The following forensic organizations are represented: the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalistica y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC). Core committee members also include forensic science educators and representatives from forensic science organizations across the United States, the American Society of Crime Laboratory Directors (ASCLD), the American Society for Testing and Materials (ASTM), and the National Institute of Standards and Technology (NIST).

Criminalistics, SWGDRUG, Drug Analysis

A209 DART®-MS Collision Induced Dissociation (CID) for Structural Analysis of Synthetic Cannabinoids

Rabi Musah, PhD, 1400 Washington Ave, Albany, NY 12222; Robert B. Cody, PhD, 11 Dearborn Rd, Peabody, MA 01960; Marek Domin, MS, Boston College, 2609 Beacon St, Chestnut Hill, MA 02467; Ashton Lesiak, BS, 1400 Washington Ave, Albany, NY 12222; John Dane, PhD, 11 Dearborn Rd, Peabody, MA 01960; and Jason Shepard, PhD, 1400 Washington Ave, Albany, NY 12222*

After attending this presentation, attendees will understand ambient ionization mass spectrometry, basics on synthetic cannabinoid detection, and how to use fragments for structural identification.

This presentation will impact the forensic science commmunity by demonstrating a cutting-edge technique applied to a current problem, and how chemical analysis can be performed without any sample preparation, extraction, or derivatization that are often required for GC/MS and LC/MS analyses.

The emergence of numerous cannabinoid designer drugs has been tied to large spikes in emergency room visits and overdoses. Identifying these substances is difficult due to: (1) the fact that the compounds are novel, structurally related, and do not usually test positive in drug screens; (2) the rapidity with which they appear on the market; (3) the absence of standard protocols for their identification; and, (4) the customized and extensive sample preparation/extraction and analysis procedures required to demonstrate their presence. Direct Analysis in Real Time Mass Spectrometry (DART®-MS) is a technique that utilizes an atmospheric pressure ion source that produces a heated stream of metastable helium species directed at sample surfaces to vaporize and ionize liquids or desorb and ionize molecules from solid surfaces in open air under ambient conditions. Semi-volatile substances, like the cannabinoids mixed on the plant material, desorb from the leaf surface and are ionized. The metastable helium atoms initiate a cascade of ion-molecule reactions in ambient air to provide protonated water clusters as a chemical ionization reagent to produce parent ions, $[M+H]^+$, from the cannabinoid drugs.

DART®-MS provided high mass accuracy, to 0.0001 Da, establishing the presence of the cannabinoids JWH-122, JWH-203, JWH-210, RCS-4, and AM-2201, alone and as mixtures of at least two cannabinoids. Mass spectra were acquired by simply suspending a small portion of sample between the ion source and the mass spectrometer. The ability to test minute amounts of sample is a major advantage when limited amounts of evidentiary material are available. This method circumvents time-consuming sample extraction, derivatization, chromatographic, and other sample preparative steps required for analysis by more traditional methods. The high throughput capabilities of DART®-MS enable the active components of designer drugs to be detected more quickly, reducing the time necessary to triage analytical evidence. Therefore, exploitation of this method has the potential to contribute to more timely criminal prosecution. In addition, DART®-MS employing CID conditions provided confirmatory structural information that was useful in characterizing the various isobaric cannabinoid analogs.

Specifically, DART®-MS CID induces fragmentation of the protonated parent ions when the electrode voltage at the inlet orifice to the mass spectrometer is increased, demonstrating the utility of fragmentation patterns for distinguishing among closely related structures. The researchers used in-source CID to produce product ions corresponding to the synthetic cannabinoid molecules desorbed from dried leaves. CID analysis illustrated that closely related compounds are likely to fragment in a similar fashion, but their inherent structural differences will result in unique fragments that vary enough between the singular cannabinoids that can serve as a means to better identify each substance. Closely related compounds fragmented with both consensus peaks and unique fragments, such that both their structural similarities and differences provided multiple diagnostic peaks that permitted additional confidence toward identification of each substance. DART®-MS spectra were acquired to rapidly differentiate among

synthetic cannabinoids contained within "herbal" products purchased locally in New York (U.S.). The spectra exhibited the following parent ion peaks and product ion fragments unique to each cannabinoid that corresponded to major structural features: JWH-122 (*m/z* 356.1997, 298, 214, 169, 141), JWH-203 (*m/z* 340.1466, 342, 214, 127, 125), JWH-210 (*m/z* 370.2179, 312, 214, 183, 155), RCS-4 (*m/z* 322.1778, 164, 214, 186, 135), and AM-2201 (*m/z* 360.1757, 284, 232, 155, 127).

DART®-MS, Cannabinoids, Ambient Ionization

A210 Profiling Methylamphetamine Synthesized Using Precursors Extracted From Proprietary Cold Medication Through "Hypo and Moscow" Synthetic Routes Using Isotope Ratio Mass Spectroscopy (IRMS)

Saravana K. Jayaram, MSc, Dept of Chemistry Malaysia, Forensic Divison, Jalan Sultan, Petaling Jaya, 46661, MALAYSIA; Niamh Nic Daeid, PhD, Univ of Strathclyde, Centre for Forensic Science, 204 George St, Glasgow, G1 1XW, SCOTLAND; William J. Kerr, PhD, Univ of Strathclyde, Dept of Pure and Applied Chemistry, 204 George St, Glasgow, G1 1XW, SCOTLAND; and Wolfram Meier-Augenstein, PhD, and Helen Kemp, PhD, The James Hutton Institute, Invergowrie, Dundee, DD2 5DA, UNITED KINGDOM*

After attending this presentation, attendees will understand basic principles of isotope ratio mass spectrometry, and how it is used in the isotope profiling of methylamphetamine produced via two similar synthetic processes. Isotope ratio mass spectrometry provides an "isotope fingerprint" of a chemical molecule which may be useful in discriminating between precursor source for the methylamphetamine synthesized and this is explored in detail.

This presentation will impact the forensic science community by providing useful insight in the use statistical approach and isotopic analysis to discriminate between batches of methylamphetamine synthesized from pure grade materials and batches of methylamphetamine synthesized from precursors extracted from cold medication using different solvents and other pharmaceutical-grade essential chemicals, i.e., iodine tinctures, hydrogen peroxide. Two routes of synthesis were investigated in this research: (1) Moscow route; and, (2) Hypophosphorous route. These routes were chosen due to their popularity in clandestine synthesis of methylamphetamine. Other key catalyst such as red phosphorous was extracted from matchbooks and iodine crystals from iodine tinctures using hydrogen peroxide. Most of the methodology of the extraction of the precursor and extracting the essential chemicals were obtained from clandestine literature. This is to produce methylamphetamine as similar to the "street samples" as possible. The methamphetamine synthesized from the two routes was analysed by the Isotope Ratio Mass Spectrometry (IRMS).

This work exposes the variation in light stable isotopic values (C,H,N) derived from the analysis of methylamphetamine synthesized from two popular clandestine routes, the Hypophosphorous and Moscow routes. The final products were repetitively synthesised using precursors, catalysts, and reducing agents that were derived from household products and cold medications. *Pseudo*ephedrine was extracted using three different solvent systems, from Sudafed®, an over-the-counter cold medication widely available in the United Kingdom. Methylamphetamine was also prepared from laboratory grade *pseudo*ephedrine. Six repetitive batches of the final products were produced in each case to provide within and between batch variations and providing a total of 48 samples (24 for each route)

The isotope ratio mass spectrometry provides an "isotope fingerprint" of a chemical molecule which is useful in discriminating between batches, determining geographic origin, and manufacturing routes. The IRMS has received a considerable amount of attention in the forensic community over the last decade, which is also used extensively as an analytical tool in the natural and life sciences field. Isotope ratio mass spectrometry analysis (IRMS) is potentially useful in the comparison and discrimination of batches of methylamphetamine produced from the same precursor materials and different synthetic routes. There appears to be a significant effect encountered as a result of the precursor extracting solvent and, to our knowledge, this is the first time IRMS has been applied to articulate these differences. IRMS was used to specifically address the potential to link the methylamphetamine product to either of the synthetic routes (Moscow or Hypo) or to link the final product by precursor extraction solvent. The ability of IRMS to discriminate the inter and intra batch variation of methylamphetamine synthesized from both clandestine routes will also be discussed.

Methylamphetamine, Illicit Synthesis, IRMS

A211 Headspace-Gas Chromatographic-Mass Spectrometric (HS-GC/MS) Analysis of South American Commercial Solvents and Their Possible Use in the Illicit Conversion of Cocaine Base to Cocaine Hydrochloride

Jennifer R. Mallette, MS, and John F. Casale, BS, DEA, Special Testing and Research Laboratory, 22624 Dulles Summit Ct, Dulles, VA 20166*

After attending this presentation, attendees will understand the methodology utilized in the clandestine processing of cocaine hydrochloride, the solvent analysis of illicit cocaine hydrochloride samples, and the conclusions made concerning types and quantities of solvents used in processing of cocaine hydrochloride.

This presentation will impact the forensic science community by providing a method by which the amount of occluded solvents in the crystal matrix of cocaine hydrochloride may be used to establish the actual ratios or makeup of solvents utilized in illicit productions, and also indicate the diversion of commercial solvents in seized illicit cocaine hydrochloride samples.

Illicit cocaine hydrochloride is normally prepared by the addition of a water miscible solvent containing hydrochloric acid to a water immiscible solvent containing dissolved cocaine base. Cocaine hydrochloride quickly crystallizes from the mixture and is recovered via filtration. In general, this process is utilized by South American clandestine cocaine laboratories; however, there are unique variations in the solvents utilized.

The two types of organic solvents typically used for the production of cocaine hydrochloride are water immiscible solvents, referred to as "Solvent-A", and water miscible solvents, referred to as "Solvent-B." Both Solvent A and Solvent B can be either pure or a mixture of compatible solvents. The various solvents in the final (combined Solvents A and B) mixture are trapped within the matrix during cocaine hydrochloride crystal growth and are referred to as "occluded" solvents. The rapid precipitation of cocaine hydrochloride is favorable to the occlusion of organic solvents within the crystal matrix. In previous studies, a wide variety of occluded solvents have been observed in illicit cocaine hydrochloride samples. However, due to differential inclusion, the ratios of occluded solvents in cocaine hydrochloride do not necessarily represent the actual ratios of the solvent combinations that were used.

Over the past 30 years, the United States has imposed strict controls on chemicals in order to prevent or reduce the diversion of solvents to illicit drug production. Several South American countries have implemented similar controls on common chemicals utilized in the production of illicit drugs such as cocaine. However, some of these restricted solvents are still diverted for illegal practices. To date, there have been no studies to establish possible correlations between occluded solvents observed from illicit cocaine hydrochloride samples and commercially manufactured organic solvents in South America. The presented research attempts to determine if diversion of commercially manufactured organic solvents in South America for the clandestine production of cocaine hydrochloride is occurring and can be documented.

Thirty-five samples of commercial solvents were obtained from four chemical manufacturing companies in South America. Each sample was individually analyzed for its component makeup and quantitated

using static headspace-gas chromatography-mass spectrometry. After obtaining a chemical profile for each solvent, individual batches of cocaine hydrochloride were prepared from cocaine base using solvents or solvent mixtures that are frequently employed in clandestine laboratories. Solvents and/or solvent mixtures selected or prepared were similar to several of the commercial products. The cocaine hydrochloride produced in-house was analyzed to determine the correlations of occluded solvents before and after processing. Quantitative data corresponding to commercial solvents and the resulting cocaine hydrochloride will be presented.

Forensic Science, Cocaine, Occluded Solvents

A212 Identification of Cannabimimetrics and Cathinones by GC/EI-MS and LC/ESI/QTOF-MS

Yuriy Uvaydov, MS, DEA Northeast Laboratory, 99 Tenth Ave, Ste 721, New York, NY 10011*

After attending this presentation, attendees will learn how Liquid Chromatography Electrospray Ionization Quadrupole Time-Of-Flight Mass Spectrometry (LC/ESI/QTOF-MS) and Gas Chromatography Electron Impact Ionization Mass Spectrometry (GC/EI-MS) can be applied to the analysis of cannabimimetrics and cathinones that are currently found in "legal high" products.

This presentation will impact the forensic science community by emphasizing an analytical approach for identifying synthetic designer drugs using accurate mass determination along with EI fragmentation elucidation. The findings and methodology will provide forensic laboratories the ability to identify alternative means for detecting and identifying designer drug substances.

The use of illegal synthetic cannabinoids and cathinone derivatives has become popular in recent years. Many of these products are often marketed using labels such as "bath salts" and "herbal blends" and are packaged with a disclaimer that they are not for human consumption. Labels on the packaging do not often reflect the actual contents, misleading the consumers that the products are safe and legitimate. Consequently, these substances are increasingly popular as legal alternatives to illicit psychoactive substances for recreational drug users. The demand is further enhanced by their widespread and easy availability on the Internet and head shops across America.

The majority of cases encountered by forensic chemists are analyzed utilizing traditional methodologies such as GC/MS, GC/FID, FTIR-ATR, and LC/MS. Identification of unknowns has been largely dependent on mass spectral libraries from SWGDRUG, Cayman Chemical, and scientific discussion forums such as Forendex. Moreover, due to the vast variety of synthetic drugs, authenticated reference standards may not be easily available, thereby increasing analysis time and cost of unusual cases. The introduction for newer and efficient methodologies into the classical workflow is essential. The objective of this study is to demonstrate how synthetic substances (target or unknown) can be identified using accurate mass spectrometry analysis alongside with EI fragmentation elucidation.

Preliminary results of this study demonstrated that ESI/QTOF-MS software-based accurate mass determination provided highly specific mass-to-charge spectral data with accuracies spanning in the milli-Dalton range for parent and fragment ions. The method employs chromatographic separation using Zorbax Extend C18, 2.1mm x 50mm, 1.8um particle size stationary phase. TOF-MS full-scan spectra were acquired in positive mode over 50-1000 m/z scan range using reference masses m/z 121.0509 and 922.0098. Additional TOF-MS parameters were set as follows: fragmentor voltage at 150 V; capillary voltage at 4000 V; skimmer voltage at 65 V; nebulizer pressure at 50 psi; gas temperature at 350 C; and gas flow rate at 13 L/min. Collision-induced-dissociation (CID) of precursor ions were obtained in targeted MS/MS mode using a collision cell with nitrogen as a collision gas.

Applications presented will include the analysis of some of the emerging cannabimimetrics such as AM-1220, AM-2233, UR-144, and XLR-11. In addition, cathinone derivatives such as butylone, ethylone, pyrrolidinopropiophenones, and 4-methylbuphedrone will be discussed. The results showed that ESI/QTOF-MS can be used in complement with GC/MS to provide principal means of identification of designer cathinones and synthetic additives in herbal mixtures. By applying these techniques, forensic laboratories will have the ability to characterize designer synthetic drugs.

Cannabinoids, Cathinones, QTOF/MS

A213 Rapid Screening of Synthetic Cannabinoids With NMR and DART®-MS

Ling Huang, PhD, Michael A. Marino, BS, and Mercurio Veltri, PharmD, Hofstra Univ, Chemistry Dept, Hempstead, NY 11549; and Robert B. Cody, PhD, and John Dane, PhD, 11 Dearborn Rd, Peabody, MA 01960*

After attending this presentation, attendees will understand the fundamental principles of Direct Analysis At Real-Time Mass Spectrometry (DART®-MS) and Nuclear Magnetic Resonance (NMR) spectroscopy, specifically their applications for rapid detection of synthetic cannabinoids in herbal incenses. Attendees also will appreciate the power of combining two spectroscopic methods to promptly elucidate accurate structures of cannabinoids with no ambiguity.

This presentation will impact the forensic science community by introducing a combined spectroscopic approach to quickly solve the challenges in identifying synthetic cannabinoids and isomers found in herbal incenses or potpourri, also known as "spice" or "fake pot."

The recently-passed S.3187 included five classes of synthetic cannabinoids into Schedule I controlled substance list. It creates great challenges for forensic scientists to rapidly screen these "cannabimimetic agents" in numerous forms of herbal incenses due to the similarity of isomer or analog structures. Newer compounds are being synthesized promptly to circumvent the ban, which exacerbates the analytical difficulties for forensic labs, some of which are already experiencing backlogs.

Our hypothesis is to combine the rapid speed of DART®-MS with H1 NMR to rapidly screen and concretely confirm the identities of synthetic cannabinoids in herbal products with minimum sample preparation. The mass spectra provide molecular weights as well as fragment information. NMR spectra confirm the structure with no ambiguity. The whole process takes less than two hours. Novel isomers and analogs can be quickly identified and structures confirmed, sometimes without the presence of standards.

As suggested in previous literature, DART® is an atmospheric ionization technique that can be used to instantly ionize illicit drugs sprayed herbal base materials with no sample preparation. The limitation, however, is the difficulty of DART-MS to elucidate structural isomers. With the help of NMR, the isomeric or analog structures can be confirmed.

A commercially available high resolution DART®-TOF mass spectrometer system was used for the direct analysis of all samples. The DART® was operated in positive ion mode using helium gas at a gas heater temperature of 300° C. The powder samples were introduced into the DART® gas stream as a coating on the outside of a glass rod. For the herbal samples, three random pieces of plant material were selected from a given sample bag and then held in the DART® gas stream with forceps. The CAD experiments were done by varying the mass spectrometer cone voltage at 0.2sec intervals to induce fragmentation. For the NMR study, a simple methanol (3mL) extraction was employed to remove synthetic cannabinoids from 50mg of solid herbs, before paper filtration, solvent evaporation and redissolving in NMR solvent such as $CDCl_3$ or d-6 acetone. After one-hour H1 NMR scan, the chemical shift values from synthetic components were detected and used to confirm DART®-MS finding. The chemical shift values of signature peaks were analyzed to identify synthetic cannabinoids. Our study suggests that most signature peaks from naphthoyl and benzoyl indoles are in 7-8.5ppm or 4-4.2ppm ranges, which do not interfere with the herbal background signals from blank

herbal extracts. A flow chart was developed to quickly identify the cannabinoids based on their signature chemical shift values.

With the combination of DART®-MS and NMR, 30 herbal samples and seven powder samples from distributors were quickly screened for synthetic cannabinoids. Three of the powder samples were found to be mislabeled and the other three contaminated with other cannabinoid(s). Synthetic cannabinoids were found in all but one herbal incense. Among the herbal samples investigated, AM-2201, JWH-122, JWH-210, and RCS-4 were found to be the predominant ingredients.

In conclusion, accurate identification of synthetic cannabinoids in powder and herbal samples can be rapidly achieved with DART®-MS along with NMR confirmation. The simple NMR method can differentiate isomers such as JWH-019, JWH-180, and JWH-122. These combined spectroscopic methods can help forensic chemists to achieve accurate identification within two hours which increases the analytical throughput and helps to decrease sample backlog.

Cannabinoids, NMR, DART-MS

A214 Visualizing Depleted Latent Fingerprints Using Columnar Thin Films

Stephanie F. Williams, BS, 210 Market St, Sunbury, PA 17801; Robert Shaler, PhD, 30 Spring St, Flemington, NJ 08822; and Drew Pulsifer, MS, and Akhlesh Lakhtakia, PhD, Penn State Univ, 212 ESM Bldg, University Park, PA 16802*

After attending this presentation, attendees will have gained knowledge of the use of the Conformal-Evaporated-Film-By-Rotation (CEFR) technique to deposit Columnar Thin Films (CTFs) on depleted latent fingerprints for development and visualization. This study aims to determine the sensitivity of the CEFR development technique by developing fingerprints which have been successively placed in order to reduce the amount of sebaceous material left behind (i.e., as a depletion series). Comparison to traditional methods is made by using depletion series of split fingerprints on several different forensically relevant surfaces. The selected forensically relevant substrates are those which previous research has shown that traditional development techniques work as well or better than the CEFR development technique.

This presentation will impact the forensic science community by adding another option for latent fingerprint development in situations where the fingerprint quality is low and traditional development techniques are not adequate.

Determining the sensitivity of this fairly new development technique may impact the forensic science community by adding another option for latent fingerprint development in situations where the fingerprint quality is low and traditional development techniques are not adequate.

By the CEFR technique, a CTF is deposited onto a latent fingerprint on a substrate that is affixed to a rotating platform in a vacuum chamber. In the vacuum chamber, a source material is evaporated by resistive heating to produce a collimated vapor flux. The vapor condenses on the rapidly rotating substrate, thereby creating a thin film that entombs the fingerprint. This thin film comprises columns with diameters on the nanometer length scale. The CTF produces an observable contrast between the fingerprint ridge detail and the underlying substrate, and thus allows the fingerprint to be visualized by its surface topology rather than by mechanical or chemical interactions.

A study was carried out to determine the sensitivity of the CEFR technique by using depletion series. For each series, sebaceous secretions were collected on a pre-cleaned finger and then fingerprints were deposited without renewal of the sebaceous material on the finger. The second, fourth, sixth, eighth, tenth, and twelfth fingerprints were each placed on a substrate of the same kind. Each substrate was prepared for split fingerprints, with one half of the fingerprint being developed by the CEFR technique and the other half by a traditional technique. The substrates used were black nylon, white nylon, black ABS plastic, white ABS plastic, brass, and stainless steel. Based on previous research, the evaporant materials utilized were chalcogenide glass and tris(8-hydroquinolinato)aluminum (Alq3). Traditional techniques utilized were: red fluorescent powder, black powder, black magnetic powder, cyanoacrylate fuming, and cyanoblue with cyanoacrylate fuming.

The depletion series were obtained by wrapping the fingertip in a clear thin plastic wrap to eliminate the interference of eccrine secretions being produced from the pores in the friction ridge skin. In a preliminary study, the eccrine secretions caused some fingerprints deposited later in the depletion series to have more material than earlier depleted fingerprints. This caused the depletion series to be ineffective and inconsistent between different trials. The inconsistency was eliminated when the plastic wrap was used.

Results obtained were qualitatively and quantitatively, examined. Qualitatively, photographs of the developed fingerprints were visually graded, and quantitatively the photographs were examined using the Universal Latent Workstation (ULW). The fingerprints examined with the ULW were graded using a custom algorithm which calculates the amount of definitive minutiae in each fingerprint as determined by the quality map produced with the ULW's extended feature set. Depletion series on brass, developed with a CTF, were qualitatively and quantitatively superior to those developed by traditional techniques, but depletion series on hard plastics gave mixed results.

Further research is still being conducted with depletion series on other substrates and with other evaporant materials. The CEFR technique will also be compared with vacuum metal deposition using the split print method in the future. The CEFR technique is also currently being evaluated for the development of partial bloody fingerprints and fingerprints on fired cartridge casings. Other fluorescent evaporant materials are also being compared to Alq3.

This work was supported by Grant No. 2010-DN-BX-K232 from the U.S. Department of Justice.

Depleted Fingerprint, Conformal-Evaporated, Columnar Thin Film

A215 MALDI/TOF-MS for Chemical Analysis of Fingerprint Residues Using Conventional Fingerprint Development Methods

Kimberly Kaplan, PhD, Mark L. Miller, PhD, and Marc A. LeBeau, PhD, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will understand the benefit of measuring chemical information from fingerprint residue, and how image chemical information is obtained from latent fingerprint residue using conventional latent fingerprint development techniques coupled with Matrix-Assisted Laser Desorption Ionization/Time-Of-Flight Mass Spectrometry (MALDI/TOF-MS).

This presentation will impact the forensic science community by demonstrating the ability to extract measurable identifiable chemical markers detected in fingerprint residue with the potential to assist in forensic investigation.

Chemical information gained from analysis of latent fingerprints, "touch chemistry," at a crime scene might provide investigative or other forensically relevant information. Studies reported in the literature demonstrate the ability to gain intelligence information (smoker/nonsmoker, drug exposure, and ingested drugs of abuse) from chemicals recovered within fingerprint residue using MALDI/TOF-MS. One of the main challenges with fingerprint imaging is the ability to integrate MALDI/TOF-MS with current protocols used by latent fingerprint examiners. For this presentation, two experimental approaches are described for imaging latent fingerprint residue. For the first design, conventional methods used by latent fingerprint examiners will be evaluated as a way of visualizing a print and acting as the matrix for MALDI in order to ascertain chemical information that can be measured in fingerprint residue. For the second experimental design, a new method incorporating a MALDI matrix will be used to compare with conventional approaches.

For the experimental design, fingerprint residues were developed with powder, cyanoacrylate fumed or lifted. Control fingerprints included grooming the fingers by rubbing across the nose or neck to include sebaceous secretions. A second groomed print was deposited next to

the control print after handling powder from either an over-the-counter pharmaceutical or explosive. The prints were developed with black powder, black magnetic powder, black magnetic nanoparticle powder, black nanomagnetic powder, or cyanoacrylate fuming. The lift experiments followed the same procedure for depositing and developing latent prints on metal surfaces. An alternative method included using a MALDI matrix sprayer to deposit alpha-Cyano-4-Hydroxycinnaminic Acid (CHCA) on dusted, cyanoacrylate fumed, and lifted fingerprints.

Fingerprint images from direct deposition and lifts gave distinct differences between the control fingerprint and the fingerprint after handling the drug or explosive. Powders of trinitrotoluene (TNT) along with three pharmaceutical products (containing aspirin, acetaminophen, and ibuprofen) were used for the handling experiments and both positive and negative ionization mode was used to collect fingerprint images. The pharmaceuticals all formed $[M+Na]^+$ and $[M+K]^+$ adducts in positive ionization mode. TNT formed an $[M]^-$ for negative ionization mode. From the MALDI image of the handled powders, the detail of the fingerprint ridges were not observed but the distribution of the powders across the finger was shown. In order to view the ridge details of the fingerprint, target ions from the groomed fingerprints were extracted. For all fingerprints analyzed, some ridge detail was observed after development by either powder or cyanoacrylate prior to MALDI analysis. Fingerprints developed with powders used less laser power and provided less chemical interferences than cyanoacrylate fuming. The cyanoacrylate method worked well for detecting the handled compounds, but the remaining spectral chemical information from the fingerprint was from the cyanoacrylate polymer. Initial experiments using nanoparticle powder visually demonstrated greater detail of the fingerprint compared to conventional black magnetic powder. However, all powders demonstrated the ability to work as MALDI matrix in the handled experiments.

With the addition of the MALDI matrix, compounds of interest were more efficiently ionized at a lower laser power and enhanced signal to noise response for the handled pharmaceuticals and explosive. By incorporating CHCA into the fingerprint method, protonated or deprotonated ions were observed for acetaminophen, aspirin, ibuprofen, and TNT. Less sodium and potassium adducts were also observed, potentially allowing for structural MS/MS information to be obtained. The conventional and new methods both demonstrated the ability to obtain chemical information from fingerprint residues using MALDI/TOF-MS.

MALDI/TOF-MS, Fingerprint Residue, MALDI/TOF-MS Imaging

A216 Evaluation of Universal Latent Workstation for Automated Minutiae Detection

Patricia Herron, BS, Clayton State Univ, 2000 Clayton State Blvd, Morrow, GA 30260; and Henry Swofford, BS, and Garold Warner, BS, 4930 N 31st St, Forest Park, GA 30297*

After attending this presentation, attendees will understand that the minutiae in a single person's fingerprint will change from one deposit to another on similar and different substrates. They will also learn that computer software programs used to automatically extract minutiae in a fingerprint are not always accurate and their assigning of minutiae changes from impression to impression as well as by the positioning of the area of interest selection box.

This presentation will impact the forensic science community by demonstrating the ability of the universal latent workstation to automatically extract minutiae in two consecutively deposited fingerprint exemplars and two consecutively deposited latent fingerprints.

A fingerprint is made up of ridge paths that form minutiae points which a latent print examiner uses in comparisons and identifications. Some examiners use software programs in the evaluation phase before comparisons to find minutiae and judge latent print quality that can aid in reducing searching time. There are a number of vendors that sell latent print search software that can also extract latent print minutiae. However, these vendors all use different computer algorithms to assign search print minutiae which cannot be readily compared because of proprietary source codes. Unfortunately, these vendors sell to multiple agencies at the local, state, and national level. This presents a problem of scanning a fingerprint using one vendor's software and trying to find a potential match in another system. The Universal Latent Workstation (ULW) was developed by the Advanced Technology Unit, Criminal Justice Information Services (CJIS) Division of the FBI to aid in solving this problem. ULW is a program developed to identify and extract minutiae in fingerprints so the print can be encoded once and searched many times in a number of vendor systems. ULW uses an algorithm called MINDTCT which locates and records minutiae.

The purpose of this preliminary study is to determine what changes, if any, are detected by ULW when minutiae are auto extracted in two sequentially recorded inked prints and in two sequentially lifted controlled latent prints using black fingerprint powder. It is expected that there will be relatively high accuracy in auto extraction in both the sequential prints and that there will be a low number of incorrectly located and labeled minutiae with few artifacts; to wit: identified and plotted minutiae where none is present.

Several volunteers supplied record inked fingerprints, controlled latent prints, and actual latent fingerprints in the collection of a ground truth fingerprint sample set for another study. Only the right index finger, finger number two, was recorded 30 times on three standard fingerprint cards using black ink. The volunteers also provided latent prints on glass slides with both uncontrolled and controlled pressure. Another latent print was collected by adding one pound of lead sheeting to a beaker and having the volunteer momentarily lift the beaker from and return it to a countertop. Two sequential recorded inked prints were randomly chosen for this preliminary study as was a single controlled latent from a glass slide. The latent print was visualized using black fingerprint powder and lifted twice. The second lift was accomplished without the reapplication of powder. The inked and latent prints were cropped and scanned at 1000ppi.

It is expected that when latent fingerprint examiners comparing fingerprints from the same individual, even if they are on different substrates or if the print has been lifted multiple times, the same minutiae should be detected. However, for a software program like ULW, it will be expected that when those same fingerprints are encoded, there will be variability in the number of minutiae assigned depending on the quality, clarity, and contrast of the print as well as the number of times the print was lifted and where the area of interest selection box is positioned.

A217 Understanding the Concept of "Sufficiency" in Friction Ridge Examination

Cedric Neumann, PhD, Penn State Univ, Eberly College of Science, 107 Whitmore Lab, University Park, PA 16802; Christophe Champod, PhD, Univ of Lausanne, Batochime, Lausanne, 1015, SWITZERLAND; Mina Yoo, PhD, Penn State Univ, Eberly College of Science, 107 Whitmore Lab, University Park, PA 16802; Glenn M. Langenburg, MS, 1430 Maryland Ave E, St. Paul, MN 55106; and Thibault Genessay, MSc, Univ of Lausanne, Batochime, Lausanne, 1015, SWITZERLAND*

After attending this presentation, attendees will have a better appreciation of the type of information that latent print examiners use during their examinations; more specifically, how examiners use that information to form opinions on the source of latent prints, while also realizing the amount of variability that exists between multiple examiners observing the same set of prints.

This presentation will impact the forensic science community by providing data on the variance in the feature selection, and the way these features are used by examiners when forming opinions on the same set of prints.

The examination of friction ridge skin impressions relies on the observation and comparison of various friction ridge features, such as the general pattern of the ridge flow, minutiae, number and location of

ridge pores, and shape of ridge edges. The observation and comparison of such friction ridge features between skin impressions recovered on crime scenes and control prints from individuals enables latent print examiners to form opinion on the identity of their source.

Following the method formalized by David Ashbaugh, examiners generally claim to rely on: (1) the quality and quantity of friction ridge features in agreement; and, (2) the lack of significant differences between two skin impressions (usually a trace and a control impression) to form their opinion.[1] Pairs of impressions displaying *sufficient* features in agreement are deemed to be from the same source; pairs of impressions displaying *insufficient* information in agreement, but no significant discordances, are deemed to be inconclusive; finally, pairs of impressions displaying disaccording features are deemed to be from different sources.

Scientific and legal scholars regularly question the accuracy and reliability of this opinion-based process. In addition, the decision-making process lacks transparency in the sense that examiners cannot describe how the information observed on pairs of impressions is used to form their opinion. Overall, this has led some scholars to raise the possibility for examiners to be subjected to bias.

Recent research projects have aimed at measuring the accuracy of latent print examination and have reported error rates.[2,3] Other projects have resulted in models measuring the quality and quantity of information present in friction ridge skin.[4] Some of these models allow for the objective quantification of the weight of fingerprint evidence in casework. Data gathered during these projects have also been used to support the development of the new SWGFAST Standards for Examining Friction Ridge Impressions and Resulting Conclusions.[5] Nevertheless, the way examiners combine the quality and quantity of information to form their conclusions has only scarcely been investigated.

This particular project aimed at using the tools and results obtained from previous projects to investigate the use of friction ridge features during the very last stages of the decision-making process by latent print examiners. During this project, an online fingerprint comparison training system was used to gather data on the observations made on pairs of fingerprints and the subsequent decisions formed by examiners on the identity of their source. More specifically, approximately 100 examiners were tasked to: (1) compare a series of pairs of latent/control prints; (2) annotate the relevant friction ridge features (quality and quantity); (3) provide their personal evaluation of the quality and quantity of information; and, (4) report their final conclusions.

Several metrics were designed to measure examiners' consistency between the quality and quantity of their annotated features and the decisions made at various stages of the fingerprint examination process on the different test prints. This presentation will report the results of this study; more specifically, we will show the amount of variability within and between examiners when annotating the same set of prints and when forming conclusions on the identity of their source.

Latent Print, Sufficiency, Variability

A218 Evidence for Expertise in Fingerprint Identification and the Ramifications for the Future Study of Forensic Expertise

Matthew B. Thompson, BSc, 2511 Abbot Kinney Blvd, Apt 2, Venice, CA 90291; Jason M. Tangen, PhD, Univ of Queensland, School of Psychology, St. Lucia, 4072, AUSTRALIA; and Duncan J. McCarthy, BASc, Queensland Police Service, Forensic Services Branch, 200 Roma St, Brisbane, 4000, AUSTRALIA*

After attending this presentation, attendees will receive an overview of recent criticisms of forensic identification, be updated on the findings of and rationale behind recent studies of expertise in fingerprint identification, and understand the implications of these experiments for expert testimony and public policy.

This presentation will impact the forensic science community by providing a rationale for the design of recent experiments on forensic expertise and put the experimental results in context for the benefit of forensic researchers, examiners, managers, and policy makers.

Although fingerprint experts have presented evidence in criminal courts for more than a century, there have been few scientific investigations of the *human* capacity to discriminate these patterns. In 2009, the National Academy of Sciences (NAS) delivered a landmark report highlighting the absence of solid scientific methods and practices in the forensic science domain.[1] Harry T. Edwards (a senior U.S. judge and co-chair of the NAS Committee) noted that forensic science disciplines, including fingerprints, are typically not grounded in scientific methodology and forensic experts are not bound by solid practices that ensure that the forensic evidence that is offered in court is valid and reliable.[2] The NAS recommended that the U.S. Congress fund basic research to help the forensic community strengthen their field, develop valid and reliable measures of performance, and establish evidence-based standards for analyzing and reporting testimony.

Recently, researchers have investigated the effect of contextual bias on fingerprint examiners; some of the special abilities and vulnerabilities of fingerprint examiners; the effect of technology; statistical models of fingerprint identification; and the accuracy of fingerprint examiners' decisions. Despite this contribution, there are still few peer-reviewed studies directly examining the extent to which experts can correctly match fingerprints to one another, how competent and proficient fingerprint experts are, how and on what basis examiners make their decisions, and what factors affect matching accuracy. The "Identifying Fingerprint Expertise" experiment was designed to find out whether fingerprint experts were any more accurate at matching prints than the average person, and to get an idea of how often they make errors of the sort that could lead to a failure to identify a criminal compared to how often they make errors of the sort that could lead to inaccurate evidence being presented in court.[3] Results show that qualified, court-practicing fingerprint experts are exceedingly accurate (and more conservative) compared with novices, but they do make errors.

In this presentation, a rationale for the design of the experiment will be provided, as well as context for interpreting the results for the benefit of researchers, forensic examiners, forensic managers, lawyers, and judges. It will be argued that fidelity, generalizability, and control must be balanced in order to answer important research questions; that the proficiency and competence of fingerprint examiners is best determined when experiments include highly similar print pairs, in a signal detection paradigm, where the ground truth is known; that determining error rates with system-wide black box studies may be inefficient at best and unnecessary at worst; and that inferring from this experiment the statement, "the error rate of fingerprint identification is 0.68%" would be disingenuous.[4] In closing, the ramifications of these findings for the future study of forensic expertise, and the implications for expert testimony and public policy will be presented.

Fingerprints, Decision-Making, Expertise

A219 Results of the NIJ Motor Vehicle Theft DNA Demonstration Program Evaluation

Kelly A. Walsh, PhD, and John K. Roman, PhD, Justice Policy Center, Urban Institute, 2100 M St NW, Washington, DC 20037*

After attending this presentation, attendees will learn the impact of DNA evidence on criminal justice outcomes for motor vehicle theft investigations in two demonstration sites (Dallas and New York), while learning about the experimental design—a randomized controlled trial (RCT)—of forensic laboratory practices applied to actual criminal events.

This presentation will impact the forensic science community by presenting the results of methodologically-rigorous but relatively rare RCT evaluation that measured the impact DNA evidence had on the investigation and prosecution of motor vehicle theft, a common and costly property crime. The information presented will be of interest to laboratory, law enforcement, and court personnel from jurisdictions that are considering expanding the use of DNA evidence beyond serious person crimes and to all who are interested in how forensic science practices may impact criminal justice system outcomes.

DNA testing has been used to aid investigations and prosecutions of serious person crimes since the 1980s. Some jurisdictions have, either routinely or intermittently, extended this practice to property crimes and lesser offenses. In 2009, The National Institute of Justice (NIJ) commissioned a demonstration project to expand DNA evidence collection and testing to motor vehicle theft investigations in two cities: Dallas, TX, and New York, NY. Additionally, the research was funded to conduct an evaluation of this dual-site demonstration program. Using cost-effectiveness analysis, impact analysis, and outcome analysis, this evaluation tested the hypothesis that using DNA evidence to aid motor vehicle theft investigations is more efficient than traditional investigative practices.

Unlike items stolen during domestic or commercial burglaries, nearly 60% of stolen motor vehicles are actually recovered, thereby increasing the chances of obtaining the DNA of recent vehicle operators from surfaces or items in the recovered vehicle. Both of the demonstration sites identified approximately 500 motor vehicle cases where DNA evidence was collected. Researchers assigned those cases to treatment and control cohorts in equal numbers. Physical evidence from cases in the treatment group underwent DNA testing, while evidence in control cases was not tested until the business-as-usual investigation was concluded.

At the case-level, the study tested whether adding DNA to traditional investigative procedures results in more: suspects identified, cases closed with an arrest, cases accepted for prosecution and convictions. In addition, analyses were conducted at the sample-level to evaluate whether there are attributes of treatment group samples that are associated with better (or worse) case outcomes, conditional on DNA testing. This study is only the second RCT ever conducted that measures the impact of forensic evidence on criminal justice outcomes.

The first, completed in 2008, found that when DNA evidence was used to aid property crime investigations, law enforcement was twice as likely to make an arrest when compared to cases where the DNA evidence was not tested. Since motor vehicle theft was excluded from that work, this experiment was a natural next step in testing the cost effectiveness of using DNA to aid criminal investigations of property crimes.

DNA, RCT, Vehicle Theft

A220 Touch DNA on Shell Casing and Cartridges: A Case Study

Nasir A. Butt, PhD, OCME, 11001 Cedar Ave, Cleveland, OH 44106*

After attending this presentation, attendees will learn the importance of DNA analysis on shell casings and live cartridges found on crime scenes, these discoveries ultimately helping to identify the shooter.

This presentation will impact the forensic science community by encouraging the use of touch DNA from shell casings as a link between the crime and the perpetrator since touch DNA can withstand the firing heat released during the discharge of a gun and, with the present PCR technology, can be helpful in solving the crimes.

This presentation will reflect the importance of DNA analysis on shell casings and live cartridges found at crime scenes. Touch DNA found on a shell casing and live cartridge at a robbery of a gas station that resulted in a homicide and the touch DNA on a live cartridge and a gun on a robbery of a dollar store helped identify the shooter.

This case study reflects that the epithelial cells or touch DNA can withstand the firing heat released during the discharge of a gun and, with the present PCR technology, can be helpful in solving the crimes. Firearms are commonly used in a majority of violent crimes. Shell casings at the crime scene are sometimes the only evidence available for the investigation. These shell casings and/or live cartridges are often sent for the analysis of latent prints with almost no success. The chances of losing any touch DNA present on this type of evidence increases when the recovery and collection of touch DNA is delayed. Various studies have shown that the heat released during the discharge of a weapon has very limited effect on the DNA.

In December 2007, an armed robbery of a gas station resulted in the murder of the owner of the business. The police recovered from the scene a 9mm live cartridge and a 9mm shell casing. The only bullet entered the victim's chest and exited his back. The shell casing and the live cartridge were brought to the laboratory for the analysis. The shell casing and live cartridge were swabbed for the analysis of touch DNA. DNA was extracted on the whole swab from each using Organic extraction methods. The extracted DNA was quantified using Quantifiler® human quantification kit using an RT-PCR instrument. Furthermore, the DNA was amplified using an ABI Identifiler® kit. The amplified DNA was loaded onto an genetic analyzer for the detection of the DNA fragments. Fragment analysis was performed using ID software. The STR DNA profiles were developed from the shell casing and the live cartridge.

In January 2008, case detectives submitted two guns and live cartridges from another robbery which took place at a dollar store. Two suspects were developed in this robbery and their buccal swab samples were submitted for analysis. The DNA found on the firearm and the cartridge was consistent with the DNA found on the shell casing and the live cartridge recovered from the December 2007 robbery and homicide scene. The STR DNA profile was consistent with one of the suspects who was later found guilty of both crimes.

The firearm examination and test firing revealed that the cartridge casing recovered from the robbery of gas station was fired from the 9mm gun submitted from the robbery of the dollar store.

The analysis of touch DNA on the shell casings and live cartridges recovered at crime scenes can thus provide a link between the crime, suspect and/ or victim, which might sometimes be the only evidence in a case.

Touch DNA, Shell Casing, STR DNA Analysis

A221 Inter-Agency Collaboration Combating Child Sexual Abuse in Zambia: Focus on Training and the Development of a Forensic DNA Laboratory

Laura D. Silva, MS, Oakland Police Department, Criminalistics Division, 455 7th St, 6th Fl, Oakland, CA 94607; Charles Clemons, MD, Georgian Foundation, 1361 Corte Loma, Walnut Creek, CA 94598; Shota Shubladze, MS, MPA, Georgian Foundation, 1361 Corte Loma, Walnut Creek, CA 94598; and Cristian J. Orrego, PhD, Univ of California, Human Rights Center, 2850 Telegraph Ave, Ste 500, Berkeley, CA 94705*

After attending this presentation, attendees will learn about the implementation and experiences of international multi-disciplinary collaborations and training to combat child sexual abuse with a focus on forensic DNA analysis, specifically on a developed and ongoing NGO fellowship training program, and share experiences of international professional exchanges between the U.S. and Zambia

This presentation will impact the forensic community by sharing the knowledge of international collaboration involving forensic science as one part of a multi-disciplinary approach to the complicated problem of stopping child sexual assault. It may help attendees start or improve their own forensic science related collaborations.

Georgian Foundation* and the Zambian Society for Child Protection** (both non-governmental organizations) have initiated a child centered multi-disciplinary program with the goal of assisting local communities in Zambia with the response to allegations of child abuse in ways that focus on the child victims. One objective is to create an effective system of inter-agency collaboration to respond to the numerous child sexual assault cases in and around Lusaka, the capital of Zambia. The program includes training in child advocacy, forensic and clinical medical examinations, police operations, forensic DNA analysis, and judicial prosecution.

To that end, an Experience Exchange Fellowship Program was created and is currently being coordinated and developed with participation of Zambian professionals across multiple disciplines. The Fellowship Program will enable healthcare, forensic, and police professionals from the Republic of Zambia to engage in practical specialty training programs in California and Utah. Police officials from Zambia have already had productive meetings and observational tours with law enforcement and forensic laboratories in the U.S. as well as attending a regional forensic science meeting in California. They also met with a District Attorney's Office prosecutor that manages investigation and prosecution of child sexual assault cases. Medical professionals from the United States with expertise in child protection have traveled to Zambia to assist with education and training of Zambian staff at the One Stop Center, a center for diagnosis and treatment of child sexual assault at the University Teaching Hospital in Lusaka.

In collaboration with the Center for Disease Control (CDC) and the University Teaching Hospital in Lusaka, the Fellowship Program will provide more intensive hands-on training experience for Zambian forensic science, police, and medical professionals. This phase of the training by forensic science professionals will include a thorough and documented forensic DNA analysis component that is expected to enhance the capacity of the participants to more effectively manage and coordinate interagency response in child sexual assault cases.

In addition to the Experience Exchange Fellowship Program, a main goal of the organization is to collaborate and support the Zambian government in establishing a forensic DNA laboratory in-country to facilitate prosecution in sexual assault cases. In the first steps toward this goal, medical and forensic science professionals from the United States have traveled to Zambia for strategic collaboration and planning with Zambian government officials.

Ultimately, the goal of the organization is to facilitate the development of an interagency working group including medical, police, forensic, and legal experts to strengthen the child sexual abuse response system in Zambia, thus reducing and preventing child sexual abuse and further transmission of HIV and AIDS.

*Georgian Foundation 501(c) 3 is an international organization registered in California, United States.

**Zambian Society for Child Protection (ZSCP) is a registered non-governmental organization founded by the Georgian Foundation.

Forensic DNA Lab, International Collaboration, Child Sexual Abuse

A222 Identification of Missing Mexican Nationals Along the U.S. — Mexico Border

Edwin F. Huffine, MS, Michael Cariola, MFS, Jon Davoren, MS, Ronald Lai, MFS, and Amy M. Jeanguenat, MFS, Bode Technology Group, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

The goal of this presentation is to educate the forensic science community on collaboration efforts between private and public industries in the United States and Mexican authorities to identify missing migrants that have crossed the U.S. – Mexico border.

This presentation will impact the forensic science community by outlining a system of identification efforts involving communication with several entities to effectively provide closure to family members who are missing loved ones. The attendees will gain knowledge of the scope of missing migrants from Mexico believed to have perished in the U.S. and how relationships can be formed to aid in identification efforts in both the U.S. and worldwide.

Each year migrants from Mexico, as well as other parts of Central America, attempt to enter the U.S. by crossing the U.S. – Mexico border and traveling across the southwestern desert areas of the U.S. Many migrants die in the desert areas during this journey due to exposure to the elements and exhaustion, and their bodies are recovered by U.S. authorities. There are numerous reasons why these bodies are not identified and why there is a need for forensic DNA testing to confirm suspected identifications. An international system has been created in recent years to aid in the identification of the missing and to have their remains repatriated to their families in their native countries. As a vendor laboratory, Bode Technology (the laboratory) has been part of this international effort, in collaboration with both U.S. and Mexican authorities, to identify missing Mexican nationals whose bodies have been recovered in the desert southwestern areas of the United States.

Up to several hundred Mexican nationals perish in the desert southwestern areas of the U.S., with most of these deaths occurring in Arizona as well as some in other states. The Mexican Foreign Ministry has taken a high interest in the identification of missing Mexican nationals and has been working with U.S. officials to aid in their identification. Most of the recovered bodies are kept at the Pima County, Arizona, mortuary facility where skeletal cuttings are collected and sent to the laboratory for forensic DNA testing. The Mexican Foreign Ministry works primarily with U.S. consulates, especially the Mexican Consulate in Tucson, Arizona. They contact family members who are missing loved ones where the families believe the individual attempted to enter the U.S., and arrange for the collection of relevant family DNA reference samples. The family reference samples are then provided to the laboratory for testing and comparison to the DNA profiles from the skeletal remains to determine if a familial relationship exists. If a familial relationship is identified, a DNA match report is generated and sent to the Consulate.

There has been a great deal of success and experience in the DNA analysis of skeletal remains, and over the years special techniques have been developed to troubleshoot these challenging samples. The DNA testing typically performed is a standard forensic test that analyzes 15 nuclear STR loci and a gender-determining marker. To date, close to 400 skeletal samples and 200 family references have been tested, resulting in more than 80 identifications from the country of Mexico. The success rate in obtaining suitable STR DNA profiles from the skeletal remains has been more than 80%. On a few occasions, additional DNA testing, such as Y-STR and mini-STR testing, was required, usually due to limited availability of family references. After the DNA profiles are obtained, they are entered into a computer software program in order to calculate kinship statistics. In the cases where a potential familial

relationship was identified, the statistical calculations have generally yielded probabilities of family relationships of more than 99.95%, thus providing a high degree of confidence. This has been a highly successful system that is ongoing and is an example of how cross-border inter-governmental cooperation with private DNA providers can lead to closure for hundreds of family members.

Missing Persons, Human Identification, US-Mexico Border

A223 It's the Right Thing to Do — Virginia's Ground-Breaking Post-Conviction Program

Lisa C. Schiermeier-Wood, MS, Dept of Forensic Science, 700 N 5th St, Richmond, VA 23219; and Shelley Edler, MS, 700 N 5th St, Richmond, VA 23219*

After attending this presentation, attendees will gain an appreciation for the logistics involved in identifying, analyzing, and reporting more than 750 post-conviction cases that involved 30-40 year-old cases in which original evidence was unavailable, existing samples were compromised, case information was incomplete, and DNA results were challenging.

This presentation will imact the forensic science community discussing Virginia's ground-breaking efforts to establish a program to inventory, test, and report on evidence in hundreds of post-conviction cases that were 30-40 years old.

In Virginia in the 1970s, an unorthodox habit believed to supplement testimony with demonstrative displays had a tremendous impact on the disposition of a number of these cases 30 to 40 years later. Despite the practice of local law enforcement agencies at that time to destroy evidence and case files for unsolved and adjudicated cases, a lead scientist at the agency and her trainees taped the swabs, cuttings, and threads used in conventional serological techniques into the corresponding worksheets for the case.

These worksheets became part of the respective case file and were kept at the facilities until they were sent to the Library of Virginia State Records Center. These documented transfers took place between the Department's custodian of records and a Records Center storage technician. It was at this point that the files were accessioned into the Library and kept in a documented location with limited entry, thus creating a chain of custody on the worksheets.

It wasn't until 1999, when a prosecutor conducted a routine inquiry for any remaining evidence retained at the Department in a particular case, that administrators saw these substrates taped into worksheets and considered them "evidence." Given that this was the only evidence remaining for the case in which the convicted offender requested DNA testing to prove his innocence, DNA polymerase chain reaction (PCR) testing was conducted using short tandem repeats (STRs) and not only demonstrated that the offender was not the source of the sexual assault evidence, but the DNA evidential profile was searched in the Virginia DNA Data Bank and a "hit" was obtained. Since there is no statute of limitations on rape in Virginia, these particular DNA results took on two roles: to support the innocence of the convicted individual, and to investigate and eventually prosecute the newly identified suspect.

Due to the success of subjecting this "taped-down" evidence to current DNA PCR techniques, then-Governor Mark Warner ordered testing in 31 sexual assault cases. The moderate success of obtaining DNA profiles from these previously compromised samples resulting in additional eliminations, some of which resulted in full pardons, led to the Governor's order in 2006 to test all appropriate cases between 1973 and 1988. In 1988, with the advent of blood-borne pathogens and accreditation, the "tape-down" practice ended. Of the 530,000 case files generated in the Department by all disciplines during that time span, over 2,100 were found to contain biological evidence taped into the case files. In order to be able to track these files created prior to the computer era, a database was created which could be updated as cases were identified, original case dispositions were determined, evidence was tested, and results were reported.

This was the beginning of a ground-breaking post-conviction testing program for Virginia. Six years into the project, over 750 cases in which convictions could be confirmed have been analyzed and countless hours have been spent by a core group of scientists and administrators who agree with Governor Warner that "a look back at these retained case files is the only morally acceptable course, and what truth they can bring only bolsters confidence in our system."

The scope of this unique project with the challenges accompanying it was unprecedented. Case files lacked essential details usually provided in current cases and were not available through the submitting agency; in fact, given the dates of these cases, the majority of the original law enforcement officials had since retired. Samples consisting of threads, swabs, or cuttings previously subjected to multiple saline washes as part of ABO blood and secretion testing resulted in partial DNA profiles (or no DNA profiles). The level of interpretation difficulty increased due to both the absence of associated known sample(s) and the lack of DNA results developed from those which were preserved. These challenges, in addition to a case study demonstrating the obstacles encountered by both scientists and prosecutors when preparing a post-conviction case for prosecution of a newly-identified suspect, will be discussed.

DNA, Post-Conviction, Virginia

A224 A Decade of Research on the Genetic Identification of the Manufacturers of Improvised Explosive Devices

David R. Foran, PhD, Michigan St Univ, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will become familiar with the large amount of research that has been conducted at Michigan State University during the past ten years on post-deflagration genetic identification of individuals who manufacture IEDs, including tests of the device itself, trigger components, and containers used to conceal the device.

This presentation will impact the forensic science community by presenting an overview of the large amount of DNA-based research that has been conducted in a laboratory on identifying those who make IEDs. Both nuclear and mitochondrial DNA testing from deflagrated pipe bombs will be covered, as will post-blast testing of items associated with IEDs, including trigger components and packaging. The presentation will summarize the most effective methodologies for isolating and analyzing DNA from this type of forensic evidence.

Improvised explosive devices have become an integral weapon for terrorists, both inside and outside the United States. IEDs are generally simple to manufacture and conceal, often being made from components easily obtained from hardware and sporting good stores, and hidden in bags or backpacks. During the blast, much of the potential forensic evidence is destroyed, including fingerprints, thus only class evidence is usually recovered, such as the type of explosive used and the hardware of the device. This evidence may have value if its origin can be traced to a specific location (e.g., a store where it was purchased), but, in general, it does not lead to the identification of the perpetrator.

For the past decade, forensic biologists at Michigan State University, in collaboration with the Michigan State Police Bomb Squad, have studied genetic methods for identifying manufacturers of IEDs, based on the premise that even if fingerprints are destroyed on a deflagrated device, enough residual cellular material may remain that an identification is possible. The first such study used standard forensic DNA techniques on pipe bomb fragments and resulted in a few alleles consistent with an assembler. MtDNA was next tested, and produced a much higher rate of identification, based on a closed population of individuals. New assays of deflagrated IEDs, including both NIST-produced and commercial miniSTRs, showed greater sensitivity than did standard STRs. The methods for retrieving DNA from deflagrated IEDs, which can be fragmented into thousands of small pieces, were assessed by comparing swabbing and soaking both deflagrated PVC and steel bombs. Similarly, positive and negative influences of cyanoacrylate fuming IED fragments were examined.

Materials associated with IEDs have also been extensively tested, based on the idea that these may be handled longer than the device itself, and are more detached from the device, so they might maintain cells/DNA better. Mock electronic triggers made up of a communication device (cell phone or walkie-talkie), battery, circuit board, and wiring, were placed adjacent to IEDs during deflagration, and the components was assayed using miniSTRs. Genetic data from each individual component were analyzed, as were data from all components *in toto*.

Likewise, IED containers were tested post-deflagration. Backpacks were used for several days, then bombs were placed inside and deflagrated. Multiple regions recovered from a backpack (e.g., zippers, straps, canvas) were tested via miniSTRs, and individual and combined results were used to identify a wearer.

The ability to analyze STR data solely or in combination with other data from the same object (e.g., components of a triggering device or parts of a backpack) helped differentiate "consensus profiles" from those that might contain rare drop-in alleles or mixtures. In most instances, consensus profiling resulted in far more accurate data for the IED/component handler than did STR results from individual objects.

Altogether, it is clear that genetic evidence can be obtained from deflagrated IEDs and the components associated with those weapons. However, such testing, while very sensitive, is dominated by low copy number and highly degraded DNA. As such, it can potentially be lost or compromised during evidence collection and processing, is susceptible to external contamination, and is affected by methods of DNA isolation, testing, and data analysis.

DNA, IED, Touch DNA

B1 A Forensic Comparison of NTFS and FAT32 File Systems

Kelsey L. Rusbarsky, MS, 2007 7th Ave, Apt 815, Huntington, WV 25703; Cynthia Smith, MS, 4150 N. Mulberry Dr, Ste 250, Kansas City, MO 64116-1696; and Joshua L. Brunty, MS, and Terry Fenger, PhD, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will: (1) understand the fundamental differences between the New Technology File System (NTFS) and the file allocation table 32-bit file system (FAT32); (2) gain an understanding of basic digital forensic knowledge of these file systems and the complications and advantages of each.

This presentation will impact the forensic science community by recognizing the importance of understanding the foundation of a science before anything more can be studied, stressing that the organization and processes of file systems must be understood. This research works to bring foundational data into one coherent discussion so that one can accurately assess advantages and disadvantages of specific file system forensic analysis.

The file system in any storage device is essential to the overall organization, storage mechanisms, and data control of the device. A file system can be thought of as an index in a book, where the book can be broken down into sections and chapters. Without this breakdown of sections and chapters in a book, it would be harder to find the information that is being searched for.

The same principles apply to file systems on a computer or storage device.[1] File systems utilize hierarchical structures to organize files and file directories into useable formats. This formatting is accomplished through the use of clusters, sectors, and data entries located on a hard disk. Within data entries are located metadata files, which store user and application data about file dates and times, length, file size, file names, and more.[2] Knowing how these file systems work and the layout of key structures, storage mechanisms, associated metadata, and file system characteristics is essential to being able to forensically investigate a computer or other device.

The focus of this research is to differentiate and compare the two file systems, New Technology File System (NTFS) and File Allocation Table (FAT32), in eight areas. The eight areas are: key structures, storage mechanisms, file names, directories, file date and time, file deletion, encryption, and forensic implications.

NTFS is a newer file system, beginning with Windows® NT and 2000, and has brought in a lot of new features, including better metadata support and advanced data structures.[3] FAT systems were originally used in DOS and Windows versions prior to Windows XP. The 32 in FAT refers to the 32-bit numbers that represent the cluster values. Even though the FAT operating system is not utilized in many newer hard drives, it is still often used as a default file system in removable media and storage devices, as well as computers with multiple operating systems.[4]

One of the major differences between the NTFS and FAT32 file systems is that NTFS uses a Master File Table (MFT) and FAT32 uses a File Allocation Table (FAT).[4,5] The MFT table houses data entries for all files. Even metadata files have an entry in the MFT table. NTFS stores all of its data in attributes, which are simply data files. One attribute will house metadata, one will house file data, like size, and one will store the actual file content.[5,6]

There are many more attributes than this. The FAT table simply points to where the file is housed within the file system. Any metadata is stored in the header at the beginning of the file.[1] Some other noted differences are the process of file naming, where FAT utilizes both long and short (8.3) names (8.3 filename, or 255 UTF-16 characters when using LFN) and that NTFS uses long file names (255 UTF-16 code units).[4] Other differences noted are with the file deletion and encryption processes. NTFS was designed with fairly advanced security, whereas FAT32 has little to no encryption capability and was not designed with security in mind.[7,8]

B2 A Narratological Approach to Digital Forensic Analysis Utilizing Natural Language Toolkit

Mark Pollitt, MS, Daytona State College, 1770 Technology Blvd, Daytona Beach, FL 32117*

After attending this presentation, attendees will gain an understanding of how narratology and natural language processing can be applied to the analysis of digital evidence.

This presentation will impact the forensic science community by providing results of initial experimentation with the application of the theory of narratology, coupled with the Natural Language Toolkit (NLTK), to a forensic corpus.

Digital forensics has made tremendous strides in the acquisition and preservation of electronically stored evidence. As stored data has grown ever larger and more complex, the ability to identify files and data that are investigatively significant and legally probative has not kept pace with this growth. The traditional approach to digital forensics has relied upon the use of metadata such as file system dates and times, classification of files by data type, and simple string searches. With the advent of ever larger storage media, the ability of digital forensic examiners to identify information of investigative or probative value has become less efficient. In earlier work the author has described the concept of narrative as relates to the search for meaning in digital evidence.[1]

Narratology has been defined as: "the ensemble of theories of narratives, narrative texts, images, spectacles, events; cultural artifacts that "tell a story."[2] Digital forensics seek to identify and tell the investigative "story" as it relates to the case under investigation. One

part of the narratological theory defines the elements that make up a narrative, such as, actors, events, and chronology. If textual material can be processed in such a way as to identify these elements, then it may be possible to extract the "story" from the text and, by extension, approximate the probative "story." This presentation will explore how this theory can be used to develop criteria for the automated processing of textual material to increase its investigative value, and how using natural language processing tools could be used to assist in the identification of these elements.

In order to test this hypothetical approach, a series of experiments, utilizing the Enron email corpus will be conducted, using a number of procedures included in the Natural Language Toolkit.[3,4] This corpus is a collection of the actual emails sent by employees in the criminal trial of several Enron employees that was admitted into evidence during their trial and was subsequently released to the public by the courts. This corpus was selected since the data is in textual format, the metadata from the email headers has been converted to text, and the "story" is known. The results of these experiments will be reported and an assessment of their value to digital forensic examination will be made.

B3 Linking Persons Based on PRNU on Social Network Sites

Zeno J. Geradts, PhD, Floris Gisolf, MSc, and Dennie Verhoeven, BSc, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, 2497 GB, NETHERLANDS*

The goal of this presentation is to learn possibilities and limitations of camera identification based on Photo Response Non-Uniformity (PRNU).

This presentation will impact the forensic science community by offering new methods to link persons on spoofed identities as a result of the massive expansion of social network sites and data it leaves behind.

Social media websites such as Facebook®, Flickr®, and YouTube® contain large numbers of photo and video material.

Photos and videos from databases, such as a child pornography database, can be linked with these social media websites, in order to find a potential suspect. It is also possible to determine if a suspect camera took certain images when a suspect camera is available. The linking of photos and videos is done by making use of the PRNU pattern.

A digital (video) camera consists of many electronic components. After the image has been formed on the image sensor, the image information will pass through all of the components before the final data file is written to flash memory. Each step in this process may add random noise to the image. Even during the image formation process itself, a noise-like pattern from the sensor may be introduced in the image. This noise-like pattern is a small but measurable systematic contribution to the signal, and is called the PRNU pattern. It is caused by small variations of pixel sensitivity to light. The visibility of this signal is limited, and may be a small difference depending on the intensity of the signal. In practice, this means that well-illuminated images will result in a better extraction of this signal compared to when the image is dark. The PRNU pattern itself can be determined from the image and is preferably done with images that have no discernible textures (flat field image for example, from a grey surface). Research so far seems to indicate that every camera has its own unique PRNU pattern. The examining of the PRNU pattern for forensic use is well researched by Jessica Fridrich and others.

The best situation would be to have the suspect camera so flat field images can be made. In practice, it is not always possible to have the camera for casework, such as when linking images in databases to social media websites. However, it is possible to determine if a set of images has been made with the same camera or a different camera based on the PRNU pattern. When the camera is available, the pattern from a questioned image can be compared with the pattern from a set of reference images made with a suspect camera. It can be determined whether the questioned image was produced with the suspect camera or not. This works when the image is authentic, but fails when the image underwent any spatial transformations (e.g., rotation, shearing, resizing) because the "fingerprint" is desynchronized, unless the same transformations are applied to the reference material. It is also possible to alter the image such that the PRNU pattern is filtered out, although this is complicated and time consuming.

Linking large image or video databases requires significant processing power and time. For a good comparison, it is important to have untampered, original images, or to know exactly what kind of operations have been conducted on the image. Since in casework the ground truth is not known, conclusions are given in a Bayesian framework.

In this presentation, an overview will be given of methods that can be used for faster calculation by using only a part of an image, as well as solutions for when the camera is not working by changing the camera module. Also, the possibilities of examining images and videostreams from social networks such as YouTube® and Facebook® are discussed.

Camera Identification, PRNU, Social Networks

B4 StealthBots: A Digital Forensics Case Study

Cory Nguyen, MSc, and Marcus Rogers, PhD, Purdue Univ, Dept of Computer and IT, 401 N Grant St, West Lafayette, IN 47907*

After attending the presentation, the attendees will be able to understand the impact that stealthbots have on digital investigations, detect footprints of a stealthbot in the file system, and explain the defense strategy that is being proffered regarding stealthbots.

This presentation will impact the forensic science community by highlighting the challenges of investigations where the stealthbot defense, almost impossible to disprove at this time, is used.

As the legal justice system becomes better educated and mature in the domain of digital investigations, standard defense strategies are appearing. One such strategy is to blame someone else. A more sophisticated expansion on this legal defense is that while the system belonging to the accused was used to perpetrate the crime, the accused was not the one sitting behind the keyboard, or was "framed" by some unknown entity. To date this defense has met with minimal success. With the introduction of stealth malware such as the Zeus bot Stealth (Zbot-Stealth) into the "wild," this defense takes on a entirely new dimension.

The Zbots have been primarily used by the criminal community to attack online banking systems. These bots have become increasingly sophisticated and can be modified to attack particular banks. The bots are "made to hire" and can be purchased online from the developers for prices ranging from $2,000 to $20,000 USD. The complex nature of these "made to order" malware programs has made the detection and investigation of cases more difficult. However, these bots tended to leave "footprints" in file systems that could be discovered and readily identified as malware. The anti-virus industry has also developed detection and removal capabilities related specifically to bots.

Recently, a new variant of the Zbot was released that has been coded to implement stealth and anti-forensics. The anti-forensics capabilities, while not technically new, allow the program to remove its traces from the infected system and obfuscate any remnants showing it was ever installed. The Zbot-stealth variants appear to be very effective at erasing all traces in the file system that they were ever installed and/or

executed on the infected system. The real novelty of the stealth variant is its ability to take control of the victim's system at the same time that the victim is still logged in and using the system. This is very unique. Prior variants relied on the standard Remote Desktop Protocol (RDP) and Virtual Network Computing (VNC) to gain access and control of the victim's system. Using the standard method of RDP, the system would terminate the access of any user logged on locally and hand over control to the remote user. This meant that the victim would be able to detect that a remote control session had occurred. The new variants have modified or "hacked" the RDP protocol and now control of the system can be gained remotely without the local logged-in user being logged-out. Now the attacker can easily "piggyback" on the victim's activity and orchestrate an attack from the victim's system with the victim still using the system. The resulting traces of the attack and the victim's normal system usage behavior become co-mingled and extremely difficult to differentiate.

The presentation will discuss the technical aspects of the Zbot-Stealth variant, the forensic challenges associated with the new attack vector used by the malware, and how to effectively examine and analyze a system that may have been infected. A case study will briefly be introduced where the Zbot-stealth defense was put forward. The case study highlights the difficulty in countering this defense given the lack of positive forensic evidence left in the digital crime scene by this new class of attacks.

Bots, Stealth, Digital

B5 Forgotten Forensics: Understanding Risk, Data Loss Prevention, and Incident Forensics in Cases of Unauthorized Access to Dial-In Conference Calling Lines and Voicemail

Alan E. Brill, MBA, Kroll Advisory Solutions, 300 Harmon Meadow Blvd, Ste 305, Secaucus, NJ 07094; and R.J. Straight, JD*, Kroll Ontrack, Inc, 1166 Ave of the Americas, New York, NY 10036*

After attending this session, attendees will understand the risks associated with dial-in conference lines and voicemail systems, understand cases in which they have been misused, legal implications of such misuse, how to conduct a forensic analysis of these systems, and preventive measures to minimize misuse of these facilities.

This presentation will impact the forensic science community by focusing on areas of digital telephony that are often overlooked by investigators and forensic scientists looking into data loss situations. In the past year, at least one major case involving interception of a call between U.S. and U.K. law enforcement personnel gained a great deal of publicity. Similarly, abuse of voicemail systems by reporters involving both crime victims and celebrities, have shaken the U.K. newspaper industry. This presentation will provide a good basis for understanding and pursuing investigations involving dial-in telephone conference calls and voicemail systems.

In 2012, members of "Anonymous" posted a recording of a conference call between U.S. and U.K. law enforcement officials. While the unauthorized party joined the call and, in fact, recorded it, none of the authorized participants knew this was happening. In another case, an employee who left one employer to join a competitor simply continued, after changing jobs, to dial into regularly-scheduled but highly confidential calls run by the original employer which provided him with valuable competitive information. Both cases resulted in legal action against the unauthorized users. It is believed; however, that conference call bridges as a source of data leakage are not generally thought about by digital investigators or by specialists in the digital and multimedia forensic sciences and often lack even the simplest defensive measures.

In addition, the break-ins to the voicemail accounts of crime victims and celebrities by U.K.-based reporters reminds us that these systems are in almost universal use in both home and business environments, and are often only protected by no more than an easily guessed password. With many systems offering a "mark as unheard" functionality, the potential for abuse is obvious.

In this presentation, attendees will be shown cases in which unauthorized access to dial-in conference call lines (sometimes called "call bridges") and voicemail systems resulted in the loss of highly proprietary, personal, sensitive, and confidential data. The major types of call-bridge and voicemail services will be described, and some of the forensic data that can be available either during a call or in a post-call investigation will be demonstrated. With this study, it is believed that these services are often overlooked when assessing risk and seeking the source of a data loss incident.

Questions to be answered during this session include:

- How are conference-calling lines and voicemail systems abused?
- How do unauthorized persons gain access to these lines?
- Can they also use the conference line for unauthorized calls at the company's expense?
- What investigative and forensic data is available, and how can it be obtained?
- What are the legal implications of this abuse?
- How can conference-call and voicemail users prevent problems, before, during, and after use of these lines?
- Who is responsible for the investigation of cases of this type?

This presentation is suitable for digital and multimedia specialists as well as lawyers, as there are important legal and procedural safeguards that should be considered, particularly in the case of calls involving privileged or highly sensitive information.

The presentation will begin with laying out the technology and the issues. This will be followed by some case studies, and then by both a legal and forensic science review of the problem, investigative guidelines, and ways to prevent misuse or abuse of these important business tools. Ample time will be provided for audience questions and answers and to share participant experience interactively. Participants will be provided with a sample guide for conference call users to enable them to minimize the likelihood of such problems occurring.

Voicemail, Conference-Line, Telephony

B6 3D Morphometric Computer-Assisted Comparison of Faces, Hands, and Other Body Features in Databases

Zeno J. Geradts, PhD, Ana Slot, MFS, and Arnout C. Ruifrok, PhD, Netherlands Forensic Institute, Ministry of Justice, Laan van Ypenburg 6, Den Haag, 2497 GB, NETHERLANDS*

The goal of this presentation is to provide a methodology for comparison, using Likelihood Ratios (LRs) for the comparison in addition to the use of reconstruction images, limitations, and possibilities.

This presentation will impact the forensic science community by showing how to combine conclusions of biometric features with a Bayesian framework.

In forensic image analysis, the question is often asked if the person on a certain image (e.g., from CCTV, documents, child porn) is the same as the suspect. Sometimes only a part of a body is visible, so only parts of a body are compared with the suspect.

The method used for comparison of objects and of humans is to position the person or object in the same position as the questioned image. If the camera system is not available, a 3D image will be made of the person, such that the 3D image can be positioned in the same way. For facial comparison, there is a methodology for comparison which is used in different scenes.

On recordings of certain crimes, the face is not always (properly) shown, unlike the hands. Therefore, the need has arisen to develop a method for the identification of people based on their hands. The research method that is applied for hand comparison is based on morphology, anthropometry, and biometry of hands. A manual test (checklist) was created which includes characteristics of both the back of the hand (e.g., the subcutaneous vascular pattern in the back of the

hand) and the palm of the hand (e.g., palm line pattern). Features that comprise both parts of the hand are also included (e.g., proportions and typica). To assess the location of pigmented lesions, the hand can be segmented into 14 regions using readily discernible anatomical landmarks. Then, each hand can be assessed for the number of features found in each area. Furthermore, a database is available that not only contains many hands, but also scripts that can compare images and provide identification rates. Initially, the scripts were only capable of identifying the palms of the hands. Recently, they are also capable of analyzing the backs of the hands.

For other parts of the body, such as the abdomen and genitals, there is no structured approach known to the authors; however, similar methods can be used. In casework, this study focused on different features of the body, where the skin characteristics as well as the shapes were used. The reference images of the body are taken by a forensic physician. During the comparison, different features are compared manually and the investigator will provide information on apparent similarities and differences which are further evaluated by classifying features as:

1. WD - Weakly discriminating, e.g., shape and size of body parts.
2. MD - Moderately discriminating, e.g., lines and position of veins.
3. SD - Strongly discriminating, e.g., the shape and position of a scar or pigmentation.

The comparison should preferably be performed by three independent investigators. The lists are combined after careful deliberation by the investigators into the list of observations added to the report. This list of observations can be used to check the reported comparison results and conclusions.

Concerning the forensic hand comparison, it has been tested to ascertain whether the manual or automated method performs better when analyzing hands from the database. Currently, it is being investigated to determine if the tests work with "homemade" photos as well. Eventually, the aim is to investigate hand images made by CCTV systems, which are often of very poor quality. There is a need for an automated comparison and a more statistical approach for this kind of research. Large databases with standardized image material could be helpful in having a Bayesian approach in this biometric comparison. Since it is not yet perfected for facial comparison, it is expected that, in the meantime, the visual comparison based on features and describing the differences and the similarities will be an important approach for this type of examination.

Facial Comparison, Hands, Other Body Features

B7 Establishing Criteria for the Authentication of Digital Imagery

Scott Anderson, MS, 2268 Marginella Dr, Reston, VA 20191; Catalin Grigoras, PhD, 1020 15th St, Ste 8I, Denver, CO 80202; and Jeffrey M. Smith, MS, 2857 S Steele St, Denver, CO 80210*

After attending this presentation, attendees will understand an analytical approach to determine if a digital image contains traces of manipulation, combining different manipulation-detecting techniques relevant to image authentication. The cognitive outline will help attendees evaluate their findings when making decisions concerning the authenticity of digital image files.

This presentation will impact the forensic science community by strengthening the criteria needed for authenticating digital images.

Digital photography has replaced film-based photography as the prominent means of acquiring images. The ability to create digital images has been integrated into cameras, cell phones, scanners, and other devices. Due to the widespread availability of image processing tools, it has become increasingly simple to modify digital image content with no perceivable indications of alteration to the naked human eye alone. When digital images are central in an investigation or produced as evidence, it may be important to verify the image files' authenticity and/or integrity. Opening, processing, and resaving a photo utilizing image processing software will create modifications in an image file. In addition, applying anti-forensic techniques to obfuscate manipulation leaves detectable traces. While there exists a wide range of manipulation detection techniques, the simple fact is that an individual with the proper tools, knowledge, and skill can create forgeries that can elude detection by any one of these techniques. However, while certain manipulation techniques can elude one or more analyses, it is difficult to elude them all.

This presentation proposes a robust authentication framework that incorporates strong manipulation detecting techniques, collectively focusing on as many unique aspects of the digital image file as possible to diminish the possibility that traces of manipulation go undetected by image analysts. Analyses of the digital file concentrate on the binary data that comprises the information about the file container, including the file format, HEX data, EXIF, MAC stamps, and file marker analysis to help uncover clear signs and traces of a digital image file's history. Global image analysis techniques examine the information that represents the overall configuration of the image content where modifications can alter the random distribution of pixel values in original images and introduce mathematical relationships not found in original, undoctored images. When analyzing the global structure, techniques focus on compression schemes, interpolation, the color filter array, RGB color distributions, quantization tables, error level analysis, and DCT coefficients. Techniques that examine the statistical relationships that exist between neighboring pixels, such as copy and paste detection, photo-response non-uniformity comparisons, correlation or probability maps, histogram equalization, and JPEG error level analysis, are included in the analysis of the local image structure. Additionally, source image identification exploits small imperfections in the image sensor, such as its Photo-Response Non-Uniformity, where pixel defects are imprinted onto the output image file consistently occurring from one image taken by the camera to the next. These irregularities can be used to determine if the image in question could have come from a specific acquisition device.

By combining techniques that examine visual image inconsistencies with different areas of a digital image structure, the probability that manipulations in a digital image will go undetected are greatly reduced. To assure quality in image authentication examinations, cross-verifying conclusive findings using a minimum of two different methods is recommended. Furthermore, when employing automated algorithms, it is necessary to verify their performance on realistic databases and image manipulation techniques before applying them in real cases. It is important to note that these techniques can only provide positive proof of image tampering. It is extremely difficult, or even impossible, to prove that an image is free of modification; the best that an analyst can do when authenticating digital images is to search for indications that support the hypothesis that the image was generated without modification. In addition to inconclusive findings, the conclusions an expert can reach shall be that the evidence is either consistent or inconsistent with an original image.

Media Forensics, Image Authentication, Media Authentication

B8 Establishing Likelihood Ratios for Patterned Garment Comparisons From Seam Measurement Data

David B. Johnson, MS, 200 N Ann Arbor St, Saline, MI 48176; Victor Perlin, PhD, 3741 Plaza Dr, Ste 1, Ann Arbor, MI 48108; Mitchell M. Rohde, PhD, 200 N Ann Arbor St, Saline, MI 48176; Alice Thomas, MS, U.S. Secret Service, Forensic Services Division, Washington, DC 20223; Cuong Q. Luu, MS, U.S. Department of Homeland Security, Science & Technology Directorate, Washington, DC 20005; and Jennifer Chang, BS, 200 Ann Arbor St, Saline, MI 48176*

After attending this presentation, attendees will understand how common garment manufacturing processes can support variations in the appearance of patterned garments, and how these variations can be

measured and exploited to calculate a conservative estimate of the probability of an accidental match between two random garments.

This presentation will impact the forensic science community by establishing a methodology to assign quantitative measures of evidence strength to patterned garment comparisons.

Surveillance images of a crime scene present a potential wealth of evidence that may be used to facilitate identification of objects relevant to an investigation; however, it is often a challenge to ascribe an objective metric of confidence for a particular identification. In the case of patterned garments, an apparent match between the item seized from a suspect and the one captured in the surveillance images of the crime scene can represent a compelling piece of evidence, if properly quantified. This work develops a rigorous statistical model for estimating such quantitative metric—the Likelihood Ratio (LR)—for this class of forensic comparisons.

A visual match between two patterned garments is established if the pattern offsets at the seams of all the visible individual pieces are sufficiently similar, i.e., all the differences can be explained by the limited precision of the measurements on the surveillance image data. Accordingly, the probability that the match is accidental (and hence its likelihood ratio) depends on the quality and resolution of the surveillance imagery, the number of visible garment seams/pieces, and the joint statistical distribution of pattern offsets of the observed garment pieces. The developed model provides a methodology to measure or estimate these parameters. Upper-bound validity is maintained throughout the model ensuring that the probability of accidental matches is not underestimated and LR not overestimated. The model builds on previous work by the authors which developed similar methods for camouflage garments based on direct measurement of the manufacturing process parameters. The new approach extends applicability to all patterned garments and greatly simplifies the model and its practical implementation by not requiring access to the manufacturing facilities. Instead, a limited set of the same garments is acquired and the statistical distributions and dependence of the pattern offsets for different garment pieces are evaluated empirically. Model simplifications and empirical parameter estimation result in larger uncertainties and, hence, somewhat lower bounds on LR values. This can be partially compensated by increasing the sample size: while not affecting the unbiased LR estimates, larger samples reduce the confidence intervals and thus generate tighter upper and lower bounds for probabilities and LR, respectively.

The model was demonstrated and validated through a large scale empirical study with simulated automatic garment comparisons and manual image comparisons. An empirical study of 12 garment sets, each with 25 to 50 samples, yielded LRs ranging from roughly 10-to-1 to over 400-to-1, i.e., from weak and inconclusive to strong evidence. In all test cases, accidental match probabilities were lower than the upper-bound model predictions, confirming that the developed framework produces conservative and defensible lower-bound LR estimates. A software tool was developed and is freely available to assist examiners in executing studies in this area.

Individualization, Patterned Garments, Statistics

B9 A Case Study in 3GP File Analysis and Repair

Jeffrey M. Smith, MS, 2857 S Steele St, Denver, CO 80210; and Catalin Grigoras, PhD, 1020 15th St, Ste 8I, Denver, CO 80202*

After attending this presentation, attendees will understand some principles in digital data analysis, multimedia file structure and repair, and how to use various software tools to reconstruct multimedia metadata. Attendees will learn the relationship between recorded data and multimedia containers revealing the usefulness of Hex data analysis and the reverse engineering of file formats.

This presentation will impact the forensic science community by discussing a real case involving the analysis and repair of a corrupt 3GP file recorded by a cell phone. An overview of the QuickTime file format specification will be provided along with comparisons to various other format specifications. Hex data analysis of recorded media will be demonstrated, highlighting things to look for when analyzing file formats for repair.

Corrupt or incomplete media files are a common problem encountered during the course of investigations. In these cases, the recorded audio and/or video material may not be playable and, therefore, important information related to a case is irretrievable. File corruption may be due to any one of several reasons, such as: hardware malfunction resulting in the file not properly being closed or wrapped following the recording process, incomplete fragments of recordings were detected and carved from physical media during the course of data imaging and analysis, deletion and overwriting of media files have rendered them corrupt, etc. However, if a forensic media analyst is resourceful, the data structure of the file may be reverse engineered and repaired making playback possible, revealing the otherwise irretrievable recorded contents. In these cases, resourcefulness is the key because the process of file repair depends on the format and codec of the recording, and not all manufacturers implement technical specifications in the same way. This means that two 3GP files, for instance, recorded on different equipment will require different procedures for repair due to inconsistently structured data. When the organization of a media file's data structure is determined, analysis and repair may be possible by referring to available file format specifications and by using Hex viewing/editing software that displays a file's binary data in hexadecimal notation and ASCII text. Last, a software tool for reconstructing large amounts of data may be necessary where manual creation of Hex data is not possible. Once a file has been repaired, investigative review can take place, or further forensic analysis is made possible.

Following the presentation of this background information, technical details regarding the analysis, repair, and reconstruction of the recovered 3GP file in the case study which resulted in making a broken file playable will be discussed. The method used to repair the file is comprised of: hex data comparison of the evidence file to playable exemplar files recorded by the same phone, identification of the missing and inaccurate metadata that made playback not possible, reconstruction of the missing Hex data using Matlab software, and amendment of the corrupt file to make playback possible.

Multimedia Forensics, Audio Forensics, Hex Analysis

B10 Live Forensic Analysis of Kernel Code for Malware Detection in Cloud Computing Environments

Irfan Ahmed, PhD, and Golden G. Richard, PhD, Univ of New Orleans, Dept of Computer Science, 2000 Lakeshore Dr, New Orleans, LA 70148*

After attending this presentation, attendees will understand key characteristics of cloud computing environments, including typical uses of virtualization and how virtualization can be used to support live forensic analysis of operating system kernel code for malware detection. Existing techniques to assess the health of kernel code require pre-computing values such as cryptographic hashes, which is problematic in the face of dynamic updates and multiple kernel versions. A technique that leverages virtual machine introspection to assess kernel code health at runtime without relying on pre-computed values will be illustrated.

This presentation will impact the forensic science community by discussing a method to perform correlation of kernel code running in multiple virtual machines in a cloud environment without relying on traditional techniques, such as cryptographic hashes. This work is important because developing and maintaining pre-computed values for kernel code components for a large number of operating systems and kernel versions is cumbersome and has a negative impact on performance.

The integrity of operating system kernel code needs to be maintained in order to avoid disruption of service and to prevent malware from either interfering with normal system operation or accessing

sensitive information. Kernel code integrity is usually violated by either patching the kernel with malicious code or loading malicious kernel modules/device drivers. Before corrective actions such as snapshot restoration can take place, malicious kernel tampering must first be detected. State-of-the-art solutions typically use a dictionary of hashes of kernel code or malware signatures for detecting malware infection. In the case of cryptographic hashes, the hashes for key "known good" kernel components are pre-computed and these values are periodically compared with the hashes of code currently loaded in the kernel. Any discrepancy indicates a potential infection.

The key problem in maintaining hashes is that code changes across different kernel versions of an operating system. Even kernel patches (e.g., for removing bugs and security vulnerabilities) change the kernel code. Thus, the dictionary needs to be maintained for all kernel versions and all the patches for each kernel version, which is a time-consuming and cumbersome task. Also, the dictionary needs to be upgraded constantly to accommodate new patches and kernel versions in order to ensure effective malware detection. Moreover, if the dictionary needs to be maintained for a cloud server where several different operating systems are run on tens or hundreds of virtual machines at a time, the scale of the problem increases significantly, requiring maintaining the dictionary for all the operating systems in the cloud server.

Recent work to automatically perform live forensic analysis of kernel code at runtime in a cloud server without maintaining a dictionary of hashes will be presented. The work uses a typical scenario in a cloud server where a pool of virtual machines runs an identical kernel version for a guest operating system. Such pools of virtual machines are maintained to simplify the maintenance process so that applying patches and upgrading systems can be automated. The technique in the presented work compares the in-memory kernel code (including kernel modules) of all the virtual machines in a pool and is based on the assumption that if kernel code has not been altered, it should be the same across all the virtual machines and any discrepancy potentially indicates a malware infection. When discrepancies are noted, additional steps such as gathering snapshots for further forensic investigation and restoring the system to a known good state can be undertaken.

A prototype implementation of the technique will be discussed in the presentation. This tool runs on a privileged virtual machine where it can access the physical memory of other virtual machines in the pool through virtual machine introspection. This technique is resistant to tampering by malware because no components run inside the guest virtual machines. This prototype is for Microsoft® Windows® and the technique has been tested against a variety of exploits, including those based on opcode replacement and DLL hooking. This technique successfully detects all of the tested exploits and does not affect the performance of the guest operating systems.

Digital Forensics, Code Integrity, Cloud Computing

B11 Personal Identification by Superimposition and Metrical Analysis: Practical Experience

Pasquale Beltempo, MS; Antonio De Donno, PhD, Sergio Lubelli, MS, Liliana Innamorato, MD, Valeria Bruno, MD, and Francesco Introna, PhD, D.I.M., Sezione di Medicina Legale, Piazza Giulio Cesare, 11, Bari, 70124, ITALY*

After attending this presentation, attendees will better understand the technique of personal identification by morphometric comparison between recorded images of a robbery and 3D photogrammetric facial avatars of the suspect.

This presentation will impact the forensic science community by showing an objective, repeatable, and non-invasive method for robber personal identification based on facial superimposition and facial landmark metrical analysis.

Among the available techniques for personal identification—morphological classification, metrical analysis, and facial superimposition—the latter seems to be the most reliable; however, very often courts require a quantification of the correspondence between recorded images and a robber's face.

The described method exploits digital photogrammetry for facial scanning. Photogrammetric 3D capturing works by multiple and synchronous photo-shooting and represents the most suitable technology for face capturing in living persons, while laser scanning is largely affected by slight movements of human faces.

In January 2010, two criminals armed with paper cutters, burglarized a bank in Bari. Their faces were covered by balaclavas when they entered the bank; however, a small camera was hidden in the bank security entrance doorpost and partially captured the robbers' faces before they were disguised.

Some months later, police officers recognized the two robbers as two local criminals who were already spending time in jail for similar offenses. The judge authorized the research group to go to the jail for the 3D acquisition phase. In order to do this, the suspects' authorization was requested and obtained.

The equipment transported to the prison consisted of four cameras (12.1 Mpixel), a proper support, the lighting system, a calibration grid, and a notebook for the synchronization of photo-shooting and data storage. The suspect 3D avatars were created with a suitable software program and were then saved as ".obj" files.

In the next step, recorded images of the robbery were carefully analyzed and only frames with a better view of facial landmarks were chosen for the 2D/3D comparison.

The hidden camera had a fisheye lens and, to proceed to the superimposition phase, fisheye distortion removal was needed. To do this, an on-site inspection of the bank entrance facilities was carried out, with accurate measurements taken of the bank entrance room furniture and walls. The selected frames were then normalized through comparison with the obtained data.

The 3D avatars of the two suspects were then spatially oriented in the same position as the robbers in the normalized frames. To check the correct spatial orientation, the 2D frames and the snapshots of the 3D avatars were superimposed and gradually blended.

In the next step, for each face and avatar at least five objective landmarks were chosen (both in lateral and in frontal view), such as glabella, exocanthions, endocanthions, pronasal point, subspinal point, and gnathion and pogonion. Repeated landmarking by different observers allowed detection of random errors and controlled the quality of the landmarking within and between operators, minimizing variability.

Finally, the absolute and relative distances between the marked points, the perimeters and the areas of the triangles obtained by connecting the points, and the compactness indexes were automatically calculated on both images in the analysis using suitable software. The correlation coefficients between the suspects' avatars and the robbers' faces values that were higher than 0.995 were judged to be consistent with a positive personal identification.

Identification, Robber, 3D

B12 A Digital Forensic Analysis on the iCloud® and Its Synchronization to Apple® Devices

Rachel Friedman, BS, 8804 Cold Spring Rd, Potomac, MD 20854; and Joshua L. Brunty, MS, and Terry Fenger, PhD, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will know what iCloud® artifacts can be found on the iPod Touch 4G® and the MacBook Pro®. Additionally, the audience will learn one way to determine if two Apple devices are synced together through the iCloud®.

This presentation will impact the forensic science community by showing preliminary steps of how to capture artifacts from iCloud®-enabled devices.

In October 2011, Steve Jobs introduced the iCloud® to Apple customers.[1] The iCloud® was a service that allowed Apple device users to sync various applications to remote servers and access the data from each of their Apple products.[2] The study of cloud computing services,

like the iCloud®, is a burgeoning area of research for the digital forensic community. The goal of this project was to show artifacts that confirmed iCloud® activation. Since the iCloud® is not a physical device that an investigator can seize, it is important for forensic examiners to know how to determine if a device is iCloud®-enabled.[3] Additionally, if multiple devices were connected to the iCloud®, there could have been residual artifacts that showed a link between the devices.

The iPod Touch® and MacBook Pro® were tested because their operating systems, iOS 5.0.1 and Mac OS X 10.7 Lion, respectively, were equipped to utilize the iCloud®, and were supported by current forensic tools. Three images were taken of the iPod Touch®: (1) before iTunes and iCloud® activation; (2) after iTunes and before iCloud® activation; and, (3) after iTunes and iCloud® activation. Two images were made of the MacBook's® solid state drive: before and after iCloud® activation. A comparison and analysis of the images were then performed to identify artifacts resulting from the enabling and use of the iCloud®.

On the iPod Touch® and MacBook Pro®, property lists (plists) differed between images created both before and after enabling the iCloud®. Certain dates and key values that were found to support the iCloud® were enabled on the iPod Touch® and MacBook Pro®. However, little evidence was found to show both devices were clearly connected to each other via iCloud®. The evidence that was identified came from the synced applications that were linked to the iCloud®. Data from certain applications were displayed on both devices, which supported the theory that the data was synchronized.

Therefore, it is possible to obtain iCloud® information from the local drives of iDevices. Further research must be done to determine the synchronization of information to and from the iCloud®. A subsequent step to take would be to attempt to monitor iCloud® traffic between Apple devices. Also, a protocol should be written on a standard way to capture the iCloud®, as well as create live image tools.

iCloud®, Apple®, Synchronization

B13 Forensic Analysis of Twitter® Artifacts Using the Twitter® Web Interface and TweetDeck®

Jonathan P. Fowler, MS, First Advantage Litigation Consulting, 1828 L St NW, Ste 1070, Washington, DC 20036; and Paul A. Taylor, MS*, First Advantage Litigation Consulting, 420 Lexington Ave, Ste 2520, New York, NY 10170*

After attending this presentation, attendees will have an understanding of types of artifacts left behind on a computer running the Windows operating system using the Twitter® web interface and using the popular TweetDeck® desktop software offered by Twitter®.

This presentation will impact the forensic science community by providing information to assist in the identification of artifacts used to determine if a suspect computer was used in the composition or review of messages using either the Twitter® web platform or the TweetDeck® desktop application. Although geared primarily toward an audience of digital forensics investigators/analysts/examiners, it is also well suited for attorneys, paralegals, or other legal professionals who often deal with evidence emanating from social media platforms, such as Twitter®.

The web interface will be tested through a variety of browsers, to include Microsoft Internet Explorer® (versions 8 and 9), Mozilla Firefox® (version 14), Apple Safari® (version 5), and Google Chrome® (version 20). The TweetDeck software will be tested by downloading and installing it on a clean installation of Windows 7. Three dummy Twitter® accounts will also be created to aid in the testing process.

Founded in 2006, Twitter® is an online social media outlet that allows its users to post micro-blogs of up to 140 characters called "tweets." The rapid growth and acceptance of Twitter® by the public is evidenced by the fact that the company now has over 500 million users; and, according to the web information site Alexa, their most recent three-month tracking numbers show that Twitter® is the eighth most popular website in the world.[1] Its social significance can also be gauged by the enormous popularity of segments on late-night talk show television programs where celebrities appear on the show to read mean-spirited tweets about themselves.

Although there currently exist multiple third-party options from which a user can access and utilize a Twitter® account (i.e., HootSuite, Tweetings, Echofon, etc.), a recent article on TechCrunch.com cites statements made by the founder of Semiocoast, a French social media monitoring company, that "Twitter's® own access points, including TweetDeck, represent 75.4% of all public tweets."[2] This statistic was used to determine the most probable methods by which Twitter® artifacts would be generated, leading to the analysis performed for this presentation.

A prime example for the need of this type of analysis can be found in a 2011 case from the U.S. District Court for the District of Colorado, *Doe vs. Hofstetter*, in which the court found that the defendant created a fake Twitter® account, impersonated the plaintiff, and "communicated with third parties using the fake Twitter® account."[3] In this particular matter, knowing the types of artifacts left by the usage of Twitter® through either the web interface or through TweetDeck could have proven beneficial to those examiners investigating the defendant's computer. Additionally, the high-profile matter involving inappropriate tweets that may or may not have been sent from former Representative Anthony Weiner's Twitter® account highlights the need for reliable research to identify what, if any, artifacts are left behind on a computer by Twitter® usage.

Twitter®, Social Media, Digital Forensics

B14 Cell Phone Images in Social Media

Nicholas K. Ng, BS, 300 E 17th, No 1022, Denver, CO 80203*

After attending this presentation, attendees will understand how to differentiate images originating from different cell phones. Furthermore, attendees will be able to differentiate images when they have been uploaded to a social media website.

This presentation will impact the forensic science community by providing a tool for law enforcement to track the origin of cell phone images posted to social media websites including Facebook®, MySpace, and Twitter®. This presentation will seek to eliminate the mystery that has surrounded images uploaded to the Internet.

Social networking websites have become a group depository of personal photos for all to see. The public availability of these images provides evidence otherwise unavailable to law enforcement; however, this valuable investigative tool comes with its drawbacks.

Very little is known about images uploaded to social networking websites. Previous successful research has been done into the usefulness of artifacts left by social networking websites, but no known research has dealt with uploaded images.[1] Currently, images uploaded to social networking websites cannot be traced back to their origin. This

presentation will provide a tool to track the origin of cell phone images posted to social media websites.

Traditional eyewitnessing of crimes is being replaced by video and image recordings. Today, almost everyone owns a cell phone and crimes are being increasingly captured on cell phone cameras. Unlike the traditional camera, people always carry their cell phones, and they are becoming increasingly user friendly.

As society is technologically evolving, evidence of crimes is increasingly posted to social networking websites. Investigators must determine where cell phone photos that find their way onto social networking websites originated. Investigators need to be able to trace exactly which social networking website an image came from and the cell phone that captured the image, but the upload process makes it difficult for investigators to determine where there images originated.

Cell phone cameras create photos in a unique way, providing a method of identification. Social networking websites alter uploaded images to normalize and reduce file size, providing a distinctive signature. Identifiers from the unique method that cell phone cameras use to capture photos and the distinctive signature produced by social networking websites are the basis of this study.

A database of cell phone camera images has been compiled to determine the unique signatures. These images were then uploaded to social media websites including Facebook®, MySpace, and Twitter® to determine which unique signatures remained for identification. The alterations done by the social media website image upload process were then recorded and compared against other social networking websites.

The database of cell phone camera images will be compared with test images of unknown origin to determine the cellphone camera that captured the photo and the social networking website that it was uploaded to. The database of images uploaded to social networking websites will be compared to determine distinctive signs of each of the social networking websites uploading process.

The final results of this research will show that images uploaded to the Internet can be identified given a sufficient database of images to compare, and known identifiers of cell phone cameras and social networking website upload systems.

Facebook®, Cell Phone, Social Media

B15 The Facebook® Faker: Case Study of an Online Romance Scam Turned Dangerously Physical

Richard D. Walter, MA, 1879 Chenango St, Montrose, PA 18801; and Peter R. Stephenson, PhD*, Norwich Univ, 158 Harmon Dr, Dewey Hall, Rm 221B, Northfield, VT 05663*

The goal of this presentation is to provide an example of the use of Cyber-Physical Crime Assessment (CPCA) techniques to characterize a crime, crime scene, and suspect, thus informing the investigation. The presenters will describe the case and apply CPCA to explain its ramifications and how CPCA might be used as an investigative tool to support a digital forensic investigation.

This presentation will impact the forensic science community by suggesting that CPCA may be useful for predicting the point at which a cyber-stalker, cyber-bully, or cyber-harasser may resort to actions and violence in the physical world. The case study supports Jaishankar's space-transition theory in cyber criminology.[1] It represents one type of romance scam where the scammer uses social media to troll for and groom victims before attempting contact in the physical world. This case study is part of the presenters' on-going research into CPCA and its direct applicability to digital forensic investigations.

DK is a 49-year-old male who entraps women and men using Facebook®, arranges meetings with them, and escalates many of those meetings to sexual encounters often with (up to 79%) violent assault. Over his history, DK has engaged with at least 84 victims. Typically, he engaged the victims using a variety of subterfuges. Likewise, he often attempted to develop a real-world relationship at the point where he perceived that he was not achieving adequate control over his victims online.

DK is overweight, indigent (living in shelters when he does not have a victim with whom to live), and expert in the use of the Internet and social media, which he accesses either from a library or using a victim's computer and Internet connection. He is reported by one of his victims to "…sleep no more than four hours per night" spending much of the rest of his time online.

He represents himself on Facebook® as younger, a bodybuilder, extremely wealthy, an ex-FBI agent, and a former private sniper who was paid by the kill. None of these is true. He uses a variety of aliases and is suspected of both identity theft and child abuse. In interviews with his 84 victims, several have indicated that he raped them; however, most women with whom he has been involved did not report him because he was careful to engage initially in consensual sex and, where possible, cohabitate with his victims.

DK represents the Power Reassurance (PR) sub-type and spikes over into the power assertive (PA) sub-type when he can no longer satisfy his need for control of his victim.[2] The PR sub-type is characterized, among other things, by the actor living in a personal fantasy. The fantasy drives his actions. The PA sub-type is characterized by aggressive assertiveness.

In the case of DK, he lives in the fantasy that he is the person he represents himself to be (PR). Then he attempts to engage his victim in *his* fantasy and, when he no longer can control his victim, he exerts more power and his actions become PA. When he no longer can exert control through his online presence, he attempts to move the relationship into the real world, often with violent results.

Analysis of chat logs, a sting operation, video of interviews with DK in the media, his emails, and tracking of his numerous Facebook® presences has allowed the presenters to develop a very clear picture of DK's behavior. Additionally, the presenters have had access to computing devices (including laptops, tablets, and smart phones) that DK used extensively. Applying CPCA to the forensic analysis of these devices allowed the presenters to test the viability of considering the computing device as a crime scene that could be analyzed in much the same way that a crime scene investigator analyzes a physical crime scene.

B16 Taking a Deeper Look Inside Microsoft's XBox® 360: The Acquisition and Investigation

Veronica Y. Serrano, 3904 Regatta Rd, Yukon, OK 73099; and Mark R. McCoy, EdD, Forensic Science Institute, 100 N University, Edmond, OK 73034*

The goals of this presentation are to discuss: (1) data preservation and forensic collection from an XBox® 360 system; (2) forensic investigation of an XBox® 360 system; and, (3) differences between the XBox® 360 FATX file system and other computing systems, such as Windows™ and Macintosh-based file system structures and file formats.

This presentation will impact the forensic science community by providing basic tools and techniques used to forensically acquire information of evidentiary value on XBox® 360 gaming devices.

The Microsoft XBox® 360 with Kinect is the latest online gaming device on the market. The addition of the Kinect gives the XBox® 360 the ability to control games without using a controller, to record voices, and to snap digital images of the users. The XBox® 360 is recognized as

a popular entertainment and educational device, as well as a platform that can be used by online predators to victimize children or store evidence of criminal activity. Because the XBox® 360 can be used in criminal activity, it is vital that digital forensics examiners be able to recover items of evidentiary value. While some research has been conducted on forensic examination of the XBox® 360, no known studies have addressed the evidence left on the XBox® 360 with Kinect. This study examines the evidentiary artifacts left by users on the XBox® 360 with Kinect and the implications for digital forensics examiners.

The first step is being able to capture the image of the drive used by the XBox® 360 system. However, despite it being able to be imaged as any other hard drive would, the file system is unsupported by Windows and can only be read by a special program. This program, known as Xplorer 360, is the only known program on the market today that has been able to read, write, and retrieve information from a hard drive used by an XBox® 360 system. Using this program, examiners will be able to retrieve information from a user's game history, saved games, achievement lists, gamer information; even photos and video bites captured from the game.

Once the basics of acquisition have been covered, a basic overview of the XBox® FATX file system will be provided so participants will be able to familiarize themselves with the system and the differences between Windows or Mac OSX file systems as well as be able to find information kept in the memory of the system taken from the XBox® 360 Kinect that is or may be of evidentiary value. A basic overview of how to use the program Xplorer 360 to retrieve such information taken by the XBox® 360 Kinect will also be provided.

Due to increasing XBox® 360 with Kinect system sales, working with these gaming devices, being able to study how they are being used in criminal activity, and understanding the system so one can retrieve any information that may be of evidentiary value is essential as the future of this technology grows. Such knowledge would prove useful in any forensic investigator's toolbox in that, should the crime related to it ever arise; such information would be greatly beneficial to getting one step closer to solving the puzzle.

Digital Forensics, Xbox® 360, Investigation

B17 Connecting Digital and Physical Crime Scenes Using Cyber-Physical Crime Assessment

Richard D. Walter, MA, 1879 Chenango St, Montrose, PA 18801; and Peter R. Stephenson, PhD*, Norwich Univ, 158 Harmon Dr, Rm 205, Dewey Hall, Northfield, VT 05663*

After attending this presentation attendees will be introduced to a novel method of conducting an investigation where there are both digital and physical data to consider. Typically investigators seize computing devices (e.g., desktop computers, laptops, smart phones, tablets, etc.) and submit them to a digital forensics laboratory for analysis. Digital forensic examiners perform tests on the devices using digital forensic tools to extract typical data and through iterative communications with investigators search for individual pieces of data of possible interest in solving the crime.

This presentation will impact the forensic science community by demonstrating how Cyber-Physical Crime Assessment (CPCA) shows promise as a method for conducting a holistic investigation of a hybrid crime (a crime with both digital and physical elements). CPCA connects the physical and digital crime scenes together as a single crime scene, each with its unique characteristics, but intended to be viewed and analyzed as an integrated whole in much the same manner as a crime scene investigator would analyze the physical scene alone.

CPCA holds promise as a methodology for conducting a holistic investigation of a hybrid crime, defining hybrid as one with both digital and physical elements.

CPCA applies physical crime/crime scene assessment techniques developed over three decades and is based upon informal analysis of over 20,000 cases of violent crime. The presenters have ported these techniques into the digital world and refined them to include both digital and physical crime scenes where a single, hybrid crime has been committed.

This type of crime assessment consists of three aspects: description of the crime/crime scene using one or more of four sub-types, matching the sub-type(s) of suspects to the sub-type(s) of the crime, and analysis of the pre- and post-crime activities of key suspects.

Temporal analysis of pre- and post-crime activities, for example, is straightforward on a computing device due to the timelines that can be constructed using such things as file metadata and machine activity (e.g., When was the computer turned on or off? What cell phone activity can be matched to the pre- and post-crime activity? How does cell tower access compare with timelines of the physical event?) By considering the physical and digital aspects of the crime as a single crime scene with an integrated clue set, these connections become more obvious and useful in solving the crime, guiding digital forensic analysis, and supporting the solution for a conviction.

The other key area of consideration is the four sub-types. These subtypes—power assertive, power reassurance, anger retaliatory, and anger excitation—are described in more detail in Stephenson and Walter, and Keppel and Walter.[1,2] Experience in physical crime has demonstrated that all crimes fit into one or more of the sub-types. There usually is a primary sub-type and there may be secondary sub-types with lesser weightings in a complicated crime.

The crime scene reveals the sub-type(s) and there may be indications that the crime has started as one sub-type and ended as another, further differentiating the potential suspects. This "spiking over" from one sub-type to another is easily seen in the digital aspects of the hybrid crime scene due to the ability to analyze computer use patterns and documents such as emails, Internet pages, and social network accesses/postings.

Once the timelines of the crime are established, the important suspects may be characterized using the same sub-type analysis as applied to the crime/crime scene. This reduces the field of suspects to those who exhibit congruent characteristics to the crime. Those primary suspects are then analyzed based upon their pre- and post-crime activities, again searching for congruence with the physical event, and a smaller, more manageable sub-set of credible suspects is likely to emerge.

CPCA is applicable to hybrid investigations where the perpetrator is unknown but a field of suspects exists as well as investigations where the perpetrator is known and support for interview/interrogation and prosecution is needed. The presenters have applied CPCA in actual investigations and are currently analyzing empirical data for statistical correlation with theoretical constructs.

Cyber Crime, Crime Assessment, Digital Forensics

B18 Computer Forensics Tool Catalog: Connecting Users With the Tools They Need

Benjamin R. Livelsberger, MS, 100 Bureau Dr, Mail Stop 8970, Gaithersburg, Maryland 20899-8970*

After attending this presentation, attendees will be introduced to the Tool Catalog website, a website that provides users with an easily searchable catalog of forensics tools. The secondary goal is to provide a map of the computer forensics tool landscape, showing where there are gaps (i.e., functions for which there are no tools). The attendees of this presentation will become familiar with the Tool Catalog website and the benefits it offers the forensics community.

This presentation will impact the forensic science community by: (1) the forensics practitioner will have a better, more efficient way of connecting with the tools and technologies they require to do their work; and, (2) the law enforcement community will gain the ability to better identify and communicate the functionalities and features they need to the development community. This is facilitated by the map of forensics functions—the Tool Taxonomy.

There are many forensics tools available. These tools perform a wide variety of functions (e.g., imaging or memory reconstruction) and work on a wide variety of technologies (from PCs to Macs, to disposable phones, to iPhones). What is missing is an effective way of connecting practitioners to the tools that meet their specific requirements. The computer forensics tool lists currently available to the community have limitations in how they are populated, and in the level of detail of information they provide about tool capabilities. Maintaining a list is time consuming and lists easily become outdated. Also, while these lists generally connect practitioners to tools, they lack specificity. For instance, a typical tool list entry for a disk imaging tool might tell a practitioner that a tool supports USB, FireWire, and SCSI drives, but will not specifically address if this support is for the tool's evidence interfaces, target interfaces, or both. It will not uniformly list the specific capabilities of similar tools, such as for a disk imaging tool: the hash algorithms and image file types they support; supported acquisition methods (disk-to-disk or disk-to-file); whether it can encrypt data; if it supports block hashing, etc. Such specifics are important for connecting practitioners to the tools they require but are very time consuming to collect.

The website has three major sections. First, there is a description of forensic functionalities and technical parameters. This is the Tool Taxonomy. Currently, eight functionalities are defined, along with associated technical parameters and technical parameter values. These allow a tool's capabilities to be characterized. Example forensic functionalities are disk imaging, deleted file recovery, and mobile device acquisition and analysis. Example technical parameters for disk imaging include runtime environment, evidence interfaces, target interfaces, supported image file formats, hash algorithms, and acquisition methods. New functionalities will be added to the Tool Catalog based on the work of the Computer Forensics Tool Testing project.

Second is a search feature to find tools. Users can select their requirements in terms of functionality needed as well as specific technical parameter values. A list of tools that match the search criteria is returned. For example, a user might formulate a search for "all disk imaging tools that have support for acquisition to a networked file system, support the dd, E01, and AFF image file formats and support the SHA256 hash algorithm."

The third section of the Computer Forensics Tool Catalog site is a set of pages for vendors to input information about their tools and for public feedback. Unlike traditional tool lists, the Tool Catalog is not populated by a single entity or via crowd sourcing; the website is populated with tools by tool vendors. Tool submissions are reviewed at NIST prior to being posted to the website. Two advantages of this approach are that it takes the pressure off the single person or entity of keeping abreast of the latest tool developments and it leaves the task of populating the tool's specific capabilities to the party who knows them best, the vendor. Comments and feedback from both vendors and the forensics community are welcomed and are key for improving and keeping the Tool Catalog current.

Digital Forensics, Tool Taxonomy, Website

B19 Deleted File Recovery Tool Testing Results

James R. Lyle, PhD, National Institute of Standards and Technology, 100 Bureau Dr, Mail Stop 8970, Gaithersburg, MD 20899*

After attending the presentation, attendees will learn about issues revealed while testing meta-databased deleted file recovery computer forensic tools by the Computer Forensics Tool Testing (CFTT) project.

The presentation will impact the forensic science community by increasing awareness in the community of tool test strategies and the ability of tool testing to reveal anomalies in tool behavior. The presentation will aid the forensic practitioner in recognizing the limitations of meta-databased deleted file recovery tools.

The CFTT project develops methodologies for testing computer forensic tools. This presentation reports on tool behaviors observed while testing digital forensics tools against a set of file deletion scenarios.

A file system is used to store data for access by a computer. The data is normally stored within a tree-structured hierarchy of directories and files. When a file or directory is deleted from a file system, the associated *metadata* entry and the stored data are no longer directly accessible to the user and appear to be completely removed. However, in many file systems, e.g., FAT, neither the metadata associated with the file nor the actual content is completely removed. This creates a situation where there is *residual metadata* (metadata remaining after a delete has occurred) that is still accessible by direct access outside the usual operating system methods and can be used to reconstruct deleted files. Many forensic tools exploit the behavior exhibited by file systems of leaving metadata behind after a file is deleted to attempt to recover deleted files. Metadata-based deleted file recovery should not be confused with *file carving*, i.e., scanning unallocated memory for the file signatures present within a file itself to identify a deleted file. The scope of this presentation is limited to metadata-based deleted file recovery tools that use file system metadata from file system structures such as directories or i-nodes to identify recoverable deleted files.

The basic approach to creating a test image is as follows:

1. Create a file system on a secondary storage device.
2. Create some files.
3. Delete some of the created files.
4. Image the storage device.
5. Use the tool under test to attempt to recover the deleted files.

The test images used cover the most widely used file systems, including FAT16, FAT32, ExFAT, NTFS, ext2, ext3, and ext4. The HFS+ file system does not leave enough residual metadata behind after a file is deleted to make recovery practical.

Some of the observations discussed in this presentation include:

- The residual metadata varies with the file system. For example, file names may be completely or partially lost, pointers to file blocks may be overwritten.
- Only the first block of a deleted file is identified for FAT16 and FAT32 file systems. Some tools guess the location of the remainder of the deleted file; this strategy often leads to recovered files that are mixed from several original files.
- The tools sometimes include blocks from active files in a recovered file.
- The tools rarely include blocks that have never been allocated to the current file system, i.e., it is not likely that a block from a recovered file was not a part of some file.
- Some tools attempt to identify overwritten files. The tools often identify (incorrectly) intact files as overwritten.
- Support for ext3 and ext4 is often lacking.
- Sometimes ExFAT is not supported.
- Interpretation of MAC times must be done carefully. Time zone information and actual semantics of the times can vary across file systems and tools.

The test images and image layout documentation are available at the CFReDS project web site http://www.cfreds.nist.gov/dfr-test-images.html. Test reports on specific tools are available for the National Institute of Justice web site http://www.nij.gov/topics/forensics/evidence/digital/standards/cftt.htm

File Recovery, Software Tool, Digital Forensics

B20 A Survey of Data Deletion Applications for OS X Systems

Jonathan P. Fowler, MS, First Advantage Litigation Consulting, 1828 L St NW, Ste 1070, Washington, DC 20036*

After attending the presentation, attendees will have a general understanding of the types of data deletion software currently available

for OS X systems, the basic functions of each program, and examples of artifacts left behind by each program upon installation and usage.

This presentation will impact the forensic science community by providing useful information for digital forensics examiners to assist in identification of data destruction activity on suspect computers running the OS X operating system. Although geared primarily toward an audience of digital forensics investigators/analysts/examiners, it is also well suited for attorneys, paralegals, or other legal professionals who often deal with the ramifications of the answers provided to the question posed at the outset.

During the course of an investigation, digital forensics investigators are often presented with this relatively simple question by prosecutors, defense attorneys, or supervisors—"Did the person delete anything from their computer?" The reality is, while the question in and of itself is seemingly simple, depending on the type of operating system in play, attempting to determine the answer to that question can be devilishly difficult.

Over the years, the Digital Forensics (DF) community as a whole has developed multiple tools and techniques to assist in answering that question. Drawing on one of the core tenets of criminological theory, Locard's Exchange Principle, one of those techniques is to identify what artifacts are left behind by the installation and subsequent running of data destruction software. Although considerable resources have been spent by the DF community to identify those artifacts—both from the software itself as well as from the operating system—the vast amount of those resources were spent primarily on computers running some version of the Windows operating system. Th goal is that this presentation helps to change that approach.

With the growing popularity of Apple's Macintosh family of computers, more resources will need to be expended to increase the community's collective knowledge of the same types of artifacts that have already been identified on Windows-based systems. This further affects the DF community because, while computers running Windows operating systems still have a virtual stranglehold on the corporate market, a January 2012 article in the *Wall Street Journal* reported that General Electric has a pilot program that allows its employees to choose Apple desktops or laptops running OS X instead of a PC running Windows. According to a *Wall Street Journal* article, around 1,000 employees are currently using an Apple computer (which represents less than 1% of the overall users at G.E.); however, more employees are taking advantage of the program as it becomes more widely known.[1]

A prime example of the disparity between the emphases placed on research of data deletion artifacts between Windows and OS X platforms can be found in one of the well-respected digital forensics books on the market today,–*Handbook of Digital Forensics and Investigation*, edited by Eoghan Casey. In Chapter 5 of that book, titled "Windows Forensic Analysis," six pages are devoted to the topic "Deletion and Destruction of Data."[2] In comparison, Chapter 7 of that book, titled "Macintosh Forensic Analysis," contains no such section; however, references to data deletion can be found scattered throughout the chapter.[3]

OS X, Macintosh, Data Deletion

B21 Bulk Data Analysis With Optimistic Decompression and Sector Hashing

Simson L. Garfinkel, PhD, 1186 N Utah St, Arlington, VA 22201; Kristina Foster, MS, Naval Postgraduate School, 900 N Glebe, Arlington, VA 22203; Joel D. Young, PhD, Naval Postgraduate School, 1 University Cir, Monterey, CA 93943; and Kevin Fairbanks, PhD, Naval Postgraduate School, 900 N Glebe, Arlington, VA 22203*

After attending this presentation, attendees will understand the difference between file-based and bulk-data approaches to digital forensics, and how bulk data approaches can be significantly empowered through the use of optimistic decompression and sector hashing.

This presentation will impact the forensic science community by providing results from controlled experiments in an area with little previous research, adding to work being carried out in digital forensics by broadening the understanding of the presence of compressed data, especially fragmented compressed data, in unallocated areas of file systems, and the availability of new techniques to decompress such data without reference to file system metadata or file type. This presentation will also build upon previous research in sector hashing (also known as piecewise hashing and with hash-based carving and show how sector hashing can be empowered through the use of a high-performance custom-built database.[1-5]

Bulk data analysis is a new digital forensics technique that eschews file extraction, and instead focuses on the processing of bulk data read directly from the target media. Unlike file-based approaches, bulk data analysis is particularly well suited to triage, as it can be parallelized and applied to random sampling.

In the first experiment, a corpus of roughly 2,000 hard drives purchased on the secondary market was analyzed for forensically important information that could only be recovered through the use of optimistic decompression of sectors that were not contained within allocated or recoverable deleted files.[6] Optimistic decompression means that all decompression algorithms are applied to all sectors with the hope that some compressed data may be identified and decompressed. This experiment employed the use of the bulk-extractor, fiwalk and identify-filenames.py tools.[7,8] This study found a significant number of email addresses, URLs, account numbers, and other kinds of information that could only be recovered through the use of optimistic decompression. This presentation show how additional processing can be used to determine which recovered features are attributable to user-generated content, and which are residual data from software distributions.

In the second experiment, three corpora (GOVDOCS1, OpenMalware 2012, and NSRL) were hashed on sector boundaries and evaluated for the presence of distinct sectors—that is, sectors which are not present in any of the sectors in the corpus.[6,9-11] Many such distinct sectors are present and how they can be used to identify the presence of either intact files or to attribute residual data to specific files of interest will be shown.

In conclusion, these two studies provide evidence that bulk data processing can be productively used by digital forensics examiners for both triage and for the extraction of case-relevant details. Examiners can use the tools presented in this presentation today. This presentation will also provide sufficient information so these techniques can be embedded into other tools.

B22 The Impact of Child Pornography Analysis on Military Legal Proceedings

Victoria Wyler, U.S. Air Force Academy, 2304 Cadet Dr, USAF Academy, CO 80841; Joseph L. White, MS, U.S. Army Criminal Investigation Laboratory, Digital Evidence – CFI, 4930 N 31st St, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High St, Sharpsburg, GA 30277*

After attending this presentation, attendees will have a general understanding of the concerns associated with the digital evidence child pornography investigation process and gain an understanding of how results are currently being used by the military judicial system.

This presentation will impact the forensic science community by providing an understanding of the effect of child pornography on the outcome of judicial proceedings, discussing how advancements in technology and the current examination processes affect the digital evidence field in child pornography cases at the USACIL.

Recently, digital evidence examiners have experienced an increase of submitted evidence due to both better agent identification of digital evidence as well as rapid advancements in technology. Storage devices will soon have the capability to hold over 60 terabytes of data. There does not exist sufficient time or manpower to effectively and efficiently keep up with today's constantly developing technology. Currently, during an investigation, digital evidence examiners at the United States Army Criminal Investigation Laboratory (USACIL) must duplicate and examine all submitted evidence, which is not only time consuming but requires a large amount of digital evidence storage capacity for both examination processing and subsequent storage of the case file. Focusing specifically on child pornography, an issue prevalent in military investigations, some form of limitation must be created to maintain current case output with the increasing amount of data required to be examined.

To facilitate this study, 66 U.S. Army case files dating from 2009 to 2011 were collected, all of which involved child pornography. Information such as the date the exam began and finished, number of digital evidence exhibits submitted, number of exhibits with child pornography, number of exhibits with information of possible interest to the investigation, as well as the amount of child pornography found on each specific device was recorded. Once all the applicable information was attained, the results showed that a large portion of exhibits submitted did not contain child pornography. The study continued by determining which cases included submitted pictures/videos that were identified by the digital examiners and sent to the National Center for Missing and Exploited Children (NCMEC). The number of pictures/videos identified by digital examiners and confirmed by NCMEC as child pornography was recorded to determine the percentage of cases where examiners successfully identified previously known and identified child victims. All of this information was collected in order to characterize which cases had confirmed child pornography and if that had an effect on the overall judicial outcome of a case.

To determine the effect of child pornography on the legal outcome of a case required each case's Commander's Report of Disciplinary or Administrative Action (DA Form 4833) and a review of case documentation within the final forensic reports. Items that were collected for correlation analysis included: the number of pictures/videos identified, numbers of items submitted for analysis, the types of items submitted, and the results of the disciplinary action. It was expected that the results would show a relationship between number of items submitted, the number of photos/videos identified, and the outcome of the judicial process. It should be noted that in 2012, the Uniform Code of Military Justice (UCMJ) implemented a revision to the code concerning child pornography, which affects how individuals are charged and sentenced pertaining to these cases. It is expected that with these modifications, there will be a more direct relationship between the number of photos/videos and the severity of punishment.

Child Pornography, Digital Evidence, Judicial Impact

B23 Optimal Distance Determination for Reference Recordings Using Reference Subtraction Filtering in Noisy Environments

Scott Rhame, BA, and William L. Hinton, BS*, Federal Bureau of Investigation, Engineering Research Facility, Bldg 27958A, Quantico, VA 22135*

After attending this presentation, attendees will understand the importance of reference subtraction filters using reference recordings made simultaneously with targeted conversation recordings in noisy environments, such as restaurants, coffee shops, or bars, to determine optimal distance from the recording reference to the target to optimize the filter's response.

This presentation will impact the forensic science community by serving as a best practice or standard when making a covert recording of a subject in noisy environments.

Reference subtraction filters work by performing a continuous and intelligent subtraction of one audio signal from another. Normally, with a forensic recording containing speech masked by loud audio, one would require a reference recording containing just the audio that needs to be removed. The audio track containing the music or other audio to be removed is called the "Reference Track." This type of filtering has had great results in a real-time reference capturing environment. It is done by placing two microphones in the area of the target conversation. One is placed near the target conversation, and the other near the source of the background noise or audio source such as a TV, stereo system, jukebox, or a live band. Then, using a reference subtraction filter that can operate in a live situation, the reference noise signal can be subtracted from the source to produce a more intelligible target conversation. These types of two-microphone, live recordings take a lot of coordination and are usually done when a hotel room is used for the targeted conversation. There is a need to use reference subtraction type filtering in a post-processing environment.

To make reference subtraction filtering effective in a noisy multi-signal environment, two separate recordings need to be made simultaneously. Making a reference recording at some distance from a targeted recording in a noisy background environment will aid in decreasing the noisy background. The key variable is determining the optimal distance that a reference recording should be made from the

targeted recording in the same noisy environment, and then use a reference subtraction filter to make the targeted conversation more intelligible.

A series of reference and source recordings will be made in different noisy environments (e.g., restaurants, coffee shops, or bars). The source recording will be made to simulate a covert recording of a suspect while in the noisy environment. The reference recording will be made simultaneously to the target recording in the same environment, but at different distances, in an attempt to eliminate the noisy environment from the target. The filtering will be done with several popular reference subtraction filters made by different audio forensic processing systems.

Real-time and post-reference subtraction filters are widely used and have been proven effective in reference subtraction of a single sound source broadcast television show or music recording. What about reference subtraction in multiple sound source situations such as restaurants, bars, or coffee shops? In many covert law enforcement targeted conversation recordings taking place in these noisy environments, tests will be done to determine the optimal distance to make a reference recording that would subtract the noisy background most effectively. Test recordings will be produced in several different noisy environments using the same type of recorders and microphones with the only variable being the distance from the source recording. The improvement in intelligibility will be reviewed aurally, spectrographically, and with signal-to-noise ratio measurements.

Audio, Enhancement, Multimedia Forensics

B24 Audio Authentication: A Comparative Analysis of Same-Room Recordings vs. Speakerphone Recordings

Jordan R. Graves, BS, 300 E 17th Ave, Apt 1022, Denver, CO 80203; Carl R. Kriigel, MA, 568 Kings Walk, Douglasville, GA 30134; and Matthew E. Graves, MFS, Geoffry Smith, BS, and Garold Warner, BS, U.S. Army Criminal Investigation Laboratory, 4930 N 31st St, Forest Park, GA 30297*

After attending this presentation, attendees will understand a methodology for examining recorded voices, with and without telephone transmission effects, to determine if conversations were recorded under conditions in which they were allegedly created.

This presentation will impact the forensic community by demonstrating a process to determine the recording conditions of an audio signal or dialogue. It will also demonstrate some ways to manipulate one set of recordings to attain similar properties of another. Analyzed material will include audio signals and speech recorded from the same room and between telephonic devices, via analog and digital audio recorders.

This research was inspired by an actual case that pertained to a conversation recorded on a microcassette. The recording was allegedly made by the victim using the recorder held to the earpiece of a cellular phone during a conversation during which he was threatened. Investigators reviewed the microcassette tape and questioned the authenticity of the recording as it sounded rehearsed. The recording was submitted for analysis to determine if the recording was produced as alleged, or if both parties were actually in the same room and possibly reading from a script.

This research will also explore techniques used to alter the characteristics of a same-room conversation to appear consistent with a two-location telephonic conversation. The ability to differentiate between recorded conversations occurring in the same room and those transmitted between telephonic devices can be an essential element of an audio authentication examination. Determinations concerning the authenticity of questioned recordings have the potential to change the dynamic of an entire case or investigation. Since a purely aural designation of tonal quality can be a subjective assessment and may vary from examiner to examiner, it is significant to point out the statistical, objective approach to measurement and characterization of the recordings used for this presentation. This approach provides a more reliable and statistical evaluation process is desired.

For this research project, several test recordings were made over different types of cellular and land-based phones, using a variety of recorders. To account for and quantify the properties of chosen recorded signals, these test recordings were analyzed using forensic audio tools, signal processors, and forensic phonetic software. The recordings were characterized by their reported correlation coefficients and mean quadratic difference values, as well as the average frequencies and standard deviations of each voice formant in each recording scenario. The comparison methods allowed for an established baseline to identify the differences between same-room and speaker phone recordings, which in turn provided a clear goal for the next element of the project.

Utilizing similar audio tools and techniques, researchers attempted to duplicate the qualities of a speaker phone recording with a manipulated same-room recording. After manipulation, the newly generated recordings were compared against same-room and speaker phone recordings of the same voice, using the same means as outlined above. A final determination was then made in regard to the effectiveness of the manipulations, and whether they rendered the forged recordings more or less similar to either scenario. This presentation will highlight the preparation, execution, and results of this study.

Audio Comparison, Audio Voice Analysis, Audio Authentication

B25 Electric Network Frequency (ENF) Database Validation for Digital Media Authenticity

Catalin Grigoras, PhD, 1020 15th St, Ste 8I, Denver, CO 80202; and Jeffrey M. Smith, MS, 2857 S Steele St, Denver, CO 80210*

After attending this presentation, attendees will better understand Electric Network Frequency (ENF) analysis for forensic media authentication and criteria necessary for creating, maintaining, and validating a database of ENF fluctuations.

This presentation will impact the forensic science community by discussing inter- and intra-variability tests conducted at the National Center for Media Forensics (NCMF) to analyze random fluctuations of ENF and the hypothesis that ENF databases would not contain repetitive sets of data.

In order to determine the time/date of a recording made where ENF is present, a time-synchronous database of ENF variations must be available and have been recorded during the time in question. At the NCMF, the ENF database configuration records non-stop ENF variations of the U.S. Western grid with an 8kHz sampling frequency and 16bit, mono, uncompressed files. Recording of ENF is redundantly made on two completely isolated computers. The NCMF is in partnership with the Target Forensic Services Lab (TFSL) in order to create a network of ENF databases currently covering the western and eastern U.S. power grids. Sites include: NCMF Denver, CO, TFSL Las Vegas, NV, and TFSL Minneapolis, MN. This network is under constant evaluation and testing and will soon be expanded to cover the Texas grid. Bi-annual validation of ENF information between the NCMF/TFSL ENF databases is scheduled which will help ensure database integrity and meet forensic best practices. Several databases have been reported in continental Europe and the UK.

After having analyzed ENF variations in Western U.S. grid over a period of one year, and continental Europe for more than nine years, it has become clear that there is no precisely repetitive pattern. The fluctuations over time around 50Hz or 60Hz are purely random. Exceptions can be considered where some events occur during the morning and in the evening that are generated especially by maintenance operations or network components switching on or off.

Even so, their shapes and values cannot be predicted. In order to maximize confidence in results yielded from ENF examinations, the method proposed by the authors relies on redundancy data at each stage of the examination: two ENF databases, minimum of two techniques for ENF extraction (Fast Fourier Transform, Zero Crossings, and/or Spectrogram), and two methods of automated ENF comparison (correlation coefficient mean quadratic difference).

This presentation will discuss inter and intra -variability tests conducted at the NCMF to analyze the random fluctuations of ENF and the hypothesis that an ENF database would not contain repetitive sets of data. Analysis was conducted using the Denver and Las Vegas databases, and both correlation coefficient and mean quadratic error methods. This consisted of comparing sets of one- to ten -minute segments against all other segments within that same period and evaluating the maximum correlation coefficient (CC) and minimum mean quadratic difference (MQD) for the corresponding and different time frames. Results indicate two things: (1) that each ten-minute segment is much more correlated to itself than any other ten-minute segment within the recorded 18-month databases; and, (2) that MQD provides better discrimination power than CC.

Labs coordinating the acquisition and archival of ENF data must be aware of potential dangers and take precautionary measures to ensure data maintains integrity and accuracy. This must extend to the procedures employed in forensic examinations. This presentation will provide a proposed format for validating database material as well as a list of known potential errors and suggested corrective actions. These are mandatory in order to meet the strict demands for accuracy and consistency of forensic materials to be used in labs, along with the development of and adherence to best practices and guidelines.

ENF, Audio Forensics, Database Validation

B26 An Approach to Conducting Automated Speaker Recognition

Hirotaka Nakasone, PhD, Federal Bureau of Investigation, Engineering Research Facility, Bldg 27958A, Quantico, VA 22135; Kenneth Marr, MS*, FBI, ERF, Bldg 27958A, Quantico, VA 22135; William L. Hinton, BS*, FBI, ERF, Bldg 27958A, Quantico, VA 22135; Alysha Jeans, BS*, FBI, ERF, Bldg 27958A, Quantico, VA 22135; and Ryan Lewis, BS*, FBI, ERF, Bldg 27958A, Quantico, VA 22135*

The goal of this presentation is to instruct participants regarding training and testing preparations prior to performing automated speaker recognition forensic examinations.

This presentation will impact the forensic science community by giving participants knowledge and insight into the training, testing, and procedures used at the FBI audio laboratory involving Automated Speaker Recognition (ASR) forensic examinations.

The automated speaker recognition technology has made significant progress in performance and accuracy in the past decade due to the rigorous and worldwide research effort. Although the performance and accuracy continues to improve, there also remain many unresolved challenges. An approach will be described to resolve such challenges in performing forensic voice comparison examinations by the use of an ASR system currently used at the Federal Bureau of Investigation for investigative use. The approach is described as an automated speaker recognition system with a human-in-the-loop which has channel-independent and language-independent capabilities. The ASR system is built on MIT Lincoln Laboratory's state-of-the-art algorithms i-Vector, Joint Factor Analysis, and Inner Product Discriminant Functions (IPDF) operated by a trained examiner. Some recent improvements have been made in the operating procedures, log Likelihood Ratio (LLR), score interpretations, test and validation methods for LLR score calibrations, examiner training curriculum, and an innovative automated human examiner training module. The final decision-making process uses five levels: "match," "probable match," "inconclusive," "probable no-match," and "no-match" based on the fused results of the ASR system and the human examiner.

The ASR examiner training consists of classroom sessions taught in-house and lectures provided by leading academic organizations, and self-paced peer-review sessions to establish whether trainees have mastered the skills and knowledge required to conduct ASR examinations. The entire training process was monitored for each trainee by a designated mentor and is documented using an ASR training curriculum. A six-month-long classroom instruction was conducted for examiner-trainees by a senior voice comparison examiner, consisting of basic audio signal processing, basic science of speech production, speech perception, phonetics, and statistics and probability theories. A specialized self-paced training program called the Forensic Training Module (FTM) is administered to each examiner-trainee to perform and successfully pass a set of more than 100 blind voice comparison tests under cross-language (the training speaker speaks language 1, while the test speaker speaks language 2), cross-channel (the training speaker speaks via telephone, while the test speaker speaks via microphone) by listening only. All voice samples in the databases used for the FTM training are truth marked, thereby providing the trainees immediate feedback for optimum learning purposes. It was determined that through the ASR development process, there are specific acoustic conditions which are encountered when conducting forensic voice comparison examinations. These conditions and the characteristics of each will be discussed.

The testing and validation of the ASR system was a culmination of years of development of automated tools, including Air Force Research Laboratory's RAPT-R system and Massachusetts Institute of Technology Lincoln Laboratory's Vocalinc system. A Test and Validation Plan was prepared and approved for the voice comparison analysis of thousands of known voices. The ground truth of the databases allowed LLR-score thresholds to be calibrated for five levels of decisions: match, probable match, inconclusive, probable no match, and no match for each of 14 separate acoustic recording conditions. Consequently, examiners use the ASR algorithms to calculate automated scores for questioned voice recordings. Research and testing to improve the ASR process continues, addressing other factors impacting the ASR performance including speech duration, signal-to-noise ratio, and the degree of reverberation in the environment.

The current policy and limitations of the use of ASR as a courtroom tool as well as some *Daubert* criteria challenges will be presented. Finally, the progress status of a new scientific working group for voice (tentatively called SWG-V) will be discussed; formulation of this group is under way and due to the joint efforts of the National Institute of Standards and Technology and the Federal Bureau of Investigation collaborating with scientific representatives from local, state, federal laboratories, academia, industry, and legal community.

ASR, Speaker ID, Voice Comparison

B27 Framework for Authenticity Analysis of Digital Audio

Catalin Grigoras, PhD, 1020 15th St, Ste 8I, Denver, CO 80202; Daniel L. Rappaport, BA, 975 Washington St, Apt 7, Denver, CO 80203; and Jeffrey M. Smith, MS, 2857 S Steele St, Denver, CO 80210*

After attending this presentation, attendees will better understand the authentication process for digital audio, using ways in which various analyses can be combined into a robust framework.

This presentation will impact the forensic science community by providing a logical and scientifically sound process for digital audio authentication.

Digital audio authentication is a complex process of establishing the provenance of a questioned recording to determine whether it is consistent with an original one or if there is evidence of tampering. It also must follow the basic principles of forensic science that include five stages: (1) occurrence of the crime (or acoustical event); (2) seizing of evidence (no material contamination of media support and no digital contamination of the data); (3) analysis; (4) interpretation; and, (5) presentation. This paper presents the organization of several

techniques in a logical manner for the authentication of digital audio. Special attention has been given to interpreting results from individual analyses and incorporating them into a holistic view of a recording's authenticity where a finding can be corroborated against the results of other analyses. Only in this way can an examiner present a conclusion with confidence and assurance that all possible hypotheses have been exhausted in the execution of this important endeavor. The proposed digital audio authentication framework involves accurate, repeatable, reliable, unbiased, and scientific analyses that come from peer-reviewed publications in order to meet the *Daubert* standard, the NAS Report recommendations, and/or appropriate criteria of international legal systems. A forensic lab should also not accept tasks that their facilities, methods, software, databases, equipment, or specialist's background, training, and experience are not equipped to perform.

The task of digital audio authenticity can be separated into two main categories: container analysis and content analysis. The container relates to the file structure, metadata (either stored in the file itself or generated by a software or operating system), etc. Renaming of the container may not necessarily affect the integrity of the contents, but may alter and/or damage the media support or wrapper. This would raise doubts about authenticity that require explanation and may make some types of analyses inconclusive. Content analysis involves checking for traces of previous signal processing or editing using various methods such as: critical listening, waveform analysis, spectrogram, signal's power, dc offset, long-term average spectrum, sorted spectrum, differentiated sorted spectrum, compression level analysis, electric network frequency, butt-splice detection, analog transfer of a digital recording, reverberates analysis, MP3 edits, phase of a mono signal, and phase of a stereo recording. It should be noted that mono signal phase has certain limitations due to clicks, pops, clippings, and other signals from the environment. Also, in many cases, such as phone-intercepted recordings, reverberates, and MP3 edit analysis have limited or even no application. It is important for an examiner to show how they arrived at their conclusions and present them in a way that neither overstates nor understates the scientific certainty. Not every case will employ every type of analysis because, for various reasons, some may not be applicable; however, as many analyses as possible should be used in order to corroborate results. While the proposed table cannot account for every possible authentication technique or alteration technique known to exist, it should be useful in forming a reliable, ultimate conclusion regarding authenticity. The types of individual analyses that an examiner performs could be modified, expanded, or substituted as the tools and accuracy of the science improve over time.

This presentation will demonstrate the proposed framework in which an examiner would start at the global level and continue to the local level based on the findings and needs of the particular case. The appropriate philosophy regarding media authenticity will be discussed as well, for example when it is not scientifically possible to say that a digital audio file is absolutely authentic, or to prove that it is a certain clone/duplicate or copy of an authentic file. Therefore, language implying 100% certainty should be avoided unless speaking about known alterations or deletions. Whenever it is necessary, the results should be presented separately for container and content analyses, in a clear and unbiased way.

Forensic Audio, Audio Authentication, Methodology

B28 Unintended Consequences: Digital Forensics Literacy and the Legal System

Barbara E. Endicott-Popovsky, PhD, and Donald J. Horowitz, JD, 4311 11th Ave NE, Ste 400, Seattle, WA 98105*

After attending this presentation, attendees will be able to achieve a retrospective of where the legal system stands with regard to digital evidence literacy, learn the potential consequences to the legal system if changes aren't initiated, and gain a description of one university's way forward.

This presentation will impact the forensic science community by voicing concerns over the alarming gap in the legal community's understanding of digital evidence. While the rule of law makes society a dependable environment in which to prosper and flourish, the lack of a predictable legal infrastructure has dire consequences.

Trust binds a society together. The rule of law makes society a dependable environment in which to prosper and flourish. The lack of a predictable legal infrastructure has dire consequences.[1] In this context, one must recognize that there is an alarming gap in the legal community's understanding of digital evidence, the technology community's understanding of how the legal system works, and how both can work constructively together.

In this presentation, one case is examined from a small community where the consequences of an inappropriate court ruling and a potential miscarriage of justice were avoided more as a matter of serendipity than of insight. Case specifics were examined, reminiscent of Amero,[2] and conclusions drawn about what this means generally to the state of digital evidence and its use in the justice system. Additionally, the evolution was traced of the general effectiveness of digital forensics evidence presentations and rulings, then extrapolate going forward as to where the evolution of technology may lead.[3-8]

Societal understanding, judgment, and decisions will always lag the development of technology; however, the consequences to the stability of the legal system as it slowly adapts to the changing nature of digital evidence and all that this implies, is staggering. Allowing the current state of digital evidence literacy to continue will likely include: decreasing trust in the predictability of legal decisions affecting the e-economy and, thus, the e-economy itself, and a general impedance of the progress of the Information Age—as online business and communications may increasingly no longer be viable or sustainable. It is incumbent upon those informed members of the technical community who are watching this potential train wreck evolve, to engage in dialogue with those communities that are impacted by the innovations but need help in digesting them and using them. Likewise, the technical community needs help in better understanding the practical ways the justice system—its laws, procedures, and decision process—work so that going forward, more relevant and effective innovations can be produced. Further, the legal system needs help in evaluating the validity and weight of evidence and other information in developing laws that affect judicial decisions.

One initiative being launched at a university law school in conjunction with an information school to deal with this problem will be presented. The goal of this study is that this example will ignite discussion not only about this effort but about what other efforts should be taken to improve the legal community's understanding of digital forensic evidence and the technical community's understanding of how the legal system works. Eventually, society does better understand technical innovation and adapts and evolves. In the meantime, inequities and even tragedies inevitably occur. This presentation will encourage dialogue about what this community can do to apply what has been most effective in understanding and using other forms of scientific evidence.

B29 The Application of Virtual Machine Introspection to Digital Forensics

Brian Hay, PhD, PO Box 84064, Fairbanks, AK 99708*

After attending this presentation, attendees will understand the general concepts associated with Virtual Machine Introspection (VMI) and how VMI can be applied to recover data of interest to a digital forensics investigator. While virtualization is increasingly common in many environments, investigations tend to still be conducted using traditional approaches (e.g., static analysis of media or "traditional" live forensics using tools executed within the Virtual Machine (VM)).

This presentation will impact the forensic science community by describing and demonstrating new capabilities that can be applied to investigations in virtualized environments.

As virtualization becomes increasingly common, it is important to explore the extent to which existing techniques can be applied to virtualized environments, and what new forensic techniques may be applicable. VMI is a process by which the virtualization layer (e.g., a hypervisor) can unobtrusively inspect the complete state of a running virtual machine. VMI is particularly applicable to live digital forensics, as it allows the state of a running VM to be examined without requiring the investigator to install (or even run) software or tools on the VM under investigation, nor does it require that the investigator possess valid user credentials for the VM. Using this technique, forensically valuable data such as process lists, network connections, user activity, and memory contents can all be transparently extracted from the VM.

Recent work for this study (with funding from the DARPA Cyber Fast Track program) in the area of VMI has extended these capabilities to include the ability to gain direct access to cryptographically protected content on the VM. In particular, a digital forensic investigator can use this newly developed VMI tool set to examine a VM and recover cryptographic keys, monitor-encrypted (e.g., SSL and SSH) communication channels, and access encrypted files and storage volumes. Much of this content is either highly volatile or inaccessible without the cryptographic keys and, as such, would be unlikely to be accessible using more traditional digital forensics techniques.

This presentation will describe the applicability of VMI to digital forensics in general, and demonstrate its use to recover system data (e.g., process and network state information) and cryptographically protected content.

Virtualization, VM Introspection, Cryptography

B30 Messaging Application Analysis for Android and iOS Platforms

Katie Corcoran, BS, 1106 11th Ave, Apt 4, Huntington, WV 25701; Aaron Read, MS, 7000 Target Pkwy, Brooklyn Park, MN 55445; and Joshua L. Brunty, MS, and Terry Fenger, PhD, 1401 Forensic Science Dr, Huntington, WV 25701*

After attending this presentation, attendees will have a better understanding of how to access information relevant to mobile device application usage and what remains in a smartphone's memory.

This presentation will impact the forensic science community by providing a straightforward explanation of what information can be found in the presence of specific applications on the two most common smartphone operating systems, Android™ and iOS™. This could help analysts efficiently process a smartphone found during an investigation by having knowledge of the type of information each application contains.

Mobile devices are a commonly encountered piece of evidence in today's investigations. The majority of the operating systems found on smartphones include versions of Android™ and iOS™. Both of these operating systems are enhanced by a multitude of third-party applications that can perform an almost infinite number of actions such as stock monitoring, banking, gaming, shopping, messaging, and photo enhancement.

This research, however, focused mainly on applications that had messaging capabilities which come in many different forms. Some applications are able to only send text and photo messages, referred to as traditional messaging; others are strictly Push-To-Talk (PTT) and operate similarly to walkie-talkies and only send audio messages. Another type of application combines both traditional and PTT messaging, referred to as multi-functional. A final type of application is one primarily for gaming, but allows players to send messages back and forth. These applications are attractive because they can be used strictly through Wi-Fi, which means they can be used on more devices and not require cellular service.

Using the number of ratings and number of downloads from Google Play™, the Android™ application market, seven applications present in both Apple's™ App Store™ and Google Play™ were chosen. Each one fell into one of the four types of messaging applications. For traditional messaging, WhatsApp Messenger™ and Facebook Messenger™ were chosen. For PTT messaging, Zello Walkie-Talkie™ was chosen. For multi-functional messaging, KakaoTalk Messenger™ and Voxer™ were chosen. For gaming applications, Words with Friends™ and Draw Something™ were chosen.

The applications were loaded onto an iPhone 4™ (iOS™ platform) and a HTC EVO 3D™ (Android™ platform) and used to test out the different capabilities of each application. After imaging the phones, the images were searched for artifacts about content and user information. The types of information searched were: text, audio and photo messages, sender/recipient information, location information, and timestamp information and were present in various forms. Text and photo messages were completely accessible except in Draw Something™. When enabled, all applications with location functions kept accurate tracking records and attached latitude and longitude coordinates to each message. Most applications also kept accurate timestamps. Audio messages were mostly unrecoverable, with Zello™ being the only application that could potentially have kept the original messages on the phone (denoted by a Speex file header). The greatest variability was in the user information kept. Not only did each application retain different information, but it also varied between platforms. The platform that generally kept more information was Android™; the Facebook Messenger™ app for Android™ recorded more information than seemed applicable to the scope of the application storing the phone number and e-mail address for each of the contacts.

Despite some limitations in the methods used, most of the information available from analysis of the messaging applications could be helpful in an investigation. Future research on mobile device applications would expand beyond just messaging applications to other types commonly found on seized phones. Another area of potential research would be to find a method that can be used to play the audio files from Zello™.

Smartphone, Messaging, Applications

B31 Mobile Device Tool Testing

Richard Ayers, MS, 100 Bureau Dr, Mailstop 8970, Gaithersburg, MD 20899-8970*

After attending the presentation, attendees will be aware of the importance of tool testing and gain an understanding of the mobile device tool testing process conducted within the Computer Forensics Tool Testing (CFTT) project.

The presentation will impact the forensic science community by increasing awareness of the role of tool testing in informing the forensic community of tool capabilities and limitations. Test reports provide a foundation for toolmakers to improve tools, help users to make informed choices, and provide interested parties with an overview of any anomalies found. The presentation will provide an overview of the motivation behind testing mobile device forensic tools and the challenges faced by toolmakers and forensic examiners.

The CFTT project has spent several years researching and testing forensic tools capable of acquiring data from the internal memory of mobile devices and Subscriber Identity Modules (SIMs). This presentation discusses all aspects of the testing process that are critical for producing a test report.

The development of mobile device forensic tools and acquisition techniques continues to grow within the field of digital forensics. Mobile subscribers far outnumber personal computer owners and studies have shown an increase of mobile device personal data storage compared to personal computers. Higher-end mobile devices present users with advanced features and capabilities similar to those of a personal computer. Mobile devices provide users with the ability to maintain contact information, upcoming appointments, day-to-day activities, important news events, and provide the ability to correspond with friends and family via telephony, text message, email, chat, and social networking sites. Over time, mobile devices can accumulate a sizeable amount of information about their owners. Data acquired from these devices may be useful in criminal cases or civil disputes.

As mobile device usage and sophistication continue to grow, so does the need for tool validation. For acquired information to be admissible in a court of law, verification of a tool's behavior and strict forensic acquisition methods are paramount. Potentially, one piece of data acquired from a mobile device may play a critical role in shedding light on an incident or, possibly, criminal activity. The need for rigorous testing conducted on a combination of forensic tools and specific families of mobile devices is critical for providing law enforcement and forensic examiners informative test results yielding known expectations of a tool's behavior, capabilities, and limitations. Over the past three years, the CFTT project at the National Institute of Standards and Technology (NIST) has tested numerous mobile device forensic tools capable of acquiring data from mobile devices operating over Global System for Mobile (GSM) communications and Code Division Multiple Access (CDMA) networks.

The presentation covers information on the motivation behind testing mobile device forensic tools, specification and test plan development, creation of a known data set, mobile device data population, and tool testing.

Mobile Forensics, Digital, Testing

B32 Using Visualization of Digital Forensic Datasets to Develop Fraud Detection Algorithms

Kara L. Nance, PhD, PO Box 81225, Fairbanks, AK 99708; Stephen McCombie, PhD, Macquarie Univ, Center for Policing, Intelligence and Counter-Terr, Macquarie, AUSTRALIA; and Ben Reardon, BS, Dataviz Australia, Macquarie, AUSTRALIA*

After attending the presentation, participants will have an understanding of abductive reasoning through visualization and an appreciation of the potential to leverage human visual processing with algorithmic development to detect and deter anomalous activities.

This presentation will impact the forensic science community by adding valuable tools and approaches to detecting anomalies in large data sets through visualization and the potential for using this information proactively to detect and prevent crime.

Mitigating card-present fraud through digital forensic analysis can be easy when the behaviors associated with the actions have been identified. The situation is much more challenging when one is not sure for what one is looking for. The human mind has a powerful ability to identify visual anomalies in large datasets. As part of a defense-in-depth strategy, this can contribute to the evolution and refinement of rule sets that facilitate the detection of the crime prior to the cash-out phase of the illegal operation. This presentation investigates the application of visualization, combined with human abductive reasoning, to the problem of identifying some behavioral characteristics of card-present fraud. It then demonstrates the behavioral characteristics in a digital forensics context, and demonstrates how this knowledge can be used to guide the evolution of analytical tools to help protect our digital assets.

The digital footprint left by individuals as they interact with technology throughout the day is astounding. As the use of Automated Teller Machine (ATM), credit, and debit cards becomes increasingly ubiquitous, the associated vulnerabilities make them more and more prevalent targets for cybercriminals. After a crime has been committed and identified, it may be possible to encode the observed information to develop an algorithmic approach to solving the problem. Since an algorithm is a step-by-step method to solve a problem or reach a goal state, clearly the process for solving the problem must be well understood. This works well when the problem is one that has been encountered, studied, and analyzed. What happens when new situations occur that are not expected? In this case, humans are able to reason abductively, and also excel at visual pattern recognition. This provides them with the ability to identify issues that are new.

Visualization is an excellent approach to facilitate these efforts as it allows the human analyst to see and evaluate datasets even when they do not know for what they are looking. Harnessing the power of visualization can provide a valuable tool in the arsenal to detect ATM usage anomalies including skimmed (counterfeited) card fraud. This presentation demonstrates how visualization techniques can be applied to couple the computational power of today's computers with the ability of the human mind to process images and reason through uncertainty. The example provided starts with abductive reasoning and is then analyzed and discussed reflexively. The intent is to demonstrate the value of visualization, in this case using parallel coordinates as a visualization tool, to identify anomalous patterns in data. The analysis of the findings can lead to the tuning of algorithmic tools to detect, and potentially prevent, future attacks using the same *modus operandi*.

This presentation will use a type of card-present fraud as an example to show how behaviors described can be detected through visualization of ATM datasets that are already being collected as part of standard operating procedure. Visualizing this data allows the human user to identify anomalies and use this information to contribute back to the design of effective algorithms to mitigate the threat. The objective of this form of data visualization is to identify and study criminal *modus operandi* in complex datasets and then use this information to design realistic automated rule sets for use in real time analytics tools. Incorporating visualizations into fraud control frameworks will help design new tools and mature existing tools and, thus, will be a positive

step forward for practitioners in the cyber crime prevention field. While there is much work remaining in this problem domain, this presentation demonstrates how anomalies can be identified and then coupled with the behavioral characteristics in context. The resulting information can be used to guide the evolution of analytical tools to help protect our digital assets.

Visualization, Digital Forensics, Fraud

B33 Assessing Skin Detail of the Dorsal Surface of the Hand: A Comparison of Methods

Christina A. Malone, MFS, USACIL, Digital Evidence, 4930 N 31st St, Bldg 925, Forest Park, GA 30297*

After attending this presentation, attendees will have an understanding of two different techniques for segmenting the dorsal surface of the hand for use in image analysis. A comparison of the two methods will generate a greater awareness of the process of evaluating skin features commonly found on the dorsal surface of the hand and used in forensic image comparisons.

This presentation will impact the forensic community by assessing two different grid systems that may be employed in the course of a forensic image comparison. By knowing the strengths and weaknesses of each system, an examiner will be able to conduct a more thorough analysis when attempting to identify an individual through an image comparison.

The skin features examined in this study include: freckles, moles, sunspots, scars, and any other features of de-pigmentation or hyper-pigmentation. As these skin features vary in appearance, both in spatial distribution and geometric shape, each characteristic may be a potentially valuable resource when conducting comparisons to establish individuality. While such marks have been employed in facial recognition, hands are another area of the body that may be captured in images of forensic interest.

Two methods are assessed in the current study; both are grid systems that segment the dorsal surface of the hand into numerous regions. The first method, presented by Malone, includes 14 regions.[1] The second method, presented by Macdonald-McMillan, includes 24 regions.[2] Both methods use anatomical landmarks to divide the dorsal surface of the hand into its respective regions. The regions are then used to determine the location and spatial relationships between skin features. It is hypothesized that the method with more regions will generate more unique results, but an additional aim of the research is to determine the forensic practicality of each method. Depending on the situation, it may be more or less useful to have a greater number of regions to examine.

Each of the hand segmentation techniques was applied to a collection of 233 images. These images of hands were collected between the years 2003 – 2005, as part of the Computer Vision Research Lab Biometric Data Set at the Department of Computer Science and Engineering, University of Notre Dame. Each method was able to accurately quantify the features found in each of the regions generating descriptive statistics on the distribution and frequency of such skin features. Once the images of hands were assessed by both methods, the results were statistically compared. The advantages and disadvantages of each method were then examined.

Through this comparison of methods, an examiner is better equipped to perform photographic comparisons of the dorsal surface of the hand and to defend his or her conclusions in the courtroom. With the abundance of digital images and the potential for skin features to be examined, more research is required to establish consistency within the field of image comparisons.

Image Comparison, Hand Identification, Image Analysis

C1 The Role of Nanotechnology in Forensic Investigations: Application of SEM in the Reconstruction of Crime Scenes

Silvia Boca, MD, Viale Europa 88100 Catanzaro, Catanzaro, ITALY; Isabella Aquila, MD*, Viale Europa, località Germaneto, Policlinico Universitario, S. Venuta- Medicina Legale, Catanzaro, 88100, ITALY; Gerardo Perozziello, PhD, Viale Europa 88100 Catanzaro, Catanzaro, ITALY; Marco Francardi, PhD, and Natalia Malara, PhD, Viale Europa, Gemaneto, Catanzaro, 88100, ITALY; Ciro Di Nunzio, MFS, PhD, Magna Graecia Univ, Viale Europa, Germaneto, Legal Medicine, Catanzaro, 88100, ITALY; Francesca Pepe, MD, Viale Europa, località Germaneto, Catanzaro, 88100, ITALY; Ester De Luca, MD, Viale Europa 88100 Catanzaro, ITALY; and Enzo M. Di Fabrizio, PhD, MD, and Pietrantonio Ricci, PhD, Viale Europa, Gemaneto, Catanzaro, ITALY*

The goal of this presentation is to underline the important role of the Scanning Electron Microscope (SEM) in forensic investigation and its usefulness in scene investigation in correctly describing the events.

This presentation will impact the forensic science community by describing SEM's potential application in forensic pathology.

In the last several years forensic pathology has increased the use of new instrumental methods of investigation. The use of nanotechnology increased in importance, particularly, the utilization of SEM.

Literature has highlighted the use of these methods, especially in the evaluation of the presence of organic and inorganic materials. These techniques are mainly used for analysis of terminal ballistics, for land surveys, and commodity surveys in the reconstruction of the crime scene. The purpose of these techniques is to provide isolation of the materials and to evaluate their eventual origin.

In this study, investigations were used to determine the compatibility of human injuries found on a cadaver with any harmful tools found at the crime scene. The purpose of this study was to detect the importance of applying these methods in the reconstruction of the crime scene by comparing the materials found in tissue organs with those recovered at the crime scene.

The case report examined a 50-year-old man found dead at work. The forensic investigation included: crime scene analysis, autopsy investigations, toxicological and histological investigations, and SEM analysis. On the scene investigation, the victim was found lying on the ground next to a cart used to transport granite blocks. On the cart were many fragments of granite. The external inspection of the body noted bleeding from the ear canals and a major injury to the right side of the face. The internal examination of the body found cranial and facial fractures and brain hemorrhages. The autopsy confirmed the presence of a serious head injury contributing to death. Histological examination showed extensive areas of cerebral hemorrhage. The external cause of injury was due to a macroscopic object compatible with different offensive tools recovered in the survey. The external characteristics suggested a crushing injury from a sheet of granite, which was not confirmed, as the body had been found, then moved to another location.

Crushing injuries are characterized by multiple, diverse, and multipolar marks. They are represented by bruising, abrasions, lacerated and contused wounds, fractures of skeletal segments, and the bursting of internal organs. In crushing by a granite slab, it is important to consider the damage caused by the surface of the plate and its weight. In this case, a section of granite and three cement fragments recovered at the crime scene were taken. At autopsy, six samples of skin tissue were collected. All samples were fixed in liquid nitrogen, stored at -80°C, and analyzed by a Microprobe Energy Dispersive (EDAX) mounted on an SEM. This analysis noted an overlap between the elements found in the granite (carbon: 28%; chromium: 63%) and tissue samples taken from the areas of injury. The overlap of data is not noted for the other materials that constitute other possible harmful tools (cement). Therefore, this technique allowed reconstruction of the crime scene, traced the lesions found on the cadaver to the tool (granite slab) recovered at the scene, and, importantly, attributed responsibility for the event.

Nanotechnology, SEM, Scene Investigation

C2 *Caveat Emptor*: What's a Residential Heating Oil Tank Owner to Do?

Carol A. Erikson, MSPH, Trillium, Inc, 356 Farragut Crossing Dr, Knoxville, TN 37934; and Elizabeth K. Dickinson, 27 LaFayette Cir, Downingtown, PA 19335*

After attending this presentation, attendees will understand the pitfalls faced by a homeowner with an underground storage tank who tries to do the right thing.

This presentation will impact the forensic science community by pointing out the non-technical perspectives to the issue of residential underground storage tanks.

You've lived in Westchester County, New York, for 10 years, and it's time to move back to Pennsylvania. So, you put your house on the market, find a buyer, and work out a sales agreement that includes performing a leak test of the Underground Storage Tank (UST) that has reliably held your heating oil since you moved in, and which, for the record, passed a similar leak test when you moved in. This time, though, it fails the test.

It's an old tank, so you decide to avoid potential future liability by removing it and replacing it with an above-ground tank in the garage. You call the contractor recommended to you by the company supplying your home heating oil. You are told it will cost you $2,800 to remove the UST and install an above-ground tank in the garage, and you pay half up front. The contractor comes out and digs a shallow ditch around the top of the tank. Now you are told there is discolored soil, and, based on a "sniff test," leaking oil was likely. The contractor collects a soil sample and tells you it will cost you an additional $3,000 for them to take care of the (alleged) contamination.

What? This is starting to feel uncomfortable, so you call your sister, who happens to be an environmental consultant. On her advice, you contact the New York State Department of Conservation (DEC) and learn that DEC had concerns about possible contractor irregularities related to UST work in Westchester County. *What?* The DEC representative comes to your house on the scheduled day for your contractor's next visit, but is left hanging when the contractor does not show. He talks to your contractor about the work on the phone and tells you the contractor is competent, but he can't come back the next day when the contractor has promised to be there. *What?!*

The contractor does show up the next day, and excavates down to the bottom of the tank. It is clear the tank is intact, and there is no evidence of contamination, by sight or smell. You are now told you will get your $3,000 back. The oil remaining in the UST is removed and transferred to the new storage tank in the garage. The contractor collects a soil sample from the excavation, re-buries the now-empty UST, and promises to return with the laboratory analysis results. *Whew … maybe it'll be okay after all.* Except that now he won't return your calls, and you can't proceed with settlement on the sale of your house.

Now you contact the Westchester County Department of Health (DOH) and tell your story, only to learn that the contractor has not followed their rules for this type of work. Settlement is delayed more

while you wait for your contractor to provide the necessary paperwork and do things right.

When he finally returns to actually remove the UST, you are there, too, with your environmental consultant brother-in-law and an inspector for the Westchester County DOH. Now you learn that the only reason the UST failed the leak test was because the original, but long-since inactive, fill pipe had never been properly disconnected. There was never any problem with the UST.

By the time the contractor files all the necessary paperwork, a 2-week project has dragged on for two months, costing you, among other things, two additional mortgage payments. You have not been reimbursed the additional $1,600 you paid, nor have you seen any laboratory results. Now what?!

We've all gotten the runaround at one time or another—dealing with health insurance companies is but one example. For the average homeowner, environmental issues are even harder to navigate. *Did it really have to be this hard? How much worse might it have been if there weren't two environmental consultants in the family?* Let the buyer beware.

UST, Residential, NYSDEC

C3 Combustible Dusts and Dusts From Combustion

James R. Millette, PhD, MVA Scientific Consultants, 3300 Breckinridge Blvd, Ste 400, Duluth, GA 30096*

After attending this presentation, attendees will understand how to identify combustible dusts and particles generated by combustion using microscopy tests.

This presentation will impact the forensic science community by providing information about combustible dusts that is an important safety concern for investigators entering dusty areas and useful forensic data in the study of explosions, fires, and sooty particulate.

When forensic investigators enter an enclosed area in a dusty building, they must be aware of the potential for a combustible dust explosion. The Occupational Safety and Health Administration (OSHA) provides a convenient poster that lists 116 combustible dusts divided into six categories: agricultural products (including corn starch), agricultural dusts (including garlic powder and raw yucca seed dust), carbonaceous dusts (including petroleum coke and pine soot), chemical dusts (including ascorbic acid and sodium stearate), metal dusts (including aluminum and iron carbonyl), and plastic dusts (including acrylonitile and epoxy resin).[1] The identification of an unknown dust as one of the OSHA 116 can usually be done by an experienced analyst with one of two microscopy tests. The shape, appearance, and optical properties as determined by Polarized Light Microscopy (PLM) are sufficient to identify many of the agricultural powders. The X-ray elemental analysis performed in the Scanning Electron Microscope (SEM-EDS) can determine which metal dust is present and the Fourier Transform Infrared Microspectrophotometry (FTIR) and Raman microscopy are capable of identifying the plastic dusts. Combinations of the four microscopy techniques (PLM, FTIR, Raman, and SEM-EDS) are used to identify the carbonaceous and chemical dusts. The identification of combustible dusts is important for both the safety of the investigators on-site and for the forensic experts reconstructing explosive or fire events.

Spontaneous combustion of agricultural materials can occur when bacteria slowly decompose the materials, producing heat. When the internal temperature reaches 185°F (85°C), hot spots and pockets may be expected. Flames will likely develop when these pockets come in contact with the air. Non-biological mechanisms may be involved with non-agricultural dusts. Pyrite oxidation has been reported as a cause of spontaneous ignition in old coal mine tailings.

After dusts have burned, microscopy tools are also used to characterize and identify the combustion products. Char particles, a product of partial combustion or a low-temperature situation, retain morphological characteristics of the original dust particles. Aciniform soot and flyash are the products of higher temperature combustion where the chemical elements of the original dust particles have reformed after being vaporized. The combination of a clear tape lift attached to a glass microscope slide and a wipe sampler is the preferred collection media set for soot testing. The clear tape lifts by themselves are helpful for screening purposes, especially to identify mold, biofilm, or other biological growth, but it is difficult to remove the particulate for other testing when a fuller analysis is in order. For instance, the finding by light microscopy of dark, opaque, aggregated particles on a tape lift suggest aciniform soot may be present, but this can only be confirmed with transmission electron microscopy as the diameters of the primary carbon particles in aciniform soot may be in the 30 – 40 nanometer range. The ASTM Standard D6602 is a method for identifying carbon black, an engineered aciniform carbon soot, that can be used to identify combustion dust particles in a variety of settings.[2]

Explosive Dust, Soot, ASTM D6602

C4 High-Throughput Environmental Forensic Investigation to Identify Contamination Sources of Polycyclic Aromatic Hydrocarbons in a Stream

Melinda Pham, BS, and Frank Dorman, PhD, 107 Whitmore Labs, University Park, PA 16802*

After attending this presentation, attendees will understand how to prepare and clean up various samples prior to Gas Chromatography/Mass Spectrometry (GC/MS) analysis for environmental forensic needs. The sample clean-up procedure to be discussed is based on USEPA 3640A, but the procedure has been modified into an automated method using J2 Scientific's automated sample preparation instrument, PrepLinc. Attendees will also learn how to identify contaminants in a complex ecosystem through a discovery analysis. Lastly, attendees will learn a technique on how to identify possible sources of contamination via receptor model called Positive Matrix Factorization (PMF).

This presentation will impact the forensic science community by demonstrating an alternative automated sample clean-up method that would require less manual labor and an increase in sample throughput. The sample clean-up method will employ Gel Permeation Chromatography (GPC) and automatic concentration via an AccuVap. The forensic community will also learn how to identify sources of contamination and the contribution of those sources in sediment samples. This will be beneficial for differentiating natural and anthropological contamination sources.

Modern society has increased the usage and varieties of organic compounds for various benefits; however, there can be a negative side of the use of these same chemicals—environmental exposure. The "contaminant" may be transported great distances through the ecosystem before detection. In addition, once detected, the compounds may undergo significant degradation, metabolism, or other processes termed "weathering." This may make the identification of the original source of the pollution more difficult. It is the identification, quantification, and determination of the source or sources of environmental pollution that largely comprise the science of environmental forensics, and the subject of this presentation. The organic contaminants of interest in this study are Persistent Organic Pollutants (POPs) like Polycyclic Aromatic Hydrocarbons (PAHs).

PAHs are organic, atmospheric pollutants created through the incomplete combustion of fossil fuels like coal and petroleum. These

airborne pollutants can travel a great distance before depositing onto surfaces via wet and dry deposition. For this presentation, PAHs deposited into and around a nationally recognized fishing stream, Spring Creek, are investigated. PAHs are of environmental concern because of their persistent, bioaccumulative, and carcinogenic properties, thus, identifying and monitoring the contributions of PAH sources becomes important.

The PAH emission sources have distinct signatures, but the complex environmental matrix interferes with the analysis. To eliminate interfering compounds in the sediment samples prior to analysis, the automated sample clean-up procedure will be presented. The cleaned samples are then analyzed via GC/MS for identification and quantification.

Besides matrix complexity, sediment samples contain a collection of PAHs from natural and anthropological sources. Thus, differentiating between the two will be beneficial for environmental forensics application. Field sediment samples from Spring Creek are analyzed to identify PAH sources and their apportionment. The PAH emission sources and their contributions are identified using a receptor model called PMF. PMF is a multivariate statistical tool used to identify contamination sources and the contribution of each source in a given sample. PMF was chosen for this investigation because of the ability to assign experimental uncertainties to individual data points. Secondly, solutions are constrained to non-negative values, thus, overcoming limitations found in other, current receptor models like Principle Components Analysis (PCA). This work specifically discussed in this presentation may be applied to numerous other forensically relevant samples, and this will also be discussed.

PAHs, Forensic, PrepLinc

C5 Environmental Chemistry

James S. Smith, PhD, Trillium, Inc, 28 Graces Dr, Coatesville, PA 19320-1206*

After attending this presentation, attendees will have a better understanding of a chemist's role in environmental litigation.

This presentation will impact the forensic science community by focusing on the expert's qualifications instead of the general area of competence.

The essence of the litigation is based on forensic environmental chemistry dealing with questions such as:

- Who released the chemicals of concern (i.e., those substances perceived to harm human health or the environment)?
- How did the release occur?
- What manufacturing process or function produced the contaminant(s)?
- When did the releases occur (age-dating environmental contaminants)?

The answers to these questions must be found in the data from the site investigation of the contaminants in the various matrices, the fate and transport of the chemicals in these matrices based on peer-reviewed literature, and the fundamentals of chemistry and physics. The forensic scenario that is built by the expert witness should be logical and thoroughly based on the documents provided in the case, the chemical data that was obtained during the site investigation and that has been provided, and the chemical literature.

A case in point concerns chemistry and an environmental matrix such as groundwater. Is a chemist allowed to testify about chemicals in groundwater including their fate and transport? The attorney stated during *voir dire* of a chemist that fate and transport of chemicals in groundwater can only be addressed by an expert hydrogeologist. A chemist is not capable of determining the direction of groundwater flow nor its velocity. The use of tracer chemicals is not in the chemist's toolbox for the determination of the source of groundwater contamination nor where chemicals are transported by groundwater. The fate of chemicals in groundwater is for the hydrogeologist to interpret and opine upon. A chemist can discuss chromatography but cannot opine on the retention of chemicals in an aquifer.

A judge as a gatekeeper must decide if a chemist can or cannot testify at trial about the fate and transport of chemicals in groundwater. This is a new question and it does not consider the expert's qualifications but does consider the definition of the area of expertise.

Environmental Chemistry, Fate & Transport, Hydrogeology

C6 Scanning Electron Microscopy — Back to Basics

Richard S. Brown, MS, MVA Scientific Consultants, 3300 Breckinridge Blvd, Ste 400, Duluth, GA 30096-893*

After attending this presentation, attendees will gain insight into the importance of SEM detector geometries and their impact on data produced by a Scanning Electron Microscopy-Energy Dispersive X-ray Spectrometry (SEM-EDS) system.

This presentation will impact the forensic science community by demonstrating basic SEM-EDS detector geometries and showing how errors in Energy Dispersive X-ray Spectrometry (EDS) spectral acquisition can be avoided.

Scanning Electron Microscopy (SEM) became commercially available around 1965. Many improvements have been made since the early commercial instruments, allowing the SEM to have a presence in many laboratories and classrooms that use and study materials. Adding EDS to the SEM allows the user to quickly obtain the elemental composition of a material. Due to the advances in SEM-EDS hardware and software, very little instruction is typically required to train an individual in the operation of an SEM-EDS system. In fact, SEM-EDS is probably the easiest microscope to use in the laboratory.

Most of the operations for sample chamber evacuation, electron gun alignment, focusing, image contrast and brightness adjustment, and EDS data acquisition have become automated, requiring only the press of a button. Images and EDS spectra, once obtained, can be dropped into word processing, spreadsheet, or presentation software with a simple click and drag of a mouse…or the touch and drag of the "touch screen" that dominates today's telephones and tablets. Data acquisition using an SEM-EDS system has progressed to the point where the user, or the "human" interface, has become the slowest interface in the SEM-EDS system. Software algorithms have been and are being produced to analyze tremendous amounts of data that can perform iterative queries and produce groups of elements or show associations of elements (phases) during an SEM-EDS analysis that may otherwise be overlooked by the human interface. All of the automation, software, and user interfaces that have been designed to aid the microscopist in his (or her) analysis of a given material are both useful and welcome. The basic geometry of SEM-EDS systems and the electron beam-specimen interactions remain relatively unchanged with the low vacuum capability of modern SEM-EDS systems being but one exception.

SOPs and recipes have put the SEM-EDS within the reach of even the most novice user. These management tools enable laboratories to train individuals and replace individuals quickly so the laboratory remains productive. Unfortunately, no SOP or recipe, no matter how thoroughly written, can guarantee that the data produced is reliable. Fundamental concepts and knowledge of the basic geometry of the SEM-EDS system is essential to ensure the data produced is reliable. A useful approach to understanding the basic detector geometry of any SEM-EDS system is to think of the SEM imaging monitor as a clock face. Locate the EDS detector on the clock face by inspecting the exterior of the microscope chamber and determine where the EDS detector is. Is the EDS detector at 10 o'clock? Is it at 12 o'clock? Locate the secondary electron detector and any other detectors that are part of the SEM-EDS system. Knowing this information will help in assessing any elemental data produced when un-even non-flat specimens, also called "everyday specimens," are analyzed. The interaction of the primary electron beam with the sample and the line-of-site trajectory of the X-rays produced can affect the quality and reliability

of any EDS data produced. Examples of EDS data produced from specimens that are analyzed by SEM-EDS will demonstrate the effects of low vacuum, non-flat specimens resulting in X-ray fluorescence and absorption and general, basic SEM-EDS practices that will aid the SEM-EDS user in the analysis of everyday specimens.

SEM-EDS, Low-Vacuum, Elemental Analysis

C7 Detection of Drugs on Fingermark Residue Using Nanoparticle-Based Fingerprint Powders Using SALDI TOF-MS/MS Technique

Fred Rowell, PhD, ARRO Forensics Ltd, Inex Business Support Facility, Hershel Annexe, Newcastle upon Tyne, Tyne and Wear NE1 7RU, UNITED KINGDOM; and Latha Sundar, PhD, ARRO Forensics Ltd, Inex Business Support Facility, Herschel Annexe, Kings Gate, Newcastle Upon Tyne, Tyne and Wear NE1 7RU, UNITED KINGDOM*

After attending this presentation, attendees will have an understanding of the dual nature of fingerprint powders to develop and detect drugs on fingermark residue using Surface Assisted Laser Desorption Ionisation Time-of-Flight Mass Spectrometry (SALDI TOF-MS) technique.

This presentation will impact the forensic science community by providing results of trials and experiment conducted using nanoparticle-based ARRO MS latent fingerprint development powder. The presentation will provide experimental evidence using the powders in enhancing the definition of the developed fingerprint and to directly analyze the drugs on the lifted fingerprints.

The presentation will provide experimental evidence of the work performed to visually identify fingerprints using nanoparticle-based fingerprint powder. The developed print can then be lifted using lifting tape and can then be directly analyzed to identify the chemical constituents present within the fingerprints which might include any contact residue of the drug handled and/or metabolites of the drugs excreted through the pores of the skin. A range of drugs including therapeutic (paracetamol, aspirin, and lisinopril) and illicit (cocaine, methadone, and amphetamine) drugs were identified on fingermark residues (with or without cyanoacrylate fuming) after developing with nanoparticle-based latent fingerprint powders (ARRO SupraNano MS black magnetic powder) and analyzing using SALDI TOF-MS technique. Peaks were identified for all the drugs under study for the lifted fingerprints dusted with MS black magnetic powder and with Dihydroxy Benzoic Acid (DHB), a commonly used maldi matrix agent. Results were compared for lifted prints with or without cyanoacrylate fuming prior to dusting. For fingerprints dusted with MS black magnetic powder, in addition to the identification of the drugs, the developed fingerprints were highly defined, revealing more details of the fingerprints, due to the smaller diameter and the sphericity of the nanoparticles.

Method: Fingerprints spiked with therapeutic (paracetamol, aspirin, and lisinopril) and illicit drugs (cocaine, amphetamine, and methadone) were deposited on a clean glass slide, followed by dusting with MS black magnetic powder. The prints were then lifted using a standard fingerprint lifting tape and were stuck to a maldi target plate with the adhesive side facing up. Analysis was performed using Shimadzu Axima Performance Maldi TOF-MS after calibration using small molecule calibration mixture for the masses ranging between 132 to 607 using positive ionisation mode. Reference spectra for the drugs under study were obtained by spotting 1µl of the drug standard (10µg/ml) along with 1µl of 10mg/ml of DHB and analyzing it in positive mode. For the lifted fingerprint, laser shots were randomly fired across the fingerprint area and the average profile of the spectrum was collected using approximately 400 shots for each fingerprint region. Similar procedure was conducted for the spiked fingerprint without any dusting agent and with DHB dusting.

Results and Discussion: The nanoparticle-based SupraNano MS black latent fingerprint powder gave superior definition, exhibiting 3rd level ridge detail with high contrast against the background. The smaller diameter and the sphericity of the nanoparticles is the prime reason for the enhanced performance of the latent fingerprint powder.

SALDI analysis of the lifted fingerprints dusted with DHB and MS black magnetic powder gave M+1 peaks for all the drugs studied. However, for fingerprints dusted with MS black magnetic powder, sodium and potassium adducts of the drugs were also identified along with the M+1 peak for most of the drugs. Nanogram levels of the drugs were able to be identified on the lifted fingerprints dusted with MS black powder. The carbon black-doped silica nanoparticles used as the active ingredient in the latent fingerprint powder aids in the ionisation process, thereby enhancing the signal intensity even at trace level concentration.

With the results obtained, it can be concluded that the MS black magnetic powder can be used for the dual purpose of developing the fingerprint (with or without cyanoacrylate fuming) for superior definition and for directly detecting the chemical constituents present within the fingerprint using SALDI TOF-MS.

Nanoparticle, Fingerprint Powder, Drug Analysis

C8 Two-Dimensional X-Ray Diffraction for Forensics and Archaeology

Bob B. He, PhD, Bruker AXS, 5465 East Cheryl Pkwy, Madison, WI 53711*

After attending this presentation, attendees will gain an understanding about the basic concept and recent advances of two-dimensional X-ray diffraction, including the key technology, configurations, and applications relevant to forensics and archaeology.

This presentation will impact the forensic science community by introducing the two-dimensional X-ray diffraction as a powerful material characterization tool as well as the advantages for forensics and archaeology. This presentation will provide experimental examples both in general material research and forensic studies.

Compared to the conventional X-ray diffraction, the two-dimensional diffraction pattern contains not only the diffraction intensity distribution in two-theta direction based on the Bragg law, but also the diffraction intensity distribution along the gamma direction (along the diffraction ring).[1] The intensity distribution and two-theta variation along the gamma direction can reveal the strain, crystallite orientation distribution, and size. The diffraction patterns, appearing identical with the conventional X-ray diffraction, can be significantly different if observed with two-dimensional diffraction. Therefore, two-dimensional X-ray diffraction can distinguish two samples with identical chemistry content and phase as long as they were formed at different conditions. Two-dimensional diffraction patterns are also easy to compare, evaluate, and present to the courtroom.[2]

The recent advances in two-dimensional X-ray diffraction have significantly benefited forensics and archaeology. The brilliant X-ray sources can deliver highest X-ray flux for fast data collection and deal with small sample volume, weak diffraction, and low concentration. The point focus preferred with the area detector is very suitable to point the X-ray beam to the interested area of evidence and controlled substance. The photon-counting area detector with a large detection area, high sensitivity, high resolution, and near-zero background noise can reveal the phase, crystal structure, crystal particle size, and crystal orientation from a very small amount of the sample. Typical analysis for forensics and archaeology involves identification of materials and structures from a small amount or a small area of samples, also referred to as microdiffraction. In order to preserve the original evidence and art, the analysis must be done non-destructively and without sample treatment. Two-dimensional X-ray diffraction is an ideal, non-destructive, and highly sensitive analytical method for examining samples of all kinds, such as metals, polymers, ceramics, soils, coatings, paints, biomaterials, and fibers for forensic science and archaeology. Sample alteration or treatment is typically not necessary and the data collection can be repeated many times without any damage to the sample. Two-dimensional diffraction patterns contain abundant information and are

easy to observe and explain in the courtroom. This presentation will cover various applications used for forensics and archaeology analysis. Experimental examples for general materials characterization, including phase identification, texture and microstructure analysis, and case study examples in forensics and archaeology are also given.

XRD, Microdiffraction, Area Detector

C9 Use of High-Definition Survey (HDS) Laser Scanning in Forensic Engineering

Steven M. Schorr, PE, DJS Associates, Inc, Forensic Engineering Services, 1603 Old York Rd, Abington, PA 19001*

After attending this presentation, attendees will gain knowledge regarding the utilization of High-Definition Survey (HDS) laser scanning. Engineers are now able to, cost-effectively and with unprecedented accuracy at the speed of (laser) light, collect millions of measurements and create a 3D world.

This presentation will impact the forensic science community by illustrating how HDS laser scan data is collected; how the data is utilized in the industry; how the data and its by-products have been presented in court; the basic costs; and the strengths and weaknesses of the technology. This presentation will also focus on the unique issues that may arise when HDS laser scanning is utilized in the forensic field, including how to prepare for the expected challenges to the data collection process and accuracy.

We view our everyday world in 3D so why should we not be able to view and analyze our collisions, incidents, accidents, and other types of occurrences in the same manner? With the advent of state-of-the-art technology in data collection, the use of HDS laser scanners now makes this possible. Through the utilization of this cutting-edge laser scanning technology, engineers are now able to, cost-effectively and with unprecedented accuracy at the speed of (laser) light, collect millions of measurements and create a three-dimensional world. The quality of an engineer's analysis is directly related to the quality of the collected data, so this new technology is rapidly advancing the field of forensic engineering.

Traditionally, forensic engineers have utilized the same equipment used by professional surveyors. Though this equipment is still a valuable tool in the engineer's toolbox, its speed limitations and measurement recording technique has been far surpassed by laser scanning technology. Before laser scanning, the data collection process prevented engineers from taking more than a couple of measurements per minute. Now, engineers can record hundreds of thousands of measured points every minute. The measurements are recorded from laser light, which reflects from objects after being projected from a series of rotating mirrors. The scanner is indiscriminate in what objects it measures, meaning that precise measurements can be taken of just about anything. This relatively new technology is rapidly becoming more and more affordable to forensic professionals. The HDS laser scanners have the ability to quickly, accurately, and thoroughly collect 3D data for almost any type of incident and environment. The HDS laser scanners are routinely utilized to collect fresh, physical evidence at building collapses, bridge failures, vehicular collisions, and anywhere there is a need for precise 3D measurements. This is especially beneficial in capturing the scene as it was at the time of the occurrence, if the incident area will be changing. HDS laser scanning data is so beneficial that, even in its raw form, it can be utilized for critical data, measurements, and even exhibits. The mass quantity of recorded raw data collected from long-range scanners (frequently referred to as a point cloud) is accurate to within a few millimeters (approximately the size of a pencil eraser). In addition, because the raw data cannot be altered or modified in its initially recorded state, the data validation process with other engineers and investigators has been greatly streamlined. The 3D data is also a foundation for other engineering analyses, providing an accurate baseline data to effectively utilize scientific tools such as photogrammetry and camera-matching. The "point cloud" data can also be used to quickly and accurately create real-world, 3D models for use in demonstrative exhibits, like simulations and animations.

HDS Laser Scanning, 3D Measurements, Camera Matching

C10 Large Area Hyperspectral Imaging of Effluents as an Example of Technology Transfer

Robert M. Pentz, BS, and Donald J. Rudy, PHD*, Aerospace Corporation, 2310 E El Segundo Blvd, El Segundo, CA 90245; Matthew Begert, BS*, Aerospace Corporation, 2350 East El Segundo Blvd, El Segundo, CA 90245-4609; and Alan M. Foonberg, MS*, and Fletcher D. Wicker, PhD*, Aerospace Corporation, 2310 E El Segundo Blvd, El Segundo, CA 90245*

After attending this presentation, attendees will learn about an airborne Hyperspectral Imager (HSI) developed for the government and the efforts to transition this device into the law enforcement arena.

This presentation will impact the forensic science community by addressing how not all laboratories doing research into new instruments/methods that have forensic applications need to be certified and the scientists performing this research need not be accredited forensic investigators for their research to be acceptable in court.

This presentation will present an airborne HyperSpectral Imaging (HSI) sensor as an example of technology developed by The Aerospace Corporation, a California nonprofit company that operates a Federally Funded Research and Development Center (FFRDC), for the federal government and the effort to transition the device into a forensic tool. This technology was first demonstrated to law enforcement and public safety personnel using a small, ground-based instrument at a court-supervised methamphetamine cook in Southern California in 1998 by the National Law Enforcement and Corrections Technology Center – Western Region (NLECTC-WR). The NLECTC-WR was a National Institute of Justice (NIJ) center run by The Aerospace Corporation. The technology uses Thermal InfraRed (TIR) spectroscopy to detect and identify hazardous chemical effluents such as such as those created by methamphetamine labs (methyl ethyl ketone, Freon, etc.) and Improvised Explosive Devices (IED) production.

A predecessor of the current instrument was flown over the debris of the World Trade Center to locate hazardous materials, such as asbestos, ammonia, etc. The current instrument is greatly improved and can acquire data over much larger areas and process that data much faster than its predecessors. The current MAKO system capability will be described in detail as well as the path forward for this technology. The effort to transition this technology to forensic applications will also be put forth.

The airborne nature of the MAKO instrument is an expansion of the concept of crime scene boundary. The scientific examination of the 9/11 Twin Towers destruction expanded the concept of the crime scene boundary. It was based on an increased scientific capability. This expanded capability through translational science is the core message of this paper. The improved metrics and capability of improved technology are described as forensic advances in this paper.

Questions raised about the legal ramifications of this and other advanced technologies will be put forth and a path forward to get answers will be discussed.

In addition, the presentation will describe short- and long-term plans for utilizing this and other tools developed by the government for military applications as real-time forensic tools to systematically improve, on a volunteer basis, security, safety, and quality of life.

1. Integrate with the national agenda of All Hazards Preparedness. National preparedness is a quest.
2. Integrate with internationally available satellite systems, such

as weather satellites and GPS, for accurate time and location of effluent events as well as their possible movements.
3. Develop synoptic displays applicable for first responders and non-scientific experts.
4. Develop concepts of operations for real-time forensics utilizing these tools.
5. Partner with law enforcement and public safety agencies to license/commercialize.
6. Provide training. Help the public differentiate fact from fiction.

Technologies, such as the HSI instrument presented here, will continue to be developed by institutions that are outside the realm of accredited forensic laboratories by scientists who are not accredited forensic technicians. There needs to be a method to transition these technologies into the forensic realm by proving their utility on actual casework and in the courts before the accreditation process can begin.

Hyperspectral, Imaging, Accreditation

C11 Crashworthiness Simulations of Glass Mat Thermoplastic (GMT) and High Strength Steel (HSS) Sedan Bumper Beam Designs Using Explicit Finite Element Analysis

Scott A. Anderson, BS, and David Bosch, PhD, 4665 S Ash Ave, Ste G4, Tempe, AZ 85282; Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Ct, Ste A, Edgewood, NM 87015; and Dean L. Jacobson, PhD, 4665 S Ash Ave, Ste G4, Tempe, AZ 85282*

After attending this presentation, attendees will be exposed to how explicit finite element analysis can be used to investigate deficiencies in crashworthiness, as well as how it can be used to suggest superior alternative designs. The state-of-the-art in bumper design will be discussed. The importance of materials testing to failure investigations will be emphasized through examples of specific cases where it proved valuable.

This presentation will impact the forensic science community by showing and recognizing shortcomings of some current bumper designs as well as broadening their exposure to tools that can be used to investigate crashworthiness in general. Identifying these problems and educating others about it will serve to create a driving force toward solving them.

Nearly all front and rear bumpers on modern sedans use either a High-Strength Steel (HSS) bumper beam or a Glass Mat Thermoplastic (GMT) composite bumper beam. GMT bumper beams are better at absorbing energy in low speed crashes than HSS and perform better in pedestrian protection tests; however, at higher speeds they fracture. GMT and HSS designs were investigated for crashworthiness at high and low speeds using explicit finite element analysis.

Three-dimentional models were created of the frame and bumper structural parts located at the front of one sedan and the rear of another. The 3D models were created using a portable Coordinate Measuring Machine (CMM). Using the CMM, data was collected from two production sedans. The data was used to create very accurate 3D models of the frame structures that contributed the most interaction in the collisions studied. The portion of the sedan that was not expected to deform or contribute much interaction other than mass and inertial properties was modeled with a sled based on the Advanced European Movable Deformable Barrier version 3.10 specification. The sleds were given the inertial properties of the modeled sedans.

Samples of bumper materials and frame materials were extracted and tested. Tensile testing was performed on all steel samples. Fourier Transform Infrared Spectroscopy (FTIR), tensile tests, flexural tests, and out-of-plane shear testing was performed on Original Equipment Manufaturer (OEM) and aftermarket GMT bumpers. Mechanical properties obtained from the tests were incorporated into the finite element model. Significant differences were found between the manufacturers' mechanical material property specifications and those obtained from testing the material. The effect of these differences was investigated with the Finite Element Analysis (FEA) model.

The sedan with the modeled front bumper was placed behind the sedan with the modeled rear bumper. The front sedan was at rest, while the rear sedan was given varying initial velocities and allowed to impact the front sedan. Simulations were performed with changes made to the front sedan's rear bumper geometry and material and results were compared. Vehicle velocity versus intrusion was plotted and the energy absorbed by the different bumper designs was compared. Real world crash testing was performed using the two sedans which was used to validate the FEA model. All simulations were performed using the commercial finite element analysis software LS-Dyna.

It was found that actual mechanical properties of tested OEM GMT bumpers were significantly less than specified by the manufacturer and that this significantly reduced the bumpers' real world performance. It was found that at speeds over 5mph the GMT bumper beam fractured and completely separated, while the HSS bumper beam did not. This leads to significant differences in the energy absorbed by the bumper beam designs at speeds higher than 5mph. It was also found that the bumper design can affect whether the bullet vehicle is directed down and into the frame or up and into the trunk where little structure exists to absorb energy and keep intrusion out of the passenger compartment.

Crashworthiness, FEA, Bumper

C12 Breakage Characteristics of Glass Drinking Vessels and Consequent Injury Potential in "Glassing" Attacks

Richard W. Earp, MEng, Dept of Engineering, Univ of Leicester, University Rd, Leicester, Leicestershire LE1 7RH, UNITED KINGDOM; Sarah V. Hainsworth, PhD, Dept of Engineering, Leicester, LE1 7RH, UNITED KINGDOM; and Malcolm D. Glendenning, PhD, Glass Technology Services, 9 Churchill Way, Chapeltown, Sheffield, South Yorkshire S35 2PY, UNITED KINGDOM*

After attending this presentation, attendees will gain awareness of typical breakage patterns of a representative selection of glass drinking vessels found in bars and pubs, and understand the particular conditions in which they occur.

This presentation will impact the forensic science community by providing a detailed account of the failure of drinking glasses, and thus giving an indication as to whether or not an alleged account of a glassing assault is likely to be valid or not.

The failure of glasses is dependent upon a complex function of: (1) flaws that are either inherently present or due to handling damage in/of the glass; (2) the glass' thermal history and, hence, the extent of residual stress present; (3) the magnitude and distribution of areas of individual stress concentrations due to loading; and, (4) the mechanical properties of the glass itself. Since nearly all commercial glasses are soda-lime silicates, the mechanical properties of glass can be assumed to have negligible effect.

Figure 1 shows a Finite Element Analysis (FEA) simulation of a pint glass subject to impact. Areas of high stress concentration are likely to serve as the origin of failure but more vulnerable areas of the glass (i.e., the rim) are likely to be the source of the most severe flaws. Failure occurs when the critical fracture toughness is exceeded. Where a large flaw is found, the energy necessary to cause fracture is low and a claim of accidental breakage and consequent injury may have merit.

The introduction of tempered glasses over the last two decades has led to an increase in glass safety by causing the glass to break into smaller and blunter fragments. A rapid cooling treatment of the glass surfaces from the glass transition temperature causes a mismatch of fictive temperatures throughout the glass wall thickness, leading to compressive stresses at the surfaces and a balancing tension stress in the core of the glass. Since glass will only fail in tension and usually from a surface flaw, the magnitude of compressive stress can be added directly to the inherent glass strength. The combination of the additional force required to cause fracture and the release of the residual stresses causes a far more dense fracture pattern.

However, the level of temper possible is dependent upon the thickness of the glass and it is found that thinner parts of the glass (i.e., closer to the rim) store far less stress and resulting fragments there are similar to that of annealed (residual stress-free) glass. This can be seen in Figure 2.

Not only does the level of residual stress vary up and down the height of the glass, but also around its diameter. This can be measured using an automated polariscope that interprets the degree of retardation of light due to stresses in the glass. A prediction of residual stress can also be made by analyzing the distribution of wall thickness, which is aided by the use of CT imaging.

This presentation will show a range of characteristic breakage patterns produced by varying types of glasses, and illustrate what factors must be incorporated into the production of a safe pint glass.

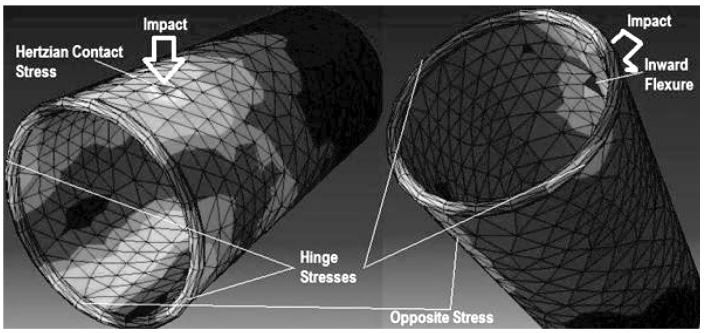

Figure 1 — Finite element simulation of stress distribution on a straight-walled pint glass due to impact. Left image shows the Von Mises stress distribution, right image shows first principal stresses.

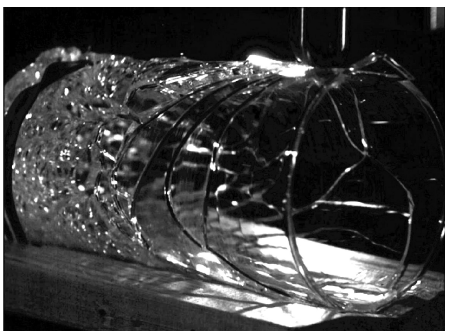

Figure 2 — A frame taken from high-speed video footage of a tempered glass fracture. Near the base of the glass, the toughening process is effective and the glass breaks into small shards. For this glass, toughening is less effective closer to the rim, resulting in larger and sharper shards.

Glass, Glassing, Fragment

C13 3D Characterization and Comparison of Fracture Surfaces

Barbara K. Lograsso, PhD, 127A Spedding Hall, Ames Laboratory, Ames, IA 50011-3020; Ashraf F. Bastawros, PhD, 2347 Howe Hall, Aerospace Engineering and Mechanics, Iowa State Univ, Ames, IA 50011; Xu Shang, BS, 1200 Howe Hall, Aerospace Engineering, Iowa State Univ, Ames, IA 50011; John R. Vanderkolk, BA, 5811 Ellison Rd, Fort Wayne, IN 46804; James F. Evans, 211 Northcrest Rd, Angola, IN 46703; Stacie Johnson, 5 Spedding Hall, Ames Laboratory, Ames, IA 50011-3020; and Taylor D. Reeves, BS, 107 Eastmoor Dr, Marshall, TX 75672-4603*

After attending this presentation, attendees will become familiar with fracture characteristics from materials and fracture events.

This presentation will impact the forensic science community by answering the National Academy of Sciences (NAS) call in the area of fracture surface matching where traditional matching techniques become limited when macroscopic surface features are degraded, and to incorporate an engineering technique.

In 2010, according to the FBI's Uniform Crime Report, over 150,000 violent crimes were reported to have a knife or other sharp, cutting instrument involved. Conclusively matching two halves of a fracture surface can be crucial to a criminal investigation. For example, if a knife tip is found at a crime scene, proving that it belongs to the suspect's knife depends upon the expert opinion of the forensic examiner. At present, a visual pattern match of the two surfaces is the most common way to match fractured pieces. The 2009 National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward* calls for reforms and major changes to current forensic science practices. The goal of this project was to answer this call in the area of fracture surface matching where traditional matching techniques become limited when macroscopic surface features are degraded, and to incorporate an engineering technique with mathematically and statistically defendable error rates to fill this gap.

The goal of this study was to determine whether surface measurements could be used to conclusively associate two fracture surfaces. With the use of instrumentation (Direct White Light Interferometry (DWLI), Scanning Electron Microscopy, and Optical Microscopy), micron level measurements were gathered from the fracture surfaces of both the knife tip and the suspect knife. The measurements would then be used to compare the two fracture surfaces and determine if they were from the same fracture event. This new method seeks to assist the examiner by providing mathematical support for an exclusion, identification, or inconclusive determination concerning the tip and suspect knife.

In order to achieve this, a two-inch section from each knife in a set of was broken off. Each knife now consists of a tip and a base. For the experiments, each knife base was assigned a random code consisting of a letter followed by two numbers to differentiate this set of samples from others. The samples were all examined and matched to the other half using an optical microscope simulating conventional forensic fracture matching.

Direct White Light Interferometry was utilized to scan the samples in three predetermined zones of the fracture surfaces. Fast Fourier Transform algorithms were used to process the topographical surface feature data to convert the data into distinct average frequencies for each surface. An algorithm was used to compare the average frequencies of each surface pre- and post-exposure to delineate match results.

The fracture surface topography measurements were collected using the DWLI. To capture the range of surface features, a magnification of 20x was chosen. The field of view at this magnification of 20X is 0.55mm by 0.55mm, representing only a portion of the entire surface during the DWLI scan. To obtain an accurate representation of each fracture surface, three scans are taken, each in a different region of the fracture surface. The DWLI records the scan in nanometers, and the output is a three-column matrix, where the first two columns designate the pixel and the third column is the height at that pixel.

The matrix is run through an algorithm which uses the Fourier Transform to compare the mean frequency of each fracture surface. The difference between the mean frequency of two fracture surfaces indicates if the surfaces are a match or not. With the narrow height range parameters used to measure the fracture surfaces on the instrumentation, the software is used to discriminate between samples. Comparisons of fracture surface feature frequencies between samples will be discussed in terms of a quality of match for a known match versus non matches.

Fracture, Steel, Interferometry

C14 Examination of Microstamped Cartridges

Taylor N. Grieve, BS, 206 Wilhelm Hall, Ames, IA 50011; L. Scott Chumbley, PhD, 214 Wilhelm, Iowa State Univ, Ames, IA 50011; M. James Kreiser, BS, 3112 Sequoia Dr, Springfield, IL 62712; and Todd Lizotte, BS, and Orest Ohar, BS, 8 Delta Dr, Londonderry, NH 03053*

After attending this presentation, attendees will gain an understanding of the durability and reliability of microstamped firing pins. The quality of the alphanumeric identifier will be discussed as well as how the gear code on microstamped firing pins can be deciphered. How the transfer of the identifier varies between different guns and ammunition will also be discussed.

This presentation will impact the forensic science community by providing results from a microstamped study, an area that is currently receiving a lot of attention. This presentation will add to research being carried out in ballistics by broadening the understanding of factors that affect the transfer of the alphanumeric identifier as well as a circumferential gear code and its decipherability.

Recently, firearm microstamping, which involves placing unique identifiers on the end of a firing pin that is then transferred to the primer upon firing, has been proposed as one method of improving forensic identification. Current microstamped marks consist of six to eight alphanumeric characters and a surrounding circular gear code, which is intended to confirm the alphanumerics. While a quick visual observation can determine which alphanumerics are clear, any distortion of the identifiers or sanding of the firing pin tip can make identification difficult. In these cases, the gear code could provide information that could fill in missing identifiers, or could replicate the whole alphanumeric code if it is illegible.

This study seeks to evaluate the transfer of gear codes from microstamped firing pins to a variety of ammunition types. The initial part of this study has already appeared in print.[1] Briefly, 1,000 cartridges were fired with three different semiautomatic handguns: a Sig Sauer P226, a Taurus PT609, and a Hi-Point C9. Microstamped firing pins for each gun were optimized with six alphanumeric characters. Of the 1,000 rounds, ten different brands of ammunition were chosen with a variety of primer types represented. The fired cartridges were then evaluated through a stereomicroscope and assigned a grade based on the number of legible alphanumeric identifiers. The poorest quality transfers from this study were chosen to be examined through Scanning Electron Microscopy (SEM).

Like the identifier evaluation in the previous study,[1] the Sig Sauer had the best transfer of gear code. The Taurus did not transfer its gear code well, and the Hi-Point transferred its gear code consistently, though only certain sections. Interestingly, the overall clarity grade was improved most, not from the gear code, but by simply changing the imaging technique. SEM allowed more of the identifiers to be clearly read, though some still were too smeared to decipher.

In addition to evaluating the poorest quality cartridges, the lowest graded clips (10 cartridges per clip) from each gun were also evaluated to examine the possibility of using parts of the gear code and identifiers to form a complete microstamp. As was the case in the earlier part of this study, the Taurus cartridges did not have good gear code transfer.[1] No gear code transferred beyond the second character; however, the identifiers did reveal the whole code. The Sig Sauer was the only gun that had every section of its gear code transfer at least once. The Hi-Point's gear code only appeared, at most, to confirm the first three identifiers.

In conclusion, this study investigated the transfer of the identifier and gear code in microstamped marks from three different guns. In no case was transfer universal. Poor transfer was also seen and, in the case of the gear code, occasionally contained errors. However, using both the gear code and the alphanumeric identifiers, the complete microstamped code could be deciphered in every case when using all the information contained on cartridges from a 10-shot clip. The identification of the alphanumeric was most easily facilitated by simply using SEM instead of a stereomicroscope for evaluation.

Microstamping, Gear Code, SEM

C15 Interpretation of Evidence Resulting From a Stabbing Event Through Single Jersey Fabrics

Elizabeth Cowper, BS, RMIT Univ, School of Fashion and Textiles, 25 Dawson St, Brunswick, Melbourne, VIC 3056, AUSTRALIA; and MacArthur Fergusson, MS, Lyndon Arnold, PhD, and Rajiv Padhye, PhD, 25 Dawson St, Brunswick, Melbourne, VIC 3056, AUSTRALIA*

After attending this presentation, attendees will learn about the physical properties of common T-shirt fabrics, the effects of laundering, how these properties influence the residual damage after a stabbing event, and the problems associated with laboratory simulations.

This presentation will impact the forensic science community by providing information on the importance of background knowledge in textiles when assessing and re-creating clothing damaged in stabbing attacks.

Stabbing is the most common cause of murder in Australia, and knitted T-shirts worn next to the skin are popular garments. The beneficial evidence gained from textile examinations in forensic science is widely acknowledged. Simulation experiments are often required to test conflicting scenarios within a homicide inquiry because fabrics from the stab attack cannot be used for simulation testing. Substitute fabrics of similar fiber composition and physical structure are then investigated using a suitable underlying body simulant. It is usually assumed that the garment from the crime scene has previously been worn and has thus been laundered multiple times. Simulant fabrics must, therefore, be appropriately pre-conditioned prior to testing. This field of forensics is currently being investigated from both forensic and textile perspectives; however, there appears insufficient emphases on the details of the physical parameters and properties of fabrics.

This study considers the physical condition of a commonly worn single-jersey fabric damaged by a stabbing attack when it is described as "new," "worn," and "old." The goal was not to present a standardized method for pre-treatment on all textile fabrics. A universal method for pre-treatment cannot be achieved since different textiles/garments have individual care procedures. A realistic Australian home-wash procedure was selected. To further degrade specimens to a level that cannot be achieved by simple domestic laundering, selected fabrics were subjected to a commercial stonewash. The intent was to identify how the physical condition of a fabric affected the residual damage inflicted by a stab penetration.

Knitted fabrics behave very differently from woven fabrics. Dyed and finished single-jersey fabrics were obtained from a local manufacturer. Pure 100% cotton knits of 140g/m^2 and 180g/m^2 were selected to determine if they behaved differently when stabbed with a given knife design and entry conditions. A 65%/35% blended polyester/cotton knit of 150g/m^2 was also evaluated.

Fabrics were laundered five times according to 5A of AS 2001.5.4-1987 and line dried between each cycle. All other fabric physical testing followed an appropriate Australian or International Standard method. The physical properties of the yarns, such as linear density, yarn twist, breaking strength, and elongation, were determined. For the fabrics, parameters such as mass per unit area, thickness, courses and wales, cover-factor, stretch and recovery, and bursting strength were determined. Dimensional stability and spirality of the knits were determined after laundering and stonewash pre-treatments. The fabrics were tested for their physical parameters and properties, in original state, after laundering, and after stonewash treatment.

One emphasis of this study has focused on re-creating the stabbing event. To produce realistic and consistent predictions, suitable human skin and tissue simulants were investigated. Due to its variability, the traditional porkbelly simulant was found to be unsuitable. Pickled

kangaroo skin placed over 10% per weight Vyse ballistic gelatin was established as an acceptable representation of the human body. Kangaroo skin also shares similar fibrous structure and directional properties to human skin. A test rig was developed that enables reproducible penetration impacts at pre-determined energies. Experiments were conducted on knitted fabrics placed over the kangaroo skin and ballistic gelatin. They were stabbed using a 20cm kitchen knife, the blade of which impacted parallel to the courses, wales, and diagonally.

As the simulation model for a human body contains no blood, a simple blood-droplet absorbency test was also undertaken on the fabrics. Commercial fabrics are subjected to a number of finishing treatments which can remain on a garment after purchase. T-shirts often have a softener applied which dramatically affects their absorbency. Extractable matter was removed from the fabric before and after laundering to confirm the quantity of treatment. A modified droplet absorbency test using horse's blood at 37±1°C determined the effects of laundering. Macroscopic and microscopic examination of the stabbed specimens revealed differences between the physical damage. These characteristics of damage were then compared to the physical parameters and properties of the fabric.

T-Shirt, Stab, Damage

C16 Comparison of Striated Marks From Slip Joint Pliers

Taylor N. Grieve, BS, 206 Wilhelm Hall, Ames, IA 50011; L. Scott Chumbley, PhD, 214 Wilhelm, Iowa State Univ, Ames, IA 50011; M. James Kreiser, BS, 3112 Sequoia Dr, Springfield, IL 62712; Max D. Morris, PhD, 2103 Snedecor Hall, Ames, IA 50011; Song Zhang, PhD, 2096 Black Engineering, Iowa State Univ, Ames, IA 50011; and Laura D. Ekstrand, BS, 2624 Howe Hall, Ames, IA 50011*

After attending this presentation, attendees will have a better understanding of the difficulties associated with quantitatively analyzing striated marks such as those produced by ~~a~~ the shear force seen when pliers are used for cutting wire. These marks are much more complex than those seen when using, for example, a screwdriver to mark a piece of lead. A statistical algorithm suitable for analysis of a simple mark has poor results when used to compare more complex marks.

This presentation will impact the forensic science community by showing there is an inherent difference in plier marks as opposed to simple linear toolmarks. It appears that entirely new methods and statistical algorithms will need to be developed in order to reliably characterize shear marks produced by pliers, bolt cutters, garden brush clippers, etc.

Studies have shown that a computer-based system developed at ISU works well when presented with striated marks, such as those made by a screwdriver, where the marks produced are a simple linear array of wide and narrow channels, which are, in essence, a negative of the surface of the screwdriver tip used to make them.[1] However, the problem becomes more difficult when the mark examined is less regular in appearance, such as those made by pliers. Although both are shear marks, it quickly becomes apparent when studying these markings that the plier marks are much more complex. The more complex marking results due to the nature of the cutting process. The cut is produced by the shearing action of two separate plier faces coming together to produce the cutting edge. Similar to screwdrivers, where each side is characteristic, yet different from, the other side, both sides of a plier cut are different. However, as a cut is being made, the cut material is subjected not just to the tip of the cutting plier face on each side, but also the material is dragged across the entire surface of the face during the cutting process. At this time it is highly probable that the original striated surface produced at the very edge of the cut will be altered/changed as the remainder of the plier face shears past it. The resultant mark consists not of a negative of the tip of the cutting face, but is a composite of the plier cutting face and deformation by the surface of the face as it travels through the material to achieve a complete cut.

To study the applicability of the current algorithm to more complex markings, fifty pairs of sequentially manufactured pliers were obtained. The pliers were as identical as possible, being taken directly from the manufacturing line and never used. Alternating sample cuts of lead and copper wire were made using the shear surfaces of the pliers. The cut surfaces of the samples were then scanned using an optical surface profilometer to obtain the surface geometry.

The resulting data files were cleaned to remove background noise, then compared using the statistical algorithm that had proven useful for the comparison of simple striated screwdriver tool marks. The comparisons with the algorithm were divided into three different groupings: known matches, known non-matches from the same pair of pliers (different sides of the cut), and known non-matches from different pairs of pliers. The results of the comparisons varied, and trends could be seen showing known matches had higher scores in general than known non-matches. However, the results are much less definitive than for the more striated marks. The effects of changing data collection locations for comparison as changing comparison parameters showed no clear trends for improvement. The details of these comparisons conducted will be discussed.

Slip-Joint Pliers, Tool Mark Comparison, Statistics

C17 Seatbacks: Rigid or Yielding?

William H. Muzzy, BS, 1509 Porter Ave, Ocean Springs, MS 39564*

The goal of this presentation is to discuss the philosophy of seatback design, whether the automobile front seatback should yield rearward or remain upright during a rear-end collision. The answer will become apparent after the discussion.

This presentation will impact the forensic science community by showing how results of three case studies and prior research should provide seat designers and decision makers with information to improve seatback designs and regulations.

This presentation will demonstrate that automotive seat designers must consider human tolerance, not federal standards, when setting seatback yield strength.

The federal standard for seatback strength is set so low that a lawn chair can pass it. Two groups are divided on front seatback design to protect occupants from rear line-of-force impacts. One group propounds that seatbacks should yield rearward to minimize forces on the body and reduce whiplash. The other group advocates a strong seatback that stays upright and contains occupants in the seat.

Whole body tolerance to +Gx impact was established experimentally in 1958. Captain Beeding recorded 82.6g on his chest accelerometer when he decelerated from 32.8mph to stop with a peak acceleration of 40.4g.

Crash data recorders, installed in race cars in the 1990s, recorded +Gx accelerations of up to 110g when the cars impacted the hard retaining walls. Drivers survived with recoverable injuries.

Human tolerance to +Gx acceleration was established and confirmed with human tests and recorded crashes with the Indy race cars.

Three case studies will show a comparison between rigid and yielding seatbacks and answer the title's question.

Case One: Both southbound lanes of a divided parkway were backed up for $1^1/_2$ miles. At the front was a truck with a large load that had stopped to measure the height of an overpass. A 1999 four-door sedan was the last vehicle in line in the outside lane with a mini-van just in front of it. Both vehicles were almost stopped on a small bridge.

A 26-foot-long two-axle truck was traveling in the outside lane with the cruise control set at 70mph. The driver claimed he did not see the stopped traffic in front of him in time to stop and impacted the rear of the sedan. This collision caused the sedan to go airborne, impact the left

guard barrier, and rotate 180 degrees. The truck continued on, crashing into the rear of the mini-van, pushing it forward.

The rear half of the sedan was severely crushed up to the B-pillar where the truck rode up over the sedan's bumper. This sedan was equipped with energy-management front seats and the seatback remained upright. The female driver got out of her car with minor injuries.

The mini-van's rear gate and quarter-panel were pushed up to the rear wheel on the left side while the right rear quarter-panel was barely deformed.

The female driver's seatback yielded rearward until it hit the rear seat cushion. She ramped up the reclined seatback, receiving a left occipital skull fracture, subarachnoid hemorrhage with possible coup-counter coup lesion, closed head injury, and left forearm fracture.

Case Two: A large 2002 four-door SUV was traveling at highway speed when the left rear tire detreaded. The vehicle swerved to the right and rotated clockwise as it left the right side of the highway. It slid off the highway until it hit a tree just behind the left B-pillar. The Principal Direction Of Force (PDOF) was between 7:00 and 8:00 at a delta V of approximately 17mph.

The left rear door and structure behind the B-pillar deformed against the driver's seatback, keeping it upright. The female driver was uninjured but the male front seat passenger's seatback yielded rearward and left. He impacted the rear seatback between the two rear seat passengers and sustained a T8 spinal cord transaction with paraplegia. The two male rear seat passengers had minor injuries.

Case Three: A 1994 four-door sedan was stopped in a line of cars when it was hit from the rear by a mid-size foreign SUV. The sedan's air bag deployed when the car was pushed forward into the rear of a vehicle in front of it. Due to a faulty seat recliner mechanism, the seatback collapsed rearward. The male driver ramped rearward into the rear seatback, resulting in quadriplegia from fractures.

Seatback, Rigid, Yielding

C18 Rural Roads, Curves, and Vehicular Loss-of-Control

Zygmunt M. Gorski, BA, 361 Hale St, London, ON N5W 1G5, CANADA*

After attending this presentation, attendees will obtain an understanding of the physical evidence that accompanies an event involving vehicular loss-of-control at a curve on a rural roadway. Original data will be presented on the chronological development of roadway edge drop-offs, the likelihood that travelling onto a drop-off will lead to a loss-of-control, the unusual motions of vehicles that might lead to a loss-of-control, the tire marks that identify a loss-of-control, and the actions drivers take when attempting to navigate through a challenging roadway curve.

This presentation will impact the forensic science community by providing orginal, objective data about the frequency of loss-of-control evidence on rural roadways that is often not officially reported, but the larger-than-reported frequency of these events may provide more accurate information about how and why loss-of-control events occur.

The loss of directional control of a vehicle leads to single vehicle rollovers and impacts with trees, poles, and roadside obstacles. It is also present prior to many serious and fatal head-on collisions. It has been observed that a large number of these events occur at curves of rural, two-way, two-lane roadways. Objective data is needed to understand how and why these events occur.

This presentation will provide a review of the physical evidence of vehicle loss-of-control that existed over three years (2009 – 2012) at the site of a complex S-curve in rural southern Ontario, Canada. This S-curve is made up of one segment that contains a small horizontal radius and a second segment of a larger radius. The segment with the shorter radius also contains an undesirable vertical alignment within the horizontal curve that would appear to make travel aligned within the lane challenging.

Detailed video footage taken over six days has been examined to explore how vehicles progress through this curve. Observations of vehicles passing through the site are summarized to identify unusual motions that lead to the potential of loss-of-control. Those vehicles conducting unusual motions are documented with respect to their type/size and their speed and how they progressed through the curve in relation to a grid of markers that was set up to document their longitudinal and lateral position in their lane.

Evaluation of edge drop-offs and estimates of the number of vehicles exiting the paved road edge are provided. Historically, roadway edge drop-off has been considered a causal factor in many loss-of-control collisions, while debate has continued over what characteristics should require early repair. As municipalities, provinces, and states are pressured by budget deficits to minimize maintenance costs, the definition of what constitutes a reasonable level of public safety is shifted. New Minimum Maintenance Standards (MMS) in Ontario define that an edge drop-off of 8 centimeters (just over 3in) existing over a full distance of 20 meters (about 65ft) is the new threshold at which maintenance of the drop-off is required. This presentation will discuss data that was collected of the changes in the edge drop-off through the three-year study and will demonstrate that deep edge drop-offs over 11 centimeters (4.5in) existed at individual locations while the criterion of 8 centimeters along the total 20 meter distance was never met. Efforts to fill in the exposed edge drop-off by plowing and then shifting the gravel back toward the edge drop-off causes a shoulder surface of deep and soft gravel which is argued to be as unsafe as leaving the area untreated.

The location/type of loss-of-control evidence in 54 incidents is reviewed. A comparison is made between the location of these events and the features of the site to provide an estimate of which features are more likely to be associated with a vehicular loss-of-control. Characteristics of the loss-of-control tire marks resulting from these events are discussed so investigators can further their ability to detect and understand this evidence.

Documentation is provided from travels through the curve in an instrumented passenger car. Longitudinal and lateral accelerations are presented as well as driver actions (braking, steering) at select speeds. These data are compared to the location of the loss-of-control incidents.

Crash, Curve, Loss-of-Control

C19 Forensic Analysis of a Seat-Belted Occupant Ejection in a Rollover Collision

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Ave, Ste D, Santa Barbara, CA 93111-2326*

The goal of this presentation is to illustrate to the forensic community that vehicle occupants wearing seat belts are still at risk of ejection and injury during a rollover collision.

This presentation will impact the forensic science community by illustrating the apparent risk of injury and/or ejection while wearing a seat belt in a rollover collision.

Introduction: Seat belts are the primary occupant restraint system in passenger cars, light trucks, and sport utility vehicles. In the event of a rollover collision, three-point lap and shoulder belts help to reduce the risk of injury due to impacts with interior components or ejection. However, it has been observed that complete ejection of seat-belted occupants can and does occur in rollover crashes.[1] This case study will detail the physical evidence supporting seat belt use at the time of collision and the subsequent forensic analysis of the occupant compartment as it relates to the ejected passenger.

Collision Sequence Overview: A 2001 model year SUV with driver and right front passenger was traveling on a highway with a posted speed limit of 70mph. A left rear tire tread belt separation caused vehicle oversteer characteristics and the SUV entered a clockwise yaw on the highway for approximately 160ft.[2] Upon entering the dirt shoulder, the vehicle continued to yaw for another 52ft before it

overturned, driver's side leading. The vehicle rolled approximately 147ft and came to rest on its wheels. The right front passenger was ejected during the rollover event.

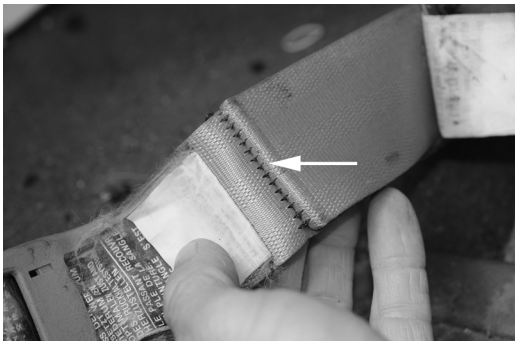
Based on stress marks observed on the driver's seat belt webbing, investigators concluded the driver was wearing the seat belt. The right front seat belt was found still buckled at the scene (Photograph 1), and the webbing did not reveal any type of stress marks. Although the investigators agreed the right front occupant was ejected, they concluded this occupant was either not wearing the seat belt properly, or was not wearing the seat belt at all.

Incident Vehicle Examination: Significant roof crush and corresponding occupant compartment intrusion is consistent with a driver's side leading rollover event (Photograph 2).[3] The left rear tire was examined and showed a near complete tread belt separation. Localized damage was observed around the left rear wheel well, on the rear bumper fascia, and exhaust system. Part of the tread belt was found still wrapped around the rear axle.

All of the vehicle's windows were fractured during the rollover. Careful examination of the right front seat belt showed approximately 15in of webbing with cut fibers consistent with interaction with fractured glass fragments. However, these fiber disturbances were found on an area of the webbing that would not be exposed to the vehicle's interior if the seat belt was stowed.

Artifacts aligned longitudinally with the webbing were found to correspond to faint striations on the plastic coating of the latch plate load surface.

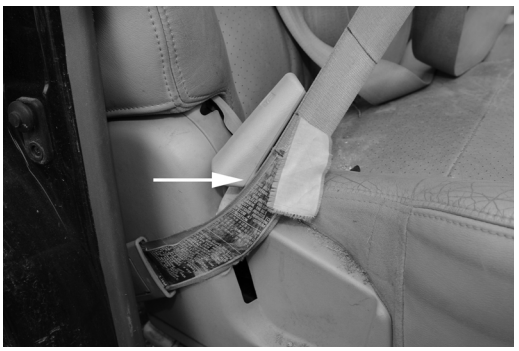
The right front seat belt features an expansion loop concealed under a rubber-like sleeve approximately 10in long.[4] Close examination of the first row of stitches revealed these stitches were under tension applied during occupant restraining forces (Photograph 3).



The right front seat back was found reclined beyond a reasonable upright posture such that the head restraint is in contact with the right roof rail within the right rear door opening. A courtesy light is installed on the interior upholstered right roof rail. The lens of the courtesy light exhibits linear scratches with plastic flow in an orientation directed toward the window and to the outside of the vehicle. The potential ejection portal was identified to be the right rear window opening.

Upon further examination, the seat back assembly was found to recline without much effort. That is, the seat back recline mechanism was not locked. The seat back recline angle adjuster is on the outboard side of the seat cushion. Pulling the lever upward allows the seat back to recline. This recline lever was found to be substantially deformed (Photograph 4).

When the right front seat belt is stowed, the webbing is nearly vertical, but when fastened the expansion loop sleeve rotates forward about the lower outboard anchor bolt. It was discovered that the rubber-like expansion loop sleeve will cause the potential for the seat belt webbing to route under the seat back recline lever (Photograph 5).



Exemplar Vehicle Examination: A similar model year exemplar vehicle was located by random selection. The right front seat cushion position of the incident vehicle was duplicated in the exemplar vehicle. When a right front occupant fastened the exemplar seat belt, the webbing caught on the tip of the recline lever. Remarkably, after the retractor was manually locked and the right front occupant rose up from the seat to put the lap belt in tension, the recline lever was actuated and the right front seat back unexpectedly reclined. The exemplar vehicle demonstration helped explain the chain of events that led to the seat-belted occupant ejection in a rollover collision.

SUV Tread Separation, Rollover Ejection, Seat Belt

C20 Toyota® SUA: A Formal and Definitive Electronic SUA Examination Protocol

William Rosenbluth, MSEE, Automotive Systems Analysis, 12015 Canter Ln, Reston, VA 20191*

The goal of this presentation is to show how the issue of the alleged Toyota® Sudden Unrequested Acceleration (SUA) has been the subject of media attention and intense Multi-District-Litigation (MDL). Various court protocols have been instituted in an attempt to standardize the examination of components, systems, and Event Data Recorder (EDR) event-records regarding the issue of the alleged SUA. This presentation teaches a method to amalgamate these protocols into a master procedure which specifies tests incorporating the three modes discussed above as possible for a specific Vehicle Under Test (VUT).

This presentation will impact the forensic science community by providing a tested and confirmed amalgamated master procedure that specifies tests incorporating the three alleged SUA vehicle test modes, such that the attendee will then be prepared for whatever field conditions he/she faces when encountering a vehicle subject to various court SUA protocols.

The issue of alleged Toyota® SUA has been the subject of media attention and intense MDL. Causes of alleged SUA can include mechanical, electrical, and computer control aspects. As a foundation to understand the technology involved, this presentation illustrates the architecture of the Toyota® Electronic Throttle Control systems (ETCS-i). This architecture includes an electronic accelerator function (Figure 1) and an electronic throttle function (Figure 2). The electronic accelerator provides a dual signal input to an Electronic Control Module (ECM) which represents an electrical accelerator-position-analog of the % pedal requested by the operator. The ECM acts on that signal, modulated by engine temperatures, current RPM, current vehicle speed, and other factors to provide a requested throttle angle to the electronic throttle. The electronic throttle actual angle is fed back via a dual signal Throttle Position Sensor (TPS), which produces an electronic throttle-position-analog to the ECM, thus forming a throttle closed-circuit feedback loop. Figure 3 is an overview schematic of this system. Additional to the primary throttle control system, the vehicle cruise control system is implemented within the ECM and it can also modulate the electronic throttle control.

In a crash event, the operating status of the vehicle is also monitored by an Event Data Recorder (EDR), and that is included in the protocol.

Examinations of these systems can happen in three modes:

1. Static component testing, no power to vehicle, including external EDR data retrieval.
2. Dynamic powered engine-not-running tests, including *in situ* EDR data retrieval.
3. Dynamic powered engine-running tests, including road tests

In Static Mode: the individual components are characterized individually by disconnecting them from the system to determine voltage and/or resistance outputs (throttle-analog and accelerator-analog) versus physical input or position. If power cannot be applied to the vehicle, the EDR data can be retrieved in a stand-alone mode.

In Dynamic Powered Engine-Not-Running Mode: the super system (accelerator, ECM, throttle) is monitored at its interface points and then actuated electrically to characterize the running voltages at the interfaces of all these components in a dynamic sense. This includes simultaneous time line recordation of CAN bus PID parameters, analog voltage parameters, and physical component positions (via synchronized four-channel video). One part of these tests is known as a "throttle-sweep," where the accelerator is actuated in fast, slow, and pulse modes to check for the compliant operation of the throttle vs. accelerator, while monitoring the above parameters. With power applied to the vehicle, the EDR data can be usually be retrieved via the normal SAE J1962 diagnostic port.

Figure 4 is an overview schematic detailing the interfaces required to accomplish the engine controls master procedure monitor points. Note that in order to accommodate a wide variety of vehicle models, the protocol includes the use of Insulation Displacing Connectors (IDC) which allow adaption to each vehicle version of interest.

In Dynamic Powered Engine-Running Tests, Including Road Tests Mode: the super system (accelerator, ECM, throttle) is monitored as above, but additional CAN bus parameters are recorded (Engine RPM, vehicle speed, brake apply functions, coolant temperature, etc.). Before such tests, it is assumed that all EDR data has been retrieved.

Generally, serious case vehicles are operationally damaged, and various court protocols have been instituted in an attempt to standardize the examination of ETCS-i components and systems, and EDR event-records on these vehicles. Thus, the application of protocol modes is vehicle condition-dependent. This presentation shows key portions of these protocols and then provides an amalgamation of these protocols into a Toyota® SUA investigation master procedure which provides for tests incorporating the three modes discussed above as possible for a specific VUT.

One of the key aspects of an alleged SUA investigation is the retrieval and interpretation of EDR data. As is commonly understood, the EDR function is incorporated into the SRS ECU. Aside from recording internal signal parameters (acceleration, etc.), the SRS ECU acquires PID parameters (braking, vehicle speed, engine RPM, throttle angle, etc.) from the CAN bus and that is the basis of an "event record." The correct/incorrect operation of the ETCS-i system is one of the keys to assessing the reliability of the EDR data.

So, the application of the ECTS-i portion of the master procedure can serve to confirm or cast doubt upon the EDR recorded event-record.

An SUA investigation, using this master procedure, is illustrated with examples of simultaneous timeline observation and documentation of analog parameters, CAN PID parameters, and multi-channel video recordation of mechanical operations versus those electrical parameters. Additionally, this presentation includes illustrations and discussion of EDR data, control pedal measurements, ECM data, ABS data, and ESC data.

Toyota® SUA, Toyota® MDL, Sudden Acceleration

C21 Evaluation of Roof-Mounted Side Curtain Airbags in Rollover Accidents

Michelle R. Hoffman, MS, Carley C. Ward, PhD, and Matthew A. Ivory, BS, 3720 E LaSalle St, Phoenix, AZ 85040*

After attending this presentation, attendees will understand how side curtain airbags protect occupants from head injury in side impact and rollover crashes.

This presentation will impact the forensic science community by explaining how roof-mounted side curtain airbags work and how to identify situations in which they have not performed in their intended manner.

History of Side Curtain Airbags: Roof-mounted inflatable side curtain airbags are designed to protect an occupant from ejection through a side window and prevent injurious head contacts to interior and exterior surfaces. They first appeared in passenger vehicles in the late 1990s.[1] They were used primarily for side impact protection.

The National Highway Traffic Safety Administration (NHTSA) tested vehicles in side impacts using a moving deformable barrier modeled after a passenger car of the 1970s. This test only examined forces on the crash test dummy's thorax and ignored forces on the dummy's head. In the early 2000s, the Insurance Institute for Highway Safety (IIHS) developed a side impact test that utilized a moving barrier that was higher than the one used in the NHTSA tests. This higher barrier was representative of a pickup or SUV. The new barrier made it possible for the crash test dummy to hit the striking barrier through the side window. In addition, the IIHS test examined the forces exerted on the dummy's head. It was felt that this new test would encourage the automakers to take advantage of the new technology of side impact head airbags. This technology was not in existence at the time that the NHTSA had created their side impact test.[2,3] The NHTSA followed IIHS's example and modified their side impact test to encourage the use of side curtain airbags. In the final rule on side impact protection (FMVSS 214), the NHTSA changed the side impact test requirements to include a lateral vehicle-into-pole impact in which the pole was positioned in line with the driver dummy's head.[4]

Side curtain airbags have also been improved upon to offer protection to occupants in the event of a rollover crash. In 2000, a major automaker offered an SUV with a side curtain airbag option that would deploy in rollover crashes. The side curtain airbags would trigger by a sensor that measured vehicle tilt and the bags would remain inflated for six seconds covering the side windows.[5] Since that time, many automakers have produced vehicles with side curtain airbags large enough to cover window openings and that remain inflated long enough to offer protection in a rollover-type crash. Recently, NHTSA's final rule on ejection mitigation (FMVSS 226) required all vehicles by September 2013 to be equipped with a curtain airbag that will deploy and offer protection in both side impacts and rollovers.[6]

Case Studies: To illustrate how side curtain airbags may fail to deploy in their intended manner, two cases are reviewed.

In the first case, the restrained left rear occupant of an SUV sustained fatal head injuries in a lateral impact and rollover crash. The side curtain airbags in the SUV did not deploy, allowing the occupant to become completely ejected. The question arose whether or not the side curtain airbag would have stayed inflated long enough to prevent the occupant's ejection and injury if it had deployed. Testing was conducted on exemplar side curtain airbags to determine the deployment path, size of the airbags, and time the bags would remain inflated. It was found that the side curtain airbag would remain inflated with enough pressure for a rollover event.

In the second case, the restrained right front passenger sustained fatal head injuries when she was partially ejected during a vehicle rollover crash. The vehicle was equipped with side curtain airbags that deployed but got stuck halfway down. A review of the NHTSA side crash tests demonstrated that this same problem had also occurred in New Car Assessment Program (NCAP) testing. Subsequent NHTSA NCAP side impact testing revealed that a design change had occurred that prevented this problem from occurring in later models. The issue in this case was what changes had been made to the side curtain airbags to eliminate the problem and would it have made a difference in the subject accident. Exemplar airbags from the early production and late production vehicles were obtained and examined. The later production side curtain airbags were changed by the addition of a plastic guard to prevent the airbag from snagging on interior components during deployment. This guard would have allowed the airbag to fully deploy in the subject accident.

Conclusions: Side curtain airbags are designed to protect an occupant from ejection through a side window and prevent injurious head contacts. They are quickly becoming an important part of automotive safety. An individual analysis must be performed to determine if they functioned properly.

C22 Relationship Between Injury Severity and Vehicle Crush in Rear Impact Collisions

John J. Smith, MSEE, PE, Torey Jones, and Devin Jones, 43766 Buckskin Rd, Parker, CO 80138*

After attending this presentation, attendees will have a greater understanding of the relationship between crush and injuries in collisions.

This presentation will impact the forensic science community by enabling attendees to more accurately analyze injury mechanisms in rear impact collisions.

The objective of the research reported in this paper was to determine if the magnitude of crush to the rear of a vehicle was indicative of the severity of the collision. The research revealed that a statistically significant correlation between the crush to the vehicle and the Abbreviated Injury Scale (AIS) injury rating was not present. This confirms that injury severity is a function of more than the crush to the vehicle and the change in velocity.

It is well known that the energy available to cause injury is a function of the non-dissipated kinetic energy in a collision. Previously published papers have raised doubts regarding the correlation of the change of velocity experienced by a vehicle in rear impact and the resultant injuries.[1,2] Similarly, research has shown a lack of an established injury threshold based on change of velocity.[1,3-9] Theoretically, the greater the damage to the vehicle, the less energy is available to cause injury at a given speed. However, the energy available to crush a vehicle increases with the square of the velocity while the momentum is a linear function. Previous research has demonstrated an energy threshold value for the onset of damage in a rear impact.[9] This is relevant because at the lower speeds momentum is the critical factor while energy is the critical element at higher speeds.

The National Automotive Sampling System (NASS) is a database of more 100,000 collisions investigated by the National Highway Traffic Safety Administration (NHTSA).[10] The various versions of the database cover well over a decade. The AIS is a measure of the severity of an injury based on lethality.[11] The NASS databases record the injuries to an occupant in terms of type, cause, and severity. The files also report crush measurements, collision sequences, and change in velocity. Two significant limitations of the database deal with the change in velocity and the severity of the injury. Velocities are often calculated using SMASH, a derivative program of CRASH3 which has limited utility in rear impacts.[12] The injuries are based primarily on initial diagnosis and do not capture subsequent diagnoses which often raise the overall severity of the injury. As an example, injuries originally coded as AIS 1 may in reality be AIS 2 or 3. However, the crush to a vehicle is actually physically measured by the investigator. For these reasons, an analysis was performed to determine if the crush to the rear of a vehicle is statistically significant in the prevalence of diagnosed injuries in rear impacts.

The crush to vehicles and the maximum AIS code for a given collision were retrieved by examining a random sample of 198 impacts taken from the NASS case list. In an attempt to obtain an unbiased sample, every 20th case in the database was selected. To be chosen, the collision had to meet certain qualifications. Only rear impacts based on an impact angle of 180° were allowed. In addition, the collision had to be a pure rear end crash with no other sources of damage such as rollover or subsequent contact with other objects. The impact could only involve two vehicles. In addition, the database had to include the injury and AIS code and include the measured crush sustained by the vehicle. If any of these conditions were not met, that case was skipped and the next case was used.

Table 1 provides the results obtained by the research. The table compares the maximum AIS with the magnitude of the measured crush in inches. The number in the table lists the number of collisions in a given range. Figure 1 is a graph of the data with greater crush discrimination. Figure 1 also includes a linear and a quadratic fit to the data.

AIS	0 < crush < 10	10 ≤ crush < 20	20 ≤ crush < 30	30 ≤ crush < 40	40 ≤ crush < 52
1	72	56	32	8	3
2	3	8	2	1	0
3	0	1	1	2	1
4	0	0	0	0	2
5	1	0	2	1	0
6	0	0	0	0	2

Table 1 – Distribution of AIS based on inches of crush

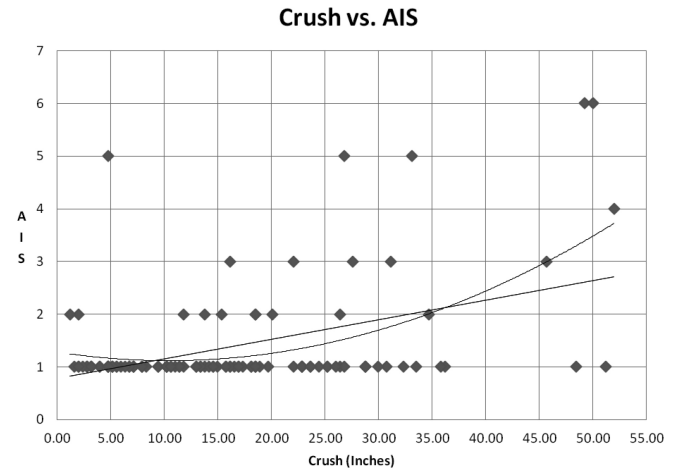

Figure 1 – Crush vs. AIS
Note: Many of the points are duplicates

An analysis was performed to determine if there was a statistically relevant correlation between the amount of crush and the initial injury level. Three tests were run on the data; Chi Squared, correlation, and Student-t. The latter was used to compare individual AIS levels. Additionally, as mentioned previously, a linear and quadratic fit to the data was determined.

Conclusion: The data reviewed demonstrates that for AIS level 1 and 2 injuries, crush to the vehicle is not a reliable indicator of injury potential. Additionally, severe injuries can occur with minimal crush while minor injuries can occur with significant crush.

None of the analysis methods applied to the complete data set resulted in a finding of statistical significance between crush depth and injury severity. The mean crush for each level was determined. A student-t test was applied to each AIS level and resulted in a finding of a statistically significant variation between AIS 1 and 2 versus AIS 3. However, it should be noted that of the 198 random sample cases, only thirteen revealed injury severities of AIS 3 or greater. The data does indicate that it is possible crush is a factor in AIS level 3 and higher injuries.

Injury, Crush, Damage

C23 Performance Evaluation of Firearm Silencers

John Nixon, MBA, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation, attendees will gain knowledge of what a firearm silencer is, how it is constructed, the safety and environmental advantages of silencers, and how silencer performance is evaluated. It is anticipated that the presentation will be of particular interest to medical professionals and criminal defense attorneys—particularly those who work in the federal arena.

This presentation will impact the forensic science community by changing the way firearm silencers are viewed, dispelling common misconceptions, and promoting research into evaluation techniques, plus health, environmental, and legal issues.

Firearms use comes with a number of potential health and environmental hazards due to the high noise levels generated. Clearly, noise reduction is a desirable goal. Firearm silencers are often more correctly referred to as sound suppressors, sound moderators, or mufflers—in the interests of consistency with federal legislation, the term "silencer" is used throughout this presentation. Firearm silencers are legal for civilian ownership and use in the majority of the U.S., though they are heavily regulated. In states where silencers are legal, their regulation is typically accomplished at the federal level, though many states do have their own laws. This presentation focuses on issues pertinent to federal legislation.

Until 1934, there were no restrictions on silencer ownership and use by private individuals. In 1934, Congress passed the National Firearms Act (NFA) which effectively made silencer manufacture and possession by private citizens, a prohibitively costly and administratively burdensome endeavor.

The NFA legislation is articulated in Title 26 of the United States Code, and this federal law is administered and enforced by the U.S. Department of Justice (DOJ) via the Bureau of Alcohol, Tobacco, Firearms and Explosives (BATFE).

The U.S. Code defines, in part, a silencer or muffler, as "any device for silencing, muffling, or diminishing the report of a portable firearm." This is a very vague definition, and in strict technical terms, it could include legitimate technologies, such as a lengthened barrel, a muzzle brake, or a flash hider, all of which will diminish, or redirect, the noise of a gunshot.

Commercially available silencers reduce firearm peak sound pressure by 30 to 40 decibels (dB). A 223 Remington (5.56mm NATO) caliber rifle will typically generate around 160dB without a silencer and just 120dB to 130dB with a typical commercially available silencer installed. Some individuals construct homemade silencers, with varying degrees of success.

Understanding sound and sound measurement is not easy, and this fact, coupled with the loose legal definition of what constitutes a silencer, leads to the prosecution of many individuals who, either deliberately or inadvertently, have procured or created a device for their firearm that reduces the measured report by only a small amount.

A study published by the American Medical Association revealed that recreational shooters suffered hearing damage following only very limited exposure to firearms noise and that damage occurred even when shooters wore hearing protection. Paradoxically, in an age when both legislators and the population at large are obsessed with environmental and health and safety issues, there exists outdated legislation in place that actually works to make an everyday item less safe for the user and less environmentally friendly from the perspective of those in the vicinity of the user.

Sound measuring equipment with a data sample time interval short enough to accurately capture a gunshot is expensive, and interpretation of results is difficult for those not well versed in the technical intricacies of acoustics.

This presentation includes a case study to illustrate the difficulty in applying the U.S. Code relating to silencers in a criminal prosecution.

It is concluded that current legislation relating to silencers provides vague technical definitions, leads to unnecessary and expensive prosecutions, has a significant adverse effect on the health of the nation, and raises significant legal, administrative, and financial barriers to those firearm owners who wish to maximize safety and minimize environmental impact.

Firearm Silencer Evaluation, Hearing Damage, Environmental Impact

C24 Was That Car Used as a Weapon or Not? Combining Reconstruction Skills to Answer a Critical Question

Michael L. Shirley, BSME, PE, 2290 County Rd 23, Waterloo, IN 46793-9415; and John Nixon, MBA*, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation, attendees will gain knowledge in the mechanics of shooting incident reconstruction and vehicle incident reconstruction, and how the two disciplines complemented one another in providing a definitive answer to a key question that was critical to an investigation and the outcome of an associated civil lawsuit. It is anticipated that the presentation will be of particular interest to engineers and that it will be of benefit to both civil and criminal attorneys and their investigators.

This presentation will impact the forensic science community by discussing how incidents involving firearms and automobiles are investigated by highlighting the overlapping technologies and demonstrating how the two disciplines complement one another when the experts work as a team.

The presentation focuses on a real world practical example of a life-and-death struggle that developed from a routine traffic stop. When a law enforcement officer pulled over a lone driver following a minor traffic infraction on a suburban roadway, he did not expect a major struggle. However, after providing false identification, the suspect became aggressive and combative and the officer called for backup. The suspect was extremely strong and the two officers used Electronic Control Devices (ECDs) in a futile attempt to subdue him. The struggle lasted for several minutes and the suspect eventually managed to get behind the wheel of his manual transmission car and move off at full throttle. One of the officers was in the vicinity of the front driver's side of the vehicle and, fearing for his safety, both officers fired shots from their handguns. Bullets entered the vehicle and the suspect was fatally wounded.

Attorneys, acting on behalf of the suspect's estate, filed a lawsuit against the two officers and their employer. The plaintiff's attorney hired a shooting reconstruction expert who produced a report that indicated the police officer at the front of the car was two to four feet away from the vehicle and, consequently, was not in danger at the time the officers fired their guns and killed the suspect. The plaintiff's expert report made a number of assumptions with regard to the incident and, importantly, the lone expert had very limited technical knowledge of vehicle mechanics and dynamics.

The defense experts conducted an investigation to determine if the police officer at the front of the vehicle was in any danger at the time the officers opened fire. The investigation began by using trajectory analysis to determine the trajectory of bullets that entered the vehicle through the front windshield. Once this was ascertained, the officer was instructed

to adopt his shooting stance and he was positioned so that his pistol was coincident with the trajectory line of the bullet going through the windshield. This established the position of the officer to be approximately 16" forward of the driver's side front wheel of the suspect's car.

The next step of the investigation was to determine if the officer was in any danger while standing in this position. Witness testimony stated that the suspect applied full left lock as he pulled away in his car at full throttle. The vehicle was examined and the steering geometry measured. Calculations were performed to determine the turn radius of the vehicle at full lock. Industry test data was used to calculate the acceleration of the vehicle as it sped away from a standing start. The turn radius, vehicle acceleration data, and the location of the police officer were used to perform calculations. The calculations demonstrated that it would have taken less than 0.5 seconds for the suspect's car to reach the officer. Additionally, a practical demonstration was performed with the officer and the vehicle—it demonstrated that the driver's side front wheel of the vehicle would have run over the police officer.

The combined use of measurements, calculations, and practical demonstration was sufficient to prove that the police officer was in danger at the time of the shooting, and that the shooting was justified. The combined expertise of two engineering disciplines proved invaluable in this investigation.

Bullet Trajectory, Vehicle Engineering, Incident Reconstruction

C25 Who Pulled the Trigger? Blood Evidence and Bullet Path Determine Whether Shooter Was Friend or Foe

Michelle R. Hoffman, MS, and Carley C. Ward, PhD, Biodynamics Engineering, Inc, 3720 E LaSalle St, Phoenix, AZ 85040; Parris Ward, JD, Biodynamics Engineering, Inc, 17383 W Sunset Blvd, Ste 290, Pacific Palisades, CA 90272; and Matthew A. Ivory, BS, Biodynamics Engineering, Inc, 3720 E LaSalle St, Phoenix, AZ 85040*

The goal of this presentation is to demonstrate how basic physics principles were used to determine who shot a man in the neck. An analysis of the blood evidence and the bullet path was used to identify who pulled the trigger.

This presentation will impact the forensic science community by showing a unique case where both the body motions of the individual who was shot and the motion of the vehicle in which he was a passenger were factors used in determining where the shooter was physically located and, ultimately, who fired the gun.

Summary of Case Facts: An adult male was the right front passenger in a sedan when he sustained gunshot wounds to his neck and right shoulder.

The sedan's driver told police that he and the victim were sitting in the vehicle parked near the corner of their apartment complex when three males approached the vehicle. The driver backed up to get away, and when he was halfway out of the parking spot, he heard three shots coming from the right rear window, which was rolled halfway down. He continued backing, hit a curb, drove forward and stopped directly in front of their apartment. The victim's wife came out and observed that her husband was bleeding from the right side of his neck. She and the driver then moved the victim to her vehicle, whereupon she took him to the hospital, which reported the incident to police.

When police inspected the vehicle, the right rear window was partially down. Blood was on the front passenger seat. Drips of blood were on the passenger B-pillar trim and doorframe of the right rear door. A .380 semi-automatic spent casing was on the back seat. No casings were found outside the vehicle at the scene. There were no slugs inside the vehicle or evidence of bullet strikes.

The victim's wife later told police she believed the driver shot her husband. She did not see anyone or any vehicles leave the scene. She stated that the driver had threatened to kill her husband a month earlier when they got into a fight.

A family friend also told police she suspected the driver and suggested he and the wife were lovers, and may have colluded to commit the assault.

Injuries: The victim sustained three external gunshot wounds to his right shoulder and neck and spinal fracture at C2. A bullet remained in the left lateral soft tissues of the neck. He had right upper extremity paralysis and right lower extremity weakness.

Analysis: Only one casing was ever found at the scene and it was in plain view on the sedan's back seat. The single bullet was lodged in the victim's neck. With the victim's right shoulder shrugged up toward his right ear, one bullet could have caused all of his wounds. The bullet entered the right shoulder just above the clavicle and exited just medial and forward of the entry location before it re-entered his body on the right side of his neck at C2. The bullet shattered C2 and lodged in the soft tissues on the left side of his neck.

The bullet contact locations were reproduced on a surrogate victim in an exemplar vehicle for two scenarios: (1) the gun being fired through the vehicle's right rear window with the victim seated in the right front seat; and, (2) the gun being fired by the driver as the victim exited the vehicle. A rod was used to analyze the bullet path in these scenarios. Both scenarios were possible, but it was unlikely that one could fire through the rear window while the vehicle was backing up. Also, the casing location was consistent with the scenario of the driver firing the gun.

Blood evidence was also more consistent with the second scenario. Blood droplets traveled vertically downward along the B-pillar trim before traveling at an angle toward the front of the car. Tests were conducted that showed that blood would travel down the B-pillar due to gravity, but would travel at an angle similar to that in the car due to rapid vehicle backing. This indicated the blood on the inside of the vehicle traveled vertically from gravity before the vehicle backed up. Significantly, this is inconsistent with the driver's statement that shots were fired as he was backing the car.

Conclusions: Due to circumstances at the time of the crime, evidence was lost and no one was prosecuted. However, later in a civil suit, the available evidence showed the driver shot his passenger.

Shooting, Blood Evidence, Bullet Path

C26 Fatal Injuries From Penetration by Weapons — Thrown or Stabbed?

Sarah V. Hainsworth, Beng, PhD, Dept of Engineering, Leicester, LE1 7RH, UNITED KINGDOM; Guy N. Rutty, MD, Univ of Leicester, Forensic Pathology Unit, Robert Kilpatrick Bldg, Leicester, LE2 7LX, UNITED KINGDOM; and Michael E. Fitzpatrick, PhD, Materials Engineering, The Open Univ, Walton Hall, Milton Keynes, UK MK7 6AA, UNITED KINGDOM*

The goals of this presentation are to consider the defense that is commonly used in fatal cases of penetration by implements such as knives, screwdrivers, or scissors, that the implement was thrown to create the injury, as opposed to stabbed, and to discuss the distances over which the weapon is claimed to have been thrown, which is typically several meters. The questions that will be addressed are: (1) is it possible for implements such as knives, screwdrivers, or scissors to penetrate human tissues to sufficient depth to create fatal injuries by a throw?; (2) how much energy is required for penetration of skin and the underlying tissues, and at what speed would the implement have to be thrown?; and, (3) can the implements be thrown with sufficient accuracy to make penetration by the blades likely or does the yaw, pitch, and tumble prevent the implements from penetrating?

This presentation will impact the forensic science community, particularly forensic pathologists but also forensic scientists and engineers who are asked to provide expert opinions on the likelihood of a stabbing versus throwing in fatal cases, by discussing whether implements used in causing death from penetrative injuries can be thrown to give the same injuries as a stab wound.

Kitchen knives, screwdrivers, and scissors are not designed for throwing. When they are thrown, there tends to be considerable yaw, pitch, roll, and tumble during flight.

It is difficult to throw an implement with precision such that it orientates itself with the point foremost on impact. Even over short distances, the rotation from throwing the implement will often lead to it impacting handle first.

Whether or not an implement would have sufficient energy to penetrate the body can be estimated by calculating the kinetic energy.

The kinetic energy of an implement can be calculated from the formula K.E. = $0.5mv^2$ where m is the mass of the knife and v is the throwing velocity. The mass of the implement and maximum throwing velocity then need to be known for someone throwing that implement.

O'Callaghan *et al.* have previously considered the throwing of a glass shard and found that the maximum throwing velocity that could be obtained was $20ms^{-1}$.[1] They measured the energy required to penetrate skin and found for a sharp glass shard an energy of 7.7 J was required to allow skin penetration.

Figure 1 shows calculation of the relationship between throwing velocity and impact energy for a typical weapon. The threshold throwing velocity to allow skin impact is arrowed.

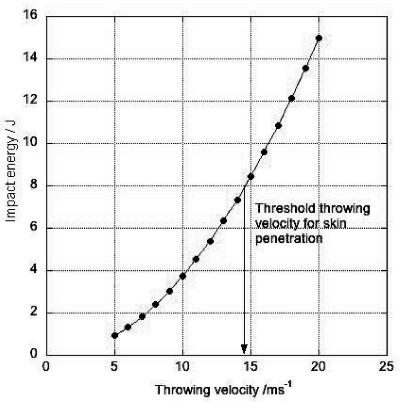

Figure 1: Impact energy versus throwing velocity for a 75g weapon. Assuming a sharp tip and that skin penetration occurs at 7.7 J, the threshold throwing velocity for skin penetration is $14.5ms^{-1}$.

This presentation will show the range of throwing velocities that can be achieved by throwers with knives, screwdrivers, and scissors and the ability of thrown knives to penetrate skin. The energy for skin penetration will be measured for the various implements and compared to their sharpness. The presentation will illustrate the different throwing characteristics of the different implements and discuss the implications of the results in interpreting throwing versus stabbing scenarios.

Stabbing, Throwing, Sharpness

C27 A Forensic Investigation Methodology for Accidental Events in Process Plants

Alberto L. Geraci, PhD, Via Domenico Tempio 3, Acicastello, Catania 95021, ITALY*

The goal of this presentation is to propose an investigative methodology to be used in forensics for accidental events occurring in process plants, to help judges determine the truth.

This presentation will impact the forensic science community by showing how the proposed methodology is based on the experience gained over the years in investigating processing plant accidents. It includes a number of cases where the accident was reconstructed and the causes were identified. Additionally, suggestions are made to prevent these accidents from happening again. Finally, ways to establish accident responsibility are shown.

Often because of the condition of aging equipment, existing plants are at risk of accidents. Even if maintenance procedures are fully compliant with required rules (API, ASME, ASTM), company standards, and local by-laws, there is still a risk of a defect. A crack may generate leakage, which is a danger for fire and explosion. Bad operations, lack of procedures, maintenance carelessness, negligence, and human errors are among the causes of a processing plant accident. According to statistics of a large number of pipe leakage accidents, media corrosion and cavitation erosion are the main reasons leading to accidental events. The percentage is higher than 50% of the total accidents.

A plant accident, often with deaths, usually leads to a court case with a judge asking why the accidental event occurred and if it should have been avoided, in order to assign responsibility. The proposed investigation methodology is based on the experience gained as a judge's consultant at different courts of law in Sicily, Italy, close to processing plant sites, and experience as a professor and researcher at the University of Catania in Sicily, working in the same field. The methodology deals with a routine procedure to be applied to process plant accident court cases.

Starting from testimonial information acquired after an accident, plant documentation is acquired and studied carefully. It includes drawings (plot plans, layouts, flow charts, Piping And Instruments Diagrams (P&ID)), operative manuals, equipment materials, and maintenance programs. Compliance with codes and standards, in force for that type of plant and the related country, is verified. Different rules are compared and checked to determine if they were followed carefully, as required. Plant components affected by the accident are tested first with Non-Destructive Testing (NDT) methods selected for the suitable application to the case.

Among them, an important role is played by Thermal Infrared Imagery (TIR), often coupled with another suitable NDT method for on-stream defects detection. This technique, developed in this research capacity, was named "adapted thermography." Subsequently, the components are subjected to destructive tests (not repeatable), to check how the accident occurred and its causes. The above tests are preceded by recalls of the main theory fundamentals, making the proposed methodology more scientifically founded.

When the causes of the accident are found and the event is reconstructed, organization charts of the personnel involved are acquired, to determine responsibility and prosecution. Several study cases regarding accidental events which occurred at the petrochemical sites of Priolo and Gela (both in Sicily), are reported and discussed with a number of figures, tables, photographs, and diagrams. The investigation was directly carried out, constituting a first-hand application of the proposed investigation methodology.

There is general expectation the methodology will become a significant part of the forensic activity of involved academic professors, researchers, engineers and professionals in the field, and judicial personnel (lawyers, judges, consultants). In fact, it provides a new routine investigation tool, for court cases involving process plant accidents.

Plant Accidents, Mechanical, Investigation

C28 A Near Electrocution by Irrigation Pipe — Case Solved by Photo Inspection

Adam K. Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will better appreciate how reviewing previously produced evidence can be very rewarding and can decide the case.

This presentation will impact the forensic science community by demonstrating how a false theory can be defeated by careful examination of the evidence.

This case that resulted in litigation occurred in the large agricultural fields of eastern Idaho. A field worker reported he had been burned and

almost electrocuted while touching or moving an irrigation pipe he found on the ground during a field clearing operation. The worker was well experienced and presented a story that at first seemed plausible; however, as the utility company and their experts reviewed the circumstances of the case, it became clear that the story represented by the worker simply did not add up. Further complicating the issue was the report by an electrical engineering expert witness who presented theories that were novel at best and unsupported by the evidence at worst. This plaintiff's expert's testimony, late in the case, meant that a jury might hear only his testimony, and no opposing view, as most of the investigators were associated in some way with the utility company.

The task of this defense investigator was to enter the case very late in the process and try to determine what happened, why, and how the plaintiff's theories were defective. The investigation combined elements of electrical engineering, human factors engineering, safety engineering, and a review of all utility records, investigation photos from the utility and sheriff's departments, as well as medical and other records.

This presentation will outline the evidence in the case, using photographic records from the various investigating agencies as well as original photos, to set the scene.

A systematic review of the evidence, including burn marks on cables, irrigation pipe, on the worker's hands, feet, and head, as well as other demonstrative evidence, will demonstrate the challenge facing the defendants.

At the heart of the matter were theories that, however illogical to the trained expert, were nevertheless compelling enough that a rural jury might be sufficiently swayed to make the verdict uncertain. These theories ignored the routine practice of utility companies to record and time stamp each event that might involve a circuit trip or fault. A detailed millisecond record existed of the initial trip event, an automatic re-set and final trip, and circuit disconnect.

In a review of routine photos that were thought to be of little significance, the missing link was revealed that finally answered the key defense question: why did the field worker raise the pipe into the 9kv electrified line, and why was his story that he found the pipe on the ground not plausible?

Part of the analysis was the investigation of similar incidents in the agricultural field, where contact with an overhead power line is unfortunately not uncommon. There is a significant statistical body of information that identifies contact by irrigation pipes and overhead lines as a major safety concern. It is this investigation into the common practice by field handlers of irrigation pipes that linked with the photographic evidence, finally providing a plausible explanation for the case.

A few comments will be made about a very short and suddenly abbreviated deposition as well as the surprise ending at trial.

Irrigation, Electrocution, Voltage

C29 Safety Evaluation of Post-Manufacture Firearm Modifications

John Nixon, MBA, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation, attendees will gain knowledge in the mechanics of firearms, how they may be modified after leaving the manufacturer, and how practical, instrumented, and calculative techniques may be employed to assess those modifications from the perspective of both performance and safety. It is anticipated that the presentation will be of particular interest to engineers, and that it will be of benefit to both civil and criminal attorneys and their investigators.

This presentation will impact the forensic science community by discussing how firearms accidents, and claimed accidents, are investigated by proposing that the firearms be assessed using a holistic approach that combines traditional practical methods coupled with modern sophisticated instrumentation, and mathematical/engineering calculations.

The presentation focuses on a real world practical example of a rifle that was modified after leaving the manufacturer. The owner of the rifle felt that the trigger "feel" was not conducive to accurate shooting and had a local gunsmith do a "trigger job" on the rifle. Following modification, the rifle discharged inside a residence, causing serious injury to a third party. The shooter stated that the rifle discharged while he was attempting to unload it by first removing the magazine, and further stated that the rifle may have been bumped against a piece of furniture immediately prior to discharge. There was some question as to whether the rifle discharged accidentally due to mechanical defect or whether it may have been due to negligent or deliberate action on the part of the operator. Due to the severity of the injuries, criminal and civil investigations, and lawsuits, ensued.

No documentation or testimony was available from the gunsmith who performed the work on the rifle, and this meant the investigation needed to ascertain exactly how the trigger mechanism had been modified. This was achieved by comparison with an exemplar rifle—new and unmodified. The operation of the rifle is described, including its trigger mechanism and its safety mechanisms. The general trigger mechanism modification options available to gunsmiths are described, and their pros and cons discussed.

The evaluation procedure commenced with basic testing of the mechanical aspects of the trigger and safety systems in both the subject rifle and the exemplar rifle. This comprised a basic operation test, followed by shock and vibration testing. Next, the trigger mechanisms were tested using an electro-mechanical trigger test apparatus linked to a computer. Finally, the rifles were disassembled and the trigger mechanism components were visually and dimensionally examined and compared. This procedure included a full evaluation of the trigger-sear springs.

The test and evaluation data were used to perform some calculations with regard to operating forces within the trigger mechanism, and the implications of these results are discussed. It was concluded that the only modification to the trigger mechanism of the subject rifle was a replacement trigger-sear spring of unknown origin. A commercially available aftermarket trigger-sear spring was procured and installed in the exemplar rifle. The test procedures were repeated for that configuration and the results compared to the "as manufactured" exemplar and to the subject rifle. Finally, the safety implications for all three systems evaluated are discussed in the context of the incident under investigation, and for firearm safety in general.

Firearm Accident, Firearm Modifications, Trigger & Safety Analysis

C30 Toward a Dual-Host Approach for Sensing of Ammonium Nitrate and Other Explosive Salts: Intermolecular Interactions Between the Dansyl Fluorophore and Anions Lead to Large Fluorescence Enhancements

Amanda M. Howett, BSc, Lissette I. Lozano-Lewis, MSc, and Konstantinos Kavallieratos, PhD, Dept of Chemistry and Biochemistry, Florida Intl Univ, 11200 SW 8th St CP326, Miami, FL 33199-0001*

After attending the presentation, attendees will have a better understanding of the interactions between the dansyl fluorophore and anions such as NO_3-, Cl-, and Br-. Such intermolecular interactions lead to significant fluorescent intensity enhancements upon anion addition, and detailed studies of intermolecular interactions by fluorescence and NMR spectroscopic methods will be presented. This can lead to future design of novel sensing devices based on simple combinations of cation and anion hosts for selective detection of ion-pair explosives, such as ammonium nitrate and uronium nitrate.

This presentation will impact the forensic science community by introducing the principles and preliminary results of a simple dual-host extraction method for sensing ammonium nitrate and other salts. The key factor is the combination of cation- and anion-sensing elements for the detection of an ion pair via a dual-host combination. As an initial step, a detailed investigation of the interaction of the dansyl fluorophore with anions, such as nitrate, is presented. The short-term goal is a

thorough understanding of the remarkable fluorescence enhancements observed upon addition of anion solution to dansyl chloride, and manipulation of host structure to induce selectivity for nitrate, in particular. The longer term goal is to combine the anion-sensing moiety based on dansyl fluorophore with cationic hosts, selective for ammonium, and achieve selective sensing for specific ion pairs, such as ammonium nitrate.

Detection of explosives plays an important role in national security. After events such as the 1995 Oklahoma City Bombing, the Anti-Terrorism and Effective Death Penalty Act was passed in 1996. The Act requires that all explosives be tagged to assist in the discovery and tracking of explosive devices as well as banning untagged explosives; however, the problem of tagging explosive substances such as ammonium nitrate that are present in common, easily obtained items such as fertilizers, remains. Because of this issue of widespread ammonium nitrate availability, research has been, and is still being done, focusing on the detection of the ammonium nitrate specifically as an ion pair, and detection methods based on solvent extraction by a dual-host supramolecular approach have been proposed.

Analytical techniques that have been used in the past in the detection of ammonium nitrate include gas-liquid chromatography and ion chromatography. These techniques are useful; however, there were still areas for improvement. Gas-liquid chromatography has a limited detection of thermally liable explosives as well as low selectivity and sensitivity for nitrogen-containing compounds. The high temperatures used can easily decompose the thermally liable explosive. The weakness of ion chromatography is that of column depletion. As the column is used and becomes depleted, artifacts can be produced that interfere with the detection of the explosives.

Fluorescence detection presents a sensitive, inexpensive, and potentially portable method for in-the-field detection of explosives. Heteroditopic receptor systems based on dual-host binding and fluorescence offer the potential for unique sensing effects via binding and extraction to the organic phase of both ionic components of the explosive salt as a tight ion pair. The dual-host complex has two different receptors, one for each ion, specific to each of the ions. The low dielectric constant of the organic medium assures close contact of the two hosts, which is essential for unique signals upon ion pair binding as opposed to binding of only one of the components.

Preliminary experiments by fluorescence spectroscopy, NMR spectroscopy, IR, and ESI-MS offer some insight on the utility of the dansyl fluorophore for nitrate detection, via supramolecular interactions. Specifically, fluorescence titrations of a $1x10^{-5}$M dansyl chloride solution with tetrabutylammonium nitrate in CH_2Cl_2 showed dramatic fluorescence enhancements upon nitrate addition (Figure 1). The chemical shift changes observed at ^{1}H- NMR titrations (Figure 2), indicate fast exchange and are apparently due to supramolecular interactions (presumably anion-pi interactions) and not to a reaction of the dansyl chloride with any added species. Preliminary determination of the binding constant for the interaction of dansyl chloride with nitrate indicates a high number (in the vicinity of 10^5M^{-1}). It should be noted, however, that there was difficulty fitting the data into a simple 1:1 binding model, and the possibility of multiple equlibria or more complex models is currently being investigated. Experiments investigating the interactions of the dansyl moiety with other anions are also in progress.

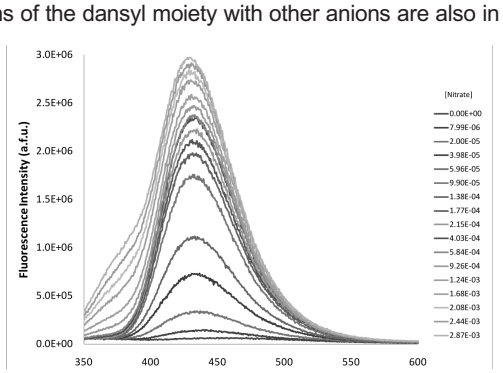

Figure 1: Fluorescence titration ($\lambda_{exc.}$. 310nm) of dansyl chloride (1 x 10^{-5}M) with Bu_4NNO_3

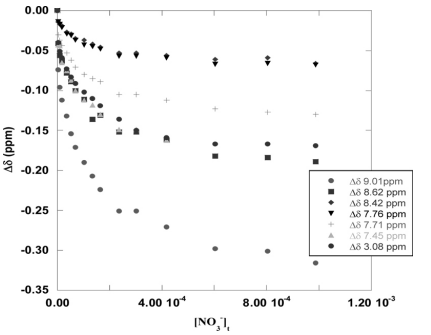

Figure 2: ^{1}H-NMR Chemical shift changes upon titration of dansyl chloride (5 x 10^{-4}M) with Bu_4NNO_3.

Fluorescence Sensing, Ammonium Nitrate, Dual-Host Extraction

C31 Principal Components Analysis Applied to the Gunshot Case Determination

Luis Chavez, BS, and Bladimir Espinoza, BS*, Anfion Muñoz 700, La Serena, Coquimbo, CHILE; and Cristian F. Lizama, BS*, Arturo Prat 19, Temuco, Araucania, CHILE*

After attending this presentation, attendees will understand the problem associated with determining who was the perpetrator of a criminal gunshot. The classical approach through the use of SEM-EXD is not possible for many developing countries due to the associated high costs. AA-GF equipment can be used as a replacement and the quantitative results interpreted with multivariate analysis techniques including Principal Components Analysis (PCA).

This presentation will impact the forensic science community by demonstrating the use of multivariate analysis giving forensic laboratories in non-developed countries the chance to determine with statistical certainty and with equipment of average value, the presence of gunshot residues on the hands of a suspect or the victim committing suicide. Through the construction of a solid database with several types of firearms, calibers, and ammunition trademarks, the quantitative analysis of metals present on the hands of an individual will allow its classification as “not shoot” and “shoot” situation, which graphically are visualized as clusters of data points represented in a 3D vector space. On the other hand, sampling is accomplished at a low cost with cotton swabs soaked with an EDTA solution along with the use of a universal reagent present in almost every chemical laboratory.

Forty volunteers with different jobs fired one different weapon each, including carbines, rifles, semiautomatic pistols, revolvers, shotguns, and submachine guns of the marks Mauser, Savage, italo Gra, Taurus, Smith and Wesson, and Sig Sauer, among others. Ammunition brands used included Remington, CBC, Federal, and TEC in the calibers .22LR, .38 special, 9mm Luger, 7x57mm, and the gauges 12 and 16. Samples were taken from the palm and back of the hands of the shooters with cotton swabs and 2% EDTA solution before and after every single shot. After dissolution and centrifugation, supernatants metal contents of lead, barium, and antimony were read using Atomic Absorption Spectrometry (AAS) into graphite furnace chambers. PCA was applied to the results, assuming that the following factors were analyzed: lead, barium, and antimony amount detected (each separately), shooter, zone analyzed in the hand and situation (before or after the gunshot). To simplify the analysis, all the variables were considered as numerical ones, defining before and after the shot as -1 and +1, identifying each shooter correlatively as 1, 2, 3, and so on. Zones tested on the hand were defined as -1 and +1 for back and palm, respectively.

Six eigenvalues were obtained for each of the sis principal components calculated previously. The first two values account for 68.9% of the variability of the data; the 3D eigenvalues explain at least 83.2% of the data variation. As could be expected, no correlation was observed between metal amount and the other variables. On the other hand, a strong relation between shooter and gunshot time-dependence is detected, which allows one to differentiate between after and before

the shot. When two score plots were displayed, at least three populations can be seen, which are split clearly into four populations, corresponding at before and after shot case for each zone on the hand.

Two cases of databases constructed for multivariated analysis of the results will be presented, showing in this way the universality of the procedure.

GSR, AA-GF, PCA

C32 Low-Energy Bone Fractures

David Pienkowski, PhD, Univ of Kentucky, Dept of Biomedical Engineering, Wenner Gren Laboratory, Lexington, KY 40506-0070*

The goals of this presentation are to increase awareness of low-energy bone fractures, review the factors potentially responsible for reducing fracture threshold, and facilitate reconciliation of low-energy events that will result in ostensibly disproportionate bone fractures.

This presentation will impact the forensic science community by reviewing the factors that reduce fracture thresholds and thereby assist the forensic investigator to reconcile seeming discrepancies between low-energy events and bone fractures. Forces calculated from reconstruction of low-velocity accidents or otherwise atraumatic incidents may appear incommensurately small compared to the accompanying human injuries. This can generate uncertainties regarding the reconstruction mechanics or incident events. Fractures of the appendicular skeleton accompanying low-energy incidents are becoming more prevalent and thus gaining greater attention.

The accident reconstructionist/human injury analyst quantifies event kinetics, calculates associated impact forces, and links these forces to the resulting injury by using probabilistic methods. Although the magnitudes of the event-related forces are generally proportional to the degree of injury, the relationship between force and injury in low-energy events is often nonlinear. Such disparities can lead to uncertainties regarding the validity of the reconstruction, inclusiveness of the events considered, or skill of the investigator.

These disparities may be partially resolved by considering the factors affecting bone's mechanical competence. Bone is both a calcium-ion reservoir and a dynamic mechanical load-bearing organ. These vital functions are enabled by a time-varying composite biomaterial with complex micro and macro skeletal structures. The mechanical competence of normal healthy bone is optimal; material or structural deviations from normal commonly result in compromised load-bearing capabilities and increased low-energy fracture susceptibility.

Bone material abnormalities can arise from inherited defects in bone metabolism that result in subnormal fracture resistance. Bone mass abnormalities are linked to sex hormone inadequacies (hypogonadism) or, more commonly, loss of estrogen in post-menopausal (natural or surgically-induced) women. Estrogen loss precedes the well-known (osteoporosis) rapid loss of bone mass due to supra-normal bone turnover. Antiresorptive drug therapies reduce turnover and bone loss, but new evidence suggests that long-term use of these drugs can adversely alter fracture resistance. This topic is currently under investigation due to the tens of millions with osteoporosis (growing ranks of aging baby boomers) and the widespread use of these drugs.

Lifestyle changes can also predispose bone to low-energy fracture. Bone mass increases rapidly during adolescence, peaks somewhere in the late-teens to mid-30s, then slowly declines throughout life. Evidence exists that exercise-induced bone mass increases persist to some degree throughout life, and conversely, inadequate skeletal loading during development prevents attainment of peak bone mass. Adults so affected begin "withdrawing bone" from a smaller "bone mass nest egg" and critical fracture thresholds are thus reached sooner.

Dietary insufficiencies also conspire against fracture resistance. Bone is a composite material made chiefly of protein and mineral (calcium hydroxyapatite). Current preferences for carbonated beverages instead of milk are thought responsible for deficiencies in calcium intake. Limiting sunlight exposure inhibits production of the active form of vitamin-D (essential for calcium absorption from the gut) and thus exacerbates the lack of calcium. Mild cases of vitamin-D deficiency are common even in otherwise well-nourished adults. Bone mass, critical for fracture resistance, cannot be gained or maintained in the absence of essential building materials.

Bone fractures are also appearing in response to low-energy events in young middle-aged pre-menopausal women with otherwise normal bone mass. The etiology of these fractures is unknown, but recent findings suggest structural defects in bone's protein component, notably abnormal collagen crosslinking.

Reconciliation of the force levels produced by low-energy events with resulting bone fractures requires a more thorough approach to understand this causal relationship. References linking force amplitudes with fractures offer data from populations, but understanding an individual's bone fracture threshold requires additional consideration of the particular material and structural aspects of the involved bone. This begins with a complete patient history, including prior surgeries, injuries, and medications. Non-invasive diagnostic tests quantifying the amount (bone mineral density) and current changes (biomarker assessments) in bone mass are also helpful and may exist in the subject's medical records. Bone biopsies are exceptionally useful, when available, and can provide the basis for a quantitative assessment of bone material composition and load-bearing structure. The forensic investigator should consider these and other factors to help understand the relationship between low-energy events, the accompanying forces, and the resulting bone injuries.

Human Injury, Injury Analyses, Accident Reconstruction

C33 Unusual Failure Modes of Large Diesel Generators in Bangladesh

Adam K. Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will have a better appreciation of difficult operating environments for these very large engines, and the local challenges in a developing country such as Bangladesh. Furthermore, classic investigating techniques are still useful even in the face of extreme destruction.

This presentation will impact the forensic science community by emphasizing how conventional forensic engineering techniques still yield results even if the odds are poor.

Large diesel engines operating on compressed natural gas or heavy fuel oil are used in electrical generating stations. These engines operate at a nominal 500rpm, are turbocharged and intercooled, and can generate on the order of 17MW per engine.

One such installation utilizes eight engines and is located on a barge in Bangladesh, providing 118MW of power to the local grid. Due to local power dispatch requirements, these engines are often stopped and re-started as load demand fluctuates. These engines accumulate many hours and many start-stop cycles. This project had accumulated some 500,000 operating hours, and 69,000 stop-start cycles during a fourteen-year operating history.

One engine had failed four years earlier, and two more engines failed catastrophically over a period of several months, and in spite of investigations by the manufacturers and other parties to the project, no satisfactory root cause was determined.

After the most recent catastrophic event in February of 2011, an investigator was sent to Dhaka, Bangladesh, to investigate the most recent failure.

The debris field was preserved for this investigation and will be shown through diagrams and photographs. The presentation will systematically present the general scene and then guide the discussion to the preliminary findings. A catastrophic failure is characterized by connecting rod separation, ejected pistons, ejected counterweights, fractured blocks, and damage to adjacent engines. A massive failure of this type requires the replacement of the entire block, a very difficult and expensive process, especially in a relatively remote location with logistic challenges. As in many such cases, the preservation of the evidence and failure artifacts is paramount.

A surprising twist occurred in this investigation. Although the investigation was to focus only on the most recent failure, in fact, the two previous failures were re-examined in light of the findings. A common failure mode was then developed, namely hydro-locking of these massive engines on start-up. But what was unknown, and a unique aspect of this work, was that multiple instances of hydro-locking could contribute successively to failures that were occurring seemingly at random.

The presentation will review other contributing factors and phenomena that, although independently would not be seen as causative factors, when confounded proved to be important elements in the failure matrix. The key to linking these events was the chance discovery and examination of artifacts from prior failures.

As in many cases, determined detailed examination of failure artifacts, in this case the cylinder liner, proved that the hydro-locking phenomenon was not a single cycle overload event, but rather that these instances could accumulate from multiple occurrences, and that the time of ultimate failure was not easily predictable. This investigation concluded with evidence of the root cause and methodology that would monitor potential failure modes, as well as preventative procedures to mitigate the likelihood of these multi-million dollar failures.

This presentation will show by photographs the important elements of the fact finding, segregation of the engine debris field, metallurgical failure modes, and the final evidence of multiple hydro-lock events.

Diesel, Hydro-lock, Wartsila

C34 Evaluation of Head Protection Provided by Sports Helmets

Matthew A. Ivory, BS, Michelle R. Hoffman, MS, and Parris Ward, JD, Biodynamics Engineering, Inc, 17383 W Sunset Blvd, Ste 290, Pacific Palisades, CA 90272; and Carley C. Ward, PhD, Biodynamics Engineering, Inc, 3720 E LaSalle St, Phoenix, AZ 85040*

After attending this presentation, attendees will have a greater understanding of sports helmet safety, with the ability to identify helmet designs and materials that can reduce risk of brain injury and concussions in helmeted head impacts.

This presentation will impact the forensic science community by demonstrating the use of a helmet drop test method with a biofidelic head form that can be used to compare helmets to meet different testing standards.

In this study various helmets were subjected to identical drop tests onto a hard flat surface and the resulting head accelerations were analyzed and compared. More than fifteen different helmets of various designs were tested. Helmets used for ice hockey, snowboarding, bicycle riding, skateboarding, football, and motorcycle riding were tested. These helmets are designed to different standards that vary according to sport and country.

Comparison of impact attenuation under the same identical hard surface impact conditions with a confirmed biofidelic head form provided a unique opportunity to evaluate the head protection in potentially serious to fatal head impacts.

Testing Method: The sports helmets were attached to an instrumented head form. The head form utilized was from 50th percentile of a standard instrumented Anthropomorphic Test Dummy (ATD) with a calibrated triaxial accelerometer mounted internally. The helmeted heads were dropped onto a hard flat asphalt surface from a height of 60 inches. The free-fall drops resulted in impact speeds of approximately 12mph. Each helmet was impacted on the top, back, right, and left sides in four separate drop tests. Each test was recorded on high-speed video (1000 frames per second) and real time video. Orthogonal ATD head accelerations versus time were recorded as specified in SAE J211, *Instrumentation for Impact Test*. Resultant head acceleration traces and Head Injury Criteria (HIC) values were compared and analyzed.

Results and Comparison: Due to the common impact velocity, the area under the acceleration curves were comparable and not a significant factor. However, peak head acceleration values and trace shapes exhibited considerable differences. The response differences are analyzed and interpreted.

For comparison, the accelerations and resultants were normalized with respect to helmet weight because the weight of the helmet influences the head acceleration. Helmet characteristics associated with the best impact attenuation were identified.

Since all head injury criteria are related in some way to head acceleration magnitude, helmets that reduce or minimize head acceleration provide better protection. Helmets with thin, soft, or non-existent liners provided the least protection. For example, a novelty type motorcycle helmet exhibited the worst performance, reducing the resultant head acceleration in a top side impact by only about 3% from a comparable bare head impact (487g). These novelty helmets are not safety certified, and although the rider wearing this helmet could circumvent helmet laws in various states, he or she would not be protected from injury in an accident. By comparison, a similarly shaped open face DOT-rated motorcycle helmet reduced the head acceleration by 50%. This reduction was the result of the Styrofoam-type liner's ability to dissipate the energy from the impact.

An even better performing helmet was the ski/snowboarder helmet, which reduced the head acceleration by 64%. Ridges in the shape of the shell deformed and helped absorb energy. However, such ridges would not be acceptable in a motorcycle helmet that needs a low friction, continuously slick hard surface. The best helmet tested was a newly designed hockey helmet that reduced the resultant head acceleration by 66%. This helmet has a liner made of hollow plastic cylinders placed adjacent to one another. The walls of the cylinders deform in the impact. This helmet performed better than an earlier designed hockey helmet with a firm foam liner that reduced head acceleration 60%. Head acceleration pulse shapes are flatter and elongated in all tests where energy is dissipated by the liners.

Conclusions: Based on the testing performed, protection varies widely from one helmet to another. All helmets provide some skull protection. Brain injury prevention requires impact attenuation. The impact attenuation provided is directly related to the liner material properties. Inadequate to non-existent liners, as in novelty helmets, provide little to no brain protection. Some sports helmets with contoured deformable shells can also help dissipate the impact energy. Most impressive is the superior protection provided by the new liner designs that utilize deformable plastic cylinders.

Head Protection, Sports Helmets, Helmet Drop Testing

C35 Analysis of the Parking Garage Vehicular Protection System in a Vehicular Crash Investigation

Daniel M. Honig, PE, Structures Consulting Engineer, PO Box 125, Swarthmore, PA 19081*

The goal of this presentation is to present a case where a vehicle traveling down an exit ramp of a parking garage exited the side of the building and landed top down in an adjacent alley. The investigation into a lack of proper and adequate perimeter safety protection will be described.

This presentation will impact the forensic science community by illustrating the relationship between strength values used in design as compared to the strength at catastrophic failure as well as emphasizing the necessity to properly apply the requirements of adopted building and maintenance codes.

Design load values are based upon the probability that the structural elements will remain in an undeformed condition as a result of an imposed load. Building codes require that the structural attachments of a vehicle barrier system be able to transfer the load to the building's structural elements.

This recent vehicle crash incident occurred on the third level of a parking garage located in a downtown metropolitan area. For unknown reasons, a driver and car traveled down the exit ramp, jumped a concrete curb, and impacted a precast concrete wall panel, thereby

knocking the panel into an alley. As a result of the vehicle loss of control within the garage and the lack of proper and adequate perimeter safety protection, the car exited the side of the building and landed upside down in the adjacent alley.

The original restraint/protective system previously located along the sides of the garage was subsequently removed at the time of an architectural facade renovation in the late 1960s. The existing perimeter system in the garage at the time of the incident was limited to two main components: architectural precast concrete panels attached to the floor slabs and concrete curbing and wheel stops. The combination of the concrete curbing element and the architectural precast wall panel was not able to resist the lateral impact loading of a vehicle traveling at less than fifteen miles per hour, as required by the building code. The architectural facade support system was not a vehicular restraint system. The absence of an additional proper and adequate code-compliant vehicle restraint system allowed the in-place architectural facade support system to fail locally under direct vehicular impact loading.

Multiple field reviews of the existing parking garage building conditions had been performed by various engineering/consulting firms over the course of an approximate thirty-year span beginning in 1978 through the time of the incident. These reviews noted the absence of adequate vehicular protection for the architectural facade system. The building owner, the parking garage management firm, and a construction administration firm were all aware that the exterior precast wall panels were potentially unable to resist vehicular impact loading prior to the incident.

The parking garage management firm and the construction administration firm suggested that the architectural precast concrete panel system was “grandfathered” into the current building code. This “grandfather” description was not correct, given that the current building code specifically stated that existing structures and building elements were not “grandfathered” with regard to general safety and welfare of the occupants and the public. The structural inability of the existing architectural facade panels and/or their connections to adequately support and transfer the code-required vehicular loading posed a threat to the general safety of the parking garage patrons and public use of adjacent surrounding areas at grade.

Structural and civil engineering practice involves the inclusion of normal factors of safety as part of a proper and thorough design process for new and existing building systems and related components. These factors are the relationship between strength values used in a design as compared to the strength at ultimate or catastrophic failure. A properly designed vehicle restraint system would take into consideration load combinations for extraordinary events as well as factors of safety. The calculated catastrophic failure point of the mechanical anchors supporting the architectural panel was significantly less than even the unfactored design values for a vehicle restraint system. Given the use of factors of safety, a vehicle restraint system properly designed would not have had a catastrophic failure until it was subjected to an excessive force.

A proper and adequate code-compliant vehicle barrier restraint system was required to be designed, installed, and maintained in order to properly resist vehicular impact loading by the building code in existence at the time of the original construction of the garage, the building code in existence at the time of the addition of the building atop the garage, and the building code in existence at the time of the preliminary condition appraisal report, as well as the recent and current editions of the property maintenance codes.

Vehicular Impact, Design Load Values, Catastrophic Failure

C36 Forensic Architecture: An Introduction and Case Studies

Robert D. Lynch, BArch, 5408 Zoysia Ct, Haymarket, VA 20169-6203*

After attending this presentation, attendees will learn what forensic architecture is, and how it differs in practice from forensic cases in other fields of science. The presentation will examine how three types of cases were successfully managed.

This presentation will impact the forensic science community by an introduction to forensic architecture with pertinent details of three forensic cases and how they apply to the practice of architecture.

Forensic architecture varies from case to case, but seems to differ from cases in other forensic sciences, as it may involve situations both before and after the occasion of injury, damage, or public disputation.

Situations arising before the occasion tend to be preventive in nature, such as surveys to identify architectural barriers, or the development of standards that serve as guidelines to building safe environments. These cases usually do not become legal situations; however, cases that arise after the occasion of injury or loss due to non-adherence to building codes, regulations and/or construction specifications, usually end up in the legal system.

Case 1: A nationally franchised chain leased a building on the main street in a small Pennsylvania town, made interior renovations, and added a ramp from the public sidewalk to the front door. The ramp was constructed in violation of the building code, and the restaurant owner filed for approval of a variance to allow the ramp to remain. The variance was refused but the owner appealed, received a new hearing, and approval of the variance. A citizen filed a petition to deny variance and the case was reopened. When data was analyzed, the ramp was found to be egregiously in violation of the building code (14.4% slope vs. allowable maximum 8.33%) and not a safe wheelchair ramp. As proof, a center-of-gravity study was presented to demonstrate the danger of allowing the center of gravity of a person using a wheelchair to fall behind the point of support, creating conditions whereby wheelchair users would fall backward. Decision is pending from the Administrative Officer of the Pennsylvania Department of Labor and Industry.

Case 2: A home modification was necessitated by the tragic aftermath of a child’s vaccination, resulting in a little girl suffering from mitochondrial disease, causing developmental delay, seizures, bronchospasm, and an inability to use her limbs. The family, who lives in suburban Atlanta, sued the Secretary of the U.S. Department of Health and Human Services. The Department of Justice undertook resolution of the matter. There was an inspection and analysis of the family’s home. Field-measured drawings, photographs, interviews with the family, review of medical records, and observation of professional therapy sessions provided necessary data. A 3D computer model of the home was created and analyzed to provide a design solution and construction cost estimate of reasonable and necessary home modifications. The modifications included a residential elevator, reconfiguration of several rooms, and use of second-story space above the foyer to accommodate an accessible bedroom and bathroom for the child on the second floor, including a ceiling-mounted, motorized personal transport system to move her from bed to bathroom fixtures. Also provided were a small desk space for a nurse and caregivers, and storage for medical supplies. The garage door opening was raised for access by a wheelchair-accessible van, and ramping added for access to the front door and rear patio. A report was presented to the Special Master who accepted the design and settled the case.

Case 3: In 1993, three weeks before the official opening of the Holocaust Memorial Museum in Washington, a complaint of non-compliance with the Americans with Disabilities Act (ADA) was received from an advocacy organization maintaining that the new museum violated design guidelines of the ADA. The main objection of the organization was the inaccessibility of the sacred central space in the Hall of Remembrance. After study of the construction and upon meeting with the general counsel of the United States Architectural Transportation and Barriers Compliance Board (ATBCB), a design was proposed for a special wheelchair lift carefully integrated into the stairs to preserve the sacred atmosphere of the space. Thus, design issues regarding noncompliance with the ADAwere resolved and the Holocaust Memorial Museum opened according to schedule.

Building, Architect, Construction

C37 Analysis of a Vinyl Railing System in a Second Story Fall Incident

Daniel M. Honig, PE, Structures Consulting Engineer, PO Box 125, Swarthmore, PA 19081*

After attending this presentation, attendees will have been introduced to a case where a fall incident occurred from the second-story exterior rear deck of a vacation residence when a vinyl railing section suddenly and unexpectedly failed at the structural connection to the railing support vertical posts. The investigation into a lack of a proper and adequate railing system will be described.

This presentation will impact the forensic science community by illustrating the need for proper design, installation, inspection, and maintenance of secondary building components, such as railing systems, emphasizing the necessity to properly apply the requirements of adopted building and maintenance codes.

Building codes require that railings/guards have the proper connection devices to transfer load to the appropriate adjacent primary structural framing elements of the building. The railing section involved in this incident had never been inspected throughout its eight-year life span, during which time it was exposed to exterior weather elements.

This fall incident occurred from the second-story rear deck of a vacation residence. The tenant of the vacation residence placed his hand on the vinyl railing of the deck for support and the railing section suddenly and unexpectedly failed at the structural connections to the vertical support posts, thereby causing both the tenant and the railing section to fall to the ground below.

The vinyl railing involved in this incident was installed by the contractor during the original time of construction. An exemplar section of the vinyl railing section was removed from the deck area after the incident. The horizontal railing members of the vinyl rail system consisted of a wood core with a vinyl cover and were toe-nailed with galvanized screws. The manufacturer's instructions called for the installation of coated aluminum brackets fastened to the bottom rail and to the sleeved post.

The manufacturer's documentation specified that the wood cores of the horizontal members be fabricated of cedar wood; however, review of the exemplar railing section confirmed the upper horizontal member consisted of two varying wood sections finger-jointed together and the lower horizontal member consisted of a nonpressure-treated standard framing member. These as-built structural wood cores were not consistent with the specifications, nor were they suitable for the intended use.

The manufacturer's installation guide recommended cutting the vinyl covering of the horizontal handrail members shorter than the wood core to allow for expansion and contraction due to weather. This procedure created an area of vulnerability where the structural wood core was not protected. During inclement weather conditions, moisture would infiltrate the horizontal wood core to vertical post connection locations. This condition continued and was inadequately maintained over time, thereby allowing the significant deterioration to occur.

The jurisdiction where the property is located required a rental license for all rental properties. Although the jurisdiction inspected and reviewed the residence at the time of original construction, according to the jurisdiction's regulations for rental properties, annual inspections of the property are mandated in order to retain a rental license. The property owner never obtained the required rental license.

According to the municipal fire inspector, an annual inspection would have required the property to be compliant with the State Fire Prevention Code. The railing system was required by the building code at the time of original construction of the deck, and the fire prevention code required that all required means of egress safeguards be maintained in good working order. The fire prevention code further required that any exterior means of egress found in a state of deterioration or determined to be unsafe by the fire official be repaired immediately.

The railing system of this elevated exterior deck could not support the code-mandated and expected lateral forces encountered during its lifetime. An experienced contractor should have been aware that toe-nailed connections would not provide adequate structural support without the use of additional brackets or connection mounts. In addition, the galvanized connection screws were subject to deterioration given direct exposure to the weather elements. An experienced contractor should have been aware that no weather-resistant protection between the horizontal structural supports and the vertical wood posts provided a vulnerable place for moisture penetration.

Given the improper as-built construction of the vinyl railing system, the improper connection of the horizontal members to the vertical support posts, and the lack of maintenance and inspection by the owner, the structural connection of the horizontal members to the vertical posts failed under normal and code-required loading, thereby allowing the tenant of the residence to fall to the ground below. The design, configuration, construction, and installation of this railing system, as well as the improper maintenance and lack of inspection by the property owners, allowed this incident to occur. Had this residence been properly licensed as a rental property, the rental unit would have been annually inspected and this incident could have been prevented.

Weather Exposure, Maintenance, Railing Failure

C38 The Effect of Polyethylene Shoe Covers on the Available Friction of Reference Surfaces

Michael A. Sapienza, BS, Fleisher Forensics, 323 Norristown Rd, Ste 130, Ambler, PA 19002*

The goals of this presentation are to demonstrate the effect of an intermediate layer of textured polyethylene material on available friction and also show the value of the protocol described in ASTM F2508 Standard Practice for Validation and Calibration of Walkway Tribometers using reference surfaces.

This presentation will impact the forensic science community by demonstrating the importance of using reference surfaces to evaluate available friction.

Method: ASTM F2508 was used as a reference to measure the effect of polyethylene shoe covers on test results using the prescribed reference surfaces with a validated and calibrated Mark II portable inclinable articulated strut tribometer. The reference surfaces were those included in the ASTM Adjunct to F2508 consisting of ADJF2508-T1 (Vinyl), ADJF2508-T2 (Ceramic), ADJF2508-T3 (Porcelain), and ADJF2508-T4 (Granite). An additional reference surface of 2"x10" pine was incorporated as an exemplar surface encountered on a basement stairway.

Service companies, such as plumbing, heating, H&V, moving, furniture, and flooring, routinely require their employees to wear shoe covers in an attempt to protect their customers' flooring and walkway surfaces from tracked-in soil and moisture. The shoe covers vary in type and some are advertised as waterproof and slip resistant on household walkway surfaces. In particular, certain waterproof, slip-resistant, textured polyethylene shoe covers were used during a routine plumbing repair that resulted in an individual slipping and falling down a flight of 2"x10" pine basement stairs.

To determine the effect of the shoe covers on the available friction of the reference surfaces, adjunct tiles from ASTM were obtained along with the ASTM F2508-11 Standard Practice for Validation and Calibration of Walkway Tribometers using Reference Surfaces. A piece of 10-year-old 2"x10" pine board was also used as an exemplar of the incident stairway. Two materials were evaluated as shoe soling, a standard Neolite® sensor material, and the same material covered with the incident-textured, plastic waterproof shoe cover.

Forty tests for each surface/sensor condition were conducted: 10 in each of 4 orthogonal directions, that is, at 0°, 90°, 180°, and 270° relative to an arbitrarily defined direction on the reference surface. A total of 400 tests were conducted (10 replications x 4 directions x five surfaces [sample] x two sensors [columns]). The tests were analyzed using ANOVA: Two Factor with Replication. Direction was not included as it had been previously found to be insignificant. Surface [Sample] and Sensor [Columns] were both highly significant (*p*-values of 1.9E-142 and 0.00 respectively).

ANOVA

Source of Variation	*SS*	*df*	*MS*	*F*	*P-value*	*F crit*
Sample [Surface]	2.86855	4	0.717138	435.8955	1.9E-142	2.394824
Columns [Sensor]	26.91534	1	26.91534	16359.87	0	3.865413
Interaction	0.080276	4	0.020069	12.19848	2.36E-09	2.394824
Within	0.64163	390	0.001645			
Total	30.5058	399				

For the 40 tests on each reference surface, the mean, Standard Deviation (SD), Standard Error (SE) of the mean, and 95th percentile Confidence Interval (CI) for the walkway tribometer test results were calculated. Using the mean and standard deviation, paired *t*-tests determined statistically significantly different results (t >1.694) for both sensors on all reference surfaces. (Neolite® — shoe-covered Neolite®).

Granite using standard Neolite®			Granite using shoe covered Neolite®			Paired t-test difference

95% CI	0.90979	0.88921	95% CI	0.33781	0.32769	t-test	>1.694

It was clear the presence of the textured polyethylene plastic, waterproof shoe covers lowered the available friction of the reference surfaces and presented a slip hazard to the individual wearing them.

An additional paired t-test was done using the inside surface of the shoe cover as the walkway surface and standard Neolite® as the sensor under wet and dry conditions to determine the effect of moisture on the inside of the shoe cover.

Shoecover using std Neolite® dry			Shoecover using std Neolite® wet			Paired t-test difference	
Mean	0.616		Mean	0.089		Mean Diff	0.527
Std Dev	0.025		Std Dev	0.018		Std Dev	0.027
Std Error	0.0039		Std Error	0.0028		T	123.577
95% CI	0.62343	0.60807	95% CI	0.09401	0.08299	t-test	>1.694

The shoe cover also presented a hazard to the wearer if used over wetted shoe soles.

Shoe Covers, Slip Resistance, Reference Surfaces

C39 Analysis of ASTM F2508 Reference Surfaces Using Logistic-Regression-Based Criteria

Howard P. Medoff, PhD, 1600 Woodland Rd, Abington, PA 19001; Marcus P. Besser, PhD, 901 Walnut St, Rm 514, Philadelphia, PA 19107; and Mark I. Marpet, PhD, PE, 14 Cowie Rd, Chester, NJ 07930-9715*

The goal of this presentation is to inform the attendees how to qualify reference surfaces and the implications of the same. ASTM 2508 is a new standard designed to qualify Walkway-Safety Tribometers. This paper uses logistic regression to analyze the quality of the reference surfaces.

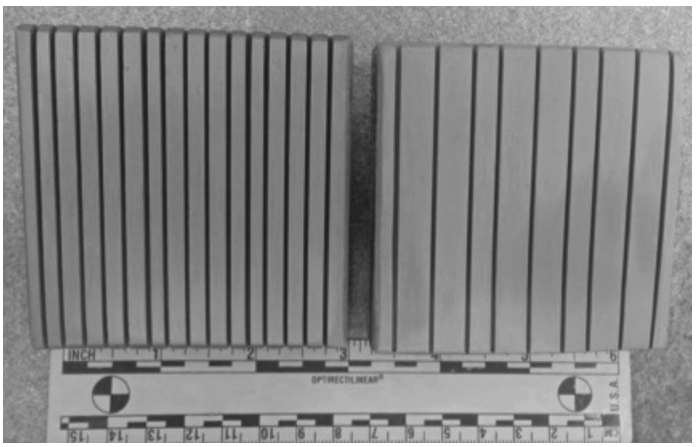
This presentation will impact the forensic science community by showing how the nuanced view of the ASTM F2508 reference-surface qualification methodology for tribometers will allow researchers and practitioners to have more than a one-dimensional "handbook" view of tribometric-test variability and reliability. This is essential for an understanding of the relationship between fall hazard and tribometric test results.

Background: The measurement of the available friction between the floor surface and a shoe (or foot) bottom is of significant import in determining pedestrian-ambulation safety. High-school and elementary college physics, for the sake of simplicity, assume the Amontons-Coulomb friction model, where it is axiomatic that friction is solely a function of the materials in contact, and independent of contact pressure, velocity, temperature, and so forth. This model holds reasonably well when the materials are non-resilient, e.g., steel and/or wood. The model is often problematic when one of the surfaces is resilient, like a shoe or foot bottom, and essentially irrelevant when the interface between the materials is lubricated. In that situation, factors other than the materials involved become significant. Importantly, the friction-measuring instrument itself (called a Walkway-Safety Tribometer, or WST) becomes a factor in the measurement. That is, different WSTs, measuring the same surfaces, will give different, sometimes very different, results. This is caused by two factors: (1) on a fundamental level, different WSTs use different friction-generating mechanisms (for example, a drag-sled or articulated-strut tribometer cannot replicate the hydrodynamic, squeeze-film phenomenon that occurs when pedestrians slip on a wet surface); and, (2) assuming that the WST is capable of replicating the appropriate friction mechanism, the parameters (especially pressure/time effects) are different, both between different models of WSTs, and different between a WST and an ambulating pedestrian. Because the ultimate purpose of WST test results is to determine if a walking surface (or shoe bottom) conveys adequate safety, the test of utility for any WST results are how they reflect pedestrian-ambulation traction. The concept that WST tests must ultimately reflect on pedestrian-ambulation safety is called biofidelity. Recognizing this, and troubled by the fact that the then-current ASTM WST standards referenced proprietary instruments, the Board of Directors of the ASTM convened a task group under the guidance of a former ASTM Chairman of the Board to address this issue. From this, ASTM-sponsored research at the University of Southern California examined the relationship between a pedestrian's utilized friction and the results of tribometric tests. The end result was a set of four reference surfaces, which are used to "standardize" the tribometer readings. These four test surfaces consist of (from the most to least slippery): (1) polished granite lubricated by a diluted non-ionic solution); (2) Porcelanosa Ferrokor tile, lubricated by distilled water; (3) Official Vinyl Composition Tile (OVCT), lubricated by distilled water; and, (4) unglazed ceramic tile, lubricated by distilled water. The calibration of tribometers using these tribometric reference surfaces is governed by ASTM standard F2508, which was first approved in 2011.

Because walkway-safety tribometry test results are standardized by these four tribometric reference surfaces, it is useful to be able to answer questions concerning the reference surfaces and their relationship to the tribometers. F2508 requires a WST to discriminate—with statistical significance—between the four reference surfaces. F2508

discrimination is verified with t-tests of the adjacent surfaces: granite vs. Porcelanosa; Porcelanosa vs. OVCT; and OVCT vs. unglazed ceramic. There was interest to see if the quality of the reference surfaces using the Slip-Test Mark II portable inclinable articulated-strut tribometer (the PIAST) and logistic regression, which was chosen as an analysis tool because the PIAST gives dichotomous (slip or no-slip) results could be better assessed.

Experiment: A PIAST was modified by fabricating and installing a mechanism to be able to tilt the mast with an order of magnitude of more accuracy than an unmodified PIAST and installed a platform for a high-precision level (0.1 degree repeatability). For the experiments, the PIAST was shod with two slightly different test feet, both of test liner, but with different siping patterns:[1]

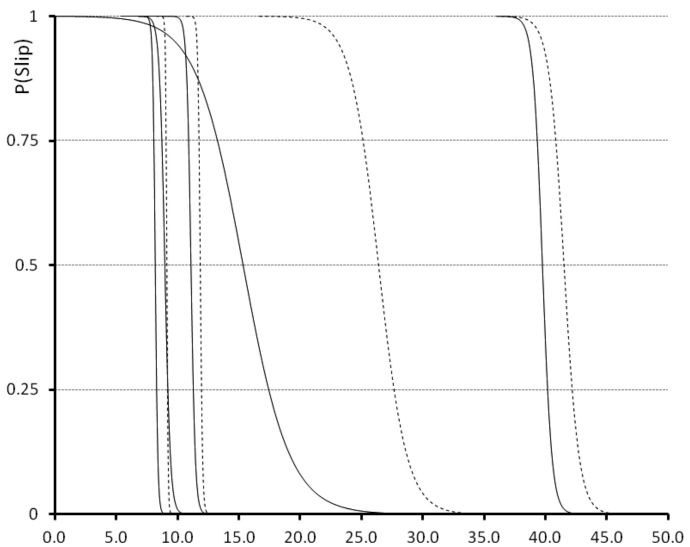


For each reference surface, the PIAST was set to a friction angle low enough so that the test foot would not slip, and the friction angle was slowly increased, typically at a fraction of a degree at a time, taking numerous (typically 25) tests at each friction angle, until slips were observed at 100% of the readings.[2] This was done with each of the two test feet. For each test-foot/reference-surface combination, between 100 and 400 friction tests were taken.

Logistic regression was used to determine the probability of a slip at a given WST setting. Ideally, the WST will always slip at exactly the same value, yielding a step function graph:

$$P(\text{Slip}) = \begin{cases} 1; & \mu \leq \mu_c \\ 0; & \mu \geq \mu_c \end{cases}$$

In reality, because slipping is—in walkway-safety tribometry as in real life—a probabilistic event, the curve obtained is s-shaped: a logistic curve. The steeper the curve, the more like a step function, and the more discriminating the reference surface. The P(slip) = 50% point on the curve is the nominal friction value of the test-foot/reference-surface combination. Here are the results:



Discussion: Visually, it is clear that the granite/diluted non-ionic solution (the leftmost three curves) and Porcelanosa/distilled-water (the fourth and fifth from the left) reference surfaces demonstrate excellent discrimination; the behavior is very close to the ideal step function for the slip/no slip condition. The test-foot-to-test-foot differences for these surfaces were also minimal. The ceramic tile (the rightmost two curves) are not quite as discriminating, but as the friction angle for the slip/no slip dichotomy is quite large (above 40°), the relative variation (analogous to the coefficient of variation for a continuous variable) is small. Problematic is the OVCT, the third and fourth curves from the right. They are both quite shallow, indicating poor discrimination; importantly, the two curves for the two test feet are widely separated, indicating that different (but similar) test feet will give disparate results.

Neither of these OVCT flaws necessarily negates the utility of F2508. As far as the lack of discrimination inherent in the OVCT, one can increase the sample size (an operator checking his equipment will typically perform 12 repetitions on each surface; a validation run requires 40 repetitions on each surface) to compensate for the increased relative variation. As far as the separation between the curves, one of the main purposes of F2508 standardization is to allow results from different tribometric instruments to be compared; this can obviously extend to different test feet on the same tribometric instrument, different operators, and so forth.

That said, it is recommended that the ASTM subcommittee that maintains F2508 (ASTM Committee F-13 on Footwear and Pedestrian/Walkway safety's subcommittee 13.1 on traction) seek to revise F2508 by researching and qualifying at least two other reference surfaces to use in the stead of OVCT.[3]

References:

1. In the graph (above), the test foot on the left is represented by the dashed curves. The test foot on the right is represented by the solid curves.
2. The friction angle is the angle of inclination of the PIAST mast. The friction coefficient is the tangent of the friction angle.
3. It is recommended that ceramic reference surfaces both having low variability and in the range of 20° and 30° friction angles be explored.

Forensic Science, Tribometry, F2508

D1 DNA Identification of Mass Disasters' Victims and Ethical Issues

Luciana Caenazzo, PhD, Dept of Enviromental Medicine and Public Health, DMM Legal Medicine, Via Falloppio, 50, Padova, 35121, ITALY; Pamela Tozzo, MD, Department of Molecular Medicine, Padova, ITALY; and Daniele Rodriguez, PhD, Univ of Padua, Via Falloppio 50, Padova, 35126, ITALY*

After attending this presentation, attendees will better understand the ethical aspects concerning the activity of identification of victims of mass disasters using DNA technology.

This presentation will impact the forensic science community by not only stressing the importance of DNA identification of victims of mass disasters, but also using caution with ethical issues with the potentially sensitive nature of DNA identification.

A mass disaster is an unexpected event that causes serious injury and death to a number of people. It may be a natural disaster (e.g., earthquake, volcano, avalanche, hurricane, and tsunami), an accidental disaster (transportation accidents and building fires), or an intentional terrorism act (e.g., terrorist activity, war, or political crisis).

Victim identification is difficult but necessary. Proper identification is necessary to notify the legal next of kin, resolve estate issues and criminal/civil litigation, and issue death certificates.

DNA profiling is increasingly becoming an important tool in the individual identification in the aftermath of mass disaster. While forensic geneticists are often not included as first responders, DNA sample collection and a strategy for DNA-based victim identification needs to be part of the community's preparedness plan. In fact, the preparedness plan of the laboratory needs to include policies for family notification, long-term sample disposition, and data archiving.

Many of the decisions which involve prioritization are made daily and often without much thought to the ethical and allocation considerations underlying them. Experienced investigators making these types of decisions are usually deciding about priority for, rather than access to, services or interventions.

One of the objectives of the forensic investigation of human remains is to identify the remains and, if possible, return them to the family of the dead person. This objective helps family members by ascertaining the fate of their relative and allowing the remains to be handled in a culturally appropriate manner, thus enabling the families of the missing to mourn their loss.

Ethical issues are associated with the use of DNA identification, because information contained in a person's DNA is sensitive and it is a unique identifier and may contain information about a person's family and intimate associations. It is widely held that the death of a person does not extinguish the interests of that individual. Indeed, family members, and others who have physical possession or access to an individual's body, tissue, or cells, have to respect certain obligations and rights following the death of the individual.

Although the ultimate goal is to obtain a match between two persons or between a biological material and a person, the specific context of each of these applications of human identity testing has its specific problems, ranging from technical approach, through statistical interpretation, to ethical issues.

There has been very little systematic effort to identify and analyze the major ethical and policy challenges associated with this new use of genetic technology. This study seeks to define some of these ethical aspects focusing on particular situations.

International law does not have any specific provisions for protecting genetic data in mass disaster. International humanitarian law and international human rights law recognize the need to provide special protection for persons affected by armed conflict. However, these bodies of law contain only general principles relating to confidentiality, privacy, non-discrimination, and human dignity that can be applied to the protection of genetic data.

It seems important to evaluate how to deal with resource allocations, incidental findings, ethical acceptance of secondary uses of the biological materials collected, and the use/misuse associated with the creation of large genetic databases. Last but not least, the issue of privacy, which has to be rigorously protected to ensure the respect of human individual rights must be addressed.

DNA Identification, Mass Disaster, Ethics

D2 Advantages of Forensic Anthropologists' Involvement in Mass Disaster Responses: A Review of the I-75 Mass Fatality

Traci L. Van Deest, MA, Univ of Florida, C.A. Pound Human Identification Laboratory, 2033 Mowry Rd, Rm G-17, Gainesville, FL 32610; Katherine Skorpinski, MA, Univ of Florida, Cancer/Genetics Research Complex, 2033 Mowry Rd., Room G17, Gainesville, FL 32610; Carrie A. Brown, MA, 121 SE 16th Ave, J202, Gainesville, FL 32601; Allysha P. Winburn, MA, Univ of Florida, C.A. Pound Identification Lab, Cancer/Genetics Research Ctr, 2033 Mowry Rd, Gainesville, FL 32610; Sarah Kiley, MS, Univ of Florida, C.A. Pound Human Identification Laboratory, 2033 Mowry Rd, Room G-17, Gainesville, FL; and Kristina M. Ballard, MA, 3224 NW 31st Ave, Gainesville, FL 32605*

After attending this presentation, attendees will learn how anthropological methods can aid in the recovery and identification of individuals in a mass disaster event involving multiple vehicle collisions. A systematic interagency approach using archaeological methods maximized the recovery of skeletal elements and personal effects necessary for identification with minimal damage resulting from the recovery process.

This presentation will impact the forensic community by demonstrating the utility of forensic anthropologists in the recovery of remains from burned and altered vehicles. The archaeological approaches used by forensic anthropologists are extremely useful in mass disasters, particularly when remains are burned, fragmentary, and commingled.

On January 29, 2012, a multi-vehicle crash occurred on Interstate 75 in the Gainesville, Florida, area as the result of reduced visibility due to fog and smoke from nearby wildfires. The crash resulted in 11 deaths and at least 23 injured. The District 8 Medical Examiner's Office consulted forensic anthropologists from the C.A. Pound Human Identification Laboratory at the University of Florida to assist in the recovery of victims within the burned vehicles. Two of the vehicles involved were towed to a secure location at the Alachua County Sheriff's Office for processing. The first vehicle contained the remains of a single individual. Although the majority of this individual was removed by medical examiner personnel with the assistance of an anthropologist at the scene of the accident, the forensic anthropologists present were able to quickly sort through the debris in the car to recover any remaining burned bone fragments.

After completion of the first vehicle, the search and recovery inside the second vehicle, a small pickup truck, began on the afternoon of January 30, 2012, and continued through the morning of February 2, 2012. The truck was severely damaged with the roof, dashboard, and

back wall of the cabin collapsed inward toward the seats. Due to the condition of the second vehicle from both the accident and subsequent vehicle fire, vehicle identification information was not accessible until the contents of the vehicle were removed. Although burned remains were evident in the passenger and driver seats, the total number of individuals inside the truck was unknown at the start of recovery. As the recovery progressed, local fire and rescue personnel assisted in removing portions of the truck cab to facilitate access inside of the vehicle. The processing of this vehicle required the modification of traditional archaeological methods. Separate areas of the vehicle (driver seat, passenger seat, backseat, console area) were defined to minimize further commingling of fragmentary remains during the recovery process. All material was removed by hand and screened using 1/8" or ¼" screens. As trained osteologists, the forensic anthropologists on scene were quickly able to distinguish between burned remains and other visually similar materials, including wood, insulation, car seat foam, and other melted and altered aspects of the car interior. In general, the skeletal remains were burned and highly fragmentary, exhibiting black to white coloration. Anthropologists and odontologists examined dental fragments recovered for developmental age and restorations that could facilitate a more rapid identification, with fixation used as needed. Other artifactual evidence useful for identification, including, jewelry and paper materials with writing, were recovered with minimal additional damage to these items. All osseous material upon removal was photographed, bagged, and labeled with the provenience (i.e., associated area of recovery). Debris determined to be non-osseous or non-evidentiary was placed in a designated area separate from bone and other material collected. Additionally, the recovery process was fully documented through photography of the vehicle during excavation.

Ultimately, three individuals were recovered from the vehicle: one in the driver's seat, one in the passenger's seat, and one in the backseat. Maintaining provenience at all times, including separate excavation areas within the vehicle, documentation, and transport to the medical examiner's office, allowed for minimal commingling of remains during recovery. Systematic screening and clearing of all debris in the vehicle resulted in the recovery of as many skeletal elements as possible, as well as personal items, which aided in the rapid identification of those individuals in the vehicle. This incident highlights the importance of interagency collaboration and the inclusion of appropriate specialists to efficiently and effectively recover and identify individuals in a mass disaster event.

Anthropology, Mass Disasters, Burned Remains

D3 Isotope Forensic Evaluation of Modern Human Remains From the University of Tennessee William M. Bass Donated Skeletal Collection

Zheng-Hua Li, PhD, 320 Sparkman Dr, NSSTC 2017, Huntsville, AL 35899; Nicholas P. Herrmann, PhD, Mississippi State Univ, Dept of Anthropology and Middle Eastern Cultures, 206 Cobb Institute, Starkville, MS 39762; Richard Jantz, PhD, Univ of Tennessee, Dept of Anthropology, Knoxville, TN 37996-0720; and Miriam E. Soto, MA, 2615 Skyview Glenn Ct, Houston, TX 77047*

After attending this presentation, attendees will gain a greater appreciation of isotopic patterns in the modern American population derived from enamel, hair, and bone, and also an introduction to novel sample preparation techniques.

The presentation will impact the forensic science community by presenting multiple isotopic values of bone collagen, bioapatite (phosphate and carbonate), and hair keratin from the William M. Bass Donated Skeletal Collection (WBDSC), the largest modern skeletal collection in the United States.

The present study builds on recent advances in isotopic forensic research by examining multiple isotopic variations in the William M. Bass Donated Skeletal Collection (WBDSC). The WBDSC represents the largest modern skeletal collection in the United States and the collection is housed at the University of Tennessee Forensic Anthropology Center (UTK FAC). For this study, the FAC Donations serve as a proxy for modern surface and buried forensic cases.

Multiple constituents including bone collagen, bioapatite (phosphate and carbonate), and hair keratin from 102 donations were prepared for $\delta^{13}C$, $\delta^{18}O$ and $\delta^{2}H$ analysis using refined protocols. The protocols were enhanced by shortening the cycle of each sample preparation period for collagen extraction utilizing a filter-bag method assisted by an ultrasonic water bath, and modifying Thermo TC/EA for improving analysis precision of phosphate $\delta^{18}O$.

Dental enamels were sampled using a NewWave Micromill and analyzed for $\delta^{18}O$ of phosphate. The averaged $\delta^{18}O$ value was 17.50±1.36‰ VSMOW (n=45). Correlation analysis of the dental $\delta^{18}O$ values with meteoric water $\delta^{18}O$ at birth location (modeled) yielded the equation ($\delta^{18}O_{tooth}=0.62\delta^{18}O_{water}+21.74$, r=0.63, n=45), which was very similar to the equation ($\delta^{18}O_{bone}=0.64\delta^{18}O_{water}+22.37$, r=0.98) generated by Longineli (1983).

Non-exchangeable $\delta^{2}H$ of hair keratins were also analyzed using Thermo TC/EA. The averaged $\delta^{2}H$ was -83.35± 6.36‰ VSMOW (n=14). The $\delta^{2}H$ values exhibit a positive correlation with the meteoric water $\delta^{18}O$ at death location (r=0.68), and a negative correlation with altitude (r=-0.73) that is consistent with isotope "Altitude Effect." In addition, 61 bioapatite carbonates were analyzed for $\delta^{13}C$ and $\delta^{18}O$. The averaged value was -9.32±1.31‰ (VPDB) for $\delta^{13}C$, and -6.91± 1.41‰ (VPDB). But there was no meaningful geographical information inferred from these bone apatite samples. Bone collagens (n=77) were extracted for N, C, N/C ratio, $\delta^{13}C$ and $\delta^{15}N$ analysis. The averaged carbon content in human phalanx bone collagen was 34.55±5.20%, 12.60±2.05% for nitrogen content. The averaged C/N ratio was 2.76±0.21. The averaged $\delta^{13}C$ value was -15.72±0.9‰ (VPDB), and 11.12±0.51‰ (AIR) for $\delta^{15}N$.

This study indicates that the dental enamel $\delta^{18}O$ values from the WBSC collections are overall reflective of the individual's birth location, whereas hair keratin $\delta^{2}H$ values are influenced by the individual's death location, which is consistent with several other isotopic studies of forensically derived human samples and suggests that the application of the dual isotope (O, H) could provide better constrain on the residential history by pin-pointing the beginning (tooth) and the ending (hair) of the individual life journey. Although the correlation coefficient of the dental $\delta^{18}O$ with local water is not as high as reported by several other researchers, the relationship; however, does follow the trend of the earlier study.[1] The potential influence of isotopic pattern of tap water will also be discussed to examine the variability seen in the WBDSC sample.[2] It is suspected that the WBDSC does not represent a more geographically heterogeneous sample and it is likely that self- or family-reported residential histories as is the practice at the UTK FAC are more variable.

This project is supported by the National Institute of Justice, Office of Justice Programs, Grant #2008-DN-BX-K193.

D4 Fatal Dog Bites in Children: Three Cases From Central Virginia

Lara Frame, MA, 400 E Jackson St, Richmond, VA 23219; Kevin D. Whaley, MD, OCME, 400 E Jackson St, Richmond, VA 23219*

After attending this presentation, attendees will have a better understanding of the circumstances surrounding child fatalities due to dog bites in central Virginia.

This presentation will impact the forensic science community by providing a generalized description of child fatalities due to dog bites in central Virginia, which may prove useful in determining how to prevent fatal dog bites in children and determining when situations involving dogs and children can prove more likely to have a fatal outcome.

In the past twelve years, three cases of fatal dog bites involving children have been investigated. The similarities and differences between these cases will be discussed in three separate case reports.

The first case occurred in 2000 involving a 6-year-old white male who was airlifted to a hospital and later died after suffering lethal dog bites to the head and neck. The victim had gone outside by himself to feed the family dog. The bites to the head were so severe that part of the skull became visible. The dog involved in this death was a wolf-German shepherd mix.

The next two cases were more recent. The case from 2009 involved a 1-year-old white female who was left alone and wandered outside to where her family's dog was chained. She sustained multiple puncture wounds to the neck. The dog involved in this attack was a pit bull.

The third case from 2011 involved a 5-month-old white male who had been left alone in the same room as the family's dog. The victim was found unresponsive after family heard growling. The victim sustained multiple lacerations to the forehead. The dog involved in this death is a rescued bulldog.

In all three cases, the events were not witnessed. Additionally, all the victims were last seen alive shortly before the attack and were not found until the child either cried out during the attack or family members heard or noticed something out of place and found the child right after the attack. In all three cases, the trigger for the attack was unknown. Three similarities emerged between the three cases: (1) all three dogs are stereotypically labeled "attack" breeds; (2) the dogs involved had no known previous violent history and no previous incidents of aggression; and, (3) all three victims had injuries to the head and neck areas. One difference between all three cases was the age difference; the victims ranged in age from five months to six years.

Further investigation into these cases will examine the living situations of the families involved, the type of dog involved in the attack, the location of the incident, and the location, depth, and severity of the injuries. Future investigation will include investigation of fatal dog attacks from the other three districts of the Virginia Medical Examiner system. The presentation of these three cases from the central region of Virginia will eventually be part of a larger study of fatal dog attacks involving children in the entire state of Virginia.

Dog Attack, Fatal, Child Investigation

D5 Medicolegal Aspects of Forensic Investigations of Mass Graves in Katyn (1940) and Tuskunenu (1947)

Vivian Visnapuu, MD, Murkionkatu, 9C-13, Turku, FINLAND; Kari Takamaa, MD, National Defense Univ, Helsinki, FINLAND; Rimantas Jankauskas, PhD, M K Ciurlionio g 21, LT-03101, Vilnius, ITHUANIA; and Helena Ranta, PhD, Univ of Helsinki, Kytösuontie 11, Helsinki, , FINLAND*

After attending this presentation, attendees will learn about medicolegal means used in the investigations of the Katyn and Tuskulenu massacres. This presentation will compare medicolegal methods used in these investigations.

This presentation will impact the forensic science community by addressing medicolegal means used in the investigations methods used in Katyn and Tuskulenu massacre investigations.

The Katyn massacre, known as the Katyn Forest massacre, refers to mass execution of Polish officers carried out by the Soviet secret police NKVD (The People Commissariat for Internal Affairs) in April – May 1940. The decision was made by the Politburo and signed by Joseph Stalin. The number of victims was estimated at about 22,000, the most commonly cited number being 21,768.[1-4]

The executions in Vilnius discovered at Tuskulėnų were carried out by a special group of NKGB/MGB staff (The People's Commissariat for State Security/The Ministry of State Security). According to gender, 762 men and five women were executed and their ethnic origins were documented. In this study, two medicolegal reports were analyzed.[5,6]

The goal of the study was to analyze by medicolegal means the Katyn and Tuskulėnų massacres and to compare two medicolegal reports of the Katyn massacre, the Germans and Burdenkos Special Commission reports in Katyn. In addition, the German reports consisted of three independent examinations. In Tuskulėnų, all of these medicolegal findings and reports are convergent and the exhumation at Tuskulėnų was conducted in 1994.

The study includes historical documents and references to the Katyn massacre.[1-4] Based on the literature, the author compares both of Katyn's medicolegal reports. The Tuskulėnų massacre was analyzed by medicolegal aspects based also on literature which includes historical documents and references, and the author measurements of the skull injuries.[5] The study analyzed medicolegal methods which had been used in Katyn and the modern medicolegal method which had been used in Tuskulėnų massacre investigation.

The Katyn massacre had been well organized and had taken a longer time than the Tuskulėnų massacre, which had been done intensively and very fast. Killing processes had been done almost similarly on both mass graves. In Katyn, there had been bullets used of calibers less than 8mm, i.e., 7.65mm or less; in a few cases, there was a caliber of more than 8mm, i.e., 9mm in the Katyn massacre.[1] The caliber of bullets were from 6.0 to 9.0 cases, with quadrangular 3 × 3cm entrance and 0.5 × 0.5cm in Tuskulėnų.

Medicolegal examination had been used in both massacres, including modern computerized methods in Tuskulėnųs report and manual methods in Katyn. Medicolegal investigation of Katyns was conducted during the Second World War.[1,2,5,6] In Tuskulėnų, investigations were carried out during the independence time of the Lithuanians without any political pressure.

In conclusion, both the Germans and Burdenkos reports were well organized and professionally conducted; however, they reflect strict political views including propaganda speculation.

Katyn, Tuskulenu, Massacre

D6 Perurac Lake, Bosnia: A Multidisciplinary Operation to Locate, Recover and Examine DNA Samples, and Identify the Missing From Balkans Conflicts

Esma Alicehajic, BSc, Admir Jugo, BS, Rene Huel, BA, Sylvain Amory, PhD, Edin Jasaragic, BA, Adnan Rizvic, MA, Thomas Parsons, PhD, Ian Hanson, MSc, and Matthew Vennemeyer, BA, ICMP, 45A Alipasina, Sarajevo, 71000, BOSNIA-HERZEGOVINA*

After attending this presentation, attendees will become aware of logistical and operational issues in locating and recovering human remains from a riverine environment, the complications these conditions create for examinations, and the impact such an environment has upon relative rates of success of DNA amplification from bone.

This presentation will impact the forensic community by illustrating the successful application of a scientific investigation process from search to identification. The efficacy of DNA analysis from human remains that have been taphonomically altered by fluvial activity over a 20 year period is demonstrated. Moreover, the anthropological re-association of remains, led by DNA linkages, combined with contextual site assessment, missing person's lists, and witness accounts provide identification and can potentially support or refute past behaviors and investigative interpretation.

Perucac Lake has been a presumed site of deposition for numerous individuals, as a result of conflicts in the region. The Lake was formed by damming the Drina for hydro-electricity. In the summer of 2010 when water levels were lowered, a malfunction in the turbines of the dam forced authorities to dramatically reduce the level of the water to enact repairs. An opportunity arose to survey a significant section of the exposed land surface with human remains observed on the banks and riverbed. A multi-national, multi-agency effort was launched with the goal of locating, identifying, and recovering as much as possible.

With the International Commission on Missing Persons (ICMP) assistance, line searches and manual excavations were conducted along on both sides of a 50 kilometer length of the lake and river from Visegrad Bridge to Bajina Basta dam. Approximately 2.5 million square meters were searched over a period of two-and-a-half months in topography along the river that varied from steep canyons to flat beach-like coastlines and mudflats.

Approximately 450 cases varying from a single bone fragment to large quantities of mixed bones, were located, recorded, and recovered from land within four municipalities in two countries: Visegrad, Srebrenica, and Rogatica in Bosnia and Herzegovina; and, Bajna Basta in Serbia. Following preliminary anthropological examination, the Minimum Number of Individuals (MNI) for all recovered cases was established to be 97, based on the right femur.

Remains recovered in Bosnia and Herzegovina were sent to Visoko Mortuary, where ICMP participated in bone sampling for DNA analysis. The remains recovered in Serbia were sent to the Forensic Medicine Institute in Belgrade, Serbia, where they also underwent bone sampling for DNA analysis. The variation in success in extracting DNA samples from different skeletal elements was statistically examined to provide guidance for future sampling strategies for similar investigations.

As of July 2012, 220 unique DNA profiles had been obtained from all the recovered cases, with anthropological re-assessments, guided by DNA profiles, re-associating body parts or single bones to identify individuals. Contextual and evidence analysis also allowed cases to be differentiated between recent conflict from those of the conflicts of previous eras. The investigation and results of the scientific process demonstrate the potential to recover remains and identify the missing from a difficult search environment after many years.

Multidisciplinary, Riverine Environment, Identification

D7 Assisted Suicide and the Next of Kin Rights

Bethany L. Bless, MS, Harris Co Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will learn the definition of assisted suicide and become familiar with the current laws governing it. Legal rights of the next of kin in relation to disposition of remains in Harris County will also be discussed.

This presentation will impact the forensic science community by increasing understanding of laws pertaining to assisted suicide and potential problems in determining the legal next of kin for disposition of remains.

Assisted suicide, also known as euthanasia, is defined as the aiding of another person in his/her suicide. The topic of assisted suicide was brought into the public eye in the 1990s with the criminal court cases against Dr. Jack Kevorkian who was charged multiple times with assisting terminal patient's death via physician-assisted suicide. After several unsuccessful attempts to convict Dr. Kevorkian, the Michigan legislature enacted a law in 1998 making assisted suicide a felony punishable by a maximum five-year prison sentence or a $10,000 fine. On March 26, 1999, a jury in Oakland County, Michigan, convicted Dr. Jack Kevorkian of second-degree murder and the illegal delivery of a controlled substance. That April, he was sentenced to 25 years in prison with the possibility of parole. Many states have also adopted laws against assisting in a suicide, Texas being one of them. Texas Penal Code 22.08 outlines assisted suicide as a criminal offense, although charges rarely are filed. Under this code, a person commits an offense if, with intent to promote or assist the commission of suicide by another, he aids or attempts to aid the other to commit or attempt to commit suicide, a misdemeanor offense. Should serious bodily injury occur to the person being assisted, the offense becomes a state felony.

The first assisted suicide case in which an individual was charged with a criminal offense in Harris County occurred in 2012. Afterward, questions arose concerning the rights of an individual to act as legal next of kin for disposition of remains if they have been charged with assisted suicide of the decedent. In Harris County, the right of a next of kin for disposition of remains is determined by Texas statutes which outline the legal succession of next of kin. According to the Texas Health and Safety Code 711.002, a person may not control the disposition of the decedent's remains if, in connection with the decedent's death, an indictment has been filed charging the person with a crime under Chapter 19, Penal Code, that involves family violence against the decedent. Assisted suicide is a charge under Penal Code Chapter 22 Assaultive Offenses, not under Chapter 19 Criminal Homicide, so there is currently no restriction of the next of kin rights to disposition of the decedent's remains, despite the pending felony charges.

Most American states currently have statutes explicitly criminalizing assisted suicide. Laws need to accommodate the matter of the next of kin's right to dispose of remains if they have been criminally charged in connection with that individual's suicide.

Assisted Suicide, Criminal, Next of Kin

D8 Histomorphology and Age Estimation of the Human Rib Cortex in Methamphetamine Users

Margaret Streeter, PhD, Dept of Anthropology, 1910 University Dr., Boise, Idaho 83725; and Robert C. Karinen, MA, Ada County Coroner, 5550 Morris Hill, Boise, ID 83703*

After attending this presentation attendees will have an understanding of observed histomorphological changes in the bone microstructure of methamphetamine users. In addition, this presentation will demonstrate how methamphetamine use may result in less accurate histological age estimations

This presentation will impact the forensic science community by demonstrating that methamphetamine abuse can be associated with changes to the bone microstructure. This has important implications for those doing histological age estimations using osteon population densities.

Histological age estimation using bone microstructure is an accepted and accurate tool when trying to determine age at death in unknown skeletonized human remains. Studies have demonstrated lifestyle choices such as poor diet, insufficient exercise, and substance abuse can negatively affect bone health. Of these lifestyle choices, the advanced decay of the dentition and pathologies associated with the oral cavity seen in chronic methamphetamine users is often noted. The purpose of this analysis is to determine if the tissue pathology associated with long-term methamphetamine use is a localized response to poor dental hygiene or an indication of a more systemic response that is discernible in the bone microstructure. Studies have associated chronic methamphetamine abuse with lower bone densities in both the axial and appendicular skeleton but to date no studies examine what methamphetamine's role may be on impacting the microscopic structure of bone.

A comparison of the fourth rib cortical bone microstructure between males that were known to be methamphetamine abusers (N=18) and individuals who did not abuse the drug was undertaken (N=19). Histomorphometric variables calculated in this analysis included mean osteon size, Osteon Population Density (OPD), and cortical area measurement. OPD and mean osteon size were found to vary significantly between study and control populations. Users of the drug had a mean OPD of 15.19. Non-users were shown to have an OPD of 21.68. Osteon population densities were found to be significantly less in methamphetamine users ($p<.01$). Users had an average mean osteon size of .041mm^2 compared to non-users at .039mm^2. Mean osteon size was found to be significantly larger in methamphetamine users at a 90% confidence interval ($p<.10$).

When histological age estimations were attempted using Stout and Paine 1992 formula, it was found that individuals who abused methamphetamine, as well as the control group, tended to have age estimations that underestimated actual age. When calculated, the methamphetamine group underaged individuals by an average of 11.6 years. This differed from the control population which on average underestimated ages by 7.1 years. This study has important implications when histological age estimations developed from OPD are conducted on methamphetamine users. As demonstrated, estimated ages for those that abuse the drug are less accurate then non-users. This study demonstrates methamphetamine abuse does affect bone microstructure and impacts the forensic science community by demonstrating that histological age estimations on unknown skeletonized human remains may be less accurate if the decedent abused methamphetamine.

Age Estimation, Skeletal Analysis, Methamphetamine

D9 Evaluation of Clandestine Methamphetamine Diffusion Through Building Materials by Ion Mobility Spectrometry and SPME-GC/MS

Holly A. McCall, BS, 433 Wilson Ave, Apt 4, Morgantown, WV 26501*

After attending this presentation, attendees will have a better understanding of clandestine methamphetamine laboratories and the contaminates that transport through structures where these exist.

This presentation will impact the forensic science community by demonstrating how current standards for clandestine methamphetamine laboratory remediation are not sufficient.

Portable Ion Mobility Spectrometry (IMS) is frequently used to gauge the success of remediation in Clandestine Methamphetamine Laboratory (CML) sites. In most cases, remediation involves surface cleaning, followed by IMS interrogation to detect any residual contaminants. Even after seizure of the facility and with most contents removed from the structure, the remnants are still heavily contaminated with hazardous chemicals as well as methamphetamine. Besides direct chemical spill contaminations, airborne contaminants are absorbed or deposited onto surfaces throughout the facility such as the flooring, walls, ceilings, and structural supports.

The transport of methamphetamine in air and through surfaces is dependent upon the protonation state of the ionizable amine center on the molecule. While transport can occur as particulate, it can also occur in the vapor phase. The vapor pressure of methamphetamine as the free base (un-protonated) is 0.163mmHg, suggesting that methamphetamine will vaporize to a significant and detectable extent under typical indoor temperatures and pressures. Because it is an amine, detection limits for airborne methamphetamine are relatively low using IMS and as such, IMS is an ideal analytical tool to study the fate and transport of methamphetamine residuals left in remediated environments.

A Plexiglas chamber of size 1.5'x1.5' x 2' was made as airtight as possible (known to be watertight). The box offers the ability to place a hot plate within for heating, and a window along one wall in order to gain access to the plate. Along another wall there are three columns of four vertical ports. The first column contains an opening for IMS "sniffing," while the second allows for Solid-Phase Microextraction (SPME) to be accomplished through septa. The third column was added to track any temperature gradient that develops. A 4-channel datalogging thermometer was used for this purpose. The third wall of the chamber contains an opening 12"x12" allowing for a building material to be exposed on one side to vapors created within the chamber. This chamber establishes mock CML conditions into which building materials could be placed

For the analysis, methamphetamine salt was converted to its basic form and extracted into hexane. After drying, the methamphetamine was then gently heated in the presence of the building material being studied. The concentration of the airborne methamphetamine in the chamber was monitored at half-hour time intervals over 24 hours by IMS and every hour by SPME. Using both methods allowed for direct calibration of the IMS response for gas-phase methamphetamine. Chamber experiments were utilized to calculate diffusion coefficients for many different building materials. The ability to measure the concentration of gaseous methamphetamine in real time using IMS significantly simplifies the analytical process required to calculate diffusion coefficients and associated quantities such as flux. Experimental results were compared to those obtained with a simple modeling program and will be discussed.

Methamphetamine, Clandestine Lab, IMS

D10 Abuse of Synthetic Cannabinoid and Cannabimimitic Smoking Blends

Elizabeth M. Guest, PhD, and Jeffrey H. Comparin, BS, 22624 Dulles Summit Ct, Dulles, VA 20166*

After attending this presentation, attendees will understand the importance of laboratory analysis to determine the contents in the various smoking blends.

This presentation will impact the forensic community by showing that assumptions cannot be made as to the contents of any smoking blend, regardless of labeling.

The abuse of synthetic cannabinoid and cannabimimetic smoking blends is prevalent among teenagers and young adults who are seeking materials that emulate the effects of marijuana. These individuals often read internet blogs to determine which brand of smoking blend will result in the best euphoric feeling or "high." Users commonly make naïve assumptions concerning the active ingredient(s) and concentration based on the brand name or packaging of the smoking blends. In reality, the users do not know what compounds they are actually consuming. At present, there are at least two dozen different compounds that have been identified in smoking blends.

In addition, the manufacturing of these smoking blends is highly inconsistent. The compound is dissolved in a solvent such as acetone and either sprayed onto the plant material or mixed with the plant material in a mixer. The irregularity in these dosing processes leads to widely varying concentrations even within individual packages. Furthermore, many manufacturers often imitate the packaging of popular brands, thus leading to additional variability in the active compound and its concentration in blends with the same brand name. And finally, some blends contain more than one active component.

The Drug Enforcement Administration frequently receives law enforcement inquiries concerning a specific brand of synthetic cannabinoid smoking blend. These inquiries often stem from numerous local incidents or overdoses where a certain brand was used by the victims. Many hospitals are being flooded with abusers who overdosed on smoking blends. Medical personnel are handicapped when attempting to determine proper treatments because of the variability between samples.

This study investigated the concentration (percent by weight) of JWH-018 on dried plant material sampled within individual packages of smoking blend products across several popular brand names, including K2, Mr. Kwik-E, and Kush. The samples were first screened using gas chromatography-mass spectrometry (GC/MS) to determine if they contained JWH-018. A GC method was used to quantitate JWH-018 in each smoking blend. Cone and sampling techniques were used to investigate the concentration of JWH-018 in individual smoking blends of the same brand. These results confirmed the variability in the concentration of these compounds even within individual packages due to the dosing process. As a result, all other studies used plant material that was ground in a coffee grinder. The variability of the JWH-018 concentration between different packages of smoking blends with the same brand name and same packaging was then studied. Next, the concentration of JWH-018 was investigated across smoking blends with the same brand name but different labels (i.e., K2 blond and K2 melon). The concentration of JWH-018 was determined across smoking blends with the same brand name but different flavors (i.e., Florida Spice and Florida Spice Melon). Finally, the concentration of JWH-018 was compared in different smoking blends (i.e., Kush, K2, and Mr. Kwik-E).

This study proves that assumptions cannot be made as to the contents of any smoking blend, regardless of labeling. All such products require laboratory analysis to determine the contents in the various smoking blends.

JWH 018, Cannabinoid, Cannabimimitic

D11 An Investigation Into Volatile Organic Compounds That Have the Potential to Cause False Positives in Blood Alcohol Analysis

Philip R. Davis, BSc, 8964 W Flagler St., Apt. 214, Miami, FL 33174; Kenneth G. Furton, PhD*, Florida Int'l Univ, Int'l Forensic Research Inst, University Park, Miami, FL 33199; and Stefan Rose, MD, Univ Med and Forensic Consult, Inc, 10130 Northlake Blvd, Ste 214, No 300, West Palm Beach, FL 33412*

After attending this presentation, attendees will understand how volatile organic compounds present in human blood can interfere with blood alcohol analysis, causing false positive results.

This presentation will impact the forensic science community by demonstrating the need for greater specificity in blood alcohol analysis.

The qualitative and quantitative analysis results of Volatile Organic Compounds (VOCs) in human blood and breath are used as biomarkers of human exposure for epidemiological monitoring and investigation, point of care testing for patient diagnosis and treatment, and as evidence in criminal cases in the forensic arena. Over 3,000 different VOCs have been identified in blood and breath samples of living people. These VOCs may be found in human blood and breath as a result of endogenous production or environmental exposure. Endogenous VOCs may be present as a result of normal metabolic activity, disease processes, or both. Exogenous VOCs detected in human blood and breath occur as a result of environmental exposure at the workplace, home, or other environments.

Some VOCs, generated as a result of normal metabolic activity, may have elevated due to metabolic diseases. For example, in diabetic patients, ketones and organic acids may be elevated in the blood during ketoacidosis. In addition, previous studies have identified key compounds, such as hydrocarbons, methylated hydrocarbons, sulfur containing compounds, nitrogen containing compounds, isoprene and acetone, as biomarkers for different systemic diseases. Also, research has shown that patients diagnosed with lung cancer, leukemia, bone cancer, and lymphoma have high levels of hexanal in their blood, while hexanal, 1-octen-3-ol, and octane were recognized as biomarkers for liver cancer. These VOCs have been detected in human blood using Solid Phase Microextraction-Gas Chromatography-Mass Spectrometry (SPME-GC/MS).

Volatile organic compounds may be released to the environment by both natural and industrial sources. Compounds such as benzene, toluene, ethylbenzene and xylenes are present in fuel emissions. All of these compounds have been analyzed quantitatively in human blood using headspace SPME-GC/MS.

Ethanol is the most widely abused drug in the world. As a result, the most commonly known forensic application of VOC analysis is the determination of the concentration of ethanol in blood and breath samples from automobile drivers charged with Driving Under the Influence (DUI). The current standard for the determination of blood ethanol concentration is static headspace dual capillary column Gas Chromatography coupled to a Flame Ionization Detector (GC-FID). Other variations include single column (capillary or packed), direct injection, and GC/MS. If any compound present in blood were to co-elute with ethanol on the GC-FID, it would lead to a false positive result. A GC/MS method should replace GC-FID as the standard method for blood alcohol analysis as it would improve specificity and decrease the possibility of false positive results due to interfering volatile organic compounds. Many forensic laboratories have not budgeted for the upgrade to GC/MS for this type of analysis, and as a result, the GC-FID is still the most widely used analytical technique for blood alcohol analysis.

In this experiment, 46 VOCs that have been previously identified in human blood and breath were analyzed using GC-FID to determine if any of these compounds may co-elute with ethanol or the internal standard n-propanol, thus interfering with blood alcohol analysis. Of these 46 compounds, 17 co-eluted or had retention times sufficiently

similar to ethanol and n-propanol so that minor variations in stationary phase composition, flow rates or temperature would be expected to cause co-elution and thus interfere with blood alcohol analysis. These results demonstrate that many VOCs commonly present in the body can yield a false positive result for the analysis of alcohol in blood. Therefore, this work supports the idea that blood alcohol analysis is no different than blood drug analysis regarding the requirement to use the selective mass spectrometry detector for qualitative analysis instead of the non-selective FID detector.

Blood alcohol analysis should meet the same standards of scientific reliability as any other chemical test performed in the forensic toxicology laboratory.

Blood Alcohol Analysis, Gas Chromatography, Co-Elution

D12 Disinterments in the Desert: A Comprehensive Project to Identify the Missing and Unidentified Persons in Maricopa County, Arizona

Laura C. Fulginiti, PhD, John A. Piakis, DDS, and Christen Eggers, MS, OCME, 701 W Jefferson St, Phoenix, AZ 85007*

After attending the presentation, attendees will gain an understanding of the successful methods used to aid in the identification of unidentified remains that had been buried for more than 40 years.

This presentation will impact the forensic science community by demonstrating how a comprehensive approach to longstanding "Jane and John Does" can result in successful resolution, regardless of the length of time since death. The advancement of technology gives promise to the idea that it is possible to identify all of the deceased currently listed as unidentified. Every unidentified person is a missing person, and one of the responsibilities of the medical examiner is to identify the unidentified so that families and investigations can move forward.

The Maricopa County Medical Examiner's Office has approximately 230 unidentified persons dating back to 1979. The unidentified cases range from young children to adults. The causes of death range from natural to homicide. The Maricopa County Medical Examiner's Office received a federal grant from the Arizona Criminal Justice Commission (through NIJ) to exhume 50 unidentified persons in the hope that these individuals can be identified and notification to family can proceed. An exhumation team composed of medicolegal death investigators, forensic anthropologist, forensic odontologist, and funeral home representatives was formed. The main concentration of cases are cases from the 1970s through the 1990s when DNA technology was not as advanced as today so DNA samples were not collected and processed. Also, digital dental radiographs were not taken as that technology did not exist decades ago. The exhumations were performed at the Tempe Twin Buttes Cemetery in Tempe, Arizona, which is a Maricopa County indigent burial cemetery. Once the decedent is exhumed, the remains are moved to a portable examination table where the anthropologist examines the remains and collects samples for age estimation and ancestry. Specific demographics of the decedent's hair, length, type, and facial hair, etc. are noted so that a postmortem sketch can be created and posted on various missing and unidentified websites. The lead investigator documents all of the clothing, documents, and any individualizing characteristics. DNA samples are then collected by the lead investigator and the anthropologist; the DNA samples usually consist of clavicles, teeth, hair, and/or femur bone. The lead investigator submits the samples to the Arizona DPS Crime Lab where a profile is derived and entered into a federal DNA database. The odontologist conducts his examination using a portable digital dental radiography unit and laptop. A full mouth series of dental radiographs are completed and the radiographs are then automatically downloaded onto a laptop. Written documentation of the dental information is done, as well as dental charting. After the lead investigator confirms that the documentation is complete, all samples are collected, and the dental radiographs are complete, the decedent is placed into a new casket and returned to his/her respective gravesite. The lead investigator ultimately creates a written report of all the events during the exhumation and synthesizes the findings. The information is entered into national and local missing person/unidentified websites by the lead investigator who also contacts the law enforcement agency with jurisdiction to update them on the results.

A detailed explanation of the exhumation process and present summary data on the identifications will be presented. Nine scientific identifications have been made as a result of our efforts and there are solid leads on four other cases. Multidisciplinary efforts are coordinating into successful resolutions as the end goal is to make the identification and notify family. The presentation will point out that new technologies are always being developed and that the decision to cremate unidentified remains, a more common practice with some Medical Examiner Officers, eliminates the possibility of further examination in these important cases. Every unidentified person is a missing person and every person should be laid to rest with their name. While these cases are very challenging, they are solvable with appropriate resources.

Exhumations, Unidentified, Scientific ID

D13 Analysis of Three Special Cases of Paternity Testing

Joseph Alape, MD, Calle 56D, No. 72, D-23 Sur, Bogotá, COLOMBIA; and William Parra, MSc*, and Erica Salguero, BS*, Calle 7 A No. 12 A-61, Bogota, COLOMBIA*

After attending this presentation, attendees will have an understanding of paternity testing analysis and statistics analysis by probability of paternity.

This presentation will impact the forensic science community by validating the analysis of three special cases of paternity testing.

In Colombia, there are daily cases of paternity testing. Forensic genetics laboratory using the ICBF-INMLyCF Convention, have annually on average from 8,000 to 9,000 cases. These include cases with an alleged father, mother and minor reconstruction, cases with genetic profiles of the alleged father from the family, and case information from the exhumation of the remains of the alleged father.

In this paper discuss three special cases will be discussed one case in the determination of maternity and two cases of determination ofmpaternity.

Case 1 – Determination of Two Alleged Mothers: Which one is the biological mother of the child? Analysis was performed in 15 genetic systems and Amelogenin included in the Identifiler Kit Direct and found that the alleged mother 1 (PM1) was included as a birth mother; as to the Alleged Mother 2 (PM2), there was only found an exclusion of the 15 genetic systems. Since in order to report a real exclusion it requires at least three exclusions, we proceeded to the analysis of 13 additional genetic systems included in the kits from Promega PowerPlex CS7 and NGM Select Applied Biosystems, for 28 genetic systems. There were no more exclusions and, therefore, an opinion was issued in the two probabilities for the judge to determine maternity, as there was a degree of kinship between the two alleged mothers (mother and daughter).

Case 2 – Research Paternity Testing: The analysis of 15 genetic systems and Amelogenin included in the Identifiler Kit Direct was performed. Exclusions found two genetic systems and, therefore, an increasing number of genetic systems were analyzed, but found no additional exclusions. As the child was male, the analysis proceeded to chromosome "Y" and found two inconsistencies in the chromosome haplotype "Y." The question arises: How likely is it that the biological father presented four mutational events?

Case 3 – Research Paternity Testing: We performed the analysis of 15 genetic systems and Amelogenin included in the Identifiler Kit Direct. Three exclusions were found, but one of them was doubtful whether it was by the father or the mother. The number of genetic systems was increased to verify more exclusions (total of 28 genetic systems). As the child was male, testing proceeded with amplification of chromosome

haplotype "Y," finding an inconsistency with the alleged putative father. The question arises: Can a real catalog of paternity be excluded?

Paternity Testing, STRs, Statistic Analysis

D14 The Need for a Comprehensive and Interactive Digital Asset Management Software

Steven Dowell, BS, 2509 Olive Ave, La Crescenta, CA 91214*

After attending this presentation, attendees will gain an understanding of the increasing amount and complexity of various types of data (digital assets) that are currently part of case evidence, and a corresponding method to contain, organize, and turn these digital assets into meaningful and retrievable information.

The impact of this presentation is to provide a meaningful method to turn the increasing load of data into information and improve access to its use as corporate information for QA, QC, teaching, training, and handling data in general.

A traditional digital asset management system (document management system) is a static, non-dynamic collection of data—an electronic filing cabinet. This type of repository solution may be adequate when used to specifically replace CDs, DVDs and disconnected hard drives as a method for data storage. However, while this solution may provide a level of security, organization, and easier access to the assets, it falls well short of what the real value could be, especially in the area of forensic science and the investigative services of law enforcement.

Many agencies traditionally just implement a simple data storage (repository) solution because of the overwhelming and the ever increasing amount and diversity of data. While this is justifiable, this is—not a progressive and powerful information producer—this approach will never allow these agencies to get beyond meeting the minimum level of digital asset management required by the regulatory and accreditation bodies.

Because the digital information created in the forensic world is not static, the multiple types of information that get generated need to support the investigative process. Therefore, digital asset/evidence management software needs to provide the tools to dynamically interact with the stored digital data and turn that data into valuable case information.

There is an increasing demand placed on every department to use these case-related digital assets in an attempt to answer the evolving questions about circumstances, cause of death, nature of evidence found, etc. Forensic agencies in general would greatly benefit from dynamically interacting with digital case information not only for themselves, but to be able to pass information on to other requesting agencies.

All of these agencies are gathering and developing an ever-growing amount of interrelated case evidence and digital image assets, audio/video files, HD data, federal and international data, and reports. To the degree that the communal change to dynamic digital asset management software is delayed, necessary training of individuals in the use and creative interaction with these powerful tools is withheld. Since all the departments ultimately work together, by default, then, the whole system is held back.

As the investigative tools are learned and the overall design is understood an individual who knows the basic concept of this type of software can easily migrate from one position/department to another. For example the adoption of a unified dynamic digital asset software package with an overall comprehensive and consistent design would not only provide useful and necessary skill for daily solution of case information but would become incredibly important and necessary in providing solutions in the chaotic aftermath of data collection and association in the event of a mass disaster.

As a solution to the above circumstances, a model will be demonstrated from the point of view of a medical examiners' office in the area of an analysis of a tool mark in biological material. This demonstration will take elements of the stored digital assets, perform the required analysis of stored images, and relate relevant investigative information and autopsy data to produce a report. Additionally, the report and all data used to inform the report will be associated in the relational database area of the software and allow for QA, QC of the report. This data and all other such stored case data represents not only stored case information but is accessible corporate knowledge that can be used for teaching, training, court room presentations, proficiency testing, and a host of other administrative uses. Additionally, such comprehensive and accessible data can facilitate the distribution to and interaction with other agencies which reduces the workload to distribute such required information.

Digital Assets, Tool Marks, Document Management

D15 A Case of Double Jeopardy: How 3D Laser Scanning Clarified the Truth

Thomas P. Mauriello, MFS, 8775 Teresa Ln, Laurel, MD 20723; and David A. Buerger, MS*, 1509 West St, Annapolis, MD 21401*

After attending this presentation, attendees will learn how 3D laser imaging can play a major role in determining characteristics and measurements of physical objects found in digital media and can "make the difference" in providing conclusive proof that in the past has been left to the subjectivity of art, rather than science.

This presentation will impact the forensic science community by bringing to their attention that having a client found "not guilty" alone may not influence the parole board's "a preponderance of the evidence" standard. Also, this case identifies an innovation in forensic image and video analysis in the area of object and facial comparison.

This is a criminal case involving first degree murder and arson, where the defendant was acquitted in 2007.[1] He was on parole for unrelated property crimes at the time of his arrest and acquittal for first degree murder and arson and therefore remanded to jail for revocation of his parole. The parole board has a different standard when determining the involvement of a parolee in a criminal act while on parole. If the parole board believes that a preponderance of the evidence suggests that the parolee committed the act in which they were charged, then the parole board can revoke the parolee's parole. This is exactly what happened in this case. Although he was completely exonerated for the murder/arson offenses, the parole board believed he was guilty, and therefore was returned to prison to serve out the rest of his unrelated 15-year sentence.

A parole revocation hearing was set and the defense attorneys contended that this was analogous to "double jeopardy," because the defendant was being retried to determine his innocence again. A forensic consultant was hired by the firm to evaluate all forensic evidence presented in the original criminal trial.

The prosecution's case relied heavily on surveillance video footage taken in the lobby of the high rise building in question. This presentation focuses on the surveillance video that shows a black man wearing a coat similar to the defendant, leaving the first-floor lobby stairwell during the time of the fire and murder. The crime scene was on the 10th floor. The investigators and prosecution contend even today that the subject in the surveillance video was the defendant leaving the scene of the crime.

The forensic consultant analyzed the video, consulted with facial recognition experts, and changed the contrast of the video in an attempt to clear up the image. He could only conclude that the person in question did not look like the defendant; he appeared to have a beard and mustache, unlike the defendant; and his build appeared to be shorter and stockier. This, together with other inconsistencies in the investigation, convinced the parole board at a parole revocation hearing and the defendant was freed from incarceration in 2008.

That should have been the end of the story, but the forensic consultant needed to know—"Was that the defendant in the stairwell or not?" The police investigator and prosecutor who tried this case are still adamant that it was. So he turned to the services of TransCon Imaging Solutions, who use 3D laser scanning to reconstruct vehicle accident scenes. In March of 2012, they used their 3D laser scanning equipment

to scan the entire lobby of the building in question, including the stairwell. Using their markers and measuring parameters, and superimposing the crime scene surveillance photos taken from the video footage over their scans, there is now conclusive evidence that the subject leaving the stairwell is 5-foot, 5-inches tall, and the defendant is 6-foot, 3-inches tall.

Double Jeopardy, Laser Scanning, Video Analysis

D16 The Hart House Report: A Multidisciplinary Discussion of Forensic Science in Canada

Michael S. Pollanen, MD, Ontario Forensic Pathology Service, Centre for Forensic Science and Medicine, 26 Grenville St., Toronto, ON M7A 2G9, CANADA; Kathy L. Gruspier, PhD, JD, Ontario Forensic Pathology Service, Centre for Forensic Science and Medicine, 26 Grenville St, Toronto, ON M7A 2G9, CANADA; Matthew J. Bowes, MD, Nova Scotia Medical Examiner Service, 5670 Spring Garden Rd, Ste 701, Halifax, NS B3M 4T5, CANADA; and Sherah L. Van Laerhoven, PhD, Univ of Windsor, Dept of Biology, 401 Sunset Ave, Rm 119, Windsor, ON N9B 3P4, CANADA*

After attending this presentation, attendees will understand the issues facing forensic science in Canada and will hear recommendations for improving deficiencies and evolving the science not only in Canada, but in local jurisdictions around the world where the legal system is questioning the reliability of forensic science.

This presentation will impact the forensic science community by providing a road map for forensic scientists in Canada and other jurisdictions to create and share advances in forensic science among academic and government practitioners. Forensic science must evolve to meet the questions and needs of the legal community on the reliability of forensic science and this presentation will offer some suggestions on how to accomplish that goal.

Over two days in May 2012, a group of forensic scientists and practitioners representing ten main disciplines within forensic science met at the University of Toronto, in a meeting sponsored by the Centre for Forensic Science and Medicine at the University of Toronto. The forensic scientists who participated were drawn from both the academic and public sectors and included the participation of a judge from the Ontario Court of Appeals.

A number of wrongful convictions and subsequent public inquiries in Canada have raised the question of reliability of forensic science in both the scientific and legal communities. This meeting was convened as an initial response to the question of reliability. There are three major trends driving change to forensic science in Canada:

1. A shift to an evidence-based paradigm, paralleling that in medicine.
2. Recognition among forensic science practitioners of the need to bridge the gap between expectations and deliverables in the presentation of expert opinion evidence.
3. The publication of the U.S. National Academy of Sciences Report.

The goals and objectives of the meeting were to:

1. Provide a description of the current state of forensic science in Canada.
2. Provide a summary of the major challenges and opportunities facing forensic science in Canada.
3. Provide recommendations on how to strengthen and develop forensic science in Canada.

Although the areas of forensic practice represented at the meeting were seemingly diverse (e.g., forensic nursing, forensic physical sciences, forensic psychiatry, amongst others), the group identified common deficiencies and adopted similar recommendations for the development and evolution of forensic science in Canada.

In the area of forensic science research, it was agreed that the ties between forensic science service providers (mostly government agencies) and universities had to be strengthened, with strategic and sustainable research programs being developed. In addition, it was agreed that national granting agencies should recognize forensic science as a discipline and apportion research funding accordingly. It was recognized that forensic science education and training would benefit from a more multidisciplinary approach and that graduate and postgraduate training should be developed and/or supported. Continuing education in best practices is necessary and this important aspect of forensic science needs to be developed more fully. In order to do this, scientific working groups and their guidelines, professional certification and accreditation and recognizing the importance of ethics, professionalism and bias will need to be instilled in practitioners. An in-depth discussion of the administration and regulation required to do this was also undertaken.

The meeting concluded by recognizing that forensic science is an integrative, multi-disciplinary science with its own theoretical basis requiring scientific inquiry. In order for forensic science to strengthen its progress in Canada, it is vital that all areas embrace the full cycle of service, teaching, and research. While the group recognized that the discussion was only introductory, a substantive document was produced which should assist in addressing these deficiencies and attaining these goals. The document does not recommend the creation of new agencies, nor does it advocate for specific systemic reforms, rather it is offered as a tool to engage stakeholders and encourage further dialog so that forensic science can continue to evolve, grow, and meet the needs of the legal system.

Forensic Science, Canada, Reliability

D17 A Practical Guide to Processing Synthetic Cannabinoid and Cathinone Operations

Jay R. Hopenwasser, MS, 10150 E Technology Blvd, Dallas, TX 75220*

After attending this presentation, attendees will gain the necessary knowledge to safely access and process an illicit operation that manufactures synthetic cannabinoid and cathinone commercial products.

This presentation will impact the forensic science community by providing an overview of the inside operations of a processing site for the manufacturing of commercial and illicit “spice” and “bath” products, recognizing the dangers with these processing sites and how to safely collect evidence.

The emergence of synthetic cannabinoids and cathinones in the illicit drug market has introduced new challenges to law enforcement and their forensic laboratories. Law enforcement has been raiding retail operations which deal in “spice” and “bath salt” products, but are now encountering processing sites that are responsible for manufacturing these commercial and illicit products. These processing sites may be unfamiliar territory for forensic chemists and law enforcement officers. These processing sites present new challenges due to their differences from a typical clandestine methamphetamine laboratory.

Respondents would be at an advantage knowing what to expect to find at these illicit operations where different chemicals, apparatuses, and potential dangers will be encountered. Furthermore, forensic laboratory and law enforcement personnel must be familiar with processes such as the preparation and application of raw powders and flavorings to plant material. This presentation will provide an overview of these synthetic compound processing sites. Furthermore, the impact of the recent federal scheduling and analogue classifications of these compounds with respect to the processing of these sites will be discussed. Participants will acquire the necessary knowledge to approach, process, and analyze these new illicit laboratories.

The sheer volume of evidence at these processing sites could be overwhelming for law enforcement. Importantly, laboratory personnel must know how to sort through the bulk material for the important items needed for evidence. Challenges that one might face while processing the site will be presented. Since these sites often contain large amounts of suspected drug substances and thousands of packaged items, ways to process the site will also be discussed.

The analysis of synthetic cannabinoids and cathinones can present challenges to the forensic chemist. The continued introduction of new synthetic compounds results in forensic chemists repeatedly encountering unknown spectra. For instance, the active drug ingredient in synthetic cannabinoid samples has changed from JWH-018 to AM-2201 and recently to UR-144 and XLR-11. Matters are further complicated with the addition of synthesis byproducts and isomers (i.e., 3-methylmethcathinone vs. 4-methylmethcathinone) of these unknown compounds. At times, sample preparation to remove impurities becomes crucial to obtain clean spectra for the verified identifications. This presentation will also provide simple steps and tips for the forensic chemist to use in the analysis and identification of these synthetic compounds.

Synthetic, Cathinone, Cannabinoid

D18 The Italian Killer of JFK: History and Evolution of Carcano Model 1891 — An Italian Bolt-Action Military Rifle

Stefano Marchiaro, BA, Via Ugo Foscolo 10, Grugliasco, 10095, ITALY; and Matteo Borrini, PhD, Via del Mattone 17A, Cadimare, La Spezia, 19131, ITALY*

After attending this presentation, attendees will understand the history of the rifle used in the JFK assassination, the Carcano Model 1891, an Italian bolt-action military rifle based on the introduction of the original 1881 model that continued production through World War II.

This presentation will impact the forensic science community by illustrating a different approach to the historical analysis of firearms.

Perhaps Oswald was not aware of the piece of history he had in his hands when he bought the weapon for the assassination attempt on President Kennedy; he based his choice on economic reasons, but that Carcano 91/38 rifle was the result of a long evolution of the main Italian service rifle during the two World conflicts.

This study proposes an anthropological approach similar to an evolutionary phylogeny of this weapon, attempting to illustrate the pressures that generated the different models which had been employed in the main war environments of the twentieth century.

The common ancestor of the Carcano Model 1891 was the Vetterli-Vitali 1870/90. The Carcano was developed in 1891 from this previous weapon after the invention of smokeless powder in 1884 and after the adoption of the bolt-action rifle Steyr-Mannlicher M1895 by the Austro-Hungarian army and the Mauser Kommission by the German army.

The Carcano rifle presents two divided branches of its "phylogenetic tree:" the first was the production of a short weapon (Moschetto Model 1891) mainly designated for the Cavalry Division, the Royal Carabinieri; and, the Bersaglieri light infantry, while the second would create the line that led to Oswald's weapon.

The substantial difference between these two models, bolt-rifle and musket, is the dimensional reduction of the second one with respect to the rifle, to the barrel, and of the bayonet cost, entirely motivated by the need to provide the high-mobility of the infantry units with an efficient, light, and short weapon.

World War I introduced an upset in European structure and dynamics, and the Carcano Model 1891 had to adapt to the changes of the forthcoming conflict. No longer fossilized in trench warfare, it had to become a rather active tool in the more diffuse mechanization of the armies. This gave birth to the short Carcano Model 1891/38, a lighter and more manageable weapon that partly seems to inherit some of the musket's characteristics. In contrast to the biological evolution that does not seem to step backward, this rifle took place a return to the caliber used in previous models (6.5 x 52mm; .268cal); this "involution" was not due to technical needs, but was realized for economic reasons: the Staff Officers wanted to recycle the surplus of old ammunitions from the first world conflict. This Model 1891/38, with strengthening of the range, made history because it fired the fatal shot to President Kennedy, but it was also the protagonist of numerous battles and action in WWII.

Nonetheless, this model does not represent the last evolutionary phase of the Carcano rifle, which is expressed by another descendent that seems again to look back upon the past. The Carcano Model 1891/41 turns out to be bigger and more cumbersome; however, it can reach an excellent performance in ballistic shooting. The extinction of the Carcano rifle as the main service weapon for the Italian Army is historically represented by the end of World War II, when a new "population" of weapons was introduced by the Allied troops.

This study will also propose to the scientific community a new evolutionary approach to reconstruct the history of a specific weapon's model, also presenting historical aspects of a very infamous rifle often left in the background of the President Kennedy assassination.

Military History, President Kennedy, Ancient Weapon

D19 Antique Firearm Examined With Scanning Electron Microscope (SEM) to Determine the Persistence of Firearms Discharge Residue (FDR)

James A. Bailey, PhD, Univ of NC Wilmington, 601 South College Rd, Wilmington, NC 28403; and Kurt E. Eylands, MS, Univ of North Dakota, Energy and Environmental Research Center, Grand Forks, ND 58201*

After attending this presentation, attendees will understand some of the developmental features and characteristics of the Smith Carbine, the type of components used in the manufacture of 19th-century ammunition, and the identification and persistence of Firearms Discharge Residue (FDR) in an antique firearm.

This presentation will impact the forensic science community by providing an in-depth Scanning Electron Microscope (SEM) examination to determine the persistence of firearm discharge residue from an 1876 Smith Carbine. The techniques used in this examination will determine if FDR remains in the bore of the barrel after a period of three decades.

The Smith Carbine fired by Henry Mason Wheeler during the Northfield Bank raid on September 7, 1876, was examined for FDR. Even though antique firearms are collected for aesthetic reasons, many continue to function as a firearm and could be used in the commission of a crime. However, limited research has been conducted on the persistence of FDR in antique firearms.

In this study, the Smith Carbine had not been fired in over 32 years. Since the 1876 raid, only six other individuals have owned the Smith Carbine other than Edward Dampier, the original owner. The six owners include: Dr. Charles Dampier, Henry Mason Wheeler, Mae McCulloch Wheeler, Henry Mason "Hank" Wheeler, Jr., Charles R. Dickson, and the present owner in Grand Forks, North Dakota, who has requested to remain anonymous.

The Smith Carbine was developed by Gilbert Smith of Buttermilk Falls, New York. Smith developed a method for sealing the chamber in a breech-loading gun and was granted patent # 15,496 on August 5, 1856. A series of patents led to the development of a carbine identified as the Smith Carbine. The carbine originally fired a manufactured paper cartridge but subsequently fired manufactured cartridges made from other materials. The actual number of Smith Carbines produced is unknown; however, the military purchased approximately 30 thousand carbines and approximately 19 million cartridges. The Smith Carbine was primarily used by the Union Cavalry during the Civil War.

The firearm examined was a single-shot breech-loading .50 caliber Smith Carbine and serial number 19359 was stamped near the hinge. A sample was collected from the barrel using a 100% cotton patch. Residue from the cotton patch was collected using two aluminum stubs with adhesive applied to the end of the stubs for SEM analysis. The sampling procedure involved contacting the adhesive end of the aluminum stub on the surface multiple times to collect the FDR.

In the early 1800s, a typical percussion cap primer mixture contained potassium chlorate, charcoal and sulfur. However, by the time the Smith Carbine was developed, the percussion cap primer mixture consisted of mercury fulminate, potassium chlorate, antimony sulfide,

and powdered glass. The metal cup that contained the priming mixture was made from copper or brass. A typical formula for black powder during the Civil War era would have consisted of 75% potassium nitrate, 15% charcoal, and 10% sulfur. Early black powder formulations substituted sodium nitrate in place of potassium nitrate; however, the powder was considered inferior because the sodium nitrate absorbed moisture. A typical alloy cast bullet contained 90% lead, 5% antimony, and 5% tin.

The type of electron microscope used in the analysis was a JEOL 5800 Low Vacuum Scanning Electron Microscope (LV SEM). The operating conditions of the SEM included an accelerating voltage of 25keV with a beam current of 0.6nA. Analyses were performed in the low-vacuum (p = 17 Pa) mode of the SEM. A working distance of 11mm was used for the examinations.

Sixteen particles were analyzed on stub #1 and 23 particles were analyzed on stub #2 to produce an elemental profile from the barrel residue. The particle sizes were found to be approximately 1µm. The Energy Dispersive Spectrometry (EDS) analysis from the residue revealed the presence of ten elements. They included antimony, barium, calcium, copper, iron, lead, potassium, silicon, sulfur, and tin. However, one element not detected was mercury.

Seven of the ten elements collected and analyzed (antimony, copper, lead, potassium, silicon, sulfur, and tin) are consistent with 19th-century ammunition components. The silicon likely originated from the powdered glass portion of the priming mixture. Since iron is not an ammunition component, this metal could possibly derive from the barrel of the carbine. The source for the barium and calcium are unknown. However, these two elements could be contaminants in the ammunition or they could have been introduced into the barrel as a result of swabbing the bore during the cleaning process.

In conclusion, the SEM examination demonstrates that FDR can persist in the bore of an antique firearm for more than three decades. The SEM did not detect any particles of mercury in the residue. Most mercury particles vaporize when the firearm is discharged and the remaining mercury particles may dissipate since mercury is a volatile element. Although it is difficult to estimate the time of discharge, absence of mercury could indicate the weapon has not been fired for an extended period of time.

SEM, Firearms Residue, Antique Firearm

D20 Soft Classification by Combined Target Factor Analysis and Bayesian Decision Theory

Michael E. Sigman, PhD, and Mary R. Williams, BS, Univ of Central Florida, NCFS, PO Box 162367, Orlando, FL 32816-2367*

The goal of this presentation is to inform attendees of a new chemometric soft classification method that can be applied to forensic problems.

This presentation will impact the forensic science community by providing information on a soft classification method that is designed to work in the presence of unspecified background interferences and provide the user with probabilities of correct class assignment.

There are analytical problems in forensic science where individualization is not currently possible; however, the analyst may benefit from assigning an analyte to one or more possible classes. This is especially true for mass produced items that do not involve DNA analysis. When analysis of the item of interest is free from significant background interference, existing classification methods (i.e., linear discriminant analysis, partial least squares discriminant analysis, etc.) may be applicable. However, when there is significant background interference, classical discriminant analysis methods may fail, especially when the background signature is unspecified and possibly unknown. Fire debris analysis is one example of this type of problem. The analyst's goal is to determine if ignitable liquid residue is present and, if so, assign the residue to a class under the American Society of Testing and Materials (ASTM) Standard Method E1618.[1] Pyrolysis product contributions may be large and by coincidence, some pyrolysis products may be the same as ignitable liquid components. In these cases, visual pattern recognition will become more challenging as the ignitable liquid signature decreases and the background signature increases. A new method of addressing this problem is examined by combining Bayesian soft classification with target factor analysis (TFA). The method will be described and test results from the analysis of fire debris data will be presented.

The method relies on analysis of the average mass spectrum across the chromatographic profile (i.e., the total ion spectrum, TIS) from multiple samples collected from a single fire scene.[2] The multiple TIS are concatenated into a single data matrix and subjected to abstract factor analysis, and target factor rotation. TIS from reference ignitable liquids with assigned ASTM classifications are used as the target factors in TFA. Class-conditional distributions of the correlations between the target and predicted TIS spectra for each ASTM class are represented by kernel functions and analyzed by Bayesian decision theory.[3] The soft classification approach assists in assessing the probability that ignitable liquid residue from a specific ASTM E1618 class is present in a set of samples from a single fire scene, even in the presence of unspecified background contributions from pyrolysis products.[3,4]

The method was tested on: (1) computationally generated data sets; (2) small-scale laboratory burn experiments; and, (3) large-scale experimental burns. In all cases, the correct classification rates exceeded 80%. The method and results will be discussed along with the potential for expanding the method to other forensic applications.

This project was supported by Award No.2008-DN-BX-K069, awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The project involved collaboration with the Bureau of Fire Standards and Training, Ocala, FL, and the Bureau of Forensic Fire and Explosives Analysis, Tallahassee, FL. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

Fire Debris, Soft Classification, Factor Analysis

D21 Validation of Semen Detection Kits for Field Application in Sexual Assault Cases

Rosa E. Chapman, MS, 149 26th St NW, Apt 1517, Atlanta, GA 30309*

After attending this presentation, attendees will have a general understanding of the sensitivity and specificity of four semen detection tests, two crime-scene-ready-kits and two used primarily in a laboratory setting. This study utilized four substrates, three US Air Force uniform fabrics and a cotton fabric, which allowed determination of semen behavior and biofluid ability when applied to these substrates.

This presentation will impact the forensic science community by indicating whether crime-scene-ready semen detection kits are comparable to laboratory kits in sensitivity and specificity, and whether or not a crime-scene-ready kit should be implemented for field application, in particular by Department of Defense (DoD) criminal investigators. Conducting such tests on certain items of evidence may possibly decrease the amount of backlog in the servicing forensic

laboratory, as investigators may be able to better identify items of evidentiary value for laboratory submission.

Synopsis: Currently, DoD, specifically United States Air Force, criminal investigators conduct presumptive tests for certain biofluids; however, field-testing for the detection of semen is not conducted at crime scenes. There are a number of concerns associated with conducting these tests at crime scenes, which include sample consumption, as well as potential erroneous test results. However, semen detection tests could also be extremely beneficial for a number of reasons. In military sexual assault cases, conducting a semen detection test could not only help corroborate a victim's statement, but also provide probable cause for a search warrant, which could garnish additional probative evidence.

In order to determine which crime scene-scene-ready kit, if any, should be used at these crime scenes, the following tests were validated: ABAcard p30 for Crime Scene, ABAcard p30 for Laboratory, Rapid Stain Identification (RSID™) – Semen, and the Serological Research Institute Acid Phosphatase (AP) Spot Test. Again, four different fabrics, used to manufacture uniforms and/or often associated with sexual assault cases, were utilized in the study. To test the sensitivity of each test, a neat sample and four dilutions (1:10, 1:100, 1:500, and 1:1000) were prepared; fifty microlitres of neat or diluted sample were applied to each substrate, and tested. Furthermore, the fabrics that provided positive results were washed, either once or twice, to determine if semen was still detectable. A volume sensitivity test was also conducted to further determine the sensitivity of each test. To test the specificity, three chemically similar biological fluids were also applied to each substrate and tested. Nine lubricants/pseudo lubricants often seen in sexual assault cases were also tested (mixed with/without semen) to determine if these interfered with the semen detection or provide a false positive result when no semen was present in the sample.

Results/Conclusion: All tests were positive when the samples were neat; however, results differed when the samples were diluted. In the washing stage of the study, the RSID™ – Semen performed the best, detecting semen on two of the four fabrics after these were swabbed a total of three times, and washed twice. The AP Spot Test performed the best in the volume sensitivity test; however, when mixed with one of the nine lubricants, the AP Spot Test failed to detect the presence of semen. These same results were obtained with the ABAcard p30 for Crime Scene kit, also with the same lubricant. All tests provided negative results when urine and saliva samples were used; however, the RSID™ – Semen provided a false positive for fecal matter.

Based on the tests conducted and observations made in this study, between the two crime-scene-ready kits, the RSID™ – Semen produced, overall, better results. A recommendation to implement the RSID™ – Semen kit for field application by DoD criminal investigators has been made.

The opinions or assertions constrained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Semen Detection, RSID, Crime Scene

D22 Behavioral Evidence: Following the Traces of a Disappearance in a Case Study

Luis A. Forero Parra, MS, and Edwin O. Olaya Molina, BA, Fiscalia General de la Nacion, Dg. 22B, No. 52-01, Edf. C P.4, Bogotá, 0 111321, COLOMBIA*

After attending this presentation, attendees will learn about the first case convicted in Colombia with behavioral evidence, and see how the criminal behavior special unit of the attorney general's office carried out analysis of a mysterious disappearance of a woman, the wife of a prestigious doctor.

This presentation will impact the forensic science community by showing the dramatic effect of behavioral analysis in a case without any physical evidence to reach a verdict in the Colombian criminal justice system.

On August 8, 2007 Luz Amanda Vargas Lemus disappeared and lost contact with her family. Her children were the last people who saw her when they went to school that day. With this information, a Missing Persons Report immediately activated the search; however, this did not provide information to her whereabouts, because her cell phone was off. After the report investigators contacted Jesus Guillermo Burgos Bacca, the victim's husband, who then disappeared without a trace and had left his job in the hospital where he was a gynecologist. Immediately the criminal behavior analysts were called and with the information obtained through interviews, the team was able to assess the victimology of the woman. She was a sociable person, emotionally expressive, but had aggressive behavioral manifestations including jealous behavior. With her two sons, she had a protective and responsible parental behavior.

The house of this family showed no signs of violence within the residence; however, the crime scene investigators apparently found blood stains. The investigators applied a latent blood reagent, which reacted showing different patterns in various parts of the house. All spots were sampled and the laboratory obtained a DNA profile that was consistent with the genetic profile of Luz Amanda. The analyst group was surprised to find no blood from Burgos, but his belongings were found, while his wife's belongings were not.

During the investigation, it was found that the couple had a dysfunctional relationship with an escalation of violence. It was very interesting for the investigation team that they found the blood of only one of them at the scene in a distribution pattern that went from the bathroom to the garage of the house. Jesus Guillermo was the only person for which there was no information about his whereabouts on August 8; he had exhibited different behavior than usual for the days before this event, including the purchase of a gun, massive withdrawals of money, and changes in work schedules in hospital. This continued with a variant in behavior culminating in his disappearance, leaving his personal and professional life. His flight intentions remained unknown until the time of his capture when he was very close to leaving the country using false documents.

Jesus Guillermo was put on trial for the crime of forced disappearance. After four weeks of hearings in which the prosecution and defense presented their evidence, the judge found him guilty based on behavioral evidence presented that showed pre-meditation and post-offense conduct. Currently he is paying a sentence of 32 years in prison. To this day the body of Luz Amanda Vargas Lemus has not been found.

Behavioral Evidence, Forced Disappearance, Criminal Behavior

D23 Forensic Pathologist, Forensic Entomologist, and Medicolegal Death Investigator: Forensic Team Approach to Death Investigation

Mary H. Dudley, MD, Jackson County MEO, 660 E 24th St, Kansas City, MO 64108; Jacylyn A. Donath, BA*, 4310 NW 79th Ter, Unit 8, Kansas City, MO 64151; Neal H. Haskell, PhD*, 425 Kannal Ave, Rensselaer, IN 47978; and Marius Tarau, MD*, Jackson County MEO, 660 E 24th St, Kansas City, MO 64108*

After attending this presentation, attendees will understand the role of the forensic pathologist, entomologist, and death investigator in determining the time of death, the cause of death, and the manner of death, also increasing the awareness of the forensic community regarding coordination of multiple forensic disciplines in death investigations.

This presentation will impact the forensic science community by showing the forensic team's value to a medical examiner/coroner's office in the investigation process, criminal trial, and for final closure for the victim's families. It also aims to allow for an organized approach to help determine if the death is criminal in nature or if the death is a result of other non-criminal circumstances.

An 18-year-old Caucasian female reportedly had been missing one week prior to being found in a remote area in a field. Reportedly, she was last seen abducted from her home by three males and forced into a

vehicle. She was found clad, in a grassy area in an open field with apparent blunt force injuries of her head, neck, and abdomen with decomposition and early maggot infestation. Autopsy findings included blunt force head injuries, multiple stab wounds, defensive injuries of the hands, asphyxia due to smothering or strangulation, and postmortem changes with insect activity and decomposition. Toxicology results were positive for cocaine. The cause of death was multiple blunt and sharp force injuries and the manner of death ruled as homicide.

This presentation will increase the awareness of the forensic community and law enforcement agencies in the attempt to show, how the forensic professionals can work together in the forensic autopsy. The focus of this case presentation will highlight the forensic team approach. The difficulty of the case stems from advanced decomposition of the body, determination of the cause and manner of death, the history behind the investigation, and the final court decision. The presentation will include the role of the medicolegal death investigator to collect insects found at the scene of a decomposed body, how the forensic pathologist determines the cause and manner of death, and how the forensic entomologist determines the time of death.

The role of the Medical Death Investigator (MDI) is to communicate with police, witnesses, and the family of the deceased, and to make observations and documentation through photography, diagrams, and written reports. The MDI conducts a preliminary examination of the body to establish postmortem interval (PMI) and discover injuries. In cases of decomposition, knowledge of collection, preparation, and packaging of insects is vital in assisting the forensic entomologist in making a determination of time of death. The forensic pathologists can make a determination of the cause and manner of death through the forensic autopsy following the forensic autopsy standards established by the National Association of Medical Examiners (NAME). In decomposed bodies, it is more difficult to recognize injury patterns, assess ante-mortem from postmortem injuries, and establish positive identification. The forensic entomologist has special knowledge regarding insect succession patterns in decomposing human remains and provides information regarding time of death and possible location of death. Certain insects will lay eggs on dead bodies. Most insects exhibit predictable life cycles. By observing the development stage of insects found on a body, and by taking certain environmental factors into account, a postmortem interval can be estimated.

In conclusion, the abilities of the forensic team approach, including the forensic pathologist, forensic entomologist, and the medicolegal death investigation, can be invaluable to a medical examiner/coroner office in the investigation process, criminal trial, and for final closure for the victim's families.

Pathology, Forensic Entomology, Scene Investigation

D24 Forensic Archaeology and the Good Friday Agreement: The Search for the Disappeared in Ireland

Niamh A. McCullagh, MA, MSc, 43 Woodbrook Rd, Bishopstown, Cork, IRELAND*

After attending this presentation, attendees will learn about the work done by the Independent Commission for the Location of Victims Remains (ICVLR) in Ireland and the specific context in which it operates and discuss the need to reassess traditional search methods to increase successful search probability.

This presentation will impact the forensic science community by illustrating the need of forensic archaeology to improve upon its theories and methods, also demonstrating the manner and means to provide a more efficient search service.

The ICLVR was set up in 1999 by legislation that derived from the Good Friday Agreement (GFA). The GFA was the legislative turning point in the solution to the political conflict that had been escalating in Northern Ireland since the late 1960s. This Agreement set out to design a system in which Northern Ireland could move away from political violence and evolve gradually toward a peaceful environment based on mutual respect. It was deemed necessary by the GFA for this reconciliation process that the governments of Ireland and Northern Ireland commit to locating the remains of victims who had "disappeared" during a particular period of paramilitary activity. The ICLVR legislation allowed for the search for victims that fall into the category and time frame described by the legislation. It specifically excluded the forensic investigation of the "recovery" sites and the use of any such information for a criminal prosecution. To date 16 people fall into the category covered by this legislation and at the time of writing, nine of them have been recovered. Currently these cases that fall into the specific legislative remit range from 1972 to 1985 and present a unique and complicated challenge to those involved in their search and location.

At the outset, search activity was delegated to local law enforcement and following an initial 30 days of intense work search, was scaled down and took place on an intermittent basis over three years. Following calls for outside expertise, an independent forensic expert was engaged in 2005 to advise on how best to proceed. This marked a new phase and a new period of fieldwork activity that began in earnest in 2007. Search activity was extended to include the employment of forensic archaeology methodology. There followed a concentrated period of search over the next five years by a team of specialist independent advisors. This paper will look at the case specifics in terms of site type and search methods employed from the perspective of the forensic archaeologist and will look at the implications that follow for those searching for victim remains in other locations and political contexts.

Thus this paper will look at the forensic methods that were used and their relationship with the site type. The search methods considered and employed will be discussed in terms of merit and usefulness in light of the requirements of the search for "the disappeared." It will also consider how direct interaction with victims' families influenced the process and how initial identification of the scenes was based on confidential information received from those involved in the original killings.

The paper will demonstrate how the accuracy and specificity of the search for buried remains can be improved by the constant reassessment and reconsideration of the methods to be deployed. This will lead to more efficient searches of a potential body recovery location.

Forensic Archaeology, Search, ICLVR

D25 Managing Mass Fatality Incident Response: Concept of Operations and Field Operating Guides for an Integrated Regional Response to Mass Fatality Incidents

David A. Boyer, MFS, Montgomery Co Hospital Dist, 1400 S Loop 336 W, Conroe, TX 77304; and Jason M. Wiersema, PhD, Harris Co Inst of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After this presentation, attendees will: (1) learn the essential components of a regionally integrated concept of operations for mass fatality incident response that reconciles variable asset availability associated with large and small jurisdictions; (2) gain a better understanding of the division of responsibilities at the incident site, morgue, and Family Assistance Center; (3) gain a better appreciation for Mass Fatality Incident (MFI) response strategies that may be applied to any type of disaster; and, (4) learn about the utility of field operating guides for providing real-time guidance to MFI responders.

This presentation will impact the forensic science community by providing guidelines for a cross-jurisdictional, multidisciplinary, collaborative response to mass-fatality incident management.

The Houston-Galveston Area Council (H-GAC) Region consists of the City of Houston and 13 surrounding counties. The Department of Homeland Security (DHS) designated the H-GAC Region as one of seven high-risk urban areas in the United States for potential catastrophic incidents and subsequently awarded grant funding for regional catastrophic response planning. In late 2010, a mass fatality

incident (MFI) planning team was assembled to develop response strategies for the H-GAC Region.

The MFI response planners developed and published a Mass Fatality Management Concept of Operation (CONOPS) for the 13 county H-GAC Region. The plan offers an integrated plan for unified response to catastrophic incidents producing mass fatalities that overwhelm local resources. This CONOPS complies with the Incident Command System and the National Incident Management System. It is designed to be flexible and scalable, and addresses four separate components of incident response: site management, morgue operations, victim identification, and Family Assistance Centers (FAC). It also recognizes that incident response starts and ends locally and external regional, state, and federal resources serve in support roles for the affected jurisdiction(s). The plan also leverages existing non-MFI related local and regional capabilities to fill MFI-related response gaps.

To develop this CONOPS, the team formed several advisory groups to assist in guiding the process. Eight specific groups were assembled: logistics, information technology, investigations, fatality management and identification, legal issues, family assistance, hazardous materials, and pan integration. Group participants (five to ten per group) represented a majority of the 13 counties within the region. Stakeholders were included from county and municipal government; federal, state, and jurisdictional agencies; private industry; non-profit organizations; and non-governmental agencies. The benefits achieved through use of advisory groups were: engaging stakeholders in the planning process, drawing from their expertise, and subsequently achieving stakeholder buy-in of the final product.

At the beginning of the project, a kickoff meeting was held for potential regional stakeholders and, after presenting a project overview, volunteers were solicited for membership to the various advisory groups. Then, specific subject matter expertise was sought out from other agencies, organizations, and jurisdictions to round out regional representation. Convening group meetings helped to identify specific concerns, develop integration strategies, and build working relationships across disciplines and the region. The advisory groups will be sustained to maintain MFI awareness in the region and to inform both future MFI responses and planning efforts.

Contents of the CONOPS included a hazard and vulnerabilities assessment, capabilities assessment, assumption statements, communications section, logistics section, various operational components, and appendices. Specific responsibilities are delineated in an appendix of Field Operating Guides (FOGs).

The FOGs are built from a comprehensive organization chart that reflects the various components necessary for an MFI response. The 52 individual FOGs are design-based from the NDMS DMORT response model. Each guide includes a mission statement; description of required knowledge, skills, and abilities; general responsibilities; and associated key tasks. The FOGs are divided into major divisions of each response element—site, morgue, victim identification, and FAC. Site management includes human remains recovery, personal effects, and human remains transport. Morgue operations are divided into admissions and processing, and forensics units. The Victim Identification Center contains sections for postmortem data collection and management, data analysis, and quality assurance. The Family Assistance Center consists of a forensic unit, family management unit, and health and human services unit.

The completed CONOPS is used to help guide the training and exercising of disaster response across the H-GAC Region. The planning initiative was funded by DHS and delivered end products are available for distribution upon request.

Fatality Management, Concept of Operation, Field Operating Guides

D26 Excavation of Mass Graves in Cyprus

Demet Karsili, MA, and Andri Palla, BA*, Ledra Palace Hotel, PO Box 21642, Nicosia, CYPRUS*

After attending this presentation, attendees will learn about mass graves in Cyprus and the techniques that are used to exhume human remains.

This presentation will impact the forensic science community by providing examples of practical methods and techniques used by the CMP bi-communal forensic team in the excavation of mass graves in Cyprus.

In 1981, talks between Turkish Cypriot and Greek Cypriot leaders were held under the auspices of the United Nations which led to an agreement for the establishment of the Committee on Missing Persons in Cyprus (CMP). The CMP is mandated to establish the fate of missing persons without investigating cause or establishing accountability. The number of missing persons from both communities stands at 1,958, with 1,464 Greek Cypriots and 494 Turkish Cypriots missing. On August 28, 2006, the CMP formalized the beginning of a bi-communal program of exhumation across the entire island.

Most mass graves excavated in Cyprus are in open fields, pits, wells, caves, hills, mountains, stream and river beds, with open fields and well excavations being the most common type of mass grave encountered in Cyprus. Despite these commonalities, once the excavations have started, methods may be modified to take into account the unique characteristics of each site as they are presented. This presentation contains examples from all the mass graves that have been exhumed by the CMP Bi-Communal Forensic Team (BCFT).

Mass graves are a complex and confusing mix of bodies, body parts, grave fill, and artifacts. A mass grave can contain complete bodies in layers or partial bodies—commingled and complete bodies in a single burial feature. The exhumation techniques focus on detailed recording; using photography, sketching, site mapping, and categorizing the recovered remains as bodies, body parts, and general body parts, which may be associated with recovered artifacts.

When mass grave burial features are encountered for the first time, the excavation proceeds in a manner to define the horizontal and vertical limits of the site grave feature and to expose the evidence *in situ*. This is particularly the case with sites under threat from development and damage. In these cases, a combination of methods is used.

After setting the boundaries of the mass grave, a bit larger than the real margin of the grave, the soil from the burial feature is removed manually and systematically. Once remains and artifacts are discovered, further removal of soil is performed by using small masonry scoops and wooden sticks. The associated grave fill is sieved in order to recover small bone fragments and unassociated teeth.

Before removing the uncovered remains, all paper bags, boxes, and forms are properly labeled with the appropriate code to ensure that provenience and context is maintained. Taking detailed photographs together with the appropriate documentation during the critical points of cleaning and lifting each skeletal unit, complete or partial skeleton, has proven essential. Placing flags in the areas where human remains have been located facilitates subsequent mapping with a total station.

At the conclusion of the fieldwork, all recovered evidence is handed over under chain of custody to the CMP Anthropology Laboratory and the BCFT prepares an excavation report describing context and associations of recovered evidence. The archaeological data and reports, when combined with the skeletal and genetic reports, form the basis of nearly all CMP identifications.

Mass Grave, Excavations, Techniques

D27 The Persistence of Forensic Soil Evidence on Denim and Car Seat Covers: Getting the Dirt on a Suspect

Keisha D. Cook, MS, 2938 NE 64th Ave, Portland, OR 97213; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Rd, La Jolla, CA 92037-1011; and Paul Stein, PhD*, 25757 Bellemore Dr, Ramona, CA 92065*

After attending this presentation, attendees will better understand the post-transfer behavior of forensic soil evidence. How forensic soil evidence acts during the transition from primary transfer to secondary and higher transfer will be discussed, as well as how the secondary sample of soil compares to the original sample. How various fabrics, specifically car seat covers, play a role in the post-transfer behavior of soil will be explored. Attendees will also have a better understanding of the difference between primary and secondary transfer. An explanation of why this information could be useful to law enforcement and crime scene investigators will be discussed. Finally, recommendations for forensic and crime scene investigators regarding the collection of forensic soil evidence, to include soil-covered clothing, will be suggested and discussed.

This presentation will impact the forensic science community by providing understanding that both fabric weave and fabric type affects the transfer and post-transfer behavior of soil. This information will be useful to forensic and crime scene investigators. When coupled with all other evidence relevant to the case, it can assist investigators in linking persons involved with the scene of a crime.

A study of the persistence of forensic soil evidence was conducted on a variety of garments and fabrics including car seat covers. Car seat covers and denim pants with different types of fiber composition and fabric weave were used. Dry soil was rapidly lost from cotton pants with a stain-resistant backing, and persisted on cotton denim pants—through walking around and then by driving a vehicle. Soil deposited with a wide range of particle sizes initially persisted through primary transfer onto denim fabric throughout secondary transfer to a car seat. Clean denim was then used to determine the post-transfer behavior of the soil.

In some trials, the secondary and higher transfer soil evidence survived motion and activity and could be examined microscopically, whereas in other trials it could not. The smaller fraction of forensic soil evidence deposits can be detected after secondary and higher transfer has occurred, even well after larger particles have been lost from the first transfer surface. This demonstrated the selective loss of larger grain particles that is often suspected in cases submitted to the crime lab.

One immediate observation made was that some soil deposits are extremely difficult to see, especially on darker colored fabrics. The research showed that both fabric weave and fabric type affects the transfer and post-transfer behavior of forensic soil evidence. The size and texture of the material being transferred may affect the persistence of trace materials, which is linked to the type of surface on which the material is being retained. This research showed that a cotton denim weave was a nice retainer for small and very small soil particles. A significant difference between primary, secondary, and higher transfer of soil was found, when compared to the exemplar sample. It was determined this was due to gravity, along with any subsequent movement made by persons involved at a crime scene. This research showed it was apparent that large soil particles were rapidly lost after the initial transfer from ground to denim. Finally, this information is found to be useful to forensic and crime scene investigators, when coupled with all other evidence relevant to the case, as it can assist investigators in linking persons involved with the scene of a crime and/or with a victim.

Forensic Evidence, Soil Evidence, Soil Particles

D28 Assessment of Portable Forensic Detection Equipment and Methodologies on Biological Evidence From Commonly Encountered Forensic Substrates

M. Neal Parsons, MS, Nani M. Grimmer, BS, Sarah Cavanaugh, MS, Robert A. Bever, PhD, and Donia Slack, MS, Bode Technology Group, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

After attending this presentation, attendees will be familiar with multiple forensic detection methods that are portable and applicable for field forensic operation, offering effectiveness at detecting biological samples from commonly encountered forensic substrates, with consideration of the influence of variable lighting conditions.

This presentation will impact the forensic science community by providing an impartial evaluation of current alternate light sources and chemical detection methods for crime scene investigation. Comparisons of portable forensic methods will be demonstrated whilst highlighting the most befitting method tested for each forensic scenario.

The ability to successfully detect individual biological samples from various evidence substrates is the first tier to an efficacious forensic process. To a great extent, this capability depends on the type and amount of biological specimen present, substrate material, and environmental conditions. Typically, the high variability of forensic circumstances requires access to an extensive amount of materials and equipment to adequately investigate all possible scenarios. Therefore, effective and multifaceted tools capable of detecting biological deposits amidst a vast range of conditions are imperative for a thorough and expeditious crime scene investigation.

In this study, seven different portable alternate light sources ranging from wavelengths of 365nm to 530nm were evaluated. Each light source was evaluated by measuring the ability to detect eight different biological contributions (blood, semen, saliva, urine, 1:1000 diluted blood, 1:3000 diluted blood, dry fingerprints, and oily fingerprints) on nine common porous and nonporous substrates. Each biological contribution was deposited onto each substrate in triplicate. During evaluation, three variable light conditions (no light, low light, and bright light) were used to simulate environmental conditions. In addition, 14 commercially available chemical detection methods were evaluated. Each developing agent was evaluated by measuring the ability to detect biological contributions on various substrates. Each chemical method was tested according to the manufacturer's recommendations, which stated biological specificity and additional developing requirements.

Evaluations for each alternate light source and chemical method were performed 24 hours after the biological contributions were deposited. Three scientists independently evaluated the detection of each biological deposit in triplicate for every substrate and lighting condition using a 1-3-9 rating scale. This measurement scale allows for a clear distinction between performing poorly (1), performing marginally (3), and performing well (9). An aggregate of 216 independent evaluations were made for each type of alternate light source using the 1-3-9 rating scale (1,512 total evaluations). Chemical methods were evaluated on biological contributions depending on the manufacturer's recommendations for specificity. Using the 1-3-9 rating scale, 1,044 total evaluations were performed using chemical developers on nine substrates. In addition to evaluating the detection of each biological deposit, the chemical methods were also evaluated on usability. Usability for this study was defined as "the ease of use in a field setting as a portable technique." Similar to the rating scale for detection, usability was rated as poor (1), marginal (3), or excellent (9).

The alternate light sources evaluated in this study did not significantly detect blood or fingerprints. Contrastingly, the chemical developers evaluated in this study did not significantly detect semen, saliva, or urine. When visualized with 410nm to 445nm alternate light sources, semen, saliva, and urine were highly detectable in most scenarios. Fluorescent fingerprint powder was highly effective at detecting fingerprints and averaged near excellent on the usability rating. Hemascein® was notably effective at detecting all contributions of blood during this study and rated excellent on the usability rating.

This study has shown that relatively few pieces of equipment are required for a forensic unit to effectively detect a large array of biological fluids on many different substrates. Throughout this study, these methodologies have also shown to be portable, resilient, and user friendly.

Forensic Detection, Biological Evidence, Portable Methods

D29 Development of a Rapid Screening Method for the Processing of Sexual Assault Kits

Elizabeth C. Dearth, BS, 10093 Azalea Grove Dr, Manassas, VA 20110; Brittany Yeager, BS*, 277 Carr Ave, Clarksburg, WV 26301; and Alexandra L. Arthurs, BS*, 10 Catalpa St, Morgantown, WV 26505*

After attending this presentation, attendees will understand the potential ability to eliminate presumptive testing in favor of a rapid screening method for sexual assault kits, its ability to be achieved after initiating analysis at Y-quantitation.

This presentation will impact the forensic science community by developing a method of rapid screening that will decrease time taken to process a sexual assault kit, which in turn could increase the percentage of reported sexual assaults, which currently stands at 50 percent.

According to the Criminal Victimization Survey of 2010, conducted by the U.S. Department of Justice, approximately 200,000 sexual assault victimizations occur annually with only a 50.0 percent report rate.[1] When a sexual assault is in fact reported, an official statement is taken followed by a thorough forensic examination. This examination is generally performed with the aid of an evidence collection kit, more commonly referred to as a rape kit. The evidence collection kit for a sexual assault generally includes instructions, bags and sheets, swabs, a comb, envelopes, nail pick, blood collection devices, and documentation forms, although the exact contents of a rape kit varies by jurisdiction.[2] These contents are used to collect victim's clothing, possible physical evidence, blood, urine, hair, and other bodily fluids. Due to the vast amount of evidence collected from the victim, it can take anywhere from six to nine months for a laboratory to begin analyzing a single rape kit.[3] The annual backlog of unprocessed rape kits in the United States is estimated to be around 180,000 with a high of 500,000.[3,4,5] The method in which a rape kit is processed is dependent on the laboratory. Typical processing consists of first preliminary testing which includes reagent and microscopic examination. Reagent testing includes, but is not limited to, prostate specific antigen (PSA) test, acid phosphatase (AP) test, human salivary amylase (HSA) test, and a sperm protein (SP) test. The PSA test confirms the presence of semen by the detection of a glycoprotein produced by the prostate gland and this test is found to be more precise than the AP test which detects the presence of the enzyme acid phosphatase which is found in semen.[6] Microscopic examination includes various staining processes of spermatozoa such as the Kernechtrot Picroindigocarmine staining method. Preliminary testing is preceded by the analysis of DNA from samples and swabs. Analysis includes extraction, quantitation, and amplification of DNA followed by the generation of a DNA profile. The objective of this experiment is to develop a method in which sexual assault kits can be rapidly and efficiently screened. This will be studied through the use of different mixture concentrations of male and female DNA to simulate samples currently encountered in sexual assault kits. Samples will undergo the traditional screening method used in crime laboratories including presumptive testing of swabs, staining and the evaluation of slides, etc. The same samples will undergo a Y-quantitation thus eliminating timely presumptive testing. Profile data from the traditional screening method will be compared to profile data for the rapid screening methods chosen. The two methods will be compared with regards to timeliness, efficiency, and cost.

D30 Effects of Corrosive Environments on Fractured Surfaces of Stainless Steel Knives

James F. Evans, 211 Northcrest R, Angola, IN 46703; and Stacie Johnson, Ames Laboratory, 5 Spedding Hall, Ames, IA 50011-3020*

After attending this presentation, attendees will be informed of the effects real-life situations may have on the fractured surface of a stainless steel knife; for example, the tip of the knife being left behind at the scene, exposed to the elements, left soaking in the victim's blood, and if the hilt of the knife was discarded in a lake or river, or was cleaned with common household cleaning agents.

This presentation will impact the forensic science community by providing effects of different environments and conditions for which evidence can be found on stainless steel knifes, an ongoing project examining several different materials, such as metals, ceramics, polymers, adhesive tapes, and paper.

Thirty-nine Chicago Cutlery stainless steel steak knives were broken using the same load mechanism leaving 39 tips and 39 hilts. Each sample was then weighed and randomized. Using the Analysis, Comparison, Evaluation, and Verification (ACE+V) method of fracture match, each tip was correctly identified and matched to its corresponding hilt. Nine samples were then exposed to blood; three for one week, three for two weeks, and three for three weeks. Nine samples were exposed to a 3.5% solution of saltwater for the same intervals. Three samples were briefly dipped in bleach and three briefly dipped in ethanol and allowed to air dry. Three samples were soaked in a 50% solution of bleach, three in a 50% ethanol solution, three in a concentrated bleach solution, and three in a concentrated ethanol solution, each for two weeks. Three control samples as well as the other half of each of the exposed samples were not exposed. All samples were stored at room temperature during exposure. After exposure, each sample was cleaned, allowed to dry, and reweighed. The ACE+V method of fracture match was used again to attempt to identify the exposed samples to their other half.

Blood samples showed zero sign of degradation and no significant loss of mass after three weeks of exposure. Saltwater samples showed visual signs of oxidation on the side of the sample within just a few hours, but none of the samples showed degradation on the fracture surface. After three weeks of exposure, they experienced an average loss of mass of 0.25%. All blood and saltwater samples were correctly identified using the ACE+V method of fracture match. None of the ethanol samples showed any visual sign of degradation nor did they experience any change in mass. One sample, however, was rendered an inconclusive result during matching using the ACE+V method. The three dip-and-dry bleach samples showed neither degradation nor any change in mass. The samples in the 50% solution of bleach showed a 3.26% increase in mass due to oxidation while the samples in the concentrated solution experienced an 8.47% increase in mass. One of the samples in the concentrated solution was yielded an inconclusive result using the ACE+V method. All other samples were correctly identified.

In order to address the recommendation expressed by the National Academy of Sciences, this project sought to provide preliminary

investigation on the impact of different environments and conditions for which evidence can be found. This is an ongoing project examining several different materials including, but not limited to, additional metals, ceramics, polymers, adhesive tapes, and paper.

Work at the Ames Laboratory was supported by the U.S. Department of Energy Science Undergraduate Laboratory Internship (SULI) Program under its contract with Iowa State University, Contract No. DE-AC02-07CH11358. This research project was also partially funded by the U.S. Department of Justice, National Institute of Justice at Ames Laboratory, under Interagency Agreement number 2011-DN-R-0230.

Fracture, Corrosion, Steel

D31 Poppy Tea: An Update of its Abuse in the United States

Diana C. Crowell, MS, 22624 Dulles Summit Ct, Dulles, VA 20166*

After attending this presentation, attendees will gain a greater awareness of the growing trend of poppy tea abuse in the United States and an understanding of the potential morphine content found in poppy tea.

This presentation will impact the forensic science community by increasing awareness of the growing trend of poppy tea abuse.

Poppy tea, an infusion made from the seeds or (more commonly) the un-lanced, dried pods of the opium poppy, is hardly a novel product. It has been used ceremonially and medicinally in Eastern and Western cultures for centuries. However, as opiates such as morphine and heroin increased in popularity both as medical remedies and drugs of abuse, poppy tea faded into relative obscurity. Thanks to information available on the internet, abuse of poppy tea has rebounded in recent years. Simple recipes for its preparation are easily found on various websites. Dried poppy pods and seeds are also readily available from Internet vendors worldwide, including within the United States.

There are several varieties of *Papaver somniferum*, the opium poppy, that are cultivated for both licit and illicit purposes. The physical characteristics and alkaloid profiles of these poppies vary by growing region. In Mexico and South America, the opium poppy pods are small and rounded, and generally less than three centimeters in diameter. The poppy pods of the Southwest Asian region (Afghanistan, Turkey) are more elongated, with diameters of around two centimeters. Southeast Asian poppy pods, found in countries such as Thailand and Myanmar, are typically larger than the varieties found in the Americas or the Southwest Asian countries, with diameters of about four centimeters. In addition to these size differences, each region's poppy pods also have varying alkaloid contents.

Users of poppy tea identify the varieties of poppy pods by their flowers, seed color, and pod size and shape. Popular tea varieties include Hens and Chicks, Danish Flag, Persian White, and Giganteum. The Giganteum (or Giganthemum) variety has extremely large sized pods ranging from two to nearly six centimeters in diameter. Many Internet vendors refer to these pods as "jumbo" or "mammoth" sized. Some of the U.S.-based sites also boast of their domestically grown "jumbo" pods. One website claims to carry "Arizona's Best" poppy pods.

In the last few years, several fatal and nonfatal morphine overdoses related to poppy tea have been reported in the United States, Canada, and the United Kingdom. Canada has seen a growing problem with "doda" (or "dode"), which is a term for the powder made from ground opium poppy pods and seeds. Recently, poppy pods have been smuggled into Canada from the United States. These developments prompted an investigation into the possible alkaloid content in poppy tea. Unusually high morphine contents were detected in batches of tea prepared from a popular variety of poppy pod illicitly grown in the United States. The teas also contained varying levels of other opium alkaloids including codeine. Many users in the United States incorrectly assume that the use of poppy tea is both legal and a safer alternative to heroin. However, given the variety and levels of opium alkaloids found in poppy tea, the potential for abuse, addiction, and overdose is significant.

Forensic Science, Poppy Tea, Opiate Abuse

D32 A Case Study of the Murder Weapon Identification Through the Trace Evidence From Crime Scene Investigation

Choi Yong-Bok, PhD, Chungnam Provincial Police Agency, 301-708, Daejeon, KOREA*

After attending this presentation, attendees will learn important aspects of collecting trace evidence with other circumstantial evidence at the same time.

This presentation will impact the forensic science community by showing the importance of collecting and analyzing trace evidence to quickly determine the cause of death.

Today, many investigators only think that an individual identification is possible through DNA analysis from body secretions such as saliva and sperm, and hair and epithelial cells which are found in a crime scene; they just try to search this to find criminal(s) from the fingerprints on the evidence. If they can't find this evidence, they would focus on searching trace evidence which is used less during investigations.

Trace evidence examination has come from Edmond Locard's (1877~1966) observation in France, 1910; "with contact between two items, there will be an exchange." Therefore, while investigating criminal cases, trace evidence has to be used like other evidence such as fingerprints.

On Oct. 2009, a victim (A, 28-year-old, female) is murdered in the master bedroom and a suspect (B, 41-year-old, male) who killed himself in the bathroom next to the master bedroom the city of Bo-Reong, Chung-nam province. While searching the crime scene, the cause of death of the victim was quickly judged as cervical compression asphyxia. Trace evidence was collected from the victim's neck, the cord which was concluded to have been used during the criminal activity, and the suspect and victim's hands, to make clear what tools the suspect used during the crime. After a postmortem examination, the cause of death is determined as cervical compression asphyxia. While there is a scratch in the epithelial cells on a horizontal line, there was not a specific injury in the cervical muscle. Therefore, it is possible the victim was strangled by ligature, which squeezes the throat using a cord; but it is also possible to squeeze the victim's throat using a hand while at the same time the suspect was squeezing the victim's throat using a cord, as there are a few scratches of tiny epithelial cells on the neck.

In this case study, fabric which was collected from the victim's neck was compared with fabric (trace evidence) collected from the cord used during criminal activity and analyzed to see if they were the same. Analysis found: (1) the fabric of the cord and the fabric collected from suspect's hand and neck were same; (2) the blue fabric of the cord and the blue fabric on victim's neck were the same; (3) the red fabric of the cord and the red fabric on victim's neck were the same; and, (4) the bleaching red fabric to collect the tape on victim's neck and the bleaching red fabric of the tape on the cord were the same. These are the scientific proofs that the crime was committed using the cord.

Today, trace evidence is less used in crime investigation because it is not interesting. In many cases of murder and unnatural death, trace evidence has not been collected and investigators depend on a result of autopsy to determine the cause of death. However, like the example case, the scientific proofs using trace evidence is as important as postmortem examination.

As many crime cases are investigated, the trace evidence has to be collected and it is possible to provide individual identification with a high degree of certainty. If the trace evidence is used with other fragmentary evidence during the investigation, this reasonable method to investigate and solve a crime will be used frequently.

Trace Evidence, Fabric, Autopsy

D33 Non-Destructive DNA Collection From Handled Documents Using an Electrostatic Detection Device

Kristofer Sarik, MSFS, Robert A. Bever, PhD, and Donia Slack, MS, Bode Technology Group, 10430 Furnace Rd, Ste 107, Lorton, VA 22079*

The goal of this presentation is to determine if general use of an Electrostatic Detection Device (EDD) on handled documents could be used to collect touch DNA from paper documents in a non-destructive manner.

This presentation will impact the forensic science community by showing the potential of an electrostatic detection device in the lifting of touch DNA from handled paper documents with a statistically significant difference between substrate types.

Evidence collected for forensic testing can be defaced or even destroyed by the collection processes, reducing the integrity of the evidence and creating artifacts that could impact downstream analyses. An example of destructive testing is the collection of touch DNA from handled paper documents using a standard swabbing method. The purpose of this study was to determine if the general use of an EDD on handled documents could be used as a means to collect touch DNA from paper documents in a non-destructive manner. An EDD apparatus uses a charged Polyethylene Terephthalate (PET) sheet and is commonly used by document examiners to develop imprinted writing and fingerprints on paper documents without the direct treatment of the document itself. The question was raised if DNA deposited onto paper documents could be lifted by the PET sheet of the EDD apparatus.

Fingerprints from three donors were deposited onto five different paper document substrates: copy paper, newsprint, cotton (resume) paper, magazine print, and currency. Fingerprints were deposited onto each type of substrate on separate days in order to regenerate similar touch conditions. Each document substrate was subjected to processing for fingerprints using an EDD. As a control, an additional fingerprint collection of each substrate was cut from each document. The cut samples were subjected to the same conditions and processing as the test samples. Post collection, the substrates were visually inspected for damage. Cutting of substrates resulted in visible substrate defacing; however, the substrates collected by the EDD did not have any visible defects. Post processing, the PET sheet of the EDD was inverted and samples were collected from locations where fingerprints were visualized using a moistened cotton swab.

All samples were extracted (Silica Particle), quantified, concentrated, amplified for Short Tandem Repeats (STRs), and analyzed in accordance with approved laboratory procedures. All samples quantified below the detectable threshold of the system. Therefore, sample extracts were concentrated from 50uL to 5uL and amplified using the highest quantity of template useable by the STR amplification kit. The end result was the identification of 11 full profiles and 27 (out of 75) useable profiles (above 62.5% of profile resolved).

In addition to the ability to generate useable profiles, this collection technique presented two interesting variables: there was correlation between percent profile detected and donor, and also a correlation between percent profile detected and paper substrate types. Variation between donors was expected due to the difference between individuals and their ability to shed DNA. Between substrates, there was a statistically significant difference between all five substrates. Cotton paper returned the highest quantity of profile averaging of 81% across all donors, with other substrates significantly lower: copy paper: 48%; magazine print: 32%; newsprint: 45%; and, currency: 36%. In comparison to cut samples, the EDD device collection was similar and in the instance of cotton paper, more effective than cut sampling.

This study has shown the potential of an EDD device in the lifting of touch DNA from handled paper documents with a statistically significant difference between substrate types. This technique also leaves no visible defacing on the document and does not interfere with downstream questioned document analyses, greatly impacting the forensic community at large

Touch DNA, Questioned Documents, Evidence Collection

D34 Object Orientation to Minimize Metallic Artifacts in Multi-Detector Computed Tomography and Maximize Resolution With Plain Radiography

Gerald J. Conlogue, MHS, Quinnipiac Univ, Diagnostic Imaging Program, 275 Mount Carmel Ave, Hamden, CT 06518; Robert Lombardo, BS, Quinnipiac Univ, 275 Mt. Carmel Ave, Hamden, CT 06518; Tania Blyth, MHS, Quinnipiac Univ, 275 Mt Carmel Ave, N1-HSC, Hamden, CT 06518; Keith Geraghty, BS, University College Dublin, School of Medicine and Medical Sciences, Dublin, IRELAND; Bill Hennessy, MHS, Quinnipiac Univ, Diagnostic Imaging Program, Hamden, CT 06518; and Natalie A. Pelletier, MHS, Quinnipiac Univ, 275 Mt Carmel Ave, Hamden, CT 06518*

After attending this presentation, attendees will have a better understanding of basic imaging principles that can be used to improve image quality in forensics that are not as easily applicable in a clinical setting.

This presentation will impact the forensic science community by providing two imaging procedures that will improve image quality. Specifically, the first, related to Multi-Detector Computed Tomography (MDCT), will minimize streak artifact most notable when the data is used to create facial reconstructions. The second, relative to plain radiography, provides a method to avoid missing an occult fracture in a newborn or infant.

Introduction: Patient positioning and radiation dose limitations associated with clinical radiology are not a consideration in forensic imaging. Eliminating these restrictions provides the opportunity to utilize basic imaging principles to improve image quality that are not as easily applicable in the clinical setting. Two examples relative to object orientation will be discussed in the following presentation. The first, regarding MDCT, considers streak artifact created by dental fillings and most notable on three-dimensional reconstruction. When performing a skull examination on a live patient, there are few positioning options. The resulting 3D skull reconstructions of a patient with numerous bilateral premolars and molar fillings will exhibit streak artifacts projecting out of the mouth at right angles to the teeth. The second example relates to the X-ray tube focal spot in general or plain radiography. An object smaller than the focal spot size will appear as a blurred structure on the resulting image. Therefore, the dimensions and orientation of the rectangular focal spot within the X-ray tube is important when positioning an object to maximize resolution of subtle defects such as an occult fracture in a premature or newborn infant. However, in the clinical setting, due to monitoring and life support lines that might be attached to the patient, there may be limited choices for X-ray tube orientation. In addition, concern over the radiation dose will limit the technical factors and image receptor selection.

Materials & Methods: For the MDCT component of the study, the skull of an individual who died in 1886 and had numerous gold fillings was used to demonstrate orientation in an MDCT examination intended for a 3D reconstruction. The detached skull provided numerous positioning options. The skull and attached mandible were positioned with the sagittal suture parallel and perpendicular to the x-ray/detector rotation. In order to demonstrate the importance of positioning relative to the shape of the X-ray tube focal spot, a preserved fetal pig with an induced transverse fracture of the left third rib was radiographed. The specimen, with a crown-rump measurement of 29cm, was positioned with the fracture oriented both perpendicular and parallel to the smaller dimension of the focal spot. In addition, 40 kilovoltage-peak, kVp, much lower than would be clinically acceptable, was used for all the exposures.

Results: In the MDCT study, when the sagittal suture was aligned parallel to the tube/detector rotation, the streak artifacts were projected posterior to the teeth and not visible external to the mandible and maxillae. With the plain radiography, the occult rib fracture was more clearly demonstrated when the fracture was oriented parallel to the smaller dimension of the X-ray tube focal spot.

Conclusion: With fewer limitations regarding patient positioning and radiation dose, basic knowledge of imaging principle can be employed in forensics to improve image quality. Object orientation in MDCT can reduce streak artifact, improving 3D data sets used in facial reconstruction. In plain radiography, low kVp and object orientation relative to the shape of the focal spot improves image quality.

MDCT, Facial Reconstruction, Radiography

D35 Tampon Pain and Injury From the Perspective of the Adolescent and Adult User

Diana K. Faugno, MSN, 35751 Gateway Dr, D414, Palm Desert, CA 92211; and Barbara W. Girardin, PhD, 916 Speight Lyons Loop, Chesapeake, VA 23322*

After attending this presentation, attendees will understand the potential for pain and injury caused by a tampon inserted by the female user during menses. Furthermore, tampon pain and injury are compared in those using tampons 100% of their menses from those using tampons along with pads.

This presentation will impact the forensic science by providing results of a survey of 125 female subjects using tampons. It is significant to the forensic community because tampons are implicated as a rival hypothesis for injury to the female genitalia in sexual assault trials. Results of this study provide further scientific evidence in which to understand the question of tampon injury both in those using tampons 100% of the time and comparing those 100% tampon users to those using tampons part of the time in addition to using pads.

The presence and character of potential tampon injury to the genitalia has been a nagging question beginning in the 1930s when tampon use became more common. Some have said tampons do not result in hymenal clefts even in virgins.[1] Others have demonstrated that hymenal clefts occur in even the sexually inactive and the possibility of those clefts being tampon induced cannot be excluded.[2] Tampons without applicators were considered in the etiology of vaginal lesions by others.[3] Recently, it has been purported, without research support, that "injury to the posterior fourchette during tampon insertion is not uncommon;"[4] however, genital injury from tampons is not clearly or consistently evident in the research literature.[1,5,6] Also, the literature present is primarily from the perspective of the provider. Tampon-induced pain or injury from the perspective of the adolescent and adult tampon user contributes clarity to this growing literature on potential tampon-induced injury.

In this study, 125 sexually active adolescent and adult females were chosen by snowball convenience selection in the United States during 2011–2012. The survey was developed by experienced sexual assault examiners. The format of the paper-and-pencil questions required simply a yes or no and explanation as participants answered questions about their tampon or pad use. Postmenopausal women also answered from recall about the years of their tampon use. The results were tabulated into spreadsheet and will be further analyzed with descriptive results and inferential testing of the difference between the two groups – those using tampons 100% of the time and those using tampons and pads. Those using pads only served as a control group.

Three groups were surveyed: those using pads only, those using pads and tampons and those who used tampons only. Results will reveal the tampon type—straight or umbrella, plastic or board applicator and usage in the two groups using tampons. Also demonstrated will be the presence of pain or injury on tampon insertion, tampon wearing, and tampon removal, or if the tampon user was ever told by the provider during an exam that she had an injury to her genitalia. If pain was present, the user described the cause of the pain and the treatment she found which gave relief.

In conclusion, this study provides evidence from the perspective of the tampon user regarding pain, potential injury, and how it was resolved. Furthermore, results reveal whether those using tampons 100% of the time are any different in their pain and injury from those using tampons part of the time, in addition to pads. Data from this study contributes to the growing research evidence regarding tampons and genital injury.

D36 Characterization of Legal Highs and Their Pyrolysis Products

Pierce V. Kavanagh, PhD, Trinity College Dublin, Pharmacology and Therapeutics, Trinity Centre, SJH, Dublin, IRELAND; Elizabeth A. Gardner, PhD, Dept. of Justice Sciences, 1530 3rd Ave S, UBOB 210, Birmingham, AL 35294-4562; and Emily D. Bouso, BS, 100 Tree Crossing Pkwy, Apt 2202, Hoover, AL 35244*

After attending this presentation, attendees will become familiar with methiopropamine (3-MPA) and 6-(2-aminopropyl)benzofuran (6-APB), two of the latest legal highs that are being sold legally, both online and in head shops across the country. The contents of these drugs have been verified; therefore, this presentation will focus on the by-products formed when MPA and 6-APB are smoked. Attendees will learn about the process of pyrolysis and the importance of identifying the pyrolysis products of legal highs.

This presentation will impact the forensic science community by informing attendees how law enforcement and health professionals are grappling with the hazards presented by the current proliferation of legal highs. Never intended as pharmaceuticals, the pharmacology of these drugs are unknown. Therefore, treatment for patients who have taken these drugs is limited to symptomatic care. This project focuses on the next level of harm, the pyrolysis products formed when the legal highs are consumed by insufflation. This information can be used not only to aid in identifying drugs in a laboratory setting and help them to become scheduled, but may also help to save lives.

Legal highs are any mind-altering substance produced and sold in a manner to avoid the legal consequences of illicit substances. They have been advertised and sold as Spice, Bath Salts, plant food, and research chemicals. They are often analogs or derivatives of classical drugs of abuse such as cathinones and amphetamines, but do not fall under the Federal Analog Act as they are marketed "not for human consumption."

The harmful substances are not limited to the primary components within the drugs, but can include potentially toxic by-products that result when the drugs are smoked. Heroin, cocaine, and methamphetamine are all known to produce toxic by-products as a result of pyrolysis.

As part of an ongoing research project, legal highs have been purchased from local head shop's Internet web sites. Some of the substances identified include methiopropamine, 6-(2-aminopropyl)benzofuran (6-APB), 5-(2-aminopropyl)benzofuran (5-APB), and UR-144 (1-Pentylindol-3-yl)-(2,2,3,3-tetramethylcyclopropyl)methanone). The objective of this project is to identify the pyrolysis products from these legal highs which may play a significant role in the pharmacological and toxicological effects of these drugs.

The powder is loaded onto an aluminum foil boat and placed in a 25ml Erlenmeyer flask. The bottom of the flask is heated with a disposable cigarette lighter until the sample is black and no more fumes are visible. The aluminum boat is removed and the residues remaining in the flask are dissolved in methylene chloride. The residues are analyzed by gas chromatography and mass spectroscopy.

The pyrolysis products of methiopropamine and 6-and 5-APB have both been analyzed. Four pyrolysis products were presumptively identified from the pyrolysis of methiopropamine. Those products include the methylation and demethylation of the nitrogen atom. Both of these products are consistent with the pyrolysis of methamphetamine, an analog of methiopropamine. Ethylation of the nitrogen atom also occurred, which may indicate the use of ethanol during the synthesis process.

The pyrolysis of APB was more complex, producing nine pyrolysis products. Of those, six have been tentatively identified. Four of those products are consistent with the pyrolysis of methamphetamine: oxidation of the carbon chain and formation of a double bond followed by removal of the nitrogen group. The other two products are consistent with the pyrolysis of the benzofuran ring: addition of a methyl group to the ring followed by a combination reaction of two APB molecules.

Methiopropamine (MPA), 6-APB, Pyrolysis

D37 The Application of Laser Scanning for Visualization Within a Courtroom Environment

David A. Errickson, MSc, 18 Woodlea, Middlesbrough, UNITED KINGDOM*

After attending this presentation, attendees will gain a better understanding of how laser scanning and three-dimensional (3D) modeling can be used for visualizing forensic evidence within a court of law.

This presentation will impact the forensic science community by determining the advantage laser-scanned evidence has compared to traditional photographic methods for reconstructing a sequence of events within a court of law.

In homicide cases, skeletal trauma can provide evidence for the specific conditions of individuals' death. Forensic anthropologists can use skeletal trauma to reconstruct the final sequence of events for an individual. Photography is then utilized as a way of interpreting this evidence within a court of law.

Photography and digital imaging are the standards for documenting forensic evidence. The use of images is important in the investigation process and allows reconstruction after the scene has altered. More recently, technology from interdisciplinary research is being adapted to record evidence at a crime scene. A laser-scanned scene can be transformed to create a three-dimensional (3D) walkthrough. Thus, a 3D model can be taken into a courtroom as an alternative to photographs. This concept of visualization can also be used to replicate forensic evidence, especially that which is too sensitive to take into a court of law. Laser scanning also allows an enhanced visual walkthrough of events that can be viewed live in front of a jury.

This research compared photographic methods against laser-scanned data. First, several human archaeological skulls were recorded that displayed signs of traumatic damage. These skulls replicate similar blunt and sharp force traumatic damage seen in present populations. In an actual forensic investigation, this type of evidence is highly sensitive for the parties involved. Photography and laser scanning allows sensitive images to be displayed without bringing the actual evidence into the courtroom.

The present study recorded the human archaeological skulls using photographic and laser scanning techniques. The non-contact 3D scanners record surfaces by using basic triangulation. The scanner records an object by building a series of point clouds as a laser line passes over it. This research utilized the a laser scan arm and a compact 3D scanner for comparison against photography. The laser scan arm has an accuracy of up to 50 micrometers (50µm) (0.002") with a repeatability standard deviation of ± 0.002". The laser line has a scan width between 34mm and 60mm and a depth of field of 85mm. The compact 3D scanner has an accuracy of 0.1mm with a resolution of 968 x 644 8 bits and an 18-55mm lens. For photography, a digital SLR camera with an 18-70mm lens was utilized.

The research showed that laser scanning is an extremely useful tool for future applications when replicating sensitive evidence. Laser-scanned data allows information to be captured more accurately than photography. Furthermore, within the editing processes, results show that actual evidence is not being removed. This research also shows the 3D model allows for more accurate visualization than photography. This novel technique has the ability to be manipulated live by rotating and zooming into specific areas of interest. Laser scanning also relays technical information within a court to non-technically-minded people.

Laser Scanning, Visualization, Courtroom

D38 The Practice of Torture Known as Falaka: Evaluation of Physical and Psychological Outcomes in Asylum Seekers

Paola Mancarella, PhD, Univ of Roma, Viale Regina Elena 336, Roma, 00161, ITALY; Francesco P. Busardo, MD*, Univ of Palermo, via Del Vespro 129, Palermo, ITALY; Simona Napoletano, MD, Via Ilio 3, Room 40, Ardea, ITALY; Arianna Giovannetti, MD, Univ of Roma, viale Regina Elena 336, Rome, ITALY; Matteo Gulino, JD, Viale Regina Margherita 336, Rome, 00161, ITALY; and Paola Frati, PhD, Univ of Roma, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, 00161, ITALY*

After attending this presentation, attendees will learn some peculiarities of the torture method known as "falaka," still extremely popular throughout the Middle East and some African countries.

This presentation will impact the forensic science community by giving insight on the importance of a thorough medical examination, including medical-forensic support on asylum seekers and refugees, to certify the outcomes of this method of torture.

Introduction: The goal of this presentation is to analyze a torture method known as "falaka." This method is extremely popular and has existed since the Ottoman Empire to recent times, throughout the East and Middle East. Because this is a very common practice, depending on the geographical area, it is sometimes called: *falanga, falaqa, fallagas, bastinado*. Falaka is the most common term which identifies the repeated application of blunt trauma to the feet (more rarely in the hands or hips), usually practiced with a truncheon or a similar weapon. The most severe complication of falaka is the compartment syndrome, which can cause muscle necrosis, vascular obstruction, or gangrene of the distal portion of the feet or toes. Because lesions are often limited to the soft areas (fractures are rare), CT and MRI are the best methods to document them, but a medical examination in the acute phase can be crucial.

The SaMiFo (Health for Forced Migrants) is a health service designed for asylum seekers and refugees, created in collaboration with the Local Health Unit (LHU) of Roma A., in operation since 2007. The SaMiFo aims to facilitate and monitor all health and social services provided by the LHU. The medicolegal examination which certifies the outcomes of torture is the last step of a diagnostic clinical course (Unit VdT-Victims of Torture) that the patient begins at SaMiFo.

Materials and Methods: The data of our research are related to the period from January 2011 to June 2011, during which the SaMiFo followed 1,500 applications for international protection. Seven percent of applicants had physical and psychological signs of torture and they were therefore referred for medicolegal examination.

Review of 100 cases was completed to include an introductory interview, the analyzing of all the clinical examinations to detect previous diseases, the threatening of the health of the applicant in case of

repatriation, and then the examination to evaluate any injuries. The way in which the clinical examination is carried out and the search for physical evidence are indicated in the Istanbul Protocol.

The presence of a post-traumatic stress disorder is very frequent in this group and it is diagnosed by the Symptom Checklist 90 – Revised, and the Harvard Trauma Questionnaire 67 (HTQ). The HTQ consists of a guided interview that begins by evaluating 46 traumatic experiences. The second section of the interview includes two open-ended questions on experiences perceived by the refugees as by far the worst ever experienced. The third section investigates the experience of trauma or abuse, which are capable of causing brain damage. The fourth section then explores 40 symptoms related to trauma and torture (16 of which related to the diagnostic criteria of DSM IV). As it is a transcultural questionnaire, it has become a widely used tool and reference point for many research fields.

Discussion and Conclusion: Considering the local migration, Africa is the country most represented in this research. Women represent 14% of the sample. Almost all asylum seekers have been beaten, 17% underwent falaka, all women have suffered sexual violence. Twenty-four percent have a chronic post-traumatic stress disorder and all patients report anxiety and adjustment disorders. Different methods of torture are used simultaneously; in fact, in falaka cases studied 40% were victims of sexual violence, 50% had signs of cigarette burns on the body, and more than 60% underwent violence in prison.

The percentage of cases of falaka of our study is consistent with data from international literature; however, there is a significant difference in the countries of origin. Africa is the most represented country in this study; other global regions where this kind of torture is practiced are the Middle East, particularly Iran, Iraq, Syria, Turkey, and the countries of the Indian region, especially Bangladesh.

Another important point concerns the long-term outcomes. In the past, it was believed that this method did not leave signs of torture. It has now been shown that a physical examination performed by medical experts and the use of imaging techniques may identify lesions that, with a high level of probability, can be considered a direct consequence of exposure to this practice.

Falaka, Methods of Torture, Asylum Keepers

D39 Differentiation of Human Subjects Based on Scent Profile

Sarah J. Milam, MS, 17 Ridgeway Rd, Stafford, VA 22556; Douglas Beussman, PhD, St. Olaf College, Dept of Chemistry, 1520 St. Olaf Ave, Northfield, MN 55057; Blake Rushing, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; Rex Stockham, MS, FBI, Evidence Response Team Unit, Quantico, VA 22135; Brian Eckenrode, PhD, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; and Christopher Tipple, PhD, FBI Laboratory, 2501 Investigation Pkwy, Quantico, VA 22135*

D40 DNA Backlog Reduction by Triage

Andrew E. Carson, MFS, SIDE Inc., 3138 Alhambra Cir, Hampton, GA 30228; and Robert C. Gaffney, MFS*, USACIL, Investigative Support, 4930 N 31st St, Forest Park, GA 30297-5205*

The goal of this presentation is to provide attendees with information regarding a different path for reducing DNA backlog within their respective laboratories, one which has immediate, profound impact, and relatively little cost. After attending this presentation, attendees will have appreciation for a new approach to solving this growing problem in the forensic community.

This presentation will impact the forensic science community by describing the problem set in dealing with DNA backlogs as a result of the significant number of sexual assault cases. This is further complicated by Congressional intervention mandating the reduction of sexual assault cases pending forensic analysis. Several potential tactics will be discussed that could be employed to reduce DNA backlog, as well as describing how the employment of these methods resulted in significant policy changes which benefitted both defense and prosecution by reducing turnaround times.

When most prosecutors, police administrators, and laboratory personnel think of the DNA Reduction Act and the money spent to reduce DNA backlogs, they immediately think of increasing throughput at the laboratory end. This means an increase in manpower and equipment resources that plague governmental institutions in seeking additional revenues. From 2005 – 2009, the year-end backlog of cases at publically funded forensic crime laboratories rose over 200%. While the sheer numbers of submissions increased, so did the number of completed cases. According to National Institute of Justice (NIJ) statistics, crime laboratories are just not able to keep up with the flood of ever-increasing DNA submissions.[1] The federal funding made available through the DNA Initiative has helped state and local governments increase the capacity of their DNA laboratories to decrease backlogs. Without the funds to purchase automated instrumentation, hire new personnel, and validate procedures that are more efficient, the backlog problem would be much worse. Capacity at the laboratories has not yet come close to the demand for DNA testing. Until the demand is met, there will continue to be backlogs.

By published statistics, about $75 million is granted by the Federal Government annually to local and state crime labs in support of the DNA backlog reduction program. This figure is on top of the budgeted costs for initial resourcing and staffing of the supported laboratories. A DNA sample collected and analyzed by a laboratory in support of criminal justice work costs between $800 – $2,500 per sample, a cost per additional suspect identified is $4,502, and a cost per additional arrest is $14,169.[2] Many government laboratories have taken the step to contract with commercial DNA labs to reduce these backlogs adding to the financial burden. Until the demand is met, there will continue to be backlogs. The presentation will cover the necessary statistics regarding the cost of DNA backlogs, and DNA testing as a basis for the cost savings associated with this tact.

This presentation will discuss the methods and rationale used at a major U.S. crime laboratory where, by using a panel of experts, we were able to quickly and efficiently reduce the physical DNA backlog by up to 40%. In addition, we will be discussing the metrics and rationale used in expeditionary laboratory environments to ensure that on the highest payoff cases, the most probative evidence is front-loaded, yielding real, actionable information for investigations.

The presentation will also address additional outcomes of the triage efforts, as well as some amusing, and less-than-probative, laboratory requests that were collaterally eliminated as a result of this effort.

DNA, Reduction, Triage

D41 Comparison of DNA Yield From Different Soft Tissues of Decomposed Human Body at 4°C and -80°C

Shashank Pooniya, MD, Sanjeev Lalwani, MD, Anupuma Raina, PhD, Tabin Millo, MD, Karthik Krishna, MBBS, and Tirath Dogra, MD, AIIMS, Dept of Forensic Medicine, New Delhi, 110029, INDIA*

After attending this presentation, attendees will understand the importance of proper selection of soft tissue from decomposed bodies and proper conditions for preserving it for DNA analysis, especially in developing countries like India.

This presentation will impact the forensic science community by giving guidance about selecting the proper tissue for DNA analysis in case of decomposed bodies and the suitable preservation condition for such tissue. It can improve the outcome of conventional methods of DNA analysis in case of decomposed bodies and can give better results while identifying unknown decomposed bodies by DNA analysis.

It is always difficult to identify dead bodies by just external features in case they are decomposed. Identification by DNA analysis becomes the most important method of identification in such cases. DNA analysis can be easily performed on fresh tissue samples because of very little, if any, chances of degradation of genomic DNA, but it is of real concern to decide the best tissue for DNA extraction and analysis, and then to preserve it at the right conditions for analysis in case the body is decomposed.

Conditions required for preservation of tissues from dead bodies for DNA analysis is of great importance especially in developing countries like India where proper facilities for preservation of dead bodies or tissues are not available at primary and secondary health care centers and even at some of the tertiary health care centers. Also, preservation conditions become important in tropical countries with warm weather which hastens the process of decomposition. Stored samples encounter problems of degradation of High Molecular Weight (HMW) genomic DNA depending upon degree and nature of storage.

The present study is focusing on determining the best suitable soft tissue (among brain, kidney, heart, and muscle) for DNA analysis in case of decomposed dead bodies and the better temperature (among 4°C and -80°C) for the preservation of soft tissue for DNA analysis. The study was conducted on 16 different decomposed dead bodies from which four tissues (brain, kidney, heart, and muscle) were selected for sample collection. The collected samples were preserved at two different temperatures (4°C and -80°C) without any preservative for one month after which DNA was extracted using Phenol Chloroform extraction method (organic method) and the DNA yield was calculated using Spectrophotometer. Quality of extracted DNA was checked using gel electrophoresis, PAGE, and PCR.

The yield of DNA was more at -80°C than at 4°C for all the four tissues collected from 16 bodies. While analyzing the DNA yield for individual tissues, it was found that the yield was remarkably higher in brain tissue followed by heart, then kidney and least for muscles in all the cases at 4°C as well as -80°C. The DNA extracted from all the tissues at both the temperatures was found to be of good quality for amplification purpose with brain having the highest amount of HMW DNA.

This study suggested that deep freezing at -80°C should be preferred for preserving tissues for DNA extraction wherever available and brain must be the preferred soft tissue followed by heart, kidney and then muscle for DNA analysis at both normal freezing (4°C) and deep freezing (-80°C) temperatures.

DNA, Decomposition, Dead body

D42 Recovery Of Human DNA Profiles From Poached Deer Remains

Shanan S. Tobe, PhD, James Govan, MSc, Stuart Bailey, MSc, and Lindsey Welch, PhD, Univ of Strathclyde, Dept of Pure and Applied Chemistry, 204 George St, Glasgow, G1 1XW, SCOTLAND*

After attending this presentation, attendees will have a new understanding of how wildlife crime can be investigated more efficiently with improved conviction results. The described method will also be applicable to other types of wildlife crime.

This presentation will impact the forensic science community by allowing wildlife crimes to be investigated and prosecuted, with the use of human DNA giving the described test wider usage and acceptance in court.

The role of forensic science in non-human crime, mainly wildlife crime, is underused. Crimes against animals have been demonstrated to be linked with other organized crime due to the high value of the crime combined with the low levels of prosecution. It is therefore important that new methods be developed that will maximize the recovery of evidence from wildlife crime as well as the probative value of that evidence for criminal investigations.

Poaching is a worldwide crime that can be difficult to investigate due to the nature of the evidence. Previous studies have focused on the identification of endangered species in cases of poaching. Difficulties arise if the poached animal is not endangered. In the United Kingdom (UK), deer have hunting seasons whereby they can legally be hunted. Therefore, identification of deer alone has little probative value as samples could have originated from legal hunting activities in season. After a deer is hunted, it is common practice to remove the innards, head, and lower limbs. The limbs are removed through manual force and represent a potential source of human "touch DNA."

The potential to recover and profile human autosomal DNA from poached deer remains was investigated. Samples from the legs of 20 culled deer were obtained using DNA minitapes. DNA from samples was extracted, quantified, and amplified to determine if it would be possible to recover human STR profiles.

Initial profiling required the use of Low Template (LT) analysis. This method is not accepted worldwide and a revised protocol was developed that did not require the use of LT analysis. The revised protocol involves combining the DNA extracts from all legs (or samples) relating to the same simulated poaching incident followed by concentration of the DNA sample. This allows the maximum amount of recovered DNA to be added to the human STR multiplex.

Near complete profiles that provided a high level of discrimination were obtained. The majority of the samples provided at least a partial profile. Incidents of drop-in were minimal considering the isolated location of the sample recovery.

This project demonstrates the recovery of human touch DNA from poached animal remains in a simulated study. This test is far superior to those targeting animal DNA due to the recognized validation of human STR testing as well as the potential for the results to be uploaded and searched against a human DNA database, for example, the UK National DNA Database. There is the potential for this test to be used in relation to other species of poached remains or other types of wildlife crimes. This is the first time that human STR profiling has been successfully applied to touch DNA in regard to wildlife crime.

Poaching, Wildlife Crime, Human STRs

D43 The Use of Finite Element Head Models to Predict Skull Base Fracture

Jean-Sébastien Raul, MD, PhD, Caroline Deck, PhD, Remy Willinger, PhD, and Bertrand Ludes, MD, PhD, Institut de Medecine Legale, 11 Rue Humann, Strasbourg, 67085, FRANCE*

After attending this presentation, attendees will be presented with the finite element method, its principles and its applications in forensic sciences focusing on a skull base fracture case, showing the possible interest in some forensic cases of the use of this method.

This presentation will impact the forensic science community by understanding the use of finite element models, their possible application in practice, and also, through the particular case reported, to be careful when a body is found floating in a river without external evidence of injury, not to conclude too fast on the cause of death.

It can be a fundamental problem in forensic investigations to establish whether a head injury is the consequence of an accident or an assault. Close examination of the wounds may help to understand the mechanism of injury, but sometimes doubt remains and it may be particularly difficult to differentiate the consequence of a fall from the consequence of a blow. During the second half of the 20th-century, engineers have tried to develop mathematical models using fundamental Newtonian principles and experimental observations to predict the mechanisms of head injury for a given scenario. Yet, inaccuracies can arise from these models in which tolerance to impact originates from various sources, including experiments on animals,

human cadavers, anthropomorphic dummies, and human volunteers. A proposed alternative method for assessing the consequence of a given head impact scenario is the use of finite-element models of the human head. Computer models are increasingly proving to be an alternative to complicated, practically unfeasible, or unethical (human or animal) experiments. The finite-element method, which is a mathematical method for solving complex physical problems on domains with complicated geometries, is commonly used in constructing such computer models. The finite-element modeling technique offers the advantage of being able to model structures with intricate shapes and indirectly quantify their complex mechanical behavior at any theoretical point. Because the finite-element method uses the theories of elasticity and static equilibrium, the effects of multiple external forces acting on a system can be assessed as physical events in terms of deformations, stresses, or strains. A finite element model of the human head has been developed in Strasbourg University to predict skull fractures and brain injuries. The geometry of the inner and outer surfaces of the skull was digitized from a human adult male skull. The main anatomical features modeled were the skull, falx, tentorium, subarachnoid space, scalp, cerebrum, cerebellum, and brainstem. For the CSF, a Lagrangian formulation was selected and the brain–skull interface was modeled by an elastic material validated against the *in-vivo* vibration analysis. The scalp was modeled by a layer of brick elements and surrounds the skull and facial bone. Globally, the model consists of over 13,000 elements. Its total mass is 4.7kg. Tolerance limits were identified relative to DAI, subdural hematoma, and skull fracture with a risk of occurrence of 50%. The complex geometry of the skull, including the evolution of the skull thickness throughout the skull, and the reinforced beams which play an important role in its dynamical response to impact have been taken into account. Previous published papers have dealt with the use of this finite element head model in forensic sciences for falls and gun injuries. This paper illustrates its possible use for predicting skull base fractures through the report of the case of a woman who was found floating in a river near Strasbourg, next to the boat where she used to live. External examination showed no particular injury. Autopsy showed a right low parietal head impact and a transverse fracture of the skull base with traumatic dilacerations of the two internal carotid arteries. Death was due to "drowning" by the victim's own blood which had obliterated the trachea passing through the skull base fracture into the pharynx. A finite element method reconstruction of the fall and the head impact on the dock where the ship had stopped was made, showing how the victim could have fallen to create her skull base fracture, thus confirming the possibility of an accidental death.

Finite Element Model, Skull Fracture, Drowning

D44 Investigation of Real-World Blunt Head Trauma Using a Commercial Skull/ Brain Surrogate

Jason M. Greb, MS, and Cynthia Bir, PhD, 818 W. Hancock, Detroit, MI 48201; and David Raymond, PhD, CSU Los Angeles, Dept of Mechanical Engineering, 5151 State University Dr, Los Angeles, CA 90032*

The goal of this presentation is to educate the forensic community on a potential surrogate available for assessment of blunt force trauma, and how to critically evaluate such surrogates.

This presentation will impact the forensic science community by displaying data, laboratory procedural background, and morphological results related to human head blunt-force impacts that will provide insight into the applicability of blunt-force trauma surrogates as tools for human skull fracture pattern prediction.

Often, the circumstances leading to skull trauma as a result of blunt impacts may be unknown due to the lack of witnesses, the inability of the injured to recall the events leading to the trauma, or even the death of the injured party. In one real-life incident, a worker investigating the outlet area of a hydraulic pump that was removing fluid from a well sustained serious head and brain injuries as fluid pressure reached the critical value needed to blow the cam-lock cover off of the pump outlet, which then struck him in the head. For such cases, human head surrogates have been developed that allow laboratories to simulate such scenarios. Thali et al. (2002) introduced a novel headform, commonly known as the "skin-skull-brain model," which was developed with the intent of observing the subjective morphological results of blunt head traumas.[1] The focus of this study was to attempt to recreate the aforementioned real-life injury on a similar surrogate. In doing so, the goal was to attain a better understanding of the circumstances surrounding the injury by comparing experimental morphological results to injury evidence, and perhaps to gain insight into the validity of the surrogate for similar blunt trauma events.

For impact testing, the human head was represented using a surrogate similar to the Thali model, consisting of a polyurethane sphere to simulate the human skull (SYNBONE) and 20% ordnance gelatin as the brain simulant. The surrogate was hung in a thin net to simulate head movement as a reaction to impact force. In an attempt to simulate the head injury event, a 1.5 lb. cam-lock cover which matched the real-life blunt trauma projectile was launched from a 2.75" section of pipe on the end of an air cannon to produce a direct impact to the surrogate. Based on the available information pertaining to the impact event, three possible impact conditions were tested: the cam-lock cover was fired from 25" at 94.8 psi (gage) while loosely fitted to the cannon pipe, from 15.25" at 95 psi with the cover partially locked onto the pipe using the cam locking mechanisms, and from 15.25" at 102.5 psi (gage) without locking the cover. After each trial, the surrogate was closely examined, photographs were then taken to document the head model damage, measurements were made when applicable, and observations and data were documented.

For the test with a partially locked cover, air pressure was not sufficient to overcome the locking mechanism and no launch resulted. The long-range impact with the loosely-fitted cam-lock yielded only a small, hair-line fracture of the head form skull. The short-range and higher pressure test resulted in a significant fracture on the head form with a maximum crack length measuring about four inches from the impact site to the end of the crack, and three resulting skull surrogate fragments, with a combined size of about 1.18" x 1.57". When morphology of the cracks and broken pieces from this trial were subjectively compared with photographs of the accident evidence, similarities were observed, suggesting similar impact conditions. Evidence from the accident, however, consisted of only a single fragment measuring approximately 1.5" x 2". This difference in skull fracture pattern may imply different experimental impact conditions, but also may indicate the inability of the surrogate to accurately reproduce human skull failure modes due to different geometry or material properties. Because correlation of experimental results with the real-life event was largely subjective, further study on the subject should include additional research to simulate the accident more precisely, high speed videography to document the ballistic impacts, a complete "skin-skull-brain" model as a more biofidelic surrogate, and laboratory study to validate the "skin-skull-brain" model biofidelity as compared to controlled studies using postmortem human subjects.

D45 Velocity and Location Effects on Bruises Created Using a Controlled Ballistic Elastic-Mass Delivery System

Donald C. Sherman, MSE, 818 W. Hancock, Detroit, MI 48201; Kenneth R. Short, PhD, Target Behavioral Response Laboratory, U.S. Army ARDEC, Picatinny Arsenal, NJ 07806; and Cynthia Bir, PhD, 818 W. Hancock, Detroit, MI 48201*

After attending this presentation, attendees will be educated on the effects of ballistic impact velocity and anatomical location on the immediate onset, size, duration, and color of bruises created on the thorax and abdomen of volunteers.

This presentation will impact the forensic science community by using bruising biomechanics to assist emergency room physicians in determining cases of possible physical abuse and forensic investigators in estimating the timing of recent blunt-impact injuries.

Existing literature contains conflicting information regarding the color changes in bruises with respect to time. There is general agreement that the first colors seen are usually deeper reds, black, and blue. Yellow is generally not seen for the first 18 – 24 hours, but after that, any color may be present. It follows that deeper tissue bruises, from higher-velocity impacts, will remain darker, longer. It is hypothesized that if mass is constant, a bruise from a slower impact will resolve more rapidly, have a smaller area with color change, and include lighter colors.

The relationship between velocity and bruise characteristics has not been thoroughly explored in published literature. Specifically of interest is the effect that impact velocity has on the affected area of color change (as measured at the point of impact and at 10, 20, and 30mm from the point of impact) as well as the magnitude of the color change. The effect of bruise location was also investigated.

Forty healthy adult volunteers completed an initial questionnaire to screen for bleeding disorders and blood thinning medications. Informed consent was garnered, and each subject had their thoracic and abdominal regions digitally photographed (Canon EOS 30D, Lake Success, NY). Prior to bruise creation, tri-stimulus light reflectance was also measured using a commercially available colorimeter (model CR-400, Konica Minolta) tri-stimulus light reflectance was reported using the three-dimensional CIE 1976 (L*, a*, b*) color space, where L* represents luminance (0 = black, 100 = white), a* represents the shift from magenta to green (green is indicated with negative values, magenta with positive values), and b* represents the shift from yellow to blue (blue is indicated with negative values, yellow with positive values). Changes in the CIE 1976 color space are represented by ΔL*, Δa* and Δb*. The overall change in the CIE 1976 space is characterized by the value ΔE, which is the vector sum or resultant of the three color space change variables ΔL*, Δa*, and Δb*.

Blunt impact injuries were inflicted using a pneumatically-fired system. The impacting projectile was a standard .68 caliber paintball, spherical in geometry with a mass of 3.1 grams. Impact velocities were either approximately 200ft/sec or 300ft/sec and impact energies were 5.75 J and 12.95 J respectively. Both body regions on each subject received impacts of the same velocity for 29 of the subjects, while 11 subjects chose to stop or the gun malfunctioned for one of the shots. The first shot location was varied randomly between two body regions and the shot velocity was varied randomly between subjects. Baseline measurements at both impact sites were compared to measurements taken immediately after impact, as well as 60, 90, and 120 minutes post impact. These measurements were taken at the point of impact and at 10, 20, and 30mm from the point of impact.

A repeated-measures analysis was performed for the 29 subjects that were impacted in both locations (SPSS version 19, IMB). A within-subjects comparison included the ΔE differences at: each body region, all four distances from impact, and all four time periods; and a between-subjects analysis was performed for the impact velocity. The color change was significantly greater at the higher impact velocity $F(1, 27) = 31.4$, $p < .05$. There was no significant difference in the color changes measured at the thorax compared to the abdomen $F(1,27) = 0.949$, $p = .339$. There was a greater color change immediately after impact when compared to all other times $F(1, 27) = 49.151$, $p < .05$. The color change decreased significantly at each increment of distance away from the point of impact $F(3, 25) = 50.697$, $p < .05$.

Bruising, Velocity, Quantification

D46 Atypical Postmortem Dental Identification

Amber D. Riley-Burns, BA, 24679 Monroe Ave, Ste 105, Murrieta, CA 92562; and Anthony R. Cardoza, DDS*, 266 B Avocado Ave, El Cajon, CA 92020*

After attending this presentation, attendees will possess a greater understanding of exceptional, non-traditional methods of postmortem dental identification when antemortem dental records do not exist or are otherwise non-retrievable.

This presentation will impact the forensic science community by emphasizing the areas of medicolegal death investigation, forensic pathology, forensic anthropology, and forensic consulting. In each of three cases discussed, human identity was confirmed within medical/legal certainty, utilizing an alliance of forensic dental autopsy and antemortem medical records or differential non-radiographic maxillofacial oral anatomy. With each case example, a greater knowledge of the scope and advantage of contemporary forensic odontology as an augment to traditional death and identity investigation will be gained.

Reasons that a forensic dental comparison is an ideal instrument in death investigation include the longevity and durability of the dental and oral anatomy, even in scenarios of extreme heat, trauma, decomposition, or a combination of all of these factors. Postmortem identification based on dental record comparison is universally recognized and consistently accurate. The reality however, that despite thorough investigation, antemortem dental records are not always recovered is addressed in this presentation. The alternative investigative methods employed that resulted in a positive dental identification, without antemortem dental records will be detailed.

The first case involved a white male seen in a parking lot pacing around a vehicle. Moments later, witnesses observed the vehicle engulfed in flames with the male sitting in the passenger seat. Emergency personnel responded and confirmed the death without intervention due to the thermal injuries. Homicide detectives were summoned to the scene and initiated an investigation. Autopsy confirmed the cause of death as inhalation of products of combustion and the manner of death as suicide. Antemortem dental records of the decedent were not recovered; however, medical radiographs of the head and neck were available. A forensic odontologist was summoned and antemortem digital radiographs, a frontal and lateral skull series highlighting a medical implant on the cervical vertebra, were offered for analysis. The dentition was visible on both radiographs and, because of the radiographic orientation, the lateral film showed the lower teeth clearer and with more detail. Tooth numbers 30 and 31 were restored with significant and unique dental restorations. Postmortem dental radiographs were taken and a positive identification was rendered based on the comparison of these dental restorations.

The second case involved a Hispanic male transient. 911 was called after a witness found the decedent floating in a creek. Paramedics arrived, recovered the body, and confirmed death. Autopsy determined the cause of death as atherosclerotic coronary artery disease with contributing factors of drowning and chronic alcohol abuse; the manner of death was accidental. The investigator summoned a forensic odontologist to complete a dental identification, yet no antemortem dental records were recovered. However, very recent frontal and lateral CT scans were collected and given to the odontologist for analysis. Postmortem dental radiographs were taken and a positive dental identification was rendered after precise antemortem image improvement to allow for a strict tooth-by-tooth comparison of the decedent's restored teeth.

The third case involved a motor vehicle collision resulting in two fatalities, a male youth and an elderly female. The bodies of both

decedents were charred beyond recognition and identification by dental record comparison was ordered by the medical examiner for both victims. Antemortem dental records for the female victim were quickly obtained and her identification was made without difficulty. The investigator learned that the youth was undergoing orthodontic treatment in Tijuana, Mexico, and it was assumed adequate dental records would be readily available for comparison; however, this assumption was wrong. No pre-orthodontic dental radiographs of any kind had been created, and only study models of the decedent's teeth, prior to orthodontic appliance placement, were available. Even with the extent of external charring, the oral cavity, dental, and palatal anatomy of the decedent remained unharmed. Dental impressions were collected on the decedent and models created from these impressions for comparison with the antemortem models. Although the tooth positions were now inconsistent due to orthodontic repositioning, the distinctive pattern of the palatal rugae had numerous consistencies and there were no unexplainable inconsistencies upon direct comparison. A positive identification was rendered based upon this comparison.

Investigation, Dental, Identification

D47 Ready for the Olympics? Disaster Victim Identification Training and Exercises as Part of a Capacity Building Process for UK Police Forces

Roland Wessling, MSc, Cranfield Univ, Cranfield Forensic Institute, Shrivenham, SN6 8LA, UNITED KINGDOM; and Mark D. Viner, MSc, Cranfield Forensic Institute, Defence Academy of the UK, Inforce Foundation, Shrivenham, SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will understand the educational philosophy and practical implications of uses of experiential learning for training and exercising in Disaster Victim Identification (DVI). Attendees will learn how the creation of scenarios that replicate, as far as is possible, key elements of a mass fatality incident will enable responders to develop the necessary skills in a controlled and educational environment.

This presentation will impact the forensic science community by presenting a systematic educational philosophy applied in police DVI exercises designed to prepare United Kingdom (UK) police forces for the London Olympics 2012.

Introduction: Following the Asian tsunami and large scale multi-centre terrorist attacks such as 9/11 and the London bombings of July 2005, DVI preparedness has been reviewed in many countries. Such reviews have covered various aspects of DVI, including team composition, local, regional, and national organization systems, inter- and intra-agency communication and co-operation, together with training and exercising.

DVI team members are drawn from a wide range of disciplines and can be broadly divided into two elements: (1) the scientific team members, such as forensic pathologists, anthropologists, odontologists, radiographers, mortuary technologists, laboratory officers, etc.; and (2) police officers or other emergency service responders. Whatever the structure and composition, it is essential that the DVI team members should be adequately trained and should have taken part in regular and comprehensive multidisciplinary exercises.

All team members typically perform their normal day-to-day role within a controlled environment. They will work with other professionals who understand their role and contribution to routine investigation. In a mass fatality incident, this will not be so; the situation will be unfamiliar and traumatic. Team members will need to act with confidence and speed and be mindful of the situation unfolding around them. The use of simulation training in a true multidisciplinary team environment helps team members gain first-hand experience of a realistic mass fatality situation, to plan and to understand the implications and limitations of their actions, and develop the necessary skills for disaster response within a controlled situation. By creating a simulated mass fatality incident in which all the elements of emergency forensic response are represented, team members can experience first-hand the multi-faceted challenges presented by such a situation. They can develop and try out their own strategies for overcoming practical and organizational challenges in a learning environment, supported by a team of experienced tutors. By use of multi-disciplinary training exercises, students gain understanding of the challenges faced by other professionals and learn to adopt a team approach to solving practical problems to achieve a common objective.

The Inforce Foundation has systematically applied the educational philosophy of experiential learning to a system of exercising that uses low-tech simulations in a number of different scenarios, ranging from mass grave excavations to mass fatality incident mortuary operations.

This presentation will concentrate on a series of simulation exercises that Inforce carried out with a number of UK police forces over the past four years. Most of these police hosted various aspects of the Olympic Games 2012. The exercises were designed to be flexible enough fit the precise needs of each force in question and work with their already existing level of qualifications and experience. By taking account of these variables, each exercise was tailored in terms of role distribution, rotation, difficulty level, and the elements of DVI operations to be included.

Results: Through these exercises, team members learned to:

- Understand the scope of a mass fatality incident.
- Adapt to changing circumstances.
- Develop the confidence to perform in different roles in the team.
- Contribute effectively to the team effort.
- Have consideration for the safety of self and others.
- Develop the confidence and skills to train other team members.
- Participate in the identification process.

Conclusion: There is no way to prepare adequately for a mass fatality incident as each and every incident will be different. However, such simulation exercises assist team members to prepare for, and adapt to, any situation as it unfolds, and to act professionally and confidently as part of a multidisciplinary team.

Capacity Building, DVI Exercise, Mass Fatality Incident

D48 Bone and Body Part Deposition in Rivers: Where to Look for the Rest of the Body

Thomas Evans, MA, Montana State Univ, Dept of Earth Sciences, PO Box 173480, Bozeman, MT 59717-3480*

After attending this presentation, attendees will learn the results of eight empirical trials performed by seeding rivers with real and synthetic bones and tracking where samples were deposited. Trends in the location (geomorphology) and river bed features at locations of deposition will be described.

This presentation will impact the forensic science community by learning about the most likely locations of deposition, which can aid law enforcement agencies in the recovery of more remains from fluvial systems, allowing search personnel to be deployed more efficiently to spend more time searching in locations with a higher likelihood of success.

Knowing the most likely locations of deposition can aid law enforcement agencies in the recovery of more remains from fluvial systems. Search personnel can be deployed more efficiently and can spend more time searching in locations with a higher likelihood of success, thus increasing the recovery rate of remains and reducing the cost of searches. In addition, since rivers are hazardous environments, personnel above and below water will be exposed to fewer hazards since searches can be targeted to higher probability locations, thus reducing the time individuals spend in and around dangerous working conditions.

To determine where skeletal remains are deposited in rivers, animal bones and casts of sheep bones were seeded in three rivers and observed yearly. Bones were seeded in the East Fork Sevier River (EFSR), UT, and Big Beef Creek (BBC), WA, and bone casts were

seeded in both these rivers and Levelock Creek (LC), AK. The EFSR is a sinuous river with a sand to gravel bed with a study reach of ~25 miles long, while BBC is a braided river with a gravel to cobble bed and a study reach of about two miles in length. LC is a highly sinuous river with a sand to fine gravel bed and a study reach length of ~1.5 miles. Empirical seeding trials were performed by placing bones or bone casts in the rivers with known initial locations and orientations then visiting the rivers every summer thereafter. During trial observations, the rivers were searched and, when samples were located, their location of deposition (geomorphology), bed characteristics (grain size, distribution, woody debris, etc.), distance downstream (measured with a fiberglass tape measure), orientation, and burial were recorded. Located samples were collected and archived for later laboratory analysis. A total of eight empirical trials utilizing bones are in progress, six in the EFSR, and two in BBC. Five empirical trials using bone casts are in progress, one in LC, three in the EFSR, and one in BBC. In addition to empirical trials, 14 rivers have been searched for skeletal material, and when remains were located, observations were recorded like the empirical trials.

Of the 6,000+ bones and 3,686 bone casts seeded, 218 bones and 307 bone casts have been recovered. While observing bones in rivers, 485 bones have been observed in addition to 33 articulated body parts. Of the 644 bones with good location descriptions, 4.3% (N=28) were found on point bars, 23.6% (N=152) on lateral bars, and 4.3% (N=28) on median bars, for a total of 32.2% of bones found on bars of one form or another. 26.4% (N=170) of bones were found on either the right or left banks, and the remaining 41.3% (N=266) were found in the thalweg (deepest part of the river channel). 24.7% (N=184) of bones were found in association with woody debris out of 744 bones with notes on woody debris associations, and three bones were found hanging in vegetation above the river bed. Results for the 307 casts recovered were broadly similar with 11.7% (N=36) found on point bars, 14.0% (N=43) on lateral bars, and 9.1% (N=28) found on median bars, for a total of 34.9% of bone casts found on bars. 33.9% (N=104) of casts were found on banks, and 31.3% (N=96) of casts were found in the thalweg. 53.1% (N=163) of casts were found in association with woody debris.

These results suggest that skeletal material can be found in any location with a change in flow competence (the ability of the river to transport material). This includes locations where rivers suddenly become deeper or shallower, like bars of any form (point, lateral, and median bars), as well as the upstream end of pools. In addition, flow obstructions (woody debris, bridge pilings, large rocks, etc.) catch skeletal material and prevent further transport, which accounted for many of the bones and casts found in thalwegs. Articulated remains showed similar trends though a large enough sample size for comparison is not yet available.

Taphonomy, Fluvial, Bones

D49 Missing Persons or Disposable Persons? Perils and Pitfalls in the Investigation of Unidentified Bodies

Kim K. Fallon, BS, and Thomas A. Andrew, MD, OCME, 246 Pleasant St., Ste 218, Concord, NH 03301*

After attending this presentation, attendees will learn of the methods in attempting to identify skeletal remains and also of the obstacles faced when working on a cold case with multiple unidentified victims.

This presentation will impact the forensic science community by familiarizing attendees with steps that can be taken in an attempt to identify victims in a cold case, and discussing the delays that can occur when wrong theories are made.

This presentation will review the efforts made to identify four homicide victims, a woman and child, then two additional children, whose skeletal remains were found in two separate barrels approximately 100 yards apart, in a forest in New Hampshire in November 1985 and May 2000, and the erroneous assumptions that were made regarding several aspects of the investigation. Presumptions regarding the value of the DNA profiles that were obtained from the victims, the usefulness of additional scientific testing, the interest of media organizations, and the capacity of technology to match missing persons to unidentified remains were not accurate. This presentation will also highlight the numerous government and non-government agencies and resources that can aid a medicolegal jurisdiction working to give a name to unidentified remains.

After attending this presentation, attendees will understand some of the challenges associated with reopening a cold case, in which the crime occurred and the bodies were discovered prior to the founding of the State Medical Examiner's office and prior to the use of computers to track evidence and store information. Difficulty locating all the skeletal remains from the four victims was encountered due to a variety of bones being sent to different labs, agencies, and authorities for analysis.

The limitations of utilizing mtDNA test results for identification purposes will be discussed, including that mtDNA profiles are not used in criminal databases, the inability to confirm there is a relationship between victims with matching mtDNA profiles, and that DNA profiles of unidentified remains cannot be compared to DNA profiles of known criminals to search for a familial match.

Scientific testing of these remains resumed within the past few years. A hair analysis of the adult victim was performed in an effort to determine what part of the country she had been in during the months preceding her death. The results were inconclusive.

Participants at this presentation will learn that, while a homicide case involving four victims, three of them children, would seem compelling in terms of public interest, unidentified remains are not as noteworthy to the media as cases of missing persons. Efforts to publicize New Hampshire's cold case have been statewide but were not picked up on the national level. While missing persons have families and friends who use the media in an attempt to find their loved ones, unidentified remains have no such advocates.

There are several websites that contain databases for missing persons and unidentified remains and New Hampshire's cold case is listed in some of these, including the National Missing and Unidentified Persons System (NamUs), a national resource for the records of missing persons and unidentified remains. It was originally believed these databases were capable of matching missing person cases to unidentified remains and that the medical examiner's office would be alerted to any possible matches of the New Hampshire victims to missing persons. It was later learned the databases are not capable of making matches and the missing person section of a database must be searched manually in order to find potential matches to unidentified remains.

Unidentified, Remains, Cold

D50 John Doe — Identified Seven Years Later: A NamUs Success Story

Bobbi Jo O'Neal, BSN, 506 Upland Pl, Mount Pleasant, SC 29464; and Suzanne M. Abel, PhD, Charleston Co Coroner's Office, 4050 Bridgeview Dr, Ste 500, Perimeter Center, North Charleston, SC 29405*

After attending this presentation, attendees will learn about the National Missing and Unidentified Persons System (NamUs) and the successful 2012 identification of a John Doe who was found in 2005. At the conclusion of this presentation, attendees will be able to discuss the importance of submitting information from unidentified persons into NamUs.

This presentation will impact the forensic science community by highlighting the need for medical examiners, coroners, and death investigators to input information regarding unidentified human remains into NamUs. This should result in an increased participation of this system, which should then result in an increased success rate of identifying previously unidentified human remains.

The National Institute of Justice (NIJ) reports that the nation's medical examiners and coroners have an estimated 40,000 unidentified human remains cases, the majority of which have been buried or

cremated before being identified. This has been named the greatest mass disaster of our time. To remedy the problem, NIJ developed NamUs, a central reporting system for unidentified human remains that is inclusive, intuitive and open to the public. NamUs is structured to allow searches for matches between missing persons and information on unidentified human remains such as skeletal profiles, dental charts, fingerprints, DNA profiles and unique scene evidence. The database also matches identified unclaimed remains with individuals reported missing within the National Missing Persons database. Those agencies whose population includes high numbers of transient individuals (vacationers, students, migrant workers, etc.) understand that casework often crosses state lines and these groups will benefit from the nationwide approach to NamUs, as highlighted in this presentation.

In 2011, the Charleston County Coroner's Office was awarded grant funds for their "Bones in Boxes" Unidentified Human Remains Project from NIJ's "Using DNA Technology to Identify the Missing" initiative. As a result of those funds, a forensic anthropologist and forensic odontologist were hired to work on cold cases involving unidentified human remains. A case study of a "John Doe" who was found in 2005 in Charleston County will be presented. At that time, investigators used many methods to try to identify the decedent without success. The case was reevaluated in 2011 and a DNA sample was submitted to the University of North Texas for analysis. The DNA profile information was then uploaded into Combines DNA Index System (CODIS) and then into State DNA Identification System (SDIS). It was then entered into National DNA Index System (NDIS), where a positive match was made after comparing the DNA to samples uploaded into the Georgia Bureau of Investigation (GBI) convicted offender DNA database. The lessons learned from this cold case, including policy changes which were implemented in the coroner's office will be discussed. The ensuing investigation, the working relationship with out-of-state agencies to confirm the decedent's identity, and the notification procedure to the legal next of kin will also be discussed.

The Charleston County Coroner's Office has subsequently been entering all data on unidentified human remains and those cases in which the remains have been identified but are unclaimed. The overall results of their grant project, including the number of remains submitted for analysis and inclusion into the NamUs system, the number of remains identified, the number of remains that have since been claimed, and other lessons learned will be discussed.

NamUs, Unidentified Remains, Identification

D51 Forensic Podiatry: Importance of Foot and Footprints in Forensic Casework

Kewal Krishan, PhD, Panjab Univ, Dept of Anthropology, Sector 14, Chandigarh, 160 014, INDIA; and John A. DiMaggio, DPM, 1450 Polaris Ln SW, Bandon, OR 97411-8816*

After attending this presentation, attendees will be exposed to an emerging discipline of forensic science, forensic podiatry, with an emphasis on estimation of stature from foot and footprints, and individual characteristics of footprints.

This presentation will impact the forensic science community by presenting a newer discipline of forensic science called forensic podiatry, which may motivate and inspire young forensic scientists to study this technique.

Forensic podiatry is a comparatively new scientific sub-discipline of forensic science. It is defined as the application of sound and researched podiatric knowledge and experience in forensic investigations, to show the association of an individual with a scene of crime, or to answer any other legal question concerned with the foot or footwear that requires knowledge of the functioning foot. One of the main tasks of forensic podiatrists is to contribute to the establishment of personal identity in forensic investigations. The need to establish the identity of dismembered remains may arise in cases of mass disasters like terrorist attacks, mass murders, transport accidents, tsunamis, floods, and earthquakes. Furthermore, forensic podiatrists help in the analysis of footprints generally recovered at the crime scene.

The human foot has been in the focus for a variety of reasons in the past for detailed study of diabetic feet, for orthopedic reasons, for anatomical purposes, study of feet by foot and shoe industries and Army, and the most important is forensic study of the foot. Now, it has been universally accepted that a mature foot and its impression are not only unique to an individual but also provides highly valuable clues regarding personal identity. Human feet separated from the body are usually recovered at the scene of mass disasters, both man-made and natural. Footprints can be found as a kind of evidence and can be collected from almost all types of crime scenes. A human foot and footprints can provide clues for personal identification in three ways, i.e., by reconstruction of body size (estimation of stature and body weight) from different segments of the foot and footprints, sex determination from dimensions of the foot and footprint, and by individualistic characteristics of the foot and footprints. Estimation of stature from the foot and footprints is based upon the fact that, like other parts of the human body, the foot also has a definite and positive relationship with stature of a person. Estimation of stature is an important parameter in forensic investigation and is considered as one of the "big fours" of forensic anthropology. Stature, age, sex, and ancestry facilitate the narrowing down of the pool of possible victim matches in the forensic investigation process and help in establishing identification of the individual.

The individualistic characteristics like corns, pits, ridges, humps, creases, deformity, an extra toe, etc. can be considered as useful forensic evidences in establishing personal identity. The presentation discusses, with examples, various methods of personal identification (e.g. estimation of stature, from individualistic characteristics) from the foot and footprint with reference to a study of North Indian population.

Forensic Podiatry, Stature Estimation, Individual Character

D52 Problematic and Perspectives of Child Abuse Investigation in Colombia

Carolina Puerto Valdivieso, BA, Calle 147, 99-52 Interior 2, Apt 401, Bogotá, 111161, COLOMBIA*

After attending this presentation, attendees will become familiar with the legal problems of child abuse in Colombia and will understand suggestions for the criminal investigation in these cases.

This presentation will impact the forensic community by describing the difficulty of the legal classification of some behaviors related with child abuse in Colombia. Attendees will also learn about useful research directives in certain cases of maltreatment that include criminal investigative strategies, check lists of data that must be recovered in any child or adolescent maltreatment or abuse case.

Child abuse and maltreatment are defined as a series of deliberate actions and/or omissions that are carried out by adults (parents, relatives, caretakers), or other children or adolescents, that result in physical or emotional damages or the imminent risk of serious damage or death.

Nevertheless, within the Colombian penal code, the child abuse phenomenon is not clearly defined. It is according to the characteristics of each case, as well as the public prosecutor criteria, that a crime can be typified as a personal injury, abortion, kidnapping, torture, human trafficking, sexual assault, sexual abuse, nutritional nonattendance, incest, or domestic violence, among others. This last one is the most frequently used to process the case. An example of this situation is the statistical results emitted by the National Institute of Legal Medicine and Forensic Sciences, which demonstrated that in 2012 there were a considerable number of medical examinations in children and adolescents involving physical injuries within the domestic violence context, sexual forensic examinations in the same population, and autopsies in cases of child or adolescent homicide. Although it can be expected, this information does not emphasize the conditions of the crimes like the specific kind of child abuse, physical evidence related, or behavioral evidence of the aggressor that can be observed in victims.

In the same way, although there are some guides and protocols about forensic medical examination on physical injuries and sexual violence, both in adults and children, there is not any manual to guide

the criminal investigation of child abuse cases. The investigation is restricted to fulfillment of routine activities which do not help provide an integral understanding of the phenomenon, undertake the right judicial decision, and achieve an effective children protection.

Doing a review of the current situation of these cases and analyzing child abuse typology, widely described in scientific and forensic literature, certain directives and checklists within the criminal investigation are suggested in order to emphasize an interdisciplinary work and approach to the victim (family and social structure, socioeconomic context, medical background, stage of development, scholastic performance, etc.), the aggressor (maltreatment antecedents, drug abuse, labor situation, mental condition, educative level, relationships, criminal antecedent, etc.), the crime scene (characteristic of the place, suitable inspection, compilation of evidence, versions given by the victim and the aggressor correspondence, etc.), and other alternative sources of information (documents, professors, neighbors, relatives, civil servants of social services, medical personnel, etc.), applicable in cases of physical abuse, Münchausen by proxy syndrome, shaken baby syndrome, negligence, psychological maltreatment, institutional abuse, sexual violence, and homicide of children.

Child Abuse, Investigation, Checklist

D53 Forensic Analysis of the Mechanisms of Death Used in Homicides Against Women by Their Partner or Ex-Partner (Femicides) Committed in Spain From 1997–2009

Lorente Miguel, PhD, Medicina Legal, Avda. Madrid, 11, Granada, 18012, SPAIN*

After attending this presentation, attendees will be introduced to the concept of Violence Against Women (VAW), a moral violence used by men against women, and how to identify the symptoms and develop strategies to prevent these kind of attacks.

This presentation will impact the forensic science community by raising awareness to common features to help identify cases of violence against women and evaluate them properly and to learn from the results to analyze risk factors and provide remedies for prevention.

Learning Objectives: Violence is usually approached in terms of results. Most of the studies try to establish differences among the distinct types of violence considering the injuries, circumstances around the aggression or the procedures used to commit the attack, but it is not enough to know the real differences among them and how forensic evaluation can help to prevent new aggression.

Violence Against Women (VAW) has different features when compared to other forms of violence. It is a "moral violence" used by men against women, especially in the context of a relationship, and that is constructed under cultural references. It means that there is a part of this violence that is considered "normal" and this feature affects the evolution of this violence, usually increasing the risk of new and more serious aggression and, even, homicide. These features must be known for the forensic exam (to evaluate and to identify and diagnose this type of violence) and to develop strategies to prevent these new possible attacks.

Hypothesis: Motivation and objectives of VAW murderers are different to other types of violence. These differences had to be present in the mechanisms and procedures used to commit the murder, and they have to give us some reference about the element (cognitive and emotional) involved in the crime.

Brief Synopsis of the Content and Summary of the Results: The Judicial Sentences from Spanish Courts and analyzed the different modus operandi used over these last years (1997 to 2009, the last year with available data) was studied. This information is based on the forensic report of the autopsy, and the study has focused around the following indicators:

- Mechanism and instrument used.
- To use a simple mechanism and instrument or more than one (simple or mixed aggression).
- Direct use of hands to kill.
- Degree of violence used during the process of murdering.
- Time of the day when the homicide was committed.

Using these indicators we got different significant conclusions for forensic science and other disciplines related to the assistance, evaluation, and analysis of Gender Based Violence:

- There is not a constant either common pattern in the mechanism of death used by men to kill their partner or ex-partner (women).
- The most common modus operandi is stabbing (in Spain there are many legal limits to access to firearms).
- Depending on the degree of violence, there exist two main groups related to the degree of violence used to commit the homicide: one is related with the number of stabs (stabbing mechanism) and hits (battering mechanism) used, and the other one is related to the use of the hands as a direct instrument to kill (mainly strangulation and suffocation). The analysis shows how the degree has evolved in time, increasing the level of violence during the last years.
- The most violent homicides usually are committed at night. This data suggests that the homicide in VAW is part of an accumulative process that starts before the circumstances that are finished in the murder

The results show that there are elements used in homicides of women within a couple's relationship that can help to identify this specific kind of violence, and that can be used to address and focus the investigation in this direction. This last possibility is very important if it is considered that in often many countries, and sometimes in all countries, these deaths (murders) are presented like suicides or accidents.

The results also give references to identify risk factors related to these murders, and provide some keys to develop strategies of prevention to stop the evolution of violence and the result of murder within relationships with Violence Against Women (VAW).

Statement of the Impact: Most of VAW cases happen within domestic atmosphere without witnesses, and many times it is difficult to investigate the circumstances related to the crime. Knowing some common features can help to identify these cases and to evaluate them properly.

VAW, Homicide, Domestic Violence

D54 Disabilities and Elderly Abuse: A Preliminary Forensic Approach

Sofia L. Frazão, MD, Instituto Nacional de Medicina Legal, Jardim Carrilho Videira, 4035-167, Porto, 4035-167, PORTUGAL; and Teresa Magalhães, MD, PhD, Instituto Nacional de Medicina Legal, Jardim Carrilho Videira, 4050-167, Porto, PORTUGAL*

The goal of this presentation is to raise awareness and to characterize elder abuse in persons with disabilities in Portugal.

This study will impact the forensic science community by promoting an earlier detection and diagnosis of elder abuse and giving better guidance for the implementation of prevention strategies.

The normal process of aging makes elders more vulnerable and fragile, and therefore more prone to poor health than the rest of population. As the dependence increases, demands on family caregivers or trained health or social workers become higher, bringing a huge socio-economic impact and stress to the families, thus facilitating an abusive environment. This fact, associated with physical and/or mental disabilities, increases even more the risk of elderly abuse. Literature studies that approach elderly abuse have only recently started to appear, and thus the association between disabilities and elderly abuse is still in a lead-off period of research. Reported cases of abuse evaluated at forensic medical services constitute only a small part of the real number of cases, but their analysis can bring us important knowledge regarding this problem. Since there are few studies in Portugal concerning this issue, the general aim of the present study is to contribute to a better characterization of elder abuse in persons with disabilities in this country.

A retrospective study was carried out at the National Institute of Legal Medicine and Forensic Sciences in the years 2010–2011 based on the forensic medical reports performed during this period. The selected sample includes alleged victims of abuse, over 64-years-old, and with physical and/or mental disabilities (n=42). A disabled person was considered as one without autonomy and with a permanent impairment rate over 70%. This number corresponds to 7.1% of the total of alleged elderly abuse victims observed at the same place and period.

The majority of the victims were: women (66.7%); retired (95.2%); married (71.4%); with physical disabilities (71.4%; e.g., motor disability), mental disabilities (14.3%; e.g., dementia), or both (14.3%; e.g., neurological disorders due to stroke). Average age was 77.6 years old. Women were mostly abused by their partners (46.4%) and men by their children (50%). The alleged offenders were mainly: males (61.9%); victim's relative (97.6%) – 54.2% victim's children; living with the victims (76.2%). In 19% abuse pointed reason was the offender's abusive alcohol consumption. Most of the reported cases were related with physical abuse (95.2%) consisting in kicking, slapping, punching, and pushing (76.2%). There were no lesions in 38.1% and in 97.6% lesions were mild. The elapsed time since the last offense and the forensic medical evaluation was superior to eight days in 31%. Abuse was recurrent in 59.5% of the cases.

Published data states that abuse is more frequent among people with high levels of dependence compared with older people not so dependent, leading one to consider that the number of cases obtained in this study is clearly underestimated and that they aren´t being detected or are underreported; actually, due to their lack of autonomy, these individuals are unable to disclose abuse, which also impairs their detection. Results corroborate some of the risk factors that are described in literature for victims (female; more than 74-years-old) and for offenders (male; victim's relative—especially children; alcohol misuse). Even without serious lesions (almost 100% of the cases) this kind of violence can have relevant physical and mental health consequences for elderly people, with socio-familial and financial repercussions, which must be considered in future studies. Therefore, it is of utmost importance to implement strategies to protect people with disabilities because this health condition increases both the risk of abuse and of nondisclosure. One of the preventive measures should be the implementation of a mandatory notification by the health care professionals to the competent entities at the time of discharge of physically or mentally impaired persons, since they completely disappear from the social and health services radar. Another measure should be creating temporary residencies for these persons in order to give the caregivers some resting time.

Elder, Abuse, Disability

D55 Combining Human Analysis With Human or Computerized Analysis to Reduce Classification Errors

Barry Cushman, BS, American Polygraph Association, PO Box 8037, Chattanooga, TN 37414; and Frank Horvath, PhD, Ntl Acad for Credibility Assessment, 7540 Pickens Ave, Fort Jackson, SC 29207-6804*

After attending this presentation, attendees will have a better understanding of how forensic analysts might decrease classification errors by complementing human, manual analysis of data with computerized analysis or with a second analysis done blindly by another human analyst. While polygraph data are used here, the concept and application applies to other disciplines that are dependent on human analysis, e.g., fingerprints or tool mark impressions.

This presentation will impact the forensic science community by challenging forensic analysts to investigate how the pairing of analyses increases the accuracy of professional opinions in their respective disciplines.

Introduction: For some time, forensic analysts have recognized the value of having a second analyst review their work. Traditionally, reviewers have served in a quality-assurance capacity and how their conclusions impact error rates is not well known. This study examined how two analyses could be combined to reduce errors.

Method: In this study, polygraph charts from 88 single-issue field polygraph examinations were independently analyzed by 10 human evaluators seeking proficiency certification. In each of these examinations, "ground truth" (i.e., the certainty of the examinee's veracity) had been confirmed by criteria typically used in published studies: 48 deceptive and 40 truthful. Each of the evaluators blind-analyzed the data in each case and made one of three classifications: truthful, deceptive, or inconclusive (unable to decide). An "inconclusive" occurs when the data are either insufficient for proper analysis or when the analyst believes a truthful or deceptive opinion is equally probable. Inconclusives are intended to provide a way to avoid errors and are generally resolved with re-testing and are therefore not counted as errors.

The polygraph data in each case were re-analyzed separately using two commercially available and regularly used computer algorithms for the analysis of polygraph data: White Star 2 and OSS-3. Both algorithms were run from within an updated version of the polygraph software that created the original data (Axciton Computerized Polygraph, version 9.2.0). Each reports the probability of truthfulness or deception. These computerized classifications were individually paired with the human evaluators' classifications. After pairing, the decision was reclassified to "inconclusive" when the two decisions disagreed (i.e., one concluded truthful; the other, deceptive). If the human evaluator did not make a decision of truthfulness or deception (i.e., the classification was inconclusive), the algorithm's classification was used. Otherwise, the human evaluator's classification did not change. Each of the 10 human evaluators' 88 decisions was, in this way, reclassified twice; first by pairing them with the White Star and then with OSS-3 analysis.

The proportion correct and erroneous were totaled for each examiner for each method, i.e., the original (human) classifications and those based on the pairing with each of the two computer algorithms as described above. The data were then analyzed to assess whether there were any differences between the human evaluators' original classifications and the two reclassifications.

Results: Pairing of the human and computer algorithm outcomes resulted in statistically significant decreases in the proportion of errors for truthful or deceptive examines, or both, with both algorithms.

Specifically, the original classifications for the 10 evaluators averaged 87% correct and 13 % errors (excluding inconclusive classifications). The OSS-3 and White Star 2 analyses resulted in 82% correct and 18% errors and 90% correct and 10% errors, respectively. The overall proportions of correct and erroneous OSS-3 and White Star classifications were not significantly different from the averages of the human evaluators. When paired with OSS-3, human classifications averaged 89% correct and 11% errors. When paired with White Star, classifications averaged 95% correct and 5% errors. More simply, errors decreased an average of 21% when paired with OSS-3 and 62% with White Star.

Discussion: This study supports the idea that "two heads are better than one," whether a human evaluator's decision is paired with another (blind) human evaluator or a computer analysis, when the goal is to reduce decision errors. While human analysts were not paired with human analysts, the algorithms appear to represent two average human evaluators, and the results provide support for the premise that when two agree in their conclusions, the likelihood their analyses will yield fewer errors increases.

Blind Analysis, Computer Analysis, Reducing Errors

D56 The "CSI Effect" in a High-Profile Animal Cruelty Prosecution

Randall Lockwood, PhD, 2214 Tulip Dr, Falls Church, VA 22046*

After attending this presentation, attendees will understand the need for better training of police, veterinarians, and animal cruelty investigators in the application of forensic sciences to the investigation and prosecution of animal cruelty.

This presentation will impact the forensic community by helping professionals understand how animal cruelty cases can be weakened by the failure of law enforcement to recognize the seriousness of such crimes, improper application of forensic methods to animal crimes, and slow and inadequate response to crimes in which animals are victims.

Potential penalties for severe animal cruelty have increased substantially in recent years. Extreme animal cruelty can be prosecuted as a felony offense in 48 states. Juries have held investigators to comparably higher standards of forensic evidence in such cases. These expectations often do not reflect the training and resources available to those involved in such investigations. This disconnect can result in unsuccessful prosecutions. A recent case history illustrating these problems and review steps that can be and are being taken to address the issue in agencies around the country is presented.

In 2007, two Baltimore, MD, boys allegedly poured gasoline on a young female pitbull and set her on fire in broad daylight. She succumbed to her injuries several days after the attack. The case of this dog, named "Phoenix" by those who cared for her, sparked international response and led to the formation of a permanent Anti-Animal Abuse Commission as part of the Baltimore City government. The case involved a variety of forms of evidence, including eyewitness testimony, expert testimony from a Baltimore gang specialist, street view video footage, veterinary records, evidence of accelerants on suspect's clothing and the dog's collar, and more. However, much of the investigation was delayed or did not follow accepted protocols of evidence collection, storage, chain of custody, and analysis due to the lack of resources and lack of police and veterinary experience in dealing with forensic evidence in criminal cases involving animal cruelty. Potentially significant evidence was either ignored or mishandled. The defense was largely based on forensic shortcomings in the investigation. Despite these problems, the initial trial of the suspects ended in an 11-to-1 jury deadlock to convict. A subsequent retrial several months later based on essentially the same evidence resulted in unanimous acquittal. Both suspects were later charged with other crimes committed against people while out on bail, including attempted homicide.

The lessons learned from this case and the implications for the proper application of veterinary forensic sciences to animal abuse investigations will be reviewed. Animals in such cases are both victims and evidence. In most cases, veterinary staff place the highest priority on meeting the victim's medical needs, which can compromise the collection of evidence. However, such interests need not conflict. Likewise, police are often unfamiliar with the evidentiary value of common elements at an animal crime scene, including feces, urine, blood, fur, and trace evidence. Efforts are underway to enhance the training of all professionals involved in animal cruelty investigation to avoid such problems in the future.

CSI Effect, Animal Cruelty, Veterinary Forensics

D57 Use of Canines to Detect Dried Human Blood and Instrumental Methods for the Determination of Odor Profiles

Lauryn DeGreeff, PhD, Florida Int'l Univ, 301 Tingey St SE, Washington, DC 20003; Deanna Snyder, MS, FBI Academy, Oak Ridge Institute for Science and Education, Quantico, VA 22135; Christopher Tipple, PhD, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; Martin Grime, BS, GSS International, Botley Rd Romsey, Hampshire, UNITED KINGDOM; Rex Stockham, MS, FBI Laboratory Federal Bureau of Investigation, Evidence Response Team Unit, Quantico, VA 22135; and Brian Eckenrode, PhD, FBI, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will learn about the principles of odor detection by canines, particularly human blood detection. Attendees will also learn of the volatile organic compounds comprising this odor and the methods for extracting and analyzing these volatiles.

This presentation will impact the forensic science community by expanding the general knowledge base concerning the abilities of canines and their use in support of law enforcement investigative challenges that require trace determinations of the Volatile Organic Compounds (VOCs) that compose the odor of dried blood.

It is widely accepted that canines have an exceptional aptitude for locating objects of interest based on odor. Recently, the first known detector canine trained specifically to locate small quantities of human blood has been utilized to assist crime scene technicians in locating hard-to-find blood spots for subsequent DNA analysis. It was hypothesized that this will be the first research to show, experimentally, that a canine is capable of locating miniscule quantities of human blood.

The capability of the blood detection canine to locate small blood spots of varying ages was evaluated using a canine that had been trained solely on aged blood, and had not been previously tested or exposed to fresh blood. To prepare the samples for evaluation, approximately one mg of blood (two blood drops) was placed onto carpet squares. The blood on the carpet squares was allowed to age in an open environment for a set amount of time. The age of the blood samples used ranged from one to twelve weeks. The canine successfully located all blood samples with no false alerts. This was the first time that the canine's ability to locate extremely small quantities of aged blood was demonstrated in an experimental setting.

In another set of experiments, the ability of the canine to locate fresh, compared to aged-blood was assessed. Two sets of samples containing human blood, aged and fresh, were presented to the canine. The aged set contained fresh blood spiked onto gauze pads and aged for two weeks prior to testing. The fresh set contained fresh blood spiked onto gauze pads within two hours of testing. The different gauze pads were placed in perforated cans for the canine to search. The canine responded positively to the aged blood samples, but did not show interest in the fresh blood. This indicates a change in odor profile from fresh to aged (decomposed) blood.

For the instrumental analysis of the odor profile of dried human blood of various ages, blood was drawn from three human subjects, placed in open glass vials, and allowed to age for a given amount of time before analysis. The headspace was extracted using Solid Phase Microextraction (SPME) and was analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). The resulting odor profiles for each aged samples were compared. A unique group of VOCs were present in only the fresh sample, and there was a distinct change in odor signature from fresh blood to decomposed blood, occurring around Day 1 and Day 2. The VOCs detected on the first day represent the odor of fresh blood, while compounds detected after Day 1 represent the compounds that have evolved due to decomposition of the blood material, and the older samples show a continual change as the decomposition of the blood progresses.

In additional experiments, the odor signatures of dried human blood collected using several extraction methods in addition to SPME were

compared. Extraction methods included SPME with various fiber types, dynamic headspace sampling onto a sorbent tube and activated charcoal sampling. The extraction methods were compared based both on the compounds in the odor profiles as well as their precision. Based on the VOCs identified, it was observed that the extraction techniques do not necessarily yield similar results, yet instead may be considered complimentary extraction methods. To gain a better understanding of which of these compounds might be recognized by blood-specific canines, mixtures of compounds based on the odor profiles determined by each extraction method were created and presented to the blood detection canine in order to observe whether the canine would elicit a similar response to the selected blood VOC mixtures as to the actual blood.

Canines, VOCs, Blood

D58 Development of Latent Fingerprints on Brass Cartridge Casings: Survival of the Firing Process and Impact of Latent Print Development Using Acidified Hydrogen Peroxide on Forensic Firearms Examinations

Lomiesha Paul, Albany State Univ, 504 College Dr, Albany, GA 31705; Henry Swofford, BS, 4930 N 31st St, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High St, Sharpsburg, GA 30277*

After attending this presentation, attendees will gain a better understanding of how often latent fingerprints deposited on brass cartridges survive the firing process and the extent to which latent print processing using acidified hydrogen peroxide interferes with forensic firearms examination.

This presentation will impact the forensic science community by demonstrating the survivability of latent fingerprints on brass cartridge cases after firing and discussing the extent to which latent print processing using acidified hydrogen peroxide interferes with forensic firearms examination.

Latent fingerprints developed on fired cartridge cases may serve as key pieces of evidence during forensic investigations; however, the success of developing latent fingerprints on fired cartridge cases has been a challenge for investigators due to the nature of the firing process. When fingerprints are placed on cartridge cases prior to or while loading of the weapon, there is a high probability they are destroyed due to the extreme temperatures and abrasive forces caused by the firing process. Despite these odds, other researchers have demonstrated that fingerprints, on occasion, do survive the firing process. Several methods for developing latent fingerprints on brass cartridge cases are available, which include cyanoacrylate ester fuming followed by Rhodamine 6G (CA/R6G) fluorescent dye stain and Acidified Hydrogen Peroxide (AHP).

While the majority of previous research has focused on identifying various techniques to develop latent fingerprints, very little research has evaluated the down-range effects of the development techniques to forensic firearm examinations. This is of particular interest with AHP since it is an irreversible reaction having the potential to corrode the brass and negatively interfere with the various impressions linking that cartridge case back to the weapon from which it was fired. The present study is separated into two phases. Phase I examines the survivability of latent fingerprints through the firing process, evaluates the development technique (CA/R6G, AHP, or CA/R6G-AHP) yielding the highest number of latent fingerprint impressions after firing, and the processing time required to develop fingerprints using AHP. Phase II examines whether and if so, the extent to which AHP may interfere with forensic firearm examinations at various processing durations.

For Phase I, the results indicate latent fingerprints deposited using the latent print matrix standards (both amino and eccrine) did survive the firing process; however, no latent prints deposited using the natural fingerprint matrix obtained from the study participant survived. Second, all three techniques were successful for developing latent fingerprints; however, AHP and CA/R6G-AHP were superior to just CA/R6G alone. Third, a maximum processing duration of 75 seconds should be observed when using AHP.

For Phase II, the results indicate firearms examiners considered all cartridge casings suitable for identification, but were able to differentiate whether a cartridge case had been processed. However, of those cartridge cases which had been processed, there was no statistical relationship between the processing technique nor the duration of processing and the level of degradation observed by the firearms examiners. Additionally, there was no statistical relationship of correlation values obtained using MATLAB of the images of the breach faces for each cartridge case before and after processing. These results warrant further research to better understand how the chemistry of fingerprint matrices, time, and normal environmental degradation of latent print residue will impact latent print development and its survival through the firing process. Additionally, further research is warranted to better understand the extent to which AHP processing may interfere with forensic firearms examinations using other types of ammunition and weapons.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Cyanoacrylate-Ester, Hydrogen Peroxide, Fingerprint

D59 Evaluation and Validation of the SABRE Hand-Held Device for Pre- and Post-Blast Explosive Detection

William Langston, Univ of Mary Washington, 1301 College Ave, Fredericksburg, VA 22401; Roman Aranda, PhD, FBI, 2501 Investigation Pkwy, Quantico, VA 22135; Kimberly A. Perusse, MS, 880 Glenwood Ave, Unit 3570, Atlanta, GA 30316; and James J. Harrell, BS, Lawrence A. Presley, MS, and Candice Bridge, PhD, USACIL, 4930 N. 31st St, Forest Park, GA 30297*

After attending the presentation, attendees will have an understanding for the use of an ion-mobility instrument in the detection of explosives and non-explosives.

The presentation will impact the forensic science community by providing a quick and easy technique for the detection and differentiation of explosives and possible false positive triggers.

Rapid detection of explosives is needed to provide real-time analysis of residues on suspected terrorists, explosive devices, and criminal offenders in military and domestic forensic settings. Instrumentation such as hand-held portable devices exists in the public market which identifies explosives with varying success. With an instrument capable of operating at a high level of accuracy and specification, personnel in theatre or security check points are capable of making informed decisions with minimal time delay. In addition, the device must be ruggedized for many different environmental conditions. The purpose of this study is to evaluate a portable hand-held device, the SABRE 5000, in the rapid identification of pre- and post-blast explosives for the defense and forensic communities. The SABRE 5000 is a recent update of its predecessor, the SABRE 4000, and utilizes Ion Mobility Spectrometry to identify the presence of explosives.

To evaluate the SABRE 5000 was conducted for pre- and post-blast explosives. For pre-blast explosives, 1,3,5-trinitroperhydro-1,3,5-triazine (RDX), Trinitrotoluene (TNT), Pentaerythritol Tetranitrate (PETN), Ammonium Nitrate (AN), and Potassium Nitrate (PN), samples were created in methanol at several concentrations from 1 ppb – 1000 ppm. Each sample at each concentration was analyzed in triplicate on the SABRE 5000 to determine its limit of detection for each explosive. Type I (false positive) and Type II (false negative) errors were calculated for each explosive as well as the sensitivity and specificity for the instrument.

In order to test for post-blast explosive samples, a test explosive consisting of an 8 gram mixture of a 60:40 TNT:PETN booster was carried out in two 55 gallon steel drums filled with saltwater. The

detonations were carried out at the surface level of the saltwater and submerged half-way below the surface. Various types of witness plates (i.e., metal plates, cardboard, aluminum foil, etc.) were included to simulate a water vessel that was attacked in a saltwater area. This would allow for analysis of PETN and TNT in this sort of environment. Samples were collected from the water surface, the water at the bottom of the water cavity, and various witness plates.

The instrument's effectiveness as a real-time analyzer was assessed using a Receiver Operating Characteristic (ROC) analysis, the area under the ROC curve, and the likelihood ratio based on the slope of the curve produced. The analysis provides a set of thresholds for a variety of explosives, such as TNT, PETN, RDX, and other nitrate salt-based explosives, thereby allowing a confidence level to be set for each explosive. The ease of use, portability, effectiveness, and durability of the IMS was assessed in this project. Explosive samples, particularly the post-blast samples, analyzed by the SABRE 5000 were verified using a gas chromatograph-mass spectrometer (GC/MS) to ensure accuracy of results. This validation study will attempt to show whether the SABRE 5000 is ready to be employed for use at airports, border patrol, as well as in theatres.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

IMS, Post-Blast Analysis, Explosives

D60 Evaluation of Ambient Pressure Ionization Mass Spectrometry Techniques for Routine Analysis of Explosives

Edward Sisco, BS, 6819 Old Waterloo Rd, Apt 1035, Elkridge, MD 21075; Jeffrey H. Dake, MSFS, 4930 N 31st St, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High St, Sharpsburg, GA 30277*

After attending this presentation, attendees will be able to identify several of the most common Ambient Pressure Ionization Mass Spectrometry (API-MS) techniques, and more specifically, their capabilities and practicalities for routine trace explosives analysis. Ease of analysis, limits of detections, and comparisons with techniques currently being used in casework will be discussed.

This presentation will impact the forensic science community by providing the forensic science community with a head-to-head comparison of API-MS techniques with current analytical techniques for trace explosives analysis. The analytical techniques which are commonly utilized in trace explosives analysis include: GC/MS, CI-GC/MS, and HPLC. All three of these techniques require sample extraction and lengthy sample runs. API-MS techniques, however, offer the ability to analyze a sample in just seconds and, in some circumstances, without sample preparation at all. Furthermore, initial studies have shown API-MS techniques to be as or more sensitive than the current analytical techniques applied to explosives analyses.

API-MS is a fairly new and rapidly evolving area of mass spectrometry. Since the development and publication on the Desorbtive Electrospray Ionization (DESI) source in 2006, numerous variations have been developed. Within the API-MS family there are several different applied principles off of which the techniques are based. Techniques such as DESI and sonic spray ionization take advantage of a charged solvent spray to bombard a sample and generate characteristic ions. Other techniques, such as Direct Analysis In Real Time (DART®) and Low Temperature Plasma (LTP), induce ionization via interaction between the sample and a plasma. A final group of API-MS sources utilizes lasers to ionize samples and includes methods such as Laser Ablation Electrospray Ionization (LAESI). Since there are different mechanisms being utilized in each of these categories of techniques, it is important to understand the benefits and drawbacks each method provides.

While a number of different studies have looked into the individual techniques for explosives analysis, this study provides a head-to-head comparison of several of these techniques including DART®, DESI, and LTP. In this study over ten explosives are analyzed from a number of different classes including nitroaromatics, cyclic nitros, straight-chain nitros, and peroxides. Using standards of known concentrations, optimized methods for analysis were developed for the API-MS techniques and compared to documented methods for CI-GC/MS and HPLC, which are currently employed in casework. In addition, limits of detection of the explosives were determined and compared. To date, it has been shown that limits of detection for analysis by DART® have been up to two orders of magnitude more sensitive than CI-GC/MS. Furthermore, the API-MS sources allow for the analysis and differentiation of peroxide explosives, which could not be accomplished using current techniques. Additional portions of this study examine the effects of different sample substrates on analysis, and the addition of dopants to create adducts and increase sensitivity. In the case of DART®, the presence of acetone has been shown to increase the sensitivity for RDX and similar compounds with no deleterious effects on the sensitivity to other explosives. The results of this study have led to the development and implementation of a method of analysis for trace explosives using DART®-MS at the USACIL. Additionally, this study will prove the viability of API-MS techniques as a screening technique for trace explosives analysis in criminal investigations.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Explosive Analysis, API-MS, Chemical Analysis

D61 Investigating Forensic Science Laboratory as an Undergraduate Student

Gina M. Ammerman, MS, 402 N Blackford St, LD 326, Indianapolis, IN 46202*

After attending this presentation, attendees will: (1) learn basic laboratory exercises that can be used in an introductory forensic science laboratory college course; (2) be able to teach students simple methods used to analyze a variety of forensic evidence; and, (3) understand the comparison of students' learning objectives throughout the course from day one to the final exam.

This presentation will impact the forensic community by showing specific laboratory exercises being developed and offered to students in undergraduate forensic science programs and courses.

With all the popular criminal investigation shows on television, most universities have seen an increase in interest of forensic science among students. Because of this increased interest in college students to pursue a degree in forensic science, many universities have either started to offer a series of forensic courses, develop a minor in forensic science within another degree, or created an entire forensic science program. Whichever the case, students come into these types of courses and programs with a media understanding of what forensic science is. This sometimes results in students changing their viewpoint on what forensic science really is and if this type of career is the right choice for them. Universities with forensic science programs have realized that being an accredited program is an important aspect for incoming freshman and the surrounding forensic community. Ensuring all forensic science degrees offer the same type of coursework is reassuring for crime laboratory directors and the students. Over the past year, nine universities in the United States received Forensic Science Education Programs Accreditation Commission (FEPAC) accreditation bringing the total to 38 accredited programs. FEPAC guidelines do not require forensic laboratory coursework until students are well advanced in their studies, such as 300 or 400 level courses. General science introductory courses are required and it is assumed that students will gain a basic laboratory experience. The addition of an introductory forensic laboratory course will aid in the student basic knowledge and understanding of the role of the forensic scientist in the criminal justice system. The ability to have students be able to perform hands on laboratory exercises at an introductory level will help them better understand how forensic evidence is analyzed in a laboratory. This

would be a stand-alone laboratory course with no congruent lecture. This will allow students to focus on the science behind the forensic science. All types of evidence would be analyzed at a very basic level, including crime scene investigation, pattern recognition, physical matches, impression comparison, serology, blood spatter, DNA analysis, chemical examination with explosives, illicit drugs, and inks, as well as trace evidence with hair and fiber examinations. Current laboratory manuals are available, however, offer a more advanced examination of these types of evidence using instrumentation or needing to have an advanced knowledge of microscopy techniques. Development of a more basic forensic laboratory manual with exercises that are simple with no need of instrumental knowledge is needed. This will satisfy the need for students to engage in a forensic laboratory learning how forensic scientists identify, characterize, individualize, and compare evidence. Being at a more basic level, students will not need to have background knowledge of chemistry and biology to enroll in the course. All types of students will be able to participate in a basic general forensic science laboratory course and gain the same understanding and knowledge about what forensic science really is all about. Students will be surveyed at the beginning of the course about their background, including major and previously completed science courses and laboratories. Before and after each individual laboratory exercise, students will be questioned on the topic. This will show the increase in understanding of forensic laboratory analysis for each type of evidence. At the end of the course, students will be given a version of the introductory to forensic science lecture final; this will then be compared to the students only in the lecture format to discover if the same knowledge is attained on the material whether is a lecture setting or laboratory stand-alone course.

Forensic Education, Laboratory Exercises, Undergraduates

D62 The Need for Background Investigations of Forensic Students

Mark Bowman, PhD, 5400 Ramsey St, Fayetteville, NC 28311*

After attending this presentation, attendees will become aware of the widespread lack of vetting of forensic students in the United States. Attendees also will be aware of the opinions of forensic educators concerning requiring background investigations of forensic students prior to participation in their forensic education programs.

This presentation will impact the forensic science community by preparing students for forensic careers with the expectations that these students are required to meet less-stringent entrance standards than other criminal justice professionals and other client-centered professions.

Two-year, four-year, and graduate programs in forensic science have proliferated in the last decade. The Bureau of Labor Statistics predicts a 19% growth in the forensic science technician occupation between 2010 and 2020. Growth in demand is likely to stimulate additional growth of forensic science programs as universities and colleges struggle to increase enrollment. The National Academy of Sciences has called for standardizing and strengthening forensic science education programs in America. Forensic science programs can be no stronger than the individuals who are educated in those programs. The National Institute of Justice guidelines concerning qualifications for a career in forensic science indicate that entrants into the profession are likely to be required to meet the same background checks as law enforcement officers. The Forensic Science Education Programs Accreditation Commission (FEPAC) standards require that accredited forensic science programs inform students that they are likely to be required to undergo the same type of background check as would a law enforcement applicant.

Some associate and baccalaureate and many post-baccalaureate professional education programs require some form of background investigation of their student participants. Most of these programs educate for professions that deliver some form of client service, such as social work, nursing, pharmacology, etc. and require client contact during the educational program. The underlying assumption operative in these vetting requirements is that by virtue of participation in the education program, the student will assume a role in which the student could potentially harm others. While client contact is uncommon in forensic education programs by virtue of the student's participation in the forensic education program, the student develops specialized knowledge that would enable the student to potentially cause great harm with that knowledge.

Voluntary basic law enforcement education programs, in which students are not sponsored by a law enforcement organization, are available in community colleges of many states. Students in those programs typically complete all the requirements for initial entry into the law enforcement profession when hired by a law enforcement organization. Some of the content in those programs provides education and training in law enforcement techniques that are typically shielded from public disclosure laws. Those programs require various forms of background investigation of prospective students.

An online survey of forensic educators with two- and four-year colleges and universities was conducted. The sample frame for the survey was those undergraduate forensic education programs in the United States that are listed on the American Academy of Forensic Sciences website. Most respondents were directors of baccalaureate forensic education programs in public institutions. Almost all respondents reported that their institutions informed prospective forensic students that they would likely be required to undergo a background investigation similar to that used for screening law enforcement applicants. A majority of respondents agreed that their forensic students were aware of disqualifiers commonly used for screening law enforcement applicants. The only form of background investigation used by only a few of those institutions was a requirement for prospective students to provide letters of reference. Almost all respondents either had no opinion or disagreed with any required form of background investigation for prospective forensic students except a requirement for letters of reference. Almost half of the respondents agreed that undergoing a background investigation would help forensic students learn about their future professional and personal ethical obligations than would learning in the classroom about those standards.

Forensic, Student, Background

D63 Transformation: Leading Change and the Roles of the Advanced Practice Forensic Nurse

L. Kathleen Sekula, PhD, Duquesne Univ, 600 Forbes Ave, Pittsburgh, PA 15282; and Joyce P. Williams, DNP*, 10809 Stansfield Rd, Randallstown, MD 21133*

The goals of this presentation are to demonstrate the roles of the advanced practice forensic nurse, provide examples of the various settings where the forensic nurse practices, describe advancements in forensic nursing education, and explore or demonstrate how interdisciplinary collaboration enhances outcomes in forensic settings.

This presentation will impact the forensic science community by demonstrating how nurses work in the collaborative role of a forensic nurse in the multidisciplinary investigative team. They provide insight as experts discriminating between intentional and unintentional injury in individuals and connect appropriate intervention models in clinical situations.

Injury continues to lead in cause of death and disability significantly impacting health care utilization and costs. Historically, medical forensic work was rooted in medical examiners in Europe, with forensic nursing beginning in the United Kingdom in psychiatric and correctional facilities. Expansion spread to North America and Australia in the roles of sexual assault nurse examiners and death investigators through on-the-job training and certificate programs supplementing basic coursework. Forensic nursing education today endorses the theoretical and scientific approach to injury analysis ascribing that intentional injuries are preventable, are predictable, and can be explained through surveillance data collection, syndromic surveillance, and modeling defining the

characteristics putting people at risk in order to optimize interventions with optimal outcomes.

In 2008, The Robert Wood Johnson Foundation (RWJF) and the Institute of Medicine (IOM) launched a two-year initiative to respond to the need to assess and transform the nursing profession with the purpose of producing a report that would make recommendations for an action-oriented blueprint for the future of nursing. Four key messages were noted throughout the deliberations culminating in the Institute of Medicine's (IOM) Report, "*The Future of Nursing: Leading Change, Advancing Health"* released in 2010. The committee developed four key messages:

1. Nurses should practice to the full extent of their education and training.
2. Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.
3. Nurses should be full partners, with physicians and other health care professionals, in redesigning health care in the United States.
4. Effective workforce planning and policy making require better data collection and an improved information infrastructure (IOM).

Forensic nurses have established their place as experts through advanced education, rigorously conducting research, translating evidence-based principles to patient care, and finally, inter-professional collaboration as members of multidisciplinary teams. Expansion of forensic nurse roles is further enhanced by the broad expertise of clinical nurse specialists such as pediatric and psychiatric nurse practitioners, consultants, researchers, and educators. Universities proactively have heeded the call to attain parity with other professions in additional to expansion of existing programs addressing the IOM Report and the National Academy of Sciences Report, "*Strengthening Forensic Science in the United States: A Path Forward*."

Advanced education prepares forensic nurses to practice as: consultants to law practices, death investigators who may also serve on fatality review teams, child abuse and elder abuse experts, correctional specialists, forensic trauma practitioners, disaster responders for the living and identification team members for the dead, critical incident stress debrief team members, and forensic psychiatric clinicians, to name a few. Each of these roles requires an understanding of theory, scientific inquiry, applied physical science, biomechanics, and crime scene and evidence collection. Core competencies essential to practice provide the ability to describe and identify injury, access, interpret, use, and synthesize violence data, design and implement prevention activities, and manage injury prevention programs. Researchers and educators develop and disseminate information related to injury risk to the community, other professionals, key policy makers, and stimulate change through policy, enforcement, and education.

Role development of forensic nurses has grown through university curricula for the advanced practice clinician. Their work with victims, perpetrators, systems, and providers globally addresses a need where violence prevention models can impact outcomes in the reduction of violence.

Inter-Professional, Advanced Practice, Forensic Nurse

D64 No Family Left Alone: The Family Assistance Unit Within the Harris County Institute of Forensic Sciences

Bethany L. Bless, MS, and Amanda Haacker, LMSW, Harris Co Institute of Forensic Sciences, 1885 Old Spanish Trl, Houston, TX 77054*

After attending this presentation, attendees will be familiar with the current role of the Harris County Institute of Forensic Science as it pertains to family assistance. The recently implemented Family Assistance Unit will be described and current responsibilities of the program will be explained. Future goals for family assistance will also be expressed. This presentation will highlight the Harris County Institute of Forensic Sciences (HCIFS) development of the Family Assistance Unit and attempt to illustrate the need for improved family assistance services within all Medical Examiner's Systems.

This presentation will impact the forensic science community by contributing to understanding the challenges in assisting grieving family members and identifying the need for a specialized program to assist with family assistance services within medical examiner and coroner jurisdictions.

In January 2012, the Harris County Institute of Forensic Sciences initiated the Family Assistance Unit with the addition of a grant-funded Victim Assistance Specialist position. This unit functions to bridge the gap between medicolegal death investigation services and family assistance by providing support services and community resources to the surviving family members. These services include assisting the family on the scene, acute grief counseling, referrals to non-profit social service organizations, and notifications of death. As a grief counseling professional, the Victim Assistance Specialist is able to offer compassionate support, active listening, and identify appropriate resources for them throughout the grieving process. Having a single point of contact for the family members within our large multi-division agency allows for continuity of information regarding the status of the case.

The act of informing family members of a death requires a responsible, well-trained, and sensitive individual who is able to cope with this mutually traumatizing experience. Family members of deceased victims have a wide range of needs and reactions to the sudden and untimely death of their loved ones. Consequently, the individuals who deliver the death notifications and the manner in which they carry out this duty factor significantly in the immediate and subsequent grief response experienced by the family. Until recently, Forensic Investigators performed notifications of death via telephone when the family was not able to be notified at a scene or hospital. While in-person notifications are always preferred, time and distance can make this impractical in a jurisdiction as large as Harris County. In March 2012, HCIFS and the Family Assistance Unit entered into a partnership with area chaplaincy organizations to provide in-person notifications of death. The chaplains are trained by the Family Assistance Unit to deliver death notifications with accuracy, sensitivity, and respect for the deceased and their families.

Future goals of the Family Assistance Unit include extending the time frame and number of contacts provided to family for assistance. With the addition of more staffed positions, the Family Assistance Unit will also be able to attend a larger number of death scenes with the Forensic Investigator in order to provide in-person acute grief counseling to the family of the deceased. The Family Assistance Unit is also working to provide workshops to employees of the Institute of Forensic Sciences that will address issues of self care, debriefing, and coping skills.

The Family Assistance Unit within the Harris County Institute of Forensic Sciences is the first of its kind in the United States to offer extended services to families by chaplains and licensed social workers. These professionals add a depth of personal service that is often lacking in the typical scientific medicolegal environment, shifting the focus from management and care of the decedent to that of the surviving family members.

Medical Examiner, Grief, Family Assistance

D65 Camera Phone Photography and AFIS Sufficiency

Justin T. Nguyen, BS, 3248 Wayne Rd, Falls Church, VA 22042; Kinjalba S. Jadeja, BS*, 5221 Brook Rd, Richmond, VA 23227; and Marilyn T. Miller, EdD, VA Commonwealth Univ, 1020 W Main St, No 2017, Box 843079, Richmond, VA 23284-3079*

After attending this presentation attendees will: (1) be introduced to the possibility of camera phones being a viable mode of photograph documentation; (2) understand the limitations and difficulties when using

camera phones; and, (3) learn digital imaging standards followed by SWIGIT and the FBI.

This presentation will impact the forensic science community by adding to the knowledge of fingerprint impression evidence documentation through introducing the idea of using camera phones as a photography device.

Relevancy and validity of camera phone fingerprint impression evidence photography may be possible by testing capabilities of many different camera phones when photographing fingerprint impressions. Digital images must be proven authentic and relevant, which is why standards of operation procedures are often followed during documentation to prevent inadmissibility of evidence.[1] Discussing difficulties with the camera phone photography and reviewing digital imaging guidelines for AFIS sufficiency may help to further understand limitations of camera phones.

This study will add to the knowledge of forensic science and may introduce the possibility of camera phones as a method of fingerprint impression documentation at crime scenes, especially where transient evidence is present. As technology keeps progressing, modern cellular phones become more capable and are used to do things other than phone calls, such as taking good quality photographs. A few examples of cell phones with eight megapixel cameras are the iPhone 4s, Samsung Galaxy II, and the Droid X. The cameras that are in many cellular phones today are capable of high-detailed photographs, but whether or not the amount of detail is acceptable for AFIS database searches was the question of this study.

Camera phones used for the photographs were obtained through faculty, friends, and family. Camera phone megapixels ranged from 1.3Mp to 8Mp and were mounted on a pseudo tri-pod made from a ring stand and clamps. Fingerprints were made on porous, semi-porous, and non-porous surfaces, which were then dusted with black or magnetic powder for enhancement. Photographs were taken while mounted on the pseudo tri-pod and also hand held. When possible, photographs were taken flash on as well as flash off.

The photographs were then sent for AFIS review to Charles Morden, lab director of the Michigan State Police, to be assessed for AFIS sufficiency. Of 16 camera phones, 11 produced photographs that were admissible for AFIS. All the camera phones which were admissible were at least 3Mp and above. The camera phones that produced photographs that were inadmissible for AFIS were 2Mp and below.

Some difficulties or limitations that became apparent during the photography of the fingerprint impressions were camera phones that have no flash, camera phones with flash that drowned out detail, and proportion distortions from hand-held photographs. Camera phones that did not have flash in some instances had a difficult time focusing. Camera phones that did have flash often caused a reflection from the surface of the fingerprint impression to wash out the details of the photograph. The hand-held photographs had distortions that could be seen on the scale of the photograph. This is evidence that the camera was not parallel to the surface at the time the photograph was taken.

Standards for fingerprint impression digital imaging are stated in the guidelines of the National Institute of Standards and Technology as being 500 ppi (NIST 2011), but the standards from the Scientific Work Group Imaging Technology state a 1000 ppi guideline (SWGIT 2010).[2,3] This makes it hard to estimate a value of megapixels that would consistently produce AFIS quality photographs.

AFIS, Fingerprints, Camera Phones

D66 19th-Century Jewish Cemetery in St. Maarten: Historic Facial Approximation Using Modern Technologies as a Doorway for Forensic Cases

Catyana Skory, MFS, 201 SE Sixth St, North Wing, Rm 1799, Fort Lauderdale, FL 33301; Dana Cohen Sprott, MS, 6433 NW 79th Way, Parkland, FL 33067; Jay Haviser, PhD, St. Maarten Archaeological Center, AT Illidge Rd, No 117, Madame Estate, NETHERLANDS ANTILLES; Anthony B. Falsetti, PhD*, ICMP, Alipasina 45A, Sarajevo, 71000, BOSNIA-HERZEGOVINA; Christopher Crain, MS, College of William and Mary, Anthropology Dept, 540 Landrum Dr, Williamsburg, VA 23187-8795; Lidia Epp, MS, College of William and Mary, Biology Dept, 540 Landrum Dr, Williamsburg, VA 23185; Mark Kemper, BS, 5803 Breckenridge Pkwy, Ste D, Tampa, FL 33610; and Fernando Gajate, 2601 W. Broward Blvd., Fort Lauderdale, FL 33312*

After attending this presentation, attendees will better understand the capabilities of modern facial reconstruction technology, as demonstrated utilizing a historic case example.

This presentation will impact the forensic science community by illustrating the results of working with multidisciplinary techniques and technology that lead to the ability to create modern 3D printed models. It will also help educate the forensic community about the current and future uses of 3D scanning and full-model 3D printing.

Facial approximations (reconstructions) are often used for medicolegal reasons, but they can also illuminate and give life to historic characters that in turn give rise to placement of historic communities in an appropriate context. Historians concur that the Isla de San Martin was discovered by Christopher Columbus on November 11, 1493 and claimed the island for Spain. For all intents and purposes, primarily Dutch and French settlers populated the Island of St. Maarten in the 1630s as Spain did not develop the island and allocated its resources elsewhere. The extent of the population of Jewish settlers was relatively unknown until the discovery of a Jewish cemetery. Historic research, anthropological methods, and, ultimately, a facial reconstruction give a face to one of the undocumented Jewish men buried at the forgotten cemetery location, and thus sheds new light on the contributions of this community to the islands economic and cultural development.

In 2010, a Jewish cemetery was discovered when research for other historical purposes was being performed. The discovery of a Jewish cemetery that was sold by the government and covered with residential houses was made. The Saint Maarten Archaeological Center (SIMARC) found remains of a decedent intact. A sample of dentition was sent to the College of William and Mary where a mitochondrial DNA analysis was performed. The remains were determined to be from the haplotype group U of Sephardic Jewish ancestry.

After an anthropological study that produced a biological profile, a facial reconstruction was made by creating a replica of the skull with photographs and measurements from the actual skull. A replica of the skull was created using silicone mold-making methods. With the replica of the skull a facial reconstruction was made with clay. State-of-the-art 3D scanning services were then donated by Engineering and Manufacturing Services (EMS), Inc. to 3D scan the reconstruction and then create a 3D resin print out of the reconstruction for museum use. A durable reconstruction was made to be placed for display at the Philipsburg Jubilee Library in Philipsburg, St. Maarten.

Ground Penetrating Radar (GPR) Systems were also used to map out the potential sites of the cemetery on nearby grounds to assist in the culmination of the documentation of the Jewish history in St. Maarten.

The ability to streamline the data using familiar methods in conjunction with modern technology has given the historical skeleton a proper placement in the community's history. These techniques demonstrate the positive results that international collaborative efforts could produce in forensic cases in the future. Issues such as preservation of chain of custody, release of materials, and other procedural concerns can be mitigated, as the original material may not ever need to leave its current locale.

Facial Approximation, 3D Laser Scanning, Historic Archaeology

D67 A Case of Manganese-Induced Parkinsonism: The Need for Safety in the Workplace

Laura Panata, MD, Via del Giochetto, Perugia, 06126, ITALY; Massimo Lancia, MD*, Via Del Giochetto, SNC, Perugia, 05100, ITALY; Federica Conforti, MD*, Via G. Valadier 11/A, Spoleto, 06049, ITALY; Valentina Rosati, MD, Via del Giochetto, Perugia, 06126, ITALY; Enrico Mei, MD, Piazza San Giovanni, Laterano 4, Roma, 00184, ITALY; Riccardo Rossi, MD, Largo Francesco Vito 1, Rome, ITALY; and Mauro Bacci, MD, Via del Giochetto. SNC, Perugia, 06126, ITALY*

Occupational exposure to manganese and the need for medical management of manganese-associated toxicity are well-established. After attending this presentation, attendees will understanding how both remain problematic in industrial settings.

This presentation will impact the forensic science community by illustrating the need to improve security rules in workplaces and to regularly inspect workplace healthiness in order to avoid possible exposure to toxic substances.

The case involved a welder who developed Manganese-Induced Parkinsonism after being exposed for twenty-six years. The welder worked in the steel industry, from the age of fifteen to forty-one years. His duties included arc and gas welding, using manganese-containing electrodes. This activity emitted welding fumes containing high levels of manganese.

At the age of thirty-six, the welder began to show extra-pyramidal rigidity, balance dysfunction, tremor at rest, bradykinesia, symmetric impairment, amimia, and "coq au pied."

Subsequently, psychiatric disorders, including major depression and manic depression-psychosis also appeared.

The welder underwent several clinical and instrumental examinations, including MRI brain scans, that indicated T1-weighted hyperintensive signal in the globus pallidus, bilateral.

These results, atypical of idiopathic Parkinson's Disease (PD), in association with the young age of the patient and his working activity, alerted the suspicion of Manganese-Induced Parkinsonism. Therefore, the welder had blood and urine tests which revealed high levels of manganese, confirming the work-related exposure.[1-6]

Instrumental research and laboratory tests, supported by clinical findings and circumstantial data, were essential to clarify the cause of extra-pyramidal symptoms.

Manganese is a heavy metal widely distributed in the environment by wind erosion and the manufacturing process. More than 90% is utilized in the manufacture of steel: it is alloyed with steel to increase strength, hardness, wear resistance, and with other metals to form highly ferromagnetic materials.

Manganese compounds are used as coloring, catalysts, oxidizers, and antiseptics. In biology, manganese is a trace element, a co-factor for a large variety of enzymes with many functions.[1,3,6]

Occupational exposure generally occurs by inhalation, then it is carried by the bloodstream to high-metabolism rate organs. Manganese half-life is approximately between 40 and 400 days and it is eliminated through fecal and bilious channels, a tiny amount by the urinary tract.

Toxic effects of manganese are related to its neurotropism; however, the basis for the selective neurotoxicity of manganese remains incompletely understood. It causes neuronal injury, especially in the globus pallidus, and also in other basal ganglia structures such as caudate and putamen, less frequently in the substantia nigra.

It primarily interferes with dopamine biology (the primary cellular energy metabolism), decreasing its receptors levels.[1,3,5,6]

An acute manganese-related disease is the metal-fume fever, resulting from inhalation of volatile metal oxides produced during welding or cutting of metal materials. The symptoms are generally nonspecific flu-like complaints including fever, fatigue, and muscle ache. Symptoms are self-limiting and typically resolved within 24 hours.[1,7,8]

Chronic manganese exposure produces an excessive accumulation of the metal in the brain that results in a neurological syndrome with cognitive, psychiatric, and movement abnormalities. The initial symptoms, manifesting within one to two years after the first exposure, are aspecific. Welders may also present neuropsychiatric disorders, popularly called "manganese madness." Over the long term, manganese-exposed workers exhibit an extrapyramidal syndrome that resembles PD: symptoms include gait disturbance ("coq au pied"), balance dysfunction, symmetric impairment, masked face, relative absence of tremor, grimace, bradykinesia, and muscular rigidity.[1,3,5,6]

MRI brain scans in manganese-intoxicated patients demonstrate a characteristic signal abnormality on T1-weighted studies that are not seen in normal individuals or in patients with PD or other forms of parkinsonism. Instrumental examinations show a hyperintensive signal, particularly in the globus pallidus. Similar changes are noted in the substantia nigra, caudate nucleus, and putamen.[5,6] Diagnosis is based on case history and neurological evaluation: in particular, hyperkinetic movements and the "coq au pied" step give evidence of a Manganese-Induced Parkinsonism rather than PD or Parkinsonism induced by other causes.

Prognosis is generally severe because neurological injuries are progressive and worsening, even after exposure cessation.[1,3,5,6]

In conclusion, this case study demonstrates the need for proactive interventions in order to improve workplace safety, minimizing manganese exposure and, therefore, preventing the onset of Manganese-Induced Parkinsonism. The disease is progressive and disabling, causing social disadvantages, especially tragic in view of the young age of onset.

D68 Misinterpretation and Inconclusive Medicolegal Evaluation Due to False Evidence Obtained From Non-Expert Crime Scene Investigations

Federica Conforti, MD, Univ of Perugia, Via del Giochetto, Perugia, 06126, ITALY; Massimo Lancia, MD*, Univ of Perugia, Via Del Giochetto, SNC, Perugia, 05100, ITALY; Laura Panata, MD*, Univ of Perugia, Via del Giochetto, Perugia, 06126, ITALY; Marco Caccianiga, PhD, Università di Milano, Via Celoria, 26, Milan, 20133, ITALY; Gualtiero Gualtieri, MD, Univ of Perugia, Via del Giochetto, Perugia, 06126, ITALY; and Mauro Bacci, MD, Univ of Perugia, Via del Giochetto, SNC, Perugia, 06126, ITALY*

After attending this presentation, attendees will understand a criminal case in which a crime scene analysis, carried out by investigators without specific knowledge of the potentials offered by forensic botany, contributed to the loss of major probatory elements.

This presentation will impact the forensic science community by exposing the lack of a quality control system at crime scenes and to start a debate about the need to train specialists to ensure complete accuracy at the crime scene.

The dead body of a young woman was found on the sofa in her house in May 2012. Considering the lack of traumatic lesions, sudden death or death due to illicit drugs was hypothesized.

After a brief crime scene investigation, the body was transported to the Section of Legal Medicine for autopsy.

Death occurred due to heroin and cocaine overdose, as the toxicological analysis demonstrated. On the subjects clothes and inside the oral vestibule, the examiners found some botanical materials, identified by the botanical laboratory as dried flowers and perulae of *Laurus nobilis* and as ovary of *Wisteria sinensis.*[1,2] This evidence, along with some small nasal and forehead contusive lesions, suggested a fall in the external environment and successive shifting of the body by another person. Since the transfer of illicit drugs and death following another crime are two separate offenses in Italy, in overdose cases this behavior is often carried out to disguise the crime.

Therefore, a second crime scene analysis was performed. Examination of the garden revealed the presence of a *Laurus nobilis* and *Wisteria sinensis* trees and that the porch pavement was covered in flowers and fruits of these species (association between the victim and the scene).

Police officers stated that other clues, such as the woman's mobile phone, a beer bottle on the porch, and the strange position of the woman's body on the sofa (the body was covered by a blanket but her T-shirt was partially raised) indicated a secondary shifting.

However, they reported that the sheet used by undertakers to wrap the body was previously placed on the porch pavement. The highly probable contamination by plant remains occurred during such operation made the evidence collected on the body almost useless, as it could not be discriminated from the successive contamination. Thus, highly informative elements could not be taken into account.

This case is a serious example of how essential probatory elements can be damaged by non-properly trained investigators, lacking specific knowledge of the potentialities of various forensic sciences.

Although over the last century the forensic science community focused its attention especially on technological innovations, quality control systems, and accreditation of forensic laboratories, in recent years there is more interest in crime scene investigation as the pivot of the entire forensic examination and detective work.

Crime scene analysis is crucial to shelter the scene and to examine, assess, interpret, record, and collect physical evidence for court purposes, but also to direct the subsequent investigations, to establish priorities, and allocation of human and economic resources.[3,4]

Therefore, crime scene investigation can be considered a central part of forensic science, although not truly scientific, and not simply a technical discipline.[5,6]

However, in spite of the elaboration of a great number of procedural protocols, aimed at unifying the operative procedures and guaranteeing an objective approach to the scene, crime scene investigations are still far from a standardized quality control system and from a uniform organization (both in different countries and in the same one). Furthermore, performance indicators show an absolute link between outcomes and the knowledge and awareness of each investigator (the examiners tend to see only what they know).[7] For this reason, it seems to be necessary to establish minimal requirements for those attending the crime scene and to set up a new organizational model with a qualified person in charge.[4] This individual requires vast knowledge of the potentialities and limits of various forensic sciences and he/she must be able to carry out a correct and precise triage of the crime scene to identify its complexity and to possibly request the help of forensic specialists to ensure maximum quality in the gathering of evidence and in chain of custody.

Quality, Triage, Training

D69 Recovery of Latent Fingerprints After Immersion in Various Aquatic Conditions

Bronwyn E. Devlin, MA, 10629 Timberidge Rd, Fairfax Station, VA 22039*

After attending this presentation, attendees will understand the factors that affect latent fingerprint evidence submerged in a freshwater stream and the differences in latent print quality that can be recovered from various aquatic conditions.

This presentation will impact the forensic science community by providing results from an experiment that took place in a natural setting. There is limited published research on the topic of submerged evidence, and even fewer of these experiments utilize a natural aquatic environment. This presentation will add to the research being carried out in the field of underwater crime scene investigation and evidence preservation by broadening the understanding of how latent fingerprints submerged in water are affected by aquatic conditions such as current velocity, sediment types, and macrophyte interaction (i.e., plants, algae, and aquatic life). In addition, it will provide documented results of the deterioration of latent fingerprint evidence as the amount of time submerged in water increases.

As the use of waterways continues to increase for recreational purposes, so do the incidents of criminals using waterways to dispose of evidence.[1] Although some may believe that items recovered underwater will have no forensic value, this research shows that identifiable fingerprints may still be recovered. An experiment was conducted to establish the value of latent fingerprint evidence that had been submerged in a natural aquatic environment. The two factors analyzed in this study that affect the deterioration rate of latent fingerprints were stream current and length of time submerged. To evaluate these factors, latent fingerprints were deposited on metallic objects simulating the substrate of a knife or gun and submerged in a freshwater stream at locations subject to various powers of current for 24, 48, and 72 hours. After recovery, the items were subjected to cyanoacrylate fuming followed by black powder processing; the prints were lifted with tape and

examined. Each print was evaluated for its individualizing power based on a scoring system. Latent fingerprints subjected to higher current velocity were significantly more deteriorated than prints subjected to little to no current. A decrease in latent fingerprint visualization with longer periods of submersion was also observed.

It is known that the quality of latent fingerprints naturally deteriorate over time and this study supports this conclusion.[2-5] However, descriptions of the deterioration of friction ridge impressions on a metallic substrate submerged in a natural aquatic environment have not been well-documented and an evaluation of the environmental factors has not been thoroughly investigated. Whereas previous studies reported the successful recovery of good to very good quality latent fingerprints after seven days of submergence, this study has shown that after only three days in a natural aquatic environment, friction ridge impressions on a non-porous stainless steel surface were almost completely obliterated.[6] This illustrates the significance of the factors at play in nature. Studies conducted in an aquarium using only tap water, no current, and no macrophyte, or sediment interaction, are likely to produce deceptive results in comparison to studies conducted in a more natural environment.

In conclusion, the results of this study demonstrate the importance of understanding the interactions between latent fingerprints and the various factors of the natural aquatic environment to better aid in criminal investigations and potentially linking evidence to a perpetrator.

Latent Fingerprints, Aquatic, Current Velocity

D70 Determinants of Turnover Intentions, Helping, and Knowledge Sharing in Crime Laboratories

David D. Dawley, PhD, West Virginia Univ, College of Business, Box 6025, Morgantown, WV; and Max M. Houck, PhD, PO Box 6250, Arlington, VA 22206*

After attending this presentation, attendees will have a better understanding of reasons why crime lab workers choose to quit their jobs, gaining insight into managerial tools for reducing turnover and creating a more productive workforce.

This presentation will impact the forensic science community by providing the first known results from a study examining crime lab worker turnover, helping behaviors, and sharing of knowledge.

Forensic scientists are knowledge workers and are a laboratory's single greatest enduring expense. Therefore, it is imperative for forensic managers to find ways to retain employees, share knowledge, and create a cohesive, coherent team perspective. Based on a discussion with a group of FORESIGHT forensic laboratory directors in 2011, four major areas of research interest were identified: (1) reducing employee turnover; (2) increasing employees' helping behaviors with colleagues; (3) knowledge sharing among employees; and, (4) creating and disseminating a strategic vision to all employees.

Helping and knowledge sharing are also known as Organizational Citizenship Behaviors (OCBs). Job satisfaction and embeddedness would help explain turnover intentions and OCBs is surmised. It is very important to note that these two job-related constructs are very different. Whereas job satisfaction is the degree to which an employee is content with his/her job, job embeddedness refers to the psychological, social, and financial influences on employee retention and behavior. Strategic planning, vision, and employees' understanding of that plan are thought to be an important part of any organization's performance. Therefore, we would expect that employee understanding of the strategic vision would be positively associated with job satisfaction and embeddedness.

A 2000 review of the academic literature spanning the prior thirty years found job satisfaction to be the strongest predictor of employee turnover and desirable OCBs. More recently, researchers have found that employee embeddedness is an important predictor of turnover and OCBs, after controlling for job satisfaction. Therefore, we hypothesize that two direct predictor variables of turnover intentions and OCBs would be job satisfaction and embeddedness.

In addition to strategic vision, there are several other determinants of job satisfaction and embeddedness. Characteristics of the job, called work design, should have an effect on the forensic laboratory employee's degree of job satisfaction and embeddedness. Accordingly, we examine the job design attributes of autonomy, accountability, task significance, efficiency, and authentic leadership style. Autonomy refers to the amount of discretion a worker has in making decisions and scheduling tasks. Accountability suggests being held answerable for one's actions. Task significance is the extent to which employees believe their job impacts others' lives. Authentic leadership is a leadership style that subordinates see as motivational, just, transparent, and ethical. The hypothesis is that these attributes (along with strategic vision) will predict job satisfaction and embeddedness, which in turn predict turnover intentions, helping, and knowledge sharing.

Using the areas of research interest, a web-based survey containing all of the aforementioned constructs of interest was conducted. Five hundred and ninety participants from nine forensic labs in the United States and Canada participated in the survey. The statistical technique, structural equations modeling, to test the causality of the relationships discussed thus far was used.

Regarding turnover intentions, it was found that both job satisfaction and embeddedness were significant predictor variables. Job embeddedness was twice as strong as job satisfaction in predicting turnover intention. The same finding held true for predicting knowledge sharing. Job satisfaction was positively associated with helping behaviors.

Strategic vision was the strongest predictor of job embeddedness. Autonomy, accountability, task significance, and leadership style were also significant predictor variables. Autonomy was the strongest predictor of job satisfaction. Strategic vision, accountability, and task significance were also significant predictor variables.

The major findings from this study include the importance of job embeddedness, strategic vision, and autonomy in forensic laboratory employees. These variables, along with accountability, task significance, efficiency, and leadership style are manageable factors. To this end, the forensic laboratory manager offers practical ways to reduce turnover intentions and increase desirable OCBs.

Turnover, Knowledge Sharing, Helping

D71 ICAN and Adolescent Suicide Coroner/Medical Examiner Investigation Procedural Guide Implementation and Evaluation

D72 To Toss Film or Not to Toss Film? That is the Question in Radiography of Occult Fractures in Infants

Natalie A. Pelletier, MHS, Quinnipiac Univ, 275 Mt Carmel Ave, Hamden, CT 06518; Tania Blyth, MHS, Quinnipiac Univ, 275 Mt Carmel Ave, N1-HSC, Hamden, CT 06518; Niall Burke, BSc, and Lorraine Healy, BSc, UCD Belfield, School of Medicine and Medical Science, Health Sciences Centre, Dublin, IRELAND; Gerald J. Conlogue, MHS, Quinnipiac Univ, Diagnostic Imaging Program, 275 Mount Carmel Ave, Hamden, CT 06518; Robert Lombardo, BS, Quinnipiac Univ, 275 Mt. Carmel Ave, Hamden, CT 06518; Bill Hennessy, MHS, Quinnipiac Univ, Diagnostic Imaging Program, Hamden, CT 06518; and Jonathan P McNulty, MSc, UCD Belfield, School of Medicine & Medical Science, Health Sciences Centre, Room A203, Dublin, IRELAND*

After attending this presentation, attendees will have a deeper understanding of key radiographic and technology-related considerations for the imaging of subtle pathology in infants using an animal model, also learning about the most and least appropriate approaches to such radiographic examinations.

This presentation will impact the forensic science community by reviewing traditional approaches to postmortem forensic imaging in infants while suggesting and validating alternate radiographic approaches in such cases.

The value of radiography in forensics is beyond question. However, employing radiography to document occult fractures in infants, less than one year old, can be challenging. In order to clearly visualize these subtle fractures, three factors must be taken into consideration; the focal spot size of the X-ray tube, the kilovoltage peak or kVp selected, and the image receptor.

The present study compared three imaging systems; a standard radiographic unit currently available in clinical settings, a dedicated mammographic unit that was no longer clinically compliant, and an X-ray cabinet unit. The largest focal spot, 0.6 x 1.2mm, was found in general radiography unit and the smallest, 0.1mm, with the cabinet X-ray system. The mammography unit had two focal spot sizes: 0.4mm for non-magnification imaging and 0.1 – 0.2mm when the magnification mode was selected. All images were recorded with either a digital, computed radiography or CR system and on X-ray film specifically intended for mammography. With film as the recording media, 30 – 40kVp was chosen to produce a high-contrast image. The kVp selection of 60 for the CR system was based on the manufacturer's guidelines for the minimum required to stimulate the receptor crystals within the imaging plate. However, in order for a more complete comparison, CR images were also taken at 40kV. The objective of the study was to determine which imaging system demonstrated a transverse fracture on the right third rib of a preserved fetal pig that had a crown-rump measurement of 29cm. A Visual Grading Analysis (VGA) methodology was employed to evaluate a total of 12 images and all images were reviewed by a radiologist, a radiologist assistant, and a senior radiographer, and compared to a reference image.

The image which scored best in terms of ability to resolve the fracture and related anatomy was acquired using the X-ray cabinet system at 35kVp and recorded on mammography film with a mean Image Quality Score (IQS) of 8.67. This was closely followed by the image acquired at 60kVp using the same combination of mammography film and the X-ray cabinet system (mean IQS = 7.33). However, the image obtained on film with the mammography unit set at 30kVp in the magnification mode clearly demonstrated the fracture despite a lower mean IQS of 1.67. The system receiving the lowest mean IQS was the general radiographic unit combined with mammography fil at 60kVp (mean IQS = -9.33) and 40 kVp (mean IQS = -10.0). Combining the general radiographic unit with CR at 60kVp resulted in a mean IQS of 3.33. Unexpectedly, the same system taken at 40kVp produced an image with similar performance (mean IQS = 5.0) to those acquired on film (mean IQS = 4.33). The manufacturer's recommendation for the higher kVp setting was intended to minimize the dose to the patient. However, in forensic imaging patient dose is not a consideration.

In conclusion, depending on the radiographic equipment that might be available, technical factors can be adjusted to demonstrate occult fractures.

Radiography, Infants, Techniques

D73 Canine Detection and Discrimination of Cadaveric Human Blood

Marcello Rendine, DBA, and Alessandro Bellifemina, BS, Univ of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY; and Irene Riezzo, PhD, and Margherita Neri, MD, PhD, Univ of Foggia, Dept Forensic Pathology, Viale degli Aviatori 1, Foggia, 71100, ITALY*

After attending this presentation, attendees will have a better understanding of how a well-trained detection dog team can maximize the collection of evidence from crime scene and improve investigative efforts

This presentation will impact the forensic science community by providing a variety of benefits to law enforcement regarding the need to improve the performance, reliability, and courtroom defensibility of detection dog teams and their optimized combination with both medical and forensic operators.

This study has determined that trained detection dogs do not alert to generic scent, rather they alert to blood traces, maximizing the location of blood trace evidence in an efficient, cost- and time-effective manner while minimizing the collection of samples not relevant to an investigation.

The scientific and medical evaluation of the crime scene requires a relatively short response time to avoid contamination of the same and, therefore, a well-trained dog allows faster coverage of very large areas of research, preserving any and all possible evidence.

The technique of shaping with positive reinforcements was used to obtain the result of blood scent detection and discrimination.

The goal of this research has been to identify and quantify the minimum mass of cadaveric blood (low concentration) required in order to potentially generate an alert by a detection canine by a *positive predictive value* (PPV).

Field trial experiments to determine canine interest in the observed blood samples were conducted.

The canine detection of blood scent in low concentration is called "*sensitivity.*"

In addition, this study reports the analysis of several potential interference odorant compounds at these blood scent traces in minimum concentration, and the associated percentages of false positive alerts (false PPV).

The canine discrimination of blood scent traces in minimum concentration is called "*specificity.*"

After training the detector canines to the cadaveric blood, a series of field trials are performed to test the canine's *"Limit Of Detection"*

(LOD) for the blood, which is the lowest quantity of a substance that the dog can distinguish from the absence of that substance (blank value).

The limit of detection (LOD) has been determined by performing scent line-ups in which various amounts of blood have been exposed and the lowest concentration of blood for which the canine can still alert have been recorded.

The study demonstrates that canines are generally not using the relatively low volatility parent substances, but instead use characteristics volatile headspace components to accurately locate specimen of blood, with the ability to distinguish between living and deceased human blood, as well as between human and animal blood.

Detection canines are the most common and widely accepted biological detectors due to the ability of canines to quickly and reliably locate the source of an odor to which they are trained.

The results of this study indicate that the well-trained cadaver dog is an outstanding tool for crime scene investigation displaying excellent sensitivity (88%), specificity (97%), and having a positive predictive value (94%), negative predictive value (98%) as well as accuracy (96%).

These recovery rates, ranged between 88% and 98%, indicate that properly trained cadaver dogs can make significant contributions in the location and recovery human cadaveric blood traces.

Canine Detection and Discrimination, Crime Scene, Cadaveric Human Blood

D74 Evaluation of Latent Fingerprint Development Techniques for Metallic Evidence

Cristina H. Hartman, PhD, FBI, CFSRU, 2501 Investigation Pkwy, Quantico, VA 22135; Alyssa Cassabaum, BS, FBI, 2501 Investigation Pkwy, Quantico, VA 22401; and JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Pkwy, Quantico, VA 22135*

After attending this presentation, attendees will understand the limitations currently associated with the development of latent fingerprints on metallic surfaces, and will learn about latent fingerprint residue components, how these are affected by exposure to different elements, and about nontraditional development techniques for latent fingerprint development on metallic evidence.

This presentation will impact the forensic science community by sharing important information that can lead to the successful development of more identifiable latent fingerprints on a variety of metallic surfaces.

Traditional latent fingerprint development techniques, such as cyanoacrylate fuming and powdering, have relatively low success rates on metallic surfaces on forensic evidence, mostly due to the nonporous nature of the metals, but also due to the fragile nature of the latent fingerprints. A latent fingerprint is composed mostly of bodily secretions (e.g., water, inorganic salts, amino acids, fatty acids, ammonia, and urea), which can degrade under extreme environmental conditions, such as high temperature and low humidity. The survivability of a latent fingerprint on any surface (metal surfaces included) depends on many factors including atmospheric conditions (e.g., temperature and humidity) and contaminants (e.g., dust, water, mud, and surface coatings). Traditional latent fingerprint development techniques rely on the physical and/or chemical interaction of the "developer" with the unaltered components (i.e., specific functional groups) of the latent fingerprint secretions. Therefore, traditional techniques are not very effective when the compounds in latent fingerprint secretions have been altered or degraded, as occurs when evidence is aged or has been exposed to extreme environmental conditions. Metals are nonporous in nature and, therefore, do not absorb fingerprint residues, rendering fingerprints exposed and, hence, easier to degrade and/or obliterate under extreme environmental conditions and/or when in contact with contaminants. Moreover, metals are excellent heat conductors; therefore, a metal surface will tend to heat faster and more uniformly than other surfaces, potentially exacerbating the degradation of the latent print residues.

Metallic evidence is critical in the forensic arena given that many weapons are constructed with metallic components. Many weapons are exposed to high temperatures, low ambient humidity, rough surroundings, and a variety of surface contaminants. Firearm cartridge casings, for example, undergo surface deformation and heat exposure when they are fired. Also, many weapons have anti-corrosive coatings or oily residues present on their surfaces, making traditional development techniques quite ineffective.

A variety of nontraditional latent fingerprint visualization techniques for metallic surfaces (e.g., modified small particle reagents, gun bluing, corrosion/oxidation etching, and nanoparticles) have been studied and modified accordingly. Natural and synthetic (sebaceous and amino acid) fingerprint residues have been placed on metallic coupons and have been subjected to controlled extreme environmental conditions (i.e., high temperatures and low relative humidity) using an environmental chamber in an attempt to degrade latent fingerprint residues. Degraded prints have been treated with traditional and nontraditional development methodologies for comparison, and developed prints have been assessed for quality and quantity of detail. The new methodologies are being evaluated to improve latent fingerprint recovery from metallic evidence, either as a replacement for or in combination with traditional nonporous processing protocols.

Latent Print, Development, Metal Evidence

D75 Evaluation and Selection of Touch DNA Evidence Using Decision-Making Software

Khudooma S. Al Na'imi, MSc, Abu Dhabi Police GHQ, Al Ain City, UNITED ARAB EMIRATES; Anwar M. Siddiqi, MSc*, Mahmoud B. Al Sharairi, BSc*, and Zainah N. Al Hatali, BSc*, Abu Dhabi Police GHQ, Abu Dhabi, UNITED ARAB EMIRATES; Ahmed A. Al Mansoori, BSc*, Abu Dhabi Police GHQ, Abu Dhabi, 253, UNITED ARAB EMIRATES; Najwa M. Al Shehhi, BSc, Abu Dhabi Police GHQ, Abu Dhabi, UNITED ARAB EMIRATES; Osamah A. Al Hmoudi, BSc*, Abu Dhabi Police GHQ, Abu Dhabi, 253, UNITED ARAB EMIRATES; Rahma A. Al Nanaee, BSc, Wafa A. Al Tayyari, MSc, and Ali M. Al Messabi, BSc, Abu Dhabi Police GHQ, Abu Dhabi, UNITED ARAB EMIRATES; Abdulla M. Al Braiki, BSc, Abu Dhabi Police GHQ, Abu Dhai, 253, UNITED ARAB EMIRATES; and Mariam A. Al Qahtany, MSc*, Abu Dhabi Police GHQ, Abu Dhabi, UNITED ARAB EMIRATES*

After attending this presentation, attendees will gain understanding about how touch DNA evidence is evaluated and selected using decision-making software for DNA analysis based on an effective case strategy. Case examples will be presented which explain how the approach is used in selection and analysis of different types of touch DNA evidence.

This presentation will impact the forensic science community by providing a business method to manage selecting suitable evidences for touch DNA analysis. This presentation will enable crime scene, forensic laboratory, criminal investigation, and prosecution to make the most of touch DNA evidence.

Touch evidence DNA is the widely used invisible evidence to prove the possible presence of biological material on a surface to connect a person to the crime scene. As the suspected surfaces for touch evidence could be large and numerous, this will increase analysis time, increase case backlogs, and increase the cost of the analysis which are considered to be major challenges to the forensic laboratories in the era of the current international financial crisis. In order to solve this problem, decision-making software was used to reduce the number of touch evidence cases, reducing the cost of analysis, and producing meaningful results to assist in the case investigation. The method will start by applying an effective case strategy management procedure, followed by the use of a decision-making program in order to evaluate different evidence according to certain criteria. An effective case strategy management includes identifying case requirements and needs through the main stakeholders. The requirements in each case can be categorized into two main sections, which are the identification

processes of the victim or the suspect and crime scene reconstruction. The case stakeholders were identified to include all main persons, groups, or organizations which are related to the victim(s), the suspect(s), criminal investigation department, prosecution, and court. After understanding the requirement of the case, touch DNA evidence will be evaluated and selected using decision making software. The V.I.S.A® (Visual Interactive Sensitivity Analysis for multi-criteria decision-making) program was used as a decision-making tool to select the most useful touch DNA evidence for the case. Possible touch DNA evidence such as shoes, pens, cans, watches, seats, cigarette, and clothes will be evaluated in the software according to differential criteria such as contamination level, DNA damage condition, level of information gained, connection to victims, connection to suspect, connection to witnesses and location in the scene. Each criteria has its own sub criteria such as contamination level which can be low or high or without contamination. A decision tree model will be constructed for the evaluated evidence. This type of filtration process can be done in the laboratory after collecting the necessary evidences from the scene. In a case example, a body was found outside a labor camp, the deceased had a blunt force wound to his face, was fully clothed, and his mobile phone was found near him. Two people were arrested in relation to the case. Initially both denied being involved in the case. Following discussion with the main stockholder of a criminal investigation department, the identification of the suspect was considered the priority. A large number of items were received for examination. Few touch DNA possible evidence were selected and several similar evidences types were excluded from analysis after evaluation on the above criteria. The selected samples in the case were enough to connect the suspect to the victim. The approach was useful in this case to reduce the cost and time in selection touch DNA evidence. It is recommended that the forensic scientist, investigator, and prosecution apply an effective case strategy management, in addition to the use of decision-making software to select and evaluate large numbers of different touch DNA evidences. These methods also can be used in other types of forensic samples. More research is needed in the field of using business management techniques in the evaluation and selection of forensic evidence.

Touch DNA, Selection, Decision-Making

D76 Accuracy of Latent Print Identification Using AFIS

Keith B. Morris, PhD, West Virginia Univ, 208 Oglebay Hall, 1600 University Ave, PO Box 6121, Morgantown, WV 26506-6121; and Elizabeth C. Dearth, BS, 10093 Azalea Grove Dr, Manassas, VA 20110*

The goals of this presentation are to simplify the comparison process, determine a threshold for the adequate amount of minutiae points needed for an identification and determine the error rates that are made by latent print examiners.

This presentation will impact the forensic science community by providing necessary data for laboratories to evaluate the advantages and disadvantages of using a numerical standard.

Minutiae have been used in the past as a measure for effecting identifications of latent fingerprints. In 1973, the International Association for Identification issued a statement regarding using minutiae for identifying latent fingerprints. The consensus was that there is no basis for using minutiae as a guideline to make identifications. Since then, there have been fluctuating opinions regarding its use. The purpose of this study will be to define error rates in latent fingerprint identification using receiver operating characteristic (ROC) curves. The study proposes to simplify the comparison process by making two assumptions: firstly, only minutiae will be used in the identification process; and, secondly, only specific, clearly identifiable ridge endings and bifurcations will be used. In the baseline study, latents of varying size (and thus varying volumes of identifying features) will be used to gain estimates of error rates.

Preliminary studies, comparing latents with varying numbers of identifiable minutiae using an AFIS, have provided interesting results. Examiners were given a number of latents and a variety of known prints. The prints were then entered into an AFIS. Three specific areas of the latent prints were focused on: tip, core, and delta. For each print, a separate analysis was performed at each of the specified areas. The analysis included selecting from 3 – 50 identifiable minutiae around the designated areas. The frequencies of minutiae combinations were recorded by choosing from 3 – 5 minutiae in relative closeness to the area of concern. The results can be analyzed in a number of ways using signal detection theory and compared for model predictability. The ROC curves will also provide a measure of discrimination irrespective of the method which the examiner provided.

In the baseline study, the error rates were defined in latent fingerprint identification using AFIS. The effectiveness of identification using AFIS was evaluated using receiver operating characteristic curves. The prime objective was to be able to clearly define how the number of minutiae can be used to understand and be applied to error rates. All minutiae are not valued to the same degree, highlighting the need for different numerical standards for the three areas that have been chosen for analysis. These standards will be used to determine the threshold and how it changes based on how the latent occurred. One must also consider at what point this threshold will change based on the area (tip, core, or delta) chosen for analysis. Clear definitions of false positive and false negative rates and their implications for latent fingerprint examiners will be established.

The results of this study may provide the necessary data for laboratories to evaluate the advantages and disadvantages of using a numerical standard. According to the Inspector General's report into the Brandon Mayfield Case, a numerical standard is where a minimum number of points must be in adequate agreement for an identification.[1] The forensic community could benefit from this adoption because "the premise of establishing such a standard is that the probability of encountering two different fingers that share that number of minutiae in common is infinitesimal and can be disregarded" which was also stated in the Inspector General's report.[1]

Latent, AFIS, ROC Curves

D77 Working Together: Utilization of Outside Resources When Dealing With a Mass Fatality

Catherine H. Weldon, MBA, and Sarah R. Weil, BA*, 606 SW 3rd Ave, Gainesville, FL 32601*

After attending this presentation, attendees will learn the importance of resource utilization by the Medical Examiner's Office when dealing with a mass fatality.

This presentation will impact the forensic science community by detailing how a small Medical Examiner's Office responded to a mass fatality incident on a major interstate, effectively, by identifying available resources and calling upon them at the onset of an incident. Instead of waiting until the scene of a mass fatality has been processed, or getting to a scene and realizing more help is needed, resources were called upon at the onset of the incident, thus allowing for an effective and precise investigation.

On January 29, 2012, fog and smoke from nearby wildfires blanketed a low-lying area of Interstate 75 in Gainesville, Florida, at approximately 0400 hours. Vehicles traveling on the roadway at high speeds suddenly experienced zero visibility, resulting in a multi-vehicle crash on the northbound and southbound lanes of the Interstate stretching a little over one mile. The Medical Examiner's Office was notified that multiple fatalities were confirmed on scene at approximately 0600 hours.

The Medical Examiner's Office consists of three full-time investigators, one part-time investigator, two autopsy technicians, and three pathologists. When the on-call investigator was notified of the

incident, contact was immediately made with the Chief Medical Examiner and the Director of Operations. Quickly, it was established that the Florida Emergency Mortuary Operations Response System (FEMORS) should be activated and deployed to offer resources and staff. All team members, which included all Medical Examiner's Office staff, FEMORS personnel, and transport personnel met at the Medical Examiner's Office at 0800 hours for a briefing.

FEMORS personnel started a Victim Identification Center (VIC) that allowed for people to report missing individuals that may have been involved in the crash, providing resources for identification. At the time of the crash, there were eight unidentified individuals. Because the VIC was implemented at the onset of the incident, antemortem information was readily available to guide the process of gathering postmortem comparison information.

The northbound lanes consisted of multiple vehicles with deceased located in two separate vehicles. Two decedents were in a small passenger car and five decedents were located in a minivan. With the assistance of FEMORS personnel, scene photography, scene sketching and decedent photography was accomplished efficiently in various stages. Prompt processing of the northbound scene allowed for decedents to be transported to the Medical Examiner's Office for processing and autopsy. FEMORS personnel located at the Medical Examiner's Office were instrumental in being able to process the decedents as they arrived to assist the two autopsy technicians and pathologists.

The southbound lane crash involved two vehicles that had become fully engulfed in flames from two semi-tractor trailers catching on fire. The result was that two vehicles with decedents were severely burned. At this time, the Medical Examiner's Office contacted the C.A. Pound Human Identification Laboratory and a board certified forensic anthropologist responded to the scene. This allowed for an expert opinion on the most effective way to preserve the burned remains. The majority of the remains of one individual from one vehicle could be removed on scene. An unknown number of individuals remained in the second vehicle. On the advice of the physical anthropologist, both vehicles were towed to a local law enforcement facility for later processing.

From January 30, 2012, through February 2, 2012, both vehicles were processed by a team of physical anthropology graduate analysts, as well as forensic odontologists from FEMORS. The expert archeological techniques and knowledge of burned bone identification and preservation allowed for maximum recovery of remains as well as identification of personal effects. Having forensic odontologists at the site allowed for *in situ* examination of dentition given the extremely fragile nature of the remains. In all, three individuals were recovered from the second vehicle.

The proactive measures of the on-call investigator and the Medical Examiner's Office team to identify, call upon, and utilize outside resources to their fullest extent allowed the Medical Examiner's Office to effectively identify the remains and investigate the deaths of eleven individuals.

Mass Fatality, Investigation, I-75

D78 Homicide vs. Suicide: Suicide by Cop Revisited

Larry D. Marshall, MFS, 47941 State Rt 248, Long Bottom, OH 45743; and William E. McElhaney, MLS, 6326 Tamworth Ct, Dublin, OH 43017*

After attending this presentation, attendees will understand the principles of suicide vs. homicide investigation and the application of an operational methodology to the investigative process to assist in the determination of the classification of manner of death.

This presentation will impact the forensic community by demonstrating the use of an operational methodology to guide and assist the standardization of the investigative process when investigating suicides, especially when the suicide involves subject-precipitated homicide.

Suicide by Cop (SbC) is a well-documented phenomenon in the forensic literature. Demographics as well as motivational considerations for SbC have been researched and detailed. But less clear is the operational methodology which investigators, including medical examiners and coroners, use to classify these incidents. Among investigators, there appears to be less reliance on standardized operational criteria for SbC and more reliance on outside, often emotional, influences such as family and social stigma, equivocal deaths and variability among medical examiners and coroner systems. As a result, these incidents may be misclassified, leading to questionable epidemiological data with regard to the problem of suicide nationwide. Homicides and suicides in the United States, and especially among members of the military, are of great concern to public health officials. Public health policy is based, in large part, on these statistics. Statistical error can result in misapplication of programming decisions with regard to reducing incidents of homicide and suicide, leading to much wasted time, effort and program dollars.

Operational criteria have been established in the literature: "*Operational Criteria for the Determination of Suicide*" (OCDS) was published in which criteria were set forth for determination of suicide;[1] "*Empirical Criteria for the Determination of Suicide Manner of Death (EDOS),*" was developed in which criteria were set forth for determination of suicide;[2] "*Police Shooting as a Method of Self-Harming: A Review of the Evidence for "Suicide by Cop" in England and Wales Between 1998 and 2001,*" developed methodology for determination of SbC based on observable acts;[3] and, "*Suicide by Cop: Police Shooting as a Method of Self-Harming,*" worked out a set of indicators to help classify SbC.[4]

A case study will be presented in which a 64-year-old white male with a history of suicide threats and addiction to drugs and alcohol, called his daughter threatening suicide by shooting himself. Law enforcement was notified and the male was subsequently shot and killed by a responding sheriff's deputy after the male pointed a shotgun at him to shoot the deputy. The shooting was ruled a homicide. The case will be analyzed using standards presented in the operational criteria discussed in the literature to determine if the case should have been ruled more properly as a suicide. A recommendation will be made that medical examiner systems and coroner systems such as that in Ohio adopt an operational methodology for the determination of suicide and in particular SbC.

D79 Case Study: From Maternal Instinct to Staged Domestic Homicide

Eric R. Ruiz Hernandez, MD, and Edwin O. Olaya Molina, BA, Fiscalía General de la Nación, Dg 22B, 52-01, Bloque F, Bogotá, 111321, COLOMBIA*

After this presentation, attendees will understand how, through a process of comprehensive analysis of the crime scene, was obtained a reconstruction of a criminal behavior and which was the driving motivation of a murder against two children perpetrated by their own mother.

This presentation will impact the forensic science community by showing how the criminal conduct of staged domestic homicide has some repetitive patterns or common characteristics in terms of planning and execution, regardless of where in the world presented, without being influenced by sociocultural or economic factors of their executors.

One mother told the police of the city of Mocoa, capital of the department of Putumayo in southern Colombia, in the early hours of September 20, 2010, an unknown individual attacked when she opened the front door of her residence, and she was attacked until she lost consciousness. After regaining consciousness, she observed that their children were in bed in the master bedroom and, when approaching them, believing them to be asleep, noted they were wet and without signs of life.

At the beginning of the investigation findings in the scene, the woman´s injuries were consistent with blunt trauma and the apparent coherence of her story led the authorities to think that there was a perpetrator who murdered two children and had left their mother seriously injured. The high social impact produced by a case of two children killed and the assault on their mother activated law enforcement, both local and national level, so that the Criminal Behavior Special Unit of the Attorney General's Office was called to support the investigation through a process of crime scene analysis and the possibly developing a criminal profile.

On the basis of the processes of crime scene analysis, patterns of blood stains found, the comprehensive study of the evidence related to the victims, the assessment of the versions provided by the surviving mother and other witnesses, and the structural characteristics and safety of the building, the investigation team re-evaluated the hypothesis of an external aggressor and redirected their attention toward the crime being committed by the mother.

This change in the case offered to the team a clear vision about the dynamics of the events that led to the deaths of the two children. With the support of the analysis of forensic evidence at the scene, the Criminal Behavior Special Unit was forced to focus their attention of finding the motivation that drove this woman to kill her own children. Therefore, the line of investigation focused on probing deeper into all areas of the life of the mother, and found an intricate world of love frustrations and abandonment, a mentally unhealthy woman, egocentric and possessive, with strong intentions to pass over any obstacle to achieve all personal desires.

After harmonizing and fitting all parts of this criminal and forensic puzzle together, the prosecutors demonstrated definitively and beyond reasonable doubt that the crime was committed by the mother, in the form of staged domestic homicide. Today this woman is listed as a fugitive from Colombian justice.

Mother's Killer, Children, Staged Domestic Homicide

D80 The Patricia Flores Cold Case: An Interdisciplinary Approach About Death and Rape After an Investigation in a School in La Paz, Bolivia

Claudia Delgado Aguacia, MSc, Carolina Restrepo, MSc*, Karen J. Rodriguez Buitrago, MA, and Fernanda Pazmiño Moncayo, MSc, Fundacion AFFIC, Centro Comercial y de Negocios Torre Central, Avenida Calle 26 No 68C-61, Oficina 321, Bogotá, 110931, COLOMBIA; and Santiago Reina Camacho, BS, World Trade Center, Calle 100 No 8 A-55, Torre C Piso 10, Bogota, COLOMBIA*

After attending this presentation, attendees will get a well-rounded view of a forensic cold case investigation in Latin America by showing the interdisciplinary forensic work about the murder and rape of a 9-year-old girl in 1999 in La Paz, Bolivia.

This presentation will impact the forensic science community by explaining the importance of the interdisciplinary work, consisting of pathology, archaeology, anthropology, psychology, and crime scene investigation, in order to investigate cold cases related to child homicide and abuse in Latin America.

On Friday August 27, 1999, Patricia Jaqueline Flores-Velasquez, a 9-year-old girl living in the city of La Paz, Bolivia (South America), disappeared from the public school she was attending and four days later her body was found inside the school warehouse. The body showed signs of asphyxia, rape, and torture. Once the body of the girl was discovered at 11 p.m., there were several mistakes related with the crime scene investigation, including analysis and technical/scientific procedures, chain of custody, the absence of sexual abuse protocols, and a proper necropsy. The Medical Examiner committed suicide just few days after Patricia's body analysis was done, apparently because of bad practices used in this case.

DNA samples were taken by the FBI of two suspects. In one of them, Patricia's DNA was found in a belt and in a shoe of the suspect, but the Bolivian court did not accept this evidence and argued contamination. The case became a cold case.

After 11 years, the criminal process was re-opened thanks to two Human Rights NGOS named Funderes (a Human Rights non-profit organization from Bolivia) and Women's link, (an international human rights non-profit organization working to ensure that gender equality is a reality around the world).

In April 2011, a group of 11 forensic scientists and criminal investigation analysts (seven Colombians and two Spaniards) started to work the case, analyzing documents, testimonies, and expert witness reports in order to help the Bolivian Justice to again open the case with forensic evidence

In August 2012, an interdisciplinary team composed a group of Colombian forensic scientists and technicians (one anthropologist, one pathologist, one crime scene analyst, one forensic photographer) who belong to the National Institute of Legal Medicine and Forensic Sciences and AFFIC foundation, went to Bolivia in order to do an exhumation of the body, a second necropsy, took new DNA and other biological samples from the body, suspects and forensic evidence, and conducted forensic psychological tests on suspects and a new analysis at the crime scene.

A group of forensic psychologists from Colombia and Spain worked on a psychological profiling in this case, including the suspect's behavior, motives, and background, in an attempt to guide the investigation. Psychologists gave a profile using both inductive and deductive approaches, trying to find if the murder was committed by a serial killer or was an isolated case.

Cold Case Bolivia, Child Abuse, Sexual Abuse

D81 Homicide or Suicide: The Shotgun is Twenty-One Feet, Six Inches From the Victim's Body

Steven E. McGibbon, MFS, PO Box 8204, Chandler, AZ 85246-8204; and Ivan M. Kaminsky, MeD*, 250 E Chicago St, Chandler, AZ 85225*

After attending this presentation, attendees will understand the necessity of experimentation to prove or disprove a theory when it involves criminal investigations. Students will receive information on a specific case where a 12-gauge pistol-grip pump shotgun was found approximately 21.5 feet away from the truck where a victim was found in the driver's seat with a contact gunshot wound to the chest. Determining how the shotgun got that far from the vehicle where the deceased was found was one piece of the puzzle to help to determine homicide or suicide.

This presentation will impact the forensic science community by showing how experimentation to prove or disprove, teamwork of forensic disciplines, and good old-fashioned investigation can come together to provide a more confident conclusion in determining the outcome of an equivocal investigation.

On January 10, 2011, a white male entered a local market and purchased a random pick lottery ticket for a date in the future. A few minutes after leaving the store, the store owner and his adult son heard what sounded like a backfire or a gunshot. The adult son went outside to the parking lot and found a white Ford F-350 pickup truck with the driver's window down and the white male lying back against the driver's seat, bleeding from the chest.

When emergency personnel arrived, it was evident the white male was deceased. The scene was secured by local law enforcement. Detectives noted a Mossberg 12-gauge pistol grip pump shotgun 21.5 feet away from the driver's door of the truck. In addition, there was not any visible blood found on the shotgun. The driver's side mirror was spattered with blood and a few drops of blood were found on the ground just below the mirror. The ignition was in the "on" position with the radio on, but the truck was not running.

The manner of death is partly based on investigation, forensic evidence, and sometimes good old-fashioned gut feeling or experience. Facts, forensic and investigative, are the only parts of information that really count when it comes to making a decision on what happened. In this particular investigation, theories were developed as to how the shotgun ended up 21.5 feet from the victim's body. Gut feelings are not facts, but are merely a platform to develop a theory or theories. Experience is not a fact either it is just a better way to develop a more accurate prediction of "what happens when." When experiments are conducted, "what happens when" can often end up with a surprising result, either proving or disproving a theory.

When a theory is developed, it needs to be proven or disproven using scientific method. As much as possible, the original circumstances need to be replicated. In this particular investigation, the original shotgun and same type of ammunition were used. All other circumstances had to be replicated by using a different truck, but in a location with a similar type of asphalt surface. Cushions and clothing were used to construct a dummy in which to shoot. For safety purposes, the experiments were conducted at a police range under the supervision of the police range master.

The key to experimentation is planning and flexibility. Accounting for every circumstance is impossible; therefore, adjustments in methodology and/or the hypothesis may have to be considered. Flexibility is important to be able to make the adjustments during experimentation. Keep in mind things can happen more than one way. In this case, more than one person was surprised with "what happens when."

Theory, Scientific Method, Experimentation

D82 The Importance of Autopsy in Deaths Due to Choking

Theodore Brown, MD, and Jeffrey M. Jentzen, MD, Univ of Michigan, NI2D19 - SPC 5452, 300 N Ingalls, Ann Arbor, MI 48109*

After attending this presentation, attendees will learn about the importance of autopsies in cases with suspected deaths due to asphyxia from choking on foreign bodies which, even when material has not been identified by emergency medical responders and caregivers, warrant an autopsy.

The presentation will impact the forensic science community by emphasizing the importance of performing an autopsy on choking-related deaths, which may have medicolegal repercussions.

In the United States, choking and suffocation accounts for the third leading cause of home and community deaths, with young children and older adults at the highest risk.[1] The lack of adequate investigation, including a formal autopsy performed by a forensic pathologist, may result in the underreporting of asphyxia deaths. In the forensic community, asphyxia from choking is defined as an obstruction from food material or foreign objects within the airways below the epiglottis.[2,3] The manner of death is most commonly an accident. Besides age being a risk factor in these cases, neurologic or mental deficits, poor dentition, and alcohol intoxication are among the most common underlying reasons that increase the likelihood of choking-related asphyxia deaths.[2]

In medical forensic cases where a suspected asphyxia from choking on food occurs, emergency medical responders and caregivers will often recognize the signs of an airway obstruction and attempt to remove the food item from the airway. However, during a review of the Wayne County and Washtenaw County Medical Examiner database from 2008 to 2012, 20 cases in which food products were identified below the epiglottis at the autopsy table had not been previously identified by emergency medical responders and caregivers at the accident scene.

Information obtained from a review of the identified cases included age, predisposing risk factors, significant neurologic or mental comorbidities, on-site findings by emergency medical responders and caregivers, and final autopsy findings. In this review, decedents ranged from the age of 13 months to 89 years old, many had risk factors that included missing teeth and acute alcohol intoxication, and several carried a previously diagnosed comorbidity, including mental retardation and dementia.

Initial on-site medical response efforts in these choking cases failed to properly identify remaining food material in the airways, most likely due to the location of the food material being lodged below the epiglottis and away from direct visualization. At the autopsy table, proper visualization of food material below the epiglottis, which obstructed the decedent's airways that lead to eventual death, could more easily be identified in all cases. These autopsy findings, given the circumstances, were assigned a cause of death due to asphyxia by choking, which was accidental in manner. This highlights the importance of performing an autopsy in suspected choking-related deaths because the cause of death may be otherwise overlooked and potential medicolegal repercussions are at stake.

As noted, a significant portion of the cases in this review involved decedents with previously diagnosed comorbidities and risk factors. Initially, some forensic pathologists may choose to assign a natural cause of death in these cases based on the on-site response finding of no food material combined with a history of a neurologic or mental deficit and/or predisposing risk factors, including acute alcohol intoxication. This may lead to the decision to either forego a formal autopsy or perform a limited external exam with toxicology studies. However, these medical forensic cases warrant a formal autopsy due to the possibility of significant findings at the autopsy table, including complete obstruction of the decedent's airways below the epiglottis.

Autopsy, Choking, Asphyxia

D83 Suicide in Children: A Study in Northern Portugal

Teresa Magalhães, MD, PhD, and Agostinho Santos, MD, PhD, National Institute of Legal Medicine, Jardim Carrilho Videira, 4050-167, Porto, PORTUGAL; and Ricardo Mendes, MD, Rua S. Sebastiao n. 10, Frossos, Braga, 4700-154, PORTUGAL*

After attending this presentation, attendees will understand information related to suicidal behavior in children and adolescents and make them aware about the need for more education, specifically by promoting a thorough psychological autopsy in these cases.

This presentation will impact the forensic science community by shedding light on a poorly studied area of forensics in northern Portugal, the iddue of child and adolescent suicide, emphasizing the requirement to develop understanding in managing autopsy cases to be supported by specific strategies.

Suicide is among the leading causes of death worldwide and is the second leading cause of death between 10 and 24 years old. Suicide behavior includes a wide spectrum of acts, with males tending to choose methods with more lethal effectiveness, making them more likely to perform a complete suicide. Lack of information about some circumstances of the death, namely underlying psychopathologic disorders and the behavioral impulse, contribute to the suicidal act; this can create flaws concerning the method of the psychological autopsy. Portuguese forensic aspects on child and adolescent suicides are unknown, so that was the aim of the present study.

Data on autopsy reports of suicide cases of people under 18-years-old at the North Services of the National Institute of Legal Medicine and Forensic Sciences of Portugal, from 2004 to 2011, including toxicological results, were obtained, and psychological autopsy data and police reports were analyzed. A total of 16 cases were found, with a male predominance (68.8%) and an age range from 12 to 17-years-old (mean age 15.25 ± 1.13). All victims but two were Caucasian. The leading suicide method was hanging (n=6), followed by shooting (n=3), and jumping in front of an oncoming train (n=3). A greater number of suicides (n=9) took place between June and September. Seven cases occurred in public areas and six at the victim's home. Alcohol intoxication was observed in two victims (blood alcohol concentration > 1.0g/L), both males, who committed suicide by jumping in front of an oncoming train. Psychological autopsy was performed in only 10 cases, which can be explained by the difficulties of forensic professionals leading during a quite early stage of grief, and also by the fact that family and friends of the victims are having trouble with providing accurate information in that moment, since they aren't able to cope with the pain, which affects and impairs their memory and concentration. This suffering can lead to feelings of blame, associated with inaptitude of accepting the suicide event. Therefore, it's highly important to develop specific competencies for the forensic professionals for this type of approach, namely in early stages of the grief process. These are some of the aspects which could explain why the main reason for suicide was not possible to determine in most cases.

Although suicide in children and adolescents is a rare event, it remains a rather important issue of public health, and should not be overlooked. Such events are probably motivated by acts of impulsiveness, thus these acts are usually unpredictable and come as a surprise to the family and friends of the victims. The chosen methods tend to be more violent than in other age groups, namely in males, which explains the gender predominance. It is of paramount importance to assure the correct course of action regarding the psychological autopsy in these cases, as well as the availability of information regarding the victims, including reviewing of the clinical history, social and emotional background, hence creating a more complete profile of these victims and maximizing the accuracy of the forensic diagnosis. This is the first study of suicide in victims under 18 years of age in the north of Portugal, and offers unique information for future programs of suicide prevention in this country and a basis for further and needed research. Prevention strategies should focus on controlling the main risk factors, namely awareness of underlying psychiatric pathologies, acts of impulsive aggression, family history of suicide, history of physical or sexual abuse, or poor relationships with parents and peers, as well as restricting the access to lethal methods, therefore promoting early assessments leading to targeted interventions and reducing the risk of suicidal behavior.

Suicide, Children, Risk Factor

D84 Epidemiology and the Cost of Falls: Monitoring the Last 22 Months at the Policlinico Hospital of Bari

Fiorenza Zotti, PhD, Univ of Bari, Dept of Legal and Forensic Medicine, Piazza Giulio Cesare 11, BARI, 70124, ITALY; Sara Sblano, PhD, Via Giustino Fortunato, 4 C/10, Bari, 70125, ITALY; Vitangelo Dattoli, MD, Univ of Bari, Dept of Legal and Forensic Medicine, Piazza Giulio Cesare 11, Bari, 70124, ITALY; Paola Frati, PhD, Univ of Roma, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, 00161, ITALY; Alessandro Bonsignore, MD, Univ of Bari, Dept of Legal and Forensic Medicine, Piazza Giulio Cesare 11, Bari, 70124, ITALY; and Alessandro Dell'Erba, PhD, Univ of Bari, Dept of Legal and Forensic Medicine, Piazza Giulio Cesare 11, Bari, 70124, ITALY*

The goal of this presentation is to show the results of a retrospective study on falls occurring at the Policlinico Hospital of Bari, Italy, in the period March 1, 2010 – December 31, 2011. Patient data and fall incident report data have been reviewed to identify risk factors associated with falls and fall-related injuries. Moreover, a systematic approach led to estimates of the average hospital cost and Length Of Stay (LOS) associated with injurious falls in the hospital.

This presentation will impact the forensic science community by offering useful insights to the forensic science community by demonstrating how important risk management can be, also, in order to save money that could be better spent for healthcare services, whilst on the other hand, it highlights how forensic sciences, especially in recent years, have focused attention on patient health and safety.

Indeed, the growth of healthcare costs over the last years has fostered careful scrutiny of both the effectiveness and efficiency of healthcare delivery.

According to this, the main purpose of the Clinical Risk Management System is to ensure patient safety through the implementation of systemic measures of identification, analysis, evaluation, and treatment of risks related to the provision of care.

Such an ambitious program aims to reduce the probability of incidence of an adverse event/error or, at least, to limit the impact of the consequences of such an event also from a "hospital efficiency" perspective.

Falls, which are not strictly related to the care process and in consideration of their possible consequences, usually entirely separate from the cause of hospital admission, represent a critical organizational node. In fact, according to the literature reviewed, they (falls) are among the most frequent adverse events—especially in acute care facilities—and they can result in substantial morbidity and mortality. Particularly, falls may lead to negative outcomes such as injury, prolonged hospitalization, delayed rehabilitation, and potential professional liability profiles.

Rates between 2.2 and 17.1 falls per 1,000 patient days, depending on hospital type and patient populations, have been reported.

The correlation between potential frequency and severity of falls identifies the key role played by them in the risk map. At the same time, it is well known that falls mainly occur in the elderly, especially amongst people suffering from neuro-psychiatric disorders, and generally related to voiding and/or toileting requirements.

The potential risk factors of falls have been studied in depth and, consequently, various hospital falls-prevention programs have been implemented in the last decades. However, most of the programs had no

sustained effects on fall reduction over extended periods of time. In this sense, it is certainly time for the forensic community to monitor the phenomenon and to play an active role in the implementation of corrective measures.

With this in mind, at the Policlinico Hospital of Bari a surveillance system based on the distribution and filing of "Fall of the Patient" record cards has long been in place.

Even though it is unrealistic to consider all falls to be preventable, it is hypothesized that a system-based fall-prevention program targeting high-risk situations would result in fewer falls. According to this, hospital managers have a leading role in creating an effective program and reducing hospital costs.

Falls, Risk Management, Epidemiology and Cost

D85 Differentiating Perpetrator from Witness Using BEOS Profiling

Anjali Yadav, MSc, 117A, New Colony, Gurgaon, 122001, INDIA; M.S. Dahiya, PhD, Directorate Of Forensic Sciences, Gandhinagar, 382007, INDIA; and C.R. Mukundan, PhD, 85-13,4th Cross, Bhavani Layout, Bangalore, 560029, INDIA*

After attending this presentation, attendees will learn about a new technique for forensic investigation and deception detection.

This presentation will impact the forensic science community by advancing research that is strongly needed in new areas of crime investigation.

Brain Electrical Oscillation Signature (BEOS) Profiling is a technique used to identify individuals with remembrance of specific experiences. The test detects the presence of specific patterns in the electrical signals (EEG) recorded from the brain, while listening to verbal statements used for cueing remembrance of components of a specific experience, acquired while committing a crime or forensically relevant act. Remembrance of autobiographic episodes may have components of motor and visual imageries associated with the actions one has executed and witnessed. If one has only witnessed a scene, he cannot have motor imageries of carrying out the same act, but will have only visual imagery. Remembrance of components of autobiographic episodes contributes to greater neural activation compared to retrieval involved in knowing. Remembrance is found to be often associated with recreation of motor and visual imageries. In BEOS Profiling, short narrative sentences are presented in sequence referring to several of the activities a suspect or accused is considered to have indulged in. The procedure can be used to test an investigator's as well as a suspect's version of the involvement of the latter.

The current study was conducted in the BEOS Laboratory at the Directorate of Forensic Science Laboratory, Mumbai, India. A participant in the experimental group executed an activity according to a pre-designed action plan, when he was accompanied by another participant from the witness group. The later merely witnessed the actions executed by the former. The activities in the experiment room consisted of playing a numerical game, searching for keys, a doll, tools, boxes, and opening the box, breaking a large flowerpot, collecting coins from it, and finally leaving the room. There were 20 pairs of participants and 13 participants in a control group. Subsequently, the BEOS test was carried out after an interval of 15 days on each participant of the experimental group. A control group of participants who did not take part in the above experiment were also administered the same probes while acquiring their EEG. The probes referred to the activities of the participant who carried out the activities in the experimental room. Several of them required the participant to recreate either both motor and visual imageries or one of them. The participant sat silently listening to the probes with his eyes closed and without giving any response.

The maximum length of a probe was never more than three sec. The EEG was acquired in the range of 0.016 – 100 Hz by Neuro Signature System, using 30 channels of scalp electrodes. Vertical and horizontal eye movements, if present, were recorded in another two channels. Continuous EEG was acquired and it was converted to 10 sec epochs, time locked to the onset of each probe, with three sec pre-probe baseline and seven sec of response segment. Analysis consisted of frequency and time domain analyses followed by statistical comparisons of the patterns in the response segment with the pre-probe baseline values. Frequency analysis was carried out in 10 frequency ranges and the time domain analysis consisted of detection of positive and negative responses of predefined morphology in comparison with the baseline levels. Significant increases in the Coherence values across pairs of fronto-central and fronto-posterior electrodes in the 35 – 85 Hz range in the response segment compared to the baseline indicated the presence of motor and visual imageries respectively.

Specific pattern of significant changes in the power spectrum values in the response segment, presence of significant increase in the phase relationship in gamma range of activities, and presence of significant ERP components indicated the presence of remembrance, which was marked as Experiential Knowledge response. The analysis indicated the presence of motor or visual imageries in response to each probe, if present. The number of probes, which produced such changes, was identified in each participant, and the scores were compared across the three groups. Comparison of results of motor and visual imageries across groups indicated significant increase in motor imageries in the perpetrator group whereas visual imageries were comparable in the perpetrator and witness groups. The control groups had significantly lesser number of EK responses.

Perpetrator, Witness, Motor and Visual Image

D86 The Phenomenon of the Urban Mummy

Brett E. Harding, MBA, District 21 MEO, 70 Danley Dr, Fort Myers, FL 33907; and Barbara C. Wolf, MD, District 5 MEO, 809 Pine St, Leesburg, FL 34748*

After attending this presentation, attendees will have an understanding of the constellation of environmental factors and events leading to human mummification in urban settings, and the importance of the multidisciplinary approach to the medicolegal investigation of such deaths.

This presentation will impact the forensic science community by contributing to the increased awareness of the study of these unusual cases, and the unique aspects of the medicolegal investigation of these deaths.

The environmental mummification of a body in an urban setting is a fairly unusual event. Florida is known for its high temperatures and humidity, which typically contribute to the rapid decomposition and putrefaction of decedent's bodies. The resulting foul order is frequently the signal leading to the discovery of the bodies of individuals whose deaths occurred in solitary locations. This, coupled with prevalence of insect activity, usually precludes the mummification process. However, under certain circumstances, Florida's unique climate provides an environment suitable for mummification. A particular constellation of human behaviors and scenarios must coincide for this phenomenon to occur in an urban setting.

The first requirement is that the decedents must have lived in socially isolated circumstances. Such isolation may result from multiple etiologies, such as illness, substance abuse, criminal activity, language barriers, and/or advanced age. Florida is home to a large number of individuals who lead an isolated existence: the homeless, who may purposely isolate themselves as a safety measure to protect themselves and their property; the mentally or physically ill, who are isolated as a result of their impairments; and, the elderly, whose longevity may result in their isolation after the deaths of friends and family, are all at risk. Reclusive behavior is almost essential for a death to go unnoticed and to meet the time requirements for the decompositional mummification process to proceed.

The apathy of nearby individuals to the welfare of the decedent or the lack of knowledge of the decedent's presence in the community is another factor. If neighbors call attention to the absence of the decedent, a well being check will usually interrupt this process. The failure of public officials to recognize the signs of a potentially

undiscovered death is also a necessary condition. These may include law enforcement, mail carriers, and/or public safety officials. Even with isolationist behavior, violations of urban laws or ordinances may result in the inspection of a home by public officials. These public service representatives must be apathetic to the absence of the decedent or equate his or her absence with the abandonment of the dwelling. Finally, the body must be in a hot, dry, closed environment where it is protected from insect and animal predation. The death of an individual in an exposed location is often appreciated by the local fauna as a ready food source, long before humans become aware of the death. This predation results in the consumption and scattering of the remains rather than their mummification.

Several cases in which mummified bodies were discovered in urban locations in southwest Florida have recently been investigated. The literature pertaining to such unusual cases is sparse. These cases highlight the importance of the multidisciplinary approach to the medicolegal investigation of such deaths and the determination of the cause and manner of death.

Urban Mummy, Medicolegal, Investigation

D87 Examinations of the Standards of Normality (SON) and Production Standards (PS) to Best Identify Critical and Definitive Information Pertaining to Alleged Nutritional Associated Dysfunctions (NAD) in Animals

Gary M. Pusillo, PhD, 2017 230th St, Marshalltown, IA 50158*

After attending this presentation, attendees will understand how to carefully reconstruct an animal facilities Standards Of Normality (SON) and Productions Standards (PS) critical to identifying their relationship to animal death and abnormalities attributed to primarily a Nutritional Associated Dysfunction (NAD).

This presentation will impact the forensic science community by providing the key components necessary to properly investigate alleged animal nutrition-related deaths or abnormalities attributable to daily rations provided to commercially raised animals.

When the use of animal feeds in commercial livestock facilities result in abnormal PS, mortality rates and/or lower-than-expected performance and health parameters, it is important that a comprehensive animal and SON diagnosis be performed

Today's production livestock are finely tuned "food producing machines" that require a balance of nutrition, environment, health care, and management; any deficiencies or inadequacies in these areas will affect the ability of an animal to perform optimally. When investigating a manifested dysfunction in a livestock operation, proper analysis for each area—nutrition, environment, health care, and management—insures that the evaluation is as scientifically accurate and valid as the data permits.

An essential component in the evaluation of animal feed-related claims is a scientifically valid set of investigative techniques required to accurately evaluate Feed Associated Dysfunctions (FAD) and NAD in animals. As an example of the practical application of these techniques, the author will present a case study involving a large dairy and a toll manufactured nutrition product alleged to be inadequate. The testing and identification of milk fever, immune system abnormalities, death, and damages to the cows' reproductive system and milk production, will be used as the focal point in providing insight into measuring and documenting causation for the professional investigating similar situations.

Formulating dairy rations primarily involves providing specific fibers, protein, energy, vitamins, and mineral ingredients for defined maintenance, reproductive, and productions requirements. Several factors affect a cow's requirement for a specific nutrient. These factors influence feed intake, which will require changing the concentration of the nutrient in the diet to meet the cow's requirement on an amount-per-day basis. This presentation will identify common factors which influence specific nutrient needs and their importance to a comprehensive NAD investigation.

The physical condition of the animal's habitat and associated living organisms that occupy it must be considered in all forensic cases involving animals. The dynamic whole of the microenvironment that immediately influences the target animal individual or population exists as an interdependence of its members.

In microenvironments such as a dairy barn, or outdoor feeding area, the targeted individuals or populations that occupy it and their nonliving environment are inseparably related and are constantly interacting with each other. The exchange of materials between the living and non-living parts of a target animal or population are intimately involved in the determination of causation in nutrition-related animal death, illness, or abnormalities.

Modern animal nutrition forensic investigations cannot separate its observations from the complexity of the environmental realities that act singly and together. At the same time, it is recognized that the animal or targeted population in turn react upon their environment, often producing marked modifications.

Problems that occur in groups of animals are often multi-factorial in cause and the result of the interaction of several risk factors, which may be characteristic of the animals, their environment, their nutrition, and/or inciting agent. In the context of an operation such as a dairy facility, managerial causes must be analyzed and either ruled out as a causative factor or incorporated and weighted as a factor accordingly.

In order for Nutrition Associated Dysfunctions (NAD) to be properly investigated, documented, and analyzed to determine causation, reconstructing daily diets, SON, and PS is essential. This presentation will provide the basic scientific techniques needed to gather evidence to determine if feed has been formulated with sufficient allowances built in to address biochemical changes associated with disease, inflammation, trauma, malabsorption syndrome, interactions, variations in bioavailability, and stressors.

Feed, Nutrition, Animals

D88 A Comparative Study of the Effect of Four Loko™ Alcoholic Beverages and Other Alcoholic Beverages on Inexperienced Drinkers

Donald Hayden, MFS, 21150 Ridgetop Ln, Waynesville, MO 65583*

After attending this presentation, attendees will be familiar with the effects of Four Loko™ alcoholic beverage compared to another alcoholic beverage and gain a better understanding of alcohol amounts necessary to become substantially incapacitated.

This presentation will impact the forensic science community by studying the abililty of law enforcement and prosecutorial personnel to successfully investigate and prosecute offenses in which incapacitation by alcohol is a factor.

A local law enforcement agency in rural Missouri initiated an investigation in which a 14-year-old minor female was given Four Loko™ alcoholic beverages, restrained, and orally sodomized. Law enforcement raised the question "Does the Four Loko™ alcoholic beverage affect an inexperienced drinker more than other non-carbonated alcoholic beverages?" Published literature failed to give any definitive insight.

Four Loko™ alcoholic beverages were originally marketed as caffeinated alcoholic malt beverages. Published reports indicate that Four Loko™ no longer contains caffeine, taurine, or guarana. Despite this published literature, Four Loko™ continues to maintain its status among youth as an "energy alcohol." Published research indicates that the effect of Four Loko™ may be due to the delivery system (fruit-flavored carbonation) combined with the alcohol content (12% Alcohol By Volume (ABV)). No published research comparing delivery systems could be located.

This study analyzed both the chemical and behavioral effects on six volunteer test subjects. The volunteers participated in two controlled "wet labs." The labs compared Four Loko™ to vodka and orange juice (commonly referred to as a "screwdriver"), in equal ABV volumes, under similar time constraints. Phase one of the study involved Four Loko™ ingestion while the second involved ingestion of "screwdrivers."

During phase one, subjects were asked to consume one can of Four Loko™ within a 45-minute period. The can was administered in 8-ounce glasses, 15 minutes apart. Intoxication levels were recorded via industry accepted standardized field sobriety tests, breathalyzer tests, vital sign collection, and chemical analysis of blood drawn from the subjects. The test was repeated for a second can. No subject consumed more than two cans. Test subjects were monitored and tested for approximately six hours.

The second, or screwdriver ingestion phase, was conducted one month later and was administered in the same manner as the first phase.

The results of the experiment revealed that intoxication levels were, not surprisingly, similar in equal ABV amounts. The intoxication levels of the test subjects ranged (at peak levels) from .14 to .177. Variation was directly attributable to body habitus. The more telling results were discovered in the social results.

During the Four Loko™ phase, all six test subjects were giggly, happy, and sexually flirtatious. During the first phase, only one of the six test subjects was unable to complete the full battery of testing. This test subject was the most inexperienced drinker of the six test subjects. All six subjects were legally intoxicated after consuming one can of Four Loko™. After ingestion of 1.5 cans (approximately 34-ounces) all six were considered substantially incapacitated.

The social results of second phase were polar opposite of the Four Loko™ phase. Three of six subjects were rendered nearly unconscious after ingestion of approximately 35-ounces of vodka and orange juice (the same volume of liquid as the first phase). Within two hours of ingesting the "screwdrivers" no test subjects were giggly, happy, or flirtatious. The test subject's reactions from screwdrivers were that of a strong desire to lay down and go to sleep, only waking to be administered field sobriety or chemical testing.

The conclusions from this very limited study indicate that while chemically Four Loko™ provides a similar blood or breath alcohol level as other intoxicants in similar ABV concentrations, the social aspects of Four Loko™ make this a product worthy of additional controlled study.

Substantial Incapacity, Four Loko™, Blood Alcohol Concentration

D89 Blast of a High-Pressure Water Pipeline: A Fatal Case With Sternal and Heart Rupture

Roberto Guarino, MD, Via del Vespro 127, Palermo, ITALY; Letizia Averna, MD, Via del Vespro 129, Palermo, 90127, ITALY; Antonina Argo, PhD, Via del Vespro 127, Palermo, 90100, ITALY; Salvatore Moscadini, MD, Via del Vespro 129, Palermo, 90127, ITALY; and Paolo Procaccianti, PhD, Via del Vespro 127, Palermo, 90100, ITALY*

After attending this presentation, attendees will understand effects of injuries resulting from a rare work accident of a welder at the local water main management company.

This presentation will impact the forensic science community by showing the causal chain between a high-pressure water jet and thoracic trauma with sternal fracture and heart rupture.

It's the case of a 47-year-old man, who was performing a preliminary inspection to repair a micro-lesion, a few centimeters in diameter, of a high-pressure water pipeline. While the worker was going close to the conduit, a high-pressure water jet widened the gap of the pipeline wall, and squirted through the breach, hitting him in the sternal region, lifting him into the air, and throwing him about 25 meters away, to a lower level with a drop of about five meters. From the testimonies of colleagues, evidence suggests that the subject performed a parabolic flight, swirling with limbs abducted, then landed on his feet, leaving two deep footprints on the ground which were found near the corpse, rebounded, and was found in a supine position.

The external examination didn't show significant injuries except two linear abrasions in the breast region and a compound fracture of the right leg. A full-thickness fracture of the sternum and a fracture of the anterior wall of the left ventricle were discovered during the autopsy. There were also multiple rib fractures on the right rear arch.

Closed thoracic trauma with sternal fractures and visceral injuries may result through three different mechanisms: direct impact injuries, by deceleration, and by compression. Most trauma affects the thoracic wall in a more or less severe way, followed by pleuro-pulmonary injuries; less frequent are heart, diaphragmatic, and esophageal lesions; the rarest are the aorta and great vessels diseases. Sternal fractures are rare. The most common causes are represented by road trauma, involving deceleration injuries, and direct trauma to the anterior chest wall. Indirect mechanisms are the rarest, represented by hyperextension of the trunk or by violent contractions of the muscles of the neck (sternocleidomastoid) and of the trunk, which can occur in several conditions (physical exercises, coughing, vomiting, etc.).

In this case, the damaging mechanism is atypical and seems to be unique in literature: the impact of a high-pressure water jet behaves like a breast injury similar to a direct trauma with a strong damaging power. The found lesions, above all the sternum and the heart, are quite similar and comparable to injuries due to direct trauma caused by a traffic accident or by a direct impact of the chest against a large area.

Bone and visceral lesions are due to the detrimental action of the high-pressure water jet that struck the subject on the anterior chest region. This study presents this case, comparing it with the literature, which was very poor regarding this theme, focusing particular attention on the damaging mechanism that acted on the bony and visceral structures, especially demonstrating the correct causal chain through the ergonomic engineering expert report.

Thoracic Trauma, Heart Rupture, Water Jet

E1 Law and Ethics in End-of-Life Decisions: Where Italy is Going in Comparison With Other EU Countries

Matteo Gulino, JD, 336, Viale Regina Margherita, 5, Viale Bruno Buozzi, 00197, Rome, ITALY; Gianluca Montanari Vergallo, JD, Viale Regina Elena, 336, Rome, ITALY; Serenella Serinelli, MD, 336, Viale Regina Margherita 00161, Rome, ITALY; Francesco P. Busardo, MD, via del Vespro, 129, Palermo, ITALY; Fabio Castrica, MD, Via Leonessa n. 30, Rome, ITALY; and Paola Frati, PhD, Univ of Rome, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Rome, ITALY*

After attending this presentation, attendees will gain insight into the current political and legal dispute, regarding the medical role in end-of-life decisions, giving a schematical account of some cases of deaths that highly impacted on Italian public opinion during the last five years (i.e., Englaro, Welby, Monicelli, Magri) in addition to comparing the trends of others EU countries. In particular, after attending this presentation, attendees will understand: (1) the main juridical and ethical aspects of Italian Law in ELD (End of Life Decisions); (2) the conceptual distinction between direct active and indirect active euthanasia, withdrawal of life-sustaining measures (passive euthanasia), assisted suicide and suicide; and, (3) the statistic data of Italian public opinion regarding euthanasia and the living will, including the acceptance trend in others EU countries.

This presentation will impact the forensic community by highlighting legal similarities and differences among EU countries in the provisions of ELD, stressing the complexity of the relationship between patient (both terminally ill and mentally ill) and physician and trying to enhance the international debate with recent Italian experiences. Exploring international legislation, there are no universal policies regarding ELD nor homogeneous guidelines for physicians faced with ELD issues.

The reconstruction of the examples mentioned above will be presented, taking into account Italian law. Direct active euthanasia, performed by the administration of toxic drugs to a patient with the purpose of inducing his/her death, is explicitly illegal in Italy, and thus punishable either as a homicide (Penal Code article 579) or as voluntary manslaughter (Penal Code article 575) with extenuating circumstances of mercy, even though these extenuating circumstances are not specifically provided for ELD issues. In contrast, indirect active euthanasia, performed by administration of drugs to relieve pain and which may lead to the death of the patient only as a side effect, is not clearly prohibited by the law, rather it may be included among the so-called palliative treatments. Assisted suicide is forbidden by Italian law, being considered a crime of instigation to commit suicide (Penal Code article 580). Similarly, passive euthanasia is also prohibited (Penal Code article 42), although it is perceived by public opinion to be less worthy of punishment. The ethical and legal concerns involving the debates upon ELD reflect the different laws in the other EU countries. Euthanasia and assisted suicide are forbidden in most EU countries. The Netherlands, Belgium, and Luxemburg have legalized euthanasia. Switzerland allows assisted suicide, and recently approved guidelines allow doctors to perform a sort of passive euthanasia in Sweden.

Although the deaths of *Englaro*, *Welby*, *Monicelli,* and *Magri* represent different type ELD cases, they increase public interest regarding ELD issues, in particular euthanasia and the right to decide in advance to give authorization or non-authorization for life-sustaining artificial treatments ("living will"). Those cases are all characterized by the desire to avoid physical and/or psychic pain and poor quality of life. The 2011 Eurispes (Italian Institute of Political Economical and Social Studies) report data will be show that 66.2% of Italians are in favor of euthanasia: 18 to 24-year-olds: 75.3%; 25 to 34-year-olds: 70.9%; 35 to 44-year-olds: 67.7%; 45 to 65-year-olds: 65%; and over 65 years: 53.7%). Additionally, 77.2% of Italians would like a bill that puts "living wills" in writing.

The primary and fundamental issue of ELD is the need of a unifying model that would identify the unique and critical relationship between patient and doctor, whose primary mission should be not only "to cure" but also "to care." It is recommended to focus the attention of forensic community on the relevance that the concept of "quality of life" may have in ELD issues.

End-of-Life Decision, Quality of Life, Patient-Physician Relationship

E2 The Spider's Web Embedded in Competency to Stand Trial: Forced Psychotropic Medication and a Defendant's Right to Due Process to Refuse

Carl N. Edwards, JD, PhD, 4113 Sunflower Ln, Temple, TX 76502; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th St, Rm 223, Erie, PA 16501; and William Bernet, MD*, 1562 Timber Ridge Dr, Brentwood, TN 37027*

After attending this presentation, attendees will better comprehend the issues surrounding this controversial concept regarding mandated or forced medication and how lawyers, judges, and experts affect a defendant's rights involving due process and loss of liberty concerns.

This presentation will impact the forensic science community by conveying knowledge, competence, and performance about diverse perspectives on these issues that will enable legal practitioners, whether lawyers or judges, to be more competent, aware and knowledgeable in the complexities of this concept for the performance of their duties in and out of the courtroom.

Fascinating legal and medical issues involving a defendant's due process under the Fourteenth Amendment to each person's liberty interest in refusing medication are raised in both criminal and civil contexts. These situations may arise where a court must decide whether a defendant is competent to stand trial and that defendant's refusal of medication asserting loss of liberty. Courts are faced with the delicate balancing which occurs where a defendant's right as a citizen is considered in light of protecting that individual and the community's safety interests. The courts then weigh due process issues while balancing a defendant's right to trial and considering the prosecutor's interests on behalf of the victim in bringing a defendant to trial. After hearing testimony from experts presented by the lawyers or from court-appointed experts, the courts then carry the responsibility to decide whether defendant possesses the capacity to make an intelligent, informed decision about the medication.

Often such competency issues involve having courts decide whether mandated psychotropic medication is necessary. Judges, lawyers, and medical experts struggle with reaching the right or appropriate decision tailored to each defendant's circumstances. Due to the importance of understanding the surrounding medical and scientific concerns, issues involved in the propriety of forced medication can be a nightmare for the judges and lawyers involved in these cases.

Judges and lawyers alike are responsible under the law for knowing what types of resource books to rely upon, selecting an appropriate expert to assist in understanding these technical pharmaceutical and medical issues, and having defendants appropriately evaluated by experts to address the requisite propriety of forced medication. Judges and lawyers in state courts have dealt with these issues in a variety of ways in civil and criminal cases. Judges consider and weigh criteria evaluating risks to determine whether defendant should be committed

due to: (1) substantial risk of physical harm to self or others; or, (2) substantial and immediate risk of serious physical impairment or injury to self; or would benefit from treatment in a hospital for mental illnesses manifested by evidence of behavior creating grave and imminent risks to substantial rights of others or self.

Before permitting courts to order forced medication, legislatures in various state and federal jurisdictions have mandated courts to consider weighing a defendant's vital interests under a variety of analyses such as defendant's (or patient's) best interests and whether a less intrusive treatment exists.

With the complexities of treatment for mental illnesses advancing significantly through the past half-century, professionals are confronted with the dilemma of overestimating the effectiveness of various medications while minimizing the extent of side-effects involved in the medications and possible alternative medications being considered. The presentation will analyze these issues as well as addressing special challenges presented to professionals in the court process where children and parental control issues are involved as well as in the circumstances of sex offenders in involuntary commitment situations.

Forced Medication, Due Process, Competency

E3 Judicial Bias and Scientific Evidence in Criminal Cases

Donald E. Shelton, JD, PhD, 101 E Huron, PO Box 8645, Ann Arbor, MI 48107*

After attending this presentation, attendees will have a better understanding of the possible predisposition of trial and appellate judges to routinely admit scientific evidence offered by the prosecution in criminal cases.

This presentation will impact the forensic science community by assisting attorneys and forensic scientists in understanding the basic psychological principles that affect judicial admissibility decisions.

What accounts for the current overwhelming court rejection of *Daubert* challenges? Judicial decisions often do not indicate that the judges weighed the scientific validity of proffered evidence meaningfully. Most of the decisions rationalize admissibility based on prior admissions of such evidence. Judges use what has been characterized as ''judicial gymnastics,'' including refusing to hold a hearing, taking "judicial notice" of admissibility, ignoring the *Kumho* case, reversing the burden of proof, or abdicating the "gatekeeper" duty by deferring to jurors to "weigh" scientific issues.

Why? One significant factor may be a systemic pro-prosecution bias on the part of judges that is reflected in admissibility decisions, regardless of the standards of *Frye* or *Daubert*. As Groscup, found, "as a general proposition, judges disfavor civil plaintiffs and criminal defendants and are more likely to rule against them than against their opposites even when presenting equivalent evidence or arguments."[1]

Systemic pro-prosecution bias by judges is a function of elementary psychological concepts. Guthrie described it as a reflection of an "attitudinal blinder," relying on significant empirical studies of judicial attitudes and actions: Whether elected or appointed, judges come to the bench with political views. This is not to say that they have pre-committed to positions in particular cases, but—judges do have opinions, and these opinions or attitudes can predispose them to rule in ways that are consistent with those opinions or attitudes.

To establish the presence of attitudinal blinders among judges, political scientists have developed, and provided empirical evidence to support, the so-called attitudinal theory or model—the evidence suggests that attitudinal blinders are an issue not only at the highest court in the land but also in these lower courts.[2]

These "attitudinal blinders" are especially prevalent in criminal cases and especially in the state courts where most criminal cases are tried. As Professor Rodney Uphoff put it, "In the end, state court judges are, for the most part, rational actors whose attitudinal biases reflect their self-interest and their backgrounds. Most are answerable to a tough-on-crime electorate and are often reluctant, therefore, to make risky political decisions upholding the constitutional rights of criminal defendants."[3] Specifically, Uphoff comments on how this attitudinal bias manifests itself in criminal cases:

Most judges, especially those with prosecutorial experience, presume that most defendants are, in fact, guilty, even though some are, in fact, innocent. This presumption of guilt, pro-prosecution perspective not only affects the manner in which many judges rule on motions, evaluate witnesses, and exercise their discretion, but it also adversely affects the willingness of many judges to police law enforcement agents and prosecutors.[4]

The current legal state of forensic science evidence in criminal cases is somewhat schizophrenic. While many scientists and scholars, and even a congressionally mandated national study, seriously question whether there is validity to non-DNA forensic evidence, trial judges simply continue to admit such evidence and appellate judges continue to affirm them.

Judicial Bias, Judges, Admissibility

E4 It Don't Rain in Indianapolis in the Summertime; the Defense Expert is Never Interested in Reliable Scientific Methods; the Government's Expert Will Always Use the Best Methods and Testify From an Unbiased Perspective; and, It Don't Snow in Minneapolis When the Winter Comes

Joseph P. Bono, MA, PO Box 2509, Leesburg, VA 20177*

After attending this presentation, attendees will become aware of the importance of an expert witness to maintain impartiality in testifying.

This presentation will impact the forensic science community by reinforcing the belief that the expert witness must avoid the "desire to win" mentality, which is a product of the adversarial process.

This presentation will examine the experiences of an "expert witness" whose perception of reality is based on decades testifying for the government and whose recognition of reality in the courtroom has faced many "what is happening here" moments.

For someone whose career spanned more than 32 years in forensic science laboratories affiliated with law enforcement agencies, there is an inherent desire to believe in truth, justice, and the American way when entering the courtroom. In the greatest majority of cases, this has and will usually be true. Most forensic science laboratories which are a part of a government organization and which are accredited conform to the requirements for reliability and relevance in following analytical protocols. Many who have spent the entirety of their careers in similar professional settings have come to believe that only the defense will "go after the expert" in the adversarial arena of the courtroom, and then only to keep the client (translation, "bad guy") out of

jail. Now, think *Porgy and Bess* – George Gershwin had it right when he wrote "*Ain't Necessarily So*." The defense does have the legal obligation to cross-examine a prosecution witness in any way deemed appropriate; and the prosecution does have a legal obligation to cross examine a defense expert to demonstrate the invalidity of contrary opinions. Winning at any cost is not supposed to be a part of the equation; however, sometimes this appears to be exactly what is happening.

The reality is that on both sides, there are always elements in any expert witness testimony which can and should be determining factors in distinguishing between what "one claims to see" (sometimes with one eye shut) from "what is." The courtroom is not always a search for the truth; and the adversarial system does influence priorities in ensuring that the process gets it right. Both sides at times start with a conclusion and then work backwards in considering only those data interpretations that supports these pre-determined conclusions. This is the scientific method in reverse. Testing the hypothesis is supposed to precede the formulation of a conclusion. There are still expert witnesses who refuse to acknowledge the fact that standardized methodology and requirements for documentation do exist, and everyone who testifies as an expert witness, especially witnesses called by the government, must conform to these standards. There are still too many government witnesses who use a cafeteria style approach to testifying as an expert. All of this and more happens on both sides in the courtroom, both pre-trial and then again during the trial. There are factors both the defense and especially the prosecution can and should consider in determining the reliability, relevance, validity and veracity of expert witness testimony:

1. The government seeks expert witness testimony outside of a government entity when the expertise exists within that entity.
2. The expert witness admits that the government retained their services to state a specific opinion.
3. The analytical approach to evidence analysis is "holistic" rather than method specific.
4. There are no documented protocols or evidence of conformance to standards.
5. The expert witness bases conclusions on "training and experience" rather than on empirical data or demonstrative evidence.
6. A laboratory which loses accreditation or which does not meet the requirements for extending accreditation has serious problems.
7. Referencing the internet as the only authoritative source is questionable at best.

These situations not only "can happen," they have all been experienced in a very narrow timeframe of two years. In the courtroom, the judge, as "gatekeeper," makes every attempt to ensure that expert witness testimony meets the standards of the jurisdictional rules of admissibility. However, that gatekeeper's responsibility and the responsibilities of all participants in the process require more than a belief that the "good guy always wears a white hat." Everyone who testifies in a courtroom has a responsibility to play by the rules, irrespective of where the subpoena to appear originates, especially when the expert is testifying "for the prosecution" in a criminal trial. This does not always happen.

The desire to win is a product of the adversary system, and this adversarial process can usually be very effective at arriving at a just verdict. However, arguments based on challenges to methodology, documentation, data, and the validity of conclusions can be more persuasive than the occasional personal attacks from both sides during the "adversarial processes" in the courtroom.

Expert Witness, Standards, Adversarial Process

E5 The Effect of the NAS Report Upon Courts in Admitting Forensic Expert Testimony

Joseph J. Maltese, JD, New York Supreme Court, 130 Stuyvesant Pl, 3rd Fl, Staten Island, NY 10301*

After attending this presentation, attendees will gain an understanding of the extent of the impact the NAS Report recommendations have had on judges deciding whether to preclude or limit expert witness testimony.

This presentation will impact the forensic community by providing the results of federal and state court decisions that have referenced the NAS Report, and to what extent certain types of forensic specialists have been precluded or limited in testifying in court.

In February of 2009, the National Research Council of the National Academy of Sciences (NAS) published their long-awaited Report entitled, "*Strenghthening Forensic Science in the United States: A Path Forward*," which is commonly refered to as NAS Report.[1] The NAS Report reviewed: the fundamentals of the scientific method as applied to forensic practice, such as hypothesis generation, testing, falsifiability, replication and peer review of scientific publications. The Report also assessed the methods and technologies of forensic science such as: the collection and analysis of forensic data; the accuracy and error rates of forensic analysis; the sources of potential bias and human error in the interpretation by forensic experts; and the proficiency testing of forensic experts.

The NAS Report, made 13 recommendations. The first and primary recommendation was to "promote the development of forensic science into a mature field of multidisciplinary research and practice," founded on the systematic collection and analysis of relevant data. In order to effectuate that over-riding recommendation, the report recommended that Congress should create a National Institute of Forensic Science (NIFS) to focus on establishing "best practices" for forensic science professionals and forensic laboratories. Once established and funded, the NIFS should establish standards for mandatory accreditation of forensic science laboratories, scientists, and medical examiners. The report recommended that NIFS should promote scholarly, competitive peer-reviewed research, and technical development in the forensic sciences. It should also develop strategies to improve forensic science research and educational programs and new technologies. Lastly, it should develop programs to improve understanding of forensic science disciplines and their limitations within the legal system.

While the Congress has not appropriated monies to fund the National Institue of Forensic Science, the NAS Report with its critique of certain forensic scpecialties has been presented to judges by attorneys in court proceedings as part of their applications to preclude certain expert witnesses, or at least to limit the extent of their testimony and opinions before the judge or jury. This study will review the 25 federal and 26 state court published decisions that have cited the NAS Report from Febrauary 2009, when the NAS Report was first published until August 1, 2012, to ascertain what impact, if any, the report has had on the court decisions to preclude or limit expert testimony.[2] The study will evaluate whether courts are merely citing to the NAS Report to acknowledge its existence, or is the NAS Report cited as a rationale for a court's decision to preclude or limit expert witness testimony.

In conclusion, this study will provide some insight into the impact the NAS Report has had on some court decisions on the admisssibility of some forensic specialties and how the forensic community can address those issues the courts found significant in the future.

NAS Report, Experts, Admissibility

E6 Federal Criminal Discovery

Linda Kenney Baden, JD, 15 W 53 St, Apt 18 B/C, New York, NY 10019; Peter Neufeld, JD*, Innocence Project, 40 Worth St, Ste 701, New York, NY 10013; Michael T. Ambrosino, JD*, U.S. Attorney's Office, 555 4th St, NW, Washington, DC 20001; Haskell M. Pitluck, JD*, 573 Lake Ave, Crystal Lake, IL 60014; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th St, Rm 223, Erie, PA 16501; and Paula H. Wulff, JD*, 3201 Russell Rd, Alexandria, VA 22305*

The goal of this presentation is to explore how the attorneys in the process can facilitate the proper transfer of discovery material.

The FBI Laboratory at Quantico processes thousands of cases every year. Many of these requests come from state agencies. Ultimately, laboratory examiners and FBI case agents may testify in state criminal trials. The interplay of federal criminal discovery in state trials varies as a result of multi-jurisdictional local rules. However, all discovery must satisfy the inherent rules of *Brady* and *Giglio*. The role of the attorneys in requesting proper discovery material and delivering or achieving the receipt of this information is very important. How such information is handled and provided to parties is inherently critical to the judicial process. This presentation will impact the forensic science community by examining the varying roles and duties of the attorney from the generic framework down to the specific concluded cases including Casey Anthony, Santae Tribble, and Kirk Odem.

Scientific evidence is a critical and crucial element in seeking the just resolution in criminal case proceedings. Federal laboratories, for example, the FBI Laboratory at Quantico, Virginia, the ATF&E Laboratory in MD, process thousands of cases every year involving evidence associated with federal and state criminal investigations. As a result, federal laboratory examiners may be called upon to produce discovery documents and testify in both federal and state criminal proceedings. The interplay of federal criminal discovery responsibilities in producing discovery material to state attorneys is further complicated as a result of multi-jurisdictional local rules which direct or provide guidance to state prosecutors regarding what must be provided to opposing counsel. However, all discovery must satisfy the inherent rules of *Brady v. Maryland, 373 U.S. 83 (1963*) and *Giglio v. United States*, 405 U.S. 150 (1972) which require prosecutors disclose exculpatory evidence or information that impeaches the credibility of government witnesses against a defendant. The role of the attorneys, as the proponent in offering the scientific evidence and associated testimony, in requesting proper and comprehensive discovery material, the laboratory's role in providing all relevant documents; and the delivery these documents by the government to the defense is inherently critical to facilitate a fair and accurate process that convicts the guilty and sets the innocent free.

More than three decades after a rape victim identified Kirk L. Odom based on eyewitness testimony, new DNA testing of evidence, a hair fragment, stains on a pillowcase, and robe confirmed Odom's innocence. The U.S. Attorney in the case in a court filing stated that "More than 30 years after Mr. Odom's conviction, DNA testing reveals that he suffered a terrible injustice. The United States expresses its profound regret for the harm suffered by Mr. Odom, and requests that this court immediately vacate Mr. Odom's convictions and dismiss the indictments against him with prejudice." In 1978, Santae Tribble was accused of murder, in part, based on a single hair that supposedly matched Tribble's "in all microscopic characteristics" from a stocking worn by the killer. In 2012, federal prosecutors moved to have Tribble's 1980 conviction vacated based, in part, on this testimony and subsequent scientific testing of the case evidence. What discovery obligations attach to any scientific testing conducted by either the government or the defense on the evidence?

From the time a defense attorney seeks discovery, for example, in a case such as *Florida v. Casey Anthony*, or begins a new challenge based on scientific evidence, what is the interplay between the forensic laboratory, the prosecutor (federal or state), and the defense? If a laboratory determines that prior scientific testing of case evidence was incorrect, how does that information get transferred to the relevant parties: the defense attorney, defendant, and the courts? How do judges view the exchange of discovery? What are the legal and ethical requirements for all involved?

This panel presentation will explore these cases and other contemporary issues involving: (1) new scientific testing of old cases and how the attorneys in the process can facilitate the proper transfer of discovery material; (2) how judges are the gatekeepers of the search for the truth; and, (3) the varying roles and duties of the attorney from the generic framework down to the specific concluded cases including cases the panelists have been involved in including those of Casey Anthony, Santae Tribble, and Kirk Odom.

Casey Anthony, FBI Lab/Quantico, Federal Criminal Discovery

E7 The Right of Being a Donor Until the Real Death and Beyond

Arianna Giovannetti, MD, viale Regina Elena 336, Rome, , ITALY; Raffaele La Russa, MD, 336, Viale Regina Elena 00161, Rome, ITALY; Matteo Gulino, JD, 336, Viale Regina Margherita, 00161, 5, Viale Bruno Buozzi, 00197, Rome, ITALY; Gianluca Montanari Vergallo, JD, Viale Regina Elena, 336, Rome, ITALY; and Paola Frati, PhD, Univ of Rome, Dept of Anat Histol Forensic and Orthop Sciences, Viale Regina Elena 336, Roma, ITALY*

After attending this presentation, attendees will understand the differences of opinion and legislation among Italian and European Union (EU) and other EU countries in the field of organ transplants as well as the definition of death.

This presentation will impact the forensic community by analyzing social, ethical, and legal aspects among different nations in the provision of organ transplants, taking into account rare aspects concerning the definition and determination of death, procedures of organ donation, and consent/right of being a donor.

This report reviews the ongoing debate concerning organ transplantation in Italy, comparing the Italian point of view with other countries'. Currently, the challenge in the EU regarding organ transplantation is to increase the supply of donors and ensure the quality and safety of the process from donation to transplantation. Therefore, in December 2008, the European Commission formulated several priorities to be enacted in order to strengthen the cooperation among Member States. These priorities were included in the "Action plan on Organ Donation and Transplantation (2009-2015): Strengthened Cooperation between Member States." The current legislation in Italy (Law 578/1993 - DM 2008) accepts two different assessments of death: an observation period of six hours with two checks, using EEG at the beginning and at the end of the period or, alternatively, continuous ECG for at least 20 minutes. Despite the obvious limitations imposed by the criteria of determination of death, the quality of the performed transplants has improved significantly with transplant outcomes comparable or superior to the main European countries (as evidenced by the main international registries). This achievement has been confirmed by a detailed study performed by the Italian Superior Health Institute (ISS - the leading technical and scientific public body of the Italian National Health Service) that, in line with European goals, has initiated a project for assessing the quality of health care with the aim of improving health conditions, raise the level of satisfaction of citizens and improve transparency.

Since 2008, due to the application of experimental protocols adopted by some leading Italian hospitals, the damages caused by prolonged cardiac observation period (20 minutes) have been minimized. These protocols are conceived to optimize logistics planning for the early identification of potential Non-Heart-Beating Donors (NHBDp). The NHBDp is a subject which doctors should consider the possibility to become a NHBD, before the assessment of clinical and legal death. The NHBDp category is essential in the organization of health care, and is compliant with legal and ethical principles. The organs preservation should be started very early (from the moment there is a possibility of evolution from a NHBDp into NHBD), applying all

actions and techniques suitable for this purpose. However, always respecting the consent and (if applicable) the status of a living person, and the dignity of the corpse. Without taking these preventive actions, that are put in place while waiting the assessment of the individual's will or, alternatively, the non-opposition of relatives or legal representative (pursuant to Law 91/1999), the medical staff may infringe the right to donate organs (or the principle of non-opposition). Therefore, it would be contrary to the purposes of the law and to the respect due to the will of the donor, not to guarantee his right of being a donor on technical grounds.

In conclusion, although Italy does not implement the provisions of the Protocol of Pittsburgh, adopted by several countries (such as US, ES, NL), we are able to obtain very encouraging results in terms of transplants thanks to maximum optimization of all the technical, organizational and logistical aspects of the organ donation process.

Organ Transplantation, Informed Consent, Death

E8 NSTC Subcommittee on Forensic Science Process and Path Forward for U.S. Crime Laboratories: A Voluntary, Consensus, Based Approach

Mark D. Stolorow, MS, NIST, Law Enforcemt Standards Office, 100 Bureau Dr, MS 8102, Gaithersburg, MD 20899-8102; Kenneth E. Melson, JD*, George Washington University Law School, 2000 H Street, NW, Washington DC, 20052; Patricia A. Manzolillo, MSFS*, U.S. Postal Inspection Service, 22433 Randolph Dr, Dulles, VA 20104-1000; Robin W. Jones, BS*, U.S. Dept of Justice, 99 New York Ave, NE, Washington, DC 2002; Jill L. Spriggs, MBA*, California Dept of Justice, Sacramento Lab, 4949 Broadway, Rm F104, Sacramento, CA 95820; and Stephanie Stoiloff, MS*, Miami-Dade Police Dept, Forensic Services Bureau, 9105 NW 25th St, Miami, FL 33172*

After attending this presentation, attendees will learn of the final recommendations of the Subcommittee on Forensic Science for ongoing improvements of forensic science, learned about a new federal Executive Branch initiative and discussed potential strategies for uniform implementation of the recommendations.

This presentation will impact the forensic science community by stressing how implementation strategies for the recommendations and the new federal initiative may dramatically affect forensic science laboratories, experts, accreditation and certification bodies, and standards development. The implementation strategies for the Subcommittee's recommendations and the new federal initiative may have a dramatic effect on forensic science service providers, experts, accreditation and certification bodies, and standards development methodologies. The National Academy of Sciences (NAS) Report, "*Strengthening Forensic Science in the United States: A Path Forward,"* called for change and significant improvement in the forensic sciences. The Federal government, the courts, law enforcement, and the forensic science enterprise as a whole have worked diligently to develop a meaningful response to the NAS report. The culture of enhanced scientific, quality, and integrity continues to evolve and improve. The question is how will forensic scientists embrace it?

In 2009, the Office of Science and Technology Policy, under the auspices of the National Science and Technology Council, established the Subcommittee on Forensic Science (SoFS). The SoFS's primary mission was to assess practical challenges and make recommendations associated with the findings of the NAS Report. Over the last three years, SoFS actively pursued the investigation and analysis of critical issues which can inform a coordinated and meaningful advancement of the concepts enunciated in the NAS Report through the SoFS five interagency working groups composed of Federal, state, and local laboratory representatives, academics, lawyers, judges, researchers, and law enforcement officials. The SoFS's detailed and comprehensive exploration has broadened the breadth of foundational knowledge and situational awareness, thereby informing a meaningful framework for moving forward. Now that the SoFS has published its recommendations, its successor entity is ready to provide sustainable leadership and direction to coordinate uniform implementation within the United States.

This presentation will discuss implementation strategies for the specific recommendations issued by the SoFS that may affect many forensic science service providers in the U.S. Foremost is a voluntary, consensus-based approach through a federal coordination body. Other strategies also exist; however, such as federal legislation, state legislation, state forensic science commissions that range in authority from advisory to regulatory, and uniform state laws created through a consortium of state governments. The vehicles for and challenges and alternatives to wide-spread, uniform implementation will be explored by the panel. Strategies for implementation and enforcement must be considered to promote quality and ensure the scientific integrity of forensic science. This panel will discuss the opportunities and challenges associated with implementing SoFS recommendations. Issues such as accreditation, certification, education, proficiency testing (and proficiency test providers), scientific working groups, vocabulary, report writing, uniform code of ethics, medicolegal death investigators and other matters will be discussed. Consideration will also be given to the role of the federal and state governments in supporting implementation of the recommendations, the role of discipline-specific working groups in forensic science standards development, the role of accreditation and certification bodies in enforcing the recommendations, and the role of each forensic science service provider in ensuring the continual improvement of forensic science in the United States.

Recommendations, Subcommittee, Federal Initiative

E9 ABA's Proposed Changes to Legal Practices That Impact Expert Testimony

Kenneth E. Melson, JD, George Washington University Law School, 2000 H Street, NW, Washington DC, 20052; Joseph I. Cassilly, JD, State's Attorney, 20 W Courtland St, Bel Air, MD 21014; Matthew F. Redle, JD*, 148 S Brooks St, Sheridan, WY 82801; and Jay A. Siegel, PhD*, 8334 Tilly Mill Ln, Indianapolis, IN 46278*

After attending this presentation, attendees will learn about the American Bar Association's recommendations on how to change legal practices to shape the interaction of law and forensic science regarding admissibility of evidence, questioning of and instructions to jurors regarding scientific evidence, contents of laboratory reports, uniform vocabulary, as well as what ethics lawyers should expect from forensic scientists they hire.

Forensic science is the application of science to the law, and is therefore dependent upon the legal system's procedures for admissibility of evidence, discovery requirements, juror education, and establishing ethics for expert witnesses. The American Bar Association is the most influential organization representing lawyers and judges in the United States. Its views and recommendations must be taken seriously by the forensic science community. Every practicing scientist will want to attend this presentation to learn what changes they may expect next time they appear in court. This presentation will impact the forensic science community by pointing out changes on the horizon, as the American Bar Association's views and recommendations must be taken seriously by the forensic science community.

The American Bar Association, America's largest organization representing attorneys, has passed several resolutions calling on lawyers and judges to change their practice and procedure in the courtroom. These resolutions will impact laboratories and the testimony of forensic scientists. Included in these resolutions are:

RESOLUTION #101, urging federal, state, territorial, and local governments to adopt pretrial discovery procedures requiring laboratories to produce comprehensive and comprehensible laboratory and forensic science reports for use in criminal trials to include identification of:

1. The procedures used in the analysis.
2. The results of the analysis.
3. The identity, qualifications, and opinion of the analyst.

4. The identity and qualifications of those who participated in the testing including peer review or other confirmatory tests; and,
5. Any additional information that could bear on the validity of the test results, interpretation or opinion.

RESOLUTION #101C, urging judges and lawyers to consider the following factors in determining the manner in which expert testimony should be presented to a jury and in instructing the jury in its evaluation of expert scientific testimony in criminal and delinquency proceedings:

1. Whether experts can identify and explain the theoretical and factual basis for any opinion given in their testimony and the reasoning upon which the opinion is based.
2. Whether experts use clear and consistent terminology in presenting their opinions.
3. Whether experts present their testimony in a manner that accurately and fairly conveys the significance of their conclusions, including any relevant limitations of the methodology used.
4. Whether experts explain the reliability of evidence and fairly address problems with evidence including relevant evidence of laboratory error, contamination, or sample mishandling.
5. Whether expert testimony of individuality or uniqueness is based on valid scientific research.
6. Whether the court should prohibit the parties from tendering witnesses as experts and should refrain from declaring witnesses to be experts in the presence of the jury.
7. Whether to include in jury instructions additional specific factors that might be especially important to a jury's ability to fairly assess the reliability of and weight to be given expert testimony on particular issues in the case.

RESOLUTION #101D, urging urges judges and lawyers to consider the following factors in formulating jury *voir dire* in criminal cases where forensic science evidence is contested:

1. Jurors' understanding of general scientific principles, including specialized training in science, knowledge or education in science and experience with laboratory practices.
2. Jurors' understanding of specific scientific principles relevant to the forensic science evidence that may be presented at trial, including specialized training, knowledge or education in the specific scientific discipline utilized in the case [chemistry, toxicology, engineering, etc.].
3. Any preconceptions that jurors may have about the forensic science evidence; and,
4. Jurors' bias for or against scientific evidence, including whether scientific results will be accepted or rejected without consideration.

PROPOSED RESOLUTION #300, urging counsel to utilize proposed Guidelines for Conduct of Experts Retained by Lawyers. These Guidelines pertain to Integrity/Professionalism; Competence; Confidentiality; Conflicts of Interest and Disclosure; and Contingent Compensation.

To assess the viability and impact of these resolutions, an expert panel of lawyers and both public and private forensic scientists will discuss the recommendations.

ABA, Admissibility, Legal Practices

E10 The Supreme Court's Decision on *Daubert* After 20 Years

Paul C. Giannelli, JD, Case Western Reserve Univ, School of Law, 11075 E Blvd, Cleveland, OH 44106*

After attending this presentation, attendees will appreciate how the U.S. Supreme Court's landmark decision in *Daubert v. Merrell Dow Pharmaceuticals* (1993) has developed over the last 20 years.

This presentation will impact the forensic science community by explaining the transformation of the *Daubert* decision from one that many believed lowered the barriers to the admissibility of expert testimony to one later described by the Supreme Court as imposing an "exacting standard."[1]

Daubert and its progeny revolutionized the way courts decide the admissibility of expert testimony. Prior to *Daubert*, the majority of courts in this country, both state and federal, followed the "general acceptance" test for determining the admissibility of scientific evidence. This test was derived from *Frye v. United States*, a 1923 decision of the D.C. Circuit. *Daubert* rejected the *Frye* test as a matter of statutory interpretation; however, from its beginning, lower courts struggled to interpret the *Daubert* opinion. Numerous passages in the opinion suggested that more evidence should be admissible under *Daubert's* new reliability test than under the *Frye* general acceptance test, which the Court rejected. Yet, over time, the judiciary's "gate keeping" role under *Daubert* developed into a stringent test—at least in civil cases. "The Federal Judicial Center conducted surveys in 1991 and 1998 asking federal judges and attorneys about expert testimony. In the 1991 survey, seventy-five percent of the judges reported admitting all proffered expert testimony. By 1998, only fifty-nine percent indicated that they admitted all proffered expert testimony without limitation. Furthermore, sixty-five percent of plaintiff and defendant counsel stated that judges are less likely to admit some types of expert testimony since *Daubert*."[2]

In contrast, *Daubert* did not have the same effect in criminal litigation. In 2000, one commentator noted, "the heightened standards of dependability imposed on expertise proffered in civil cases has continued to expand, but expertise proffered by the prosecution in criminal cases has been largely insulated from any change in pre-*Daubert* standards or approach."[3] In addition, an extensive study of reported criminal cases found that "the *Daubert* decision did not impact on the admission rates of expert testimony at either the trial or appellate court levels."[4]

The disparate treatment of federal civil and criminal cases has been criticized, including in the National Academy of Sciences 2009 Report on forensic science. After noting that "trial judges rarely exclude or restrict expert testimony offered by prosecutors," the report commented: "The situation appears to be very different in civil cases. Plaintiffs and defendants, equally, are more likely to have access to expert witnesses in civil cases, while prosecutors usually have an advantage over most defendants in offering expert testimony in criminal cases. Ironically, the appellate courts appear to be more willing to second-guess trial court judgments on the admissibility of purported scientific evidence in civil cases than in criminal cases."[5] The report went on to conclude: "The bottom line is simple: In a number of forensic science disciplines, forensic science professionals have yet to establish either the validity of their approach or the accuracy of their conclusions, *and the courts have been utterly ineffective in addressing this problem*." *Id.* at 53.

The cause of this disparity remains disputed, as does the advantages of *Daubert* when compared to *Frye*. A dozen or so states have retained the general acceptance test. Because many of these jurisdictions are populous (e.g., California, New York, Florida), *Frye* remains important.

Yet, *Daubert's* impact on forensic science has been substantial. Along with the advent of DNA in the late 1980s, *Daubert's* emphasis on empirical testing resulted in a paradigm shift in the treatment of expert testimony in criminal trials. Within two years of *Daubert*, a courtroom challenge to the admissibility of handwriting evidence had occurred. These were followed by attacks on fingerprint and then firearms identification comparisons. Although these attacks have had limited success, they did expose the lack of an empirical bases for many common techniques. Moreover, these challenges would not have occurred under the *Frye* test. Interestingly, other techniques, such as bite mark and hair comparisons seem immune from attack under *Daubert*.

E11 Anatomy of a Crime Lab: How Even a Lawyer Can Investigate the Reliability of Test Results

Christine Funk, JD, and Lauri Traub, JD*, 919 Vermillion St, Ste 200, Hastings, MN 55033*

After attending this presentation, attendees will understand basic tools with which to arm themselves when investigating the reliability of forensic science intended to be offered in court.

This presentation will impact the forensic science community by demonstrating the importance of investigating the conclusions provided to lawyers by forensic scientists. It will provide prosecutors and defense attorneys with a basic road map to face the challenge of assuring foundational reliability of evidence offered in court.

In the spring of 2012, a lawyer with an undergraduate degree in business administration sought to learn more about the test results offered by the Saint Paul Police Department Crime Lab in a case involving drug chemistry. With the assistance of a lawyer with a Bachelor of Arts in Social Work, a request for the underlying file was made. Reviewing the file, much of it made no sense whatsoever. An appointment was made to meet with the analyst to review the file. At the time the appointment was made with the analyst, the lawyers expected nothing more than to have the science of drug testing and the contents of the testing file explained to them. The thought that something was very wrong in the St. Paul Police Department Crime Lab never entered their minds. The attorneys notified the prosecutor of the meeting as a professional courtesy. The meeting with the lab analyst lasted a little more than an hour and was memorialized in notes taken by the prosecutor.

In very short order, questions about the file were raised – including issues of record keeping, the lack of the use of blanks, deviations from protocols, and the absence of validation studies.

The lawyers left the meeting with more questions than answers. Using SWGDRUG minimum guidelines, the lawyers returned to the lab. In a meeting with the lab director, the lawyers became more alarmed. The lab director had taken the position that SWGDRUG guidelines were just that, guidelines, and therefore they did not have to follow them.

Armed with this information, a meeting was scheduled with a local expert. His response? "This is Houston all over again." He agreed to work on the case and spent countless hours teaching two attorneys the science of drug testing.

This presentation will include an overview of the history of this and other crime lab failures. Some of the fault can be laid at the feet of crime labs operating outside generally accepted practices; however, some of the fault must also be ascribed to the judges tasked as gatekeepers, prosecutors who for years introduced reports without question, and defense attorneys who lacked the time, knowledge or motivation to investigate.

Determining what witnesses should be called, what documents should be introduced, how to work with your experts to learn the science and effectively cross-examine the witnesses and what testimony should be sought in a hearing to challenge the admissibility of evidence will also be explored.

Frye-Mack, Drug Testing, St. Paul Crime Lab

E12 Forensic Chemistry and Toxicology Laboratory Tests: Are Reliable Principles Being Reliably Applied?

Glenn Hardin, MPH, Hamline Univ, Forensic Sciences Program, 1536 Hewitt Ave, MB 239, St. Paul, MN 55104-1284*

After attending this presentation, attendees will understand the principles that make forensic chemistry and toxicology laboratory test results reliable, what laboratory documents are necessary to assess whether those reliable principles have been reliably applied to the case at hand, and how to evaluate the requested documents to determine if the reported results are, in fact, reliable.

This presentation will impact the forensic science community by describing the importance of examining all relevant laboratory documents. Attorneys play a critical role in the criminal justice system since they are the last reviewers before the trier of fact evaluates the physical evidence. To be effective in this role, knowledge of what documents to request and what documents demonstrate reliability, skills in how to evaluate the documents, and understanding to recognize when to consult with an expert.

Why it is that so often attorneys accept crime laboratory reports at face value and fail to request critical documents? Most testing methodologies used in forensic chemistry and toxicology are decades, if not centuries, old. As methodologies, the principles of screening tests (color, microcrystal, and immunoassay tests) are reliable; the principles of confirmation tests (gas chromatography-mass spectrometry (GC/MS), liquid chromatography-mass spectrometry (LC/MS), and infrared (IR)) are reliable; and, the principles of determining sample weights using analytical balances are reliable. However, reliable principles must be reliably applied. Critical laboratory documents hold the key to determining if the crime laboratory's reported results are reliable.

Naming practices for laboratory documents vary from state to state and laboratory to laboratory. Familiarity with a laboratory's nomenclature is crucial. Attorneys sometimes use boilerplate request-for-discovery letters that contain lists of documents that were drafted by an attorney in a different state. Often much of what is requested is not provided by the laboratory, as the laboratory uses different language to describe their documents. If requesting attorneys don't understand what they are requesting and why, they may not realize that they are not getting the documents they need to properly evaluate the physical evidence. If a red document is requested, one that the laboratory calls a fuchsia document, the laboratory probably won't provide the desired document and they won't inform the requestor why the requested documents are not being provided.

The reliability, or lack thereof, of scientific findings affects criminal, civil, and family court matters. Cases will be presented illustrating how reliability can turn on large details and seemingly small ones as well.

Small elements that can result in a laboratory result being excluded include a police officer's missing signature on a breath-alcohol test report, a missing internal (laboratory) sample chain of custody, or a failure to demonstrate analytical sensitivity through proper use of calibrators and controls. Large occurrences that can affect a laboratory result include a lack of written laboratory protocols, training records, bench notes, and method validation. Evaluation of the documents of reliability can lead to a sample result being excluded or in some cases —shutting down an entire laboratory.

Reliability must be demonstrated for every test on every item of physical evidence in every case. Reliability can only be demonstrated through documents.

Reliability, Evidence, Testing

E13 An Independent Forensic Laboratory May Reduce Bias

Everard J. Cowan, PhD, Fairleigh Dickinson Univ, Institute for Forensic Science Administration, 285 Madison Ave, M-MS1-03, Madison, NJ 07940*

After attending this presentation, the attendees will understand and be able to apply the four forensic science laboratory design principles: independence, democratic and local management, scientific inquiry, and scientific truth, also taking into account the tight relationships among the prosecution, police, and crime labs may introduce bias into forensic analysis. Attendees will learn to appreciate the importance of who the boss is. Attendees will understand how the alignment among the three organizations is created by having the same objectives, e.g., maximize number of convictions; by who funds the laboratory, determines and measures the success of the lab directors or supervisors; and by the integrated culture created among the prosecution, police and forensic scientists. Finally, attendees will learn the basic principles concerning how to change this relationship to minimize bias and to apply the design principles to redesign an organization. They will learn that these principles may require changing the principal (the boss) and the incentives leading to the crime laboratory identifying with the prosecution or police. They will learn that laboratories may need to report to a board of directors, rather than the prosecutor and police; may need to develop compensation plans for middle managers to encourage them to build a culture of learning based on error tolerant systems rather than error punishment; and may need to facilitate identity changes by the middle managers to encourage them to engage in the necessary organizational changes.

This presentation will impact the forensic science community by ensuring the lab is independent of the prosecution or defense and by describing monetary and non-monetary incentives that focus on producing scientific truth, leading to support a criminal justice system that will be seen as fair and impartial.

This presentation suggests that creating an independent forensic laboratory may reduce bias caused by the current tight relationship among the prosecution, police, and crime lab. When crime laboratories are funded by and aligned with the objectives of the prosecution or police, there is an increasing probability of conviction. This relationship may create the incentive to convict, with the matter of guilt or innocence as a secondary matter. This incentive to convict may induce unconscious bias in forensic-science analyses and interpretations. Labs that are independent of the prosecution and police (and the defense) will tend to be less subject to unconscious bias and bias-induced errors.

Who the boss is, is important. In any organization, it is the boss who sets the agenda, determines what success is and how that success is measured and rewarded. Organizational economics refers to this as a principal-agent relationship. The principal, in the tight relationship among the prosecution, the police, and the forensic laboratory, is either the prosecution or the police. The agent is the forensic laboratory. The direct agents are the directors and laboratory supervisors, i.e., the middle managers. The agents are motivated by monetary and non-monetary incentives. These incentives encourage the managers and the scientists to identify with the objectives of the principal. In a tight-knit relationship, the objectives of the principal and agent are aligned. In the criminal justice system, an objective is to achieve a high conviction rate. The prosecution, police, and crime lab are aligned in this objective. Incentives are built around this objective. This leads to strategic screening of who to bring to trial, what evidence to process through the crime lab and what evidence to present to decision makers, the judge, or jury. If errors are not made, then this process would be acceptable.

Unfortunately, errors of both commission and omission have occurred and will, in all likelihood, continue to occur. The tight relationships among the prosecution, police and the crime lab ensure that strategic screening will continue to occur; bias will creep into cases; and errors, convicting the wrong person or freeing the actual perpetrator, will continue. This paper proposes to level the playing field between the prosecution and defense and to ensure that the crime laboratory delivers unbiased scientific evidence to both the prosecution and defense witnesses.

Organization, Bias, Independent

E14 How Do Confrontation Clause Requirements Apply to Crime Laboratory Reports? Effective Direct and Cross-Examination of Forensic Scientists Following Williams vs. Illinois, 567 U.S. ___, 132 S.Ct 2221 (2012)

Winona J. Agbabiaka, JD, Brian J. Walsh, JD*, and Anne C. Petty, JD*, Office of the Cook County, Public Defender, 69 W Washington, 17th Fl, Chicago, IL 60602*

After attending this presentation, attendees will understand the current developments regarding presentation of expert witness testimony, where the witness bases his or her opinion on the reports of a non-testifying expert.

This presentation will impact the forensic science community by facilitating improvement of communication of scientific evidence by prosecutors and defense attorneys to the courts in keeping with the requirements of the Constitution. This will help lawyers communicate to judges and jurors both the capabilities and the limitations of forensic science issues to fully present and challenge the methods used to arrive at expert opinions.

Judges, lawyers, and laymen have come a long way in understanding and entering into the world of forensic science. However, there is a need for additional research and education in order to avoid the common misconceptions of forensic science infallibility and absolute certainty and to ensure that the constitutional protections of criminal defendants including the right of confrontation and the prosecution's burden of proof are not diminished or given short shrift. Numerous publications have addressed the misconception that DNA evidence has a special aura of certainty and mystic infallibility.

Despite these misconceptions, prosecutors have a duty and a responsibility to safeguard the constitutional rights of all citizens including the defendant and their preeminent goal is not victory, but justice.[1] Defense attorneys have a duty to engage evidentiary rules to shield their client from a decision based on unreliable evidence and to appreciate and understand the legal principles applicable to the case.[2]

Several recent United States Supreme Court decisions have addressed the application of the constitutional duties imposed on the prosecution and defense in the area of forensic science testimony. The decision in *Williams v. Illinois* is a 5-4 plurality decision in which a majority of the Court agrees with the result, but not the rationale of the opinion. The decision, concurrences and dissent present several different approaches to the issue of what the Constitution requires when expert witness testimony is at issue in a criminal trial.

Which approach should be followed in court proceedings involving the use of expert witness testimony following the Court's decision in *Williams v. Illinois*? The four main perspectives provided by the Court will be discussed. The main approaches proposed by the decision and dissent include: (1) the reports of non-testifying experts relied on by testifying experts are not offered for the truth of matter asserted and are not subject to the confrontation clause; (2) the lab report is not testimonial and is therefore presumptively admissible; however the defense may call the lab witnesses if they are available. Moreover, should the defense show good cause to doubt the competence of the laboratory producing the report or the validity of its accreditation, then the accused would be entitled to confrontation clause protection; (3) the report is offered for the truth of the matter asserted therein, however it is not testimonial and thus does not violate the confrontation clause; and, (4) prior Supreme Court decisions should govern, find that lab reports of non- testifying experts relied on by expert witnesses are indeed testimonial and should not be admitted in evidence without allowing

cross-examination of the persons who performed the testing and prepared the reports.

Although the discussion and litigation of these issues is not settled; judges, prosecutors and defense attorneys must determine how to proceed in keeping with their respective constitutional duties and responsibilities. This presentation will focus on which witnesses should be called to testify regarding a specific DNA report and why.

Expert Testimony, Confrontation Clause, Forensic Science

E15 Forensic Expert Testimony Meets the Confrontation Clause

James K. Record, LLM, California Univ of PA, Dept of Justice, Law & Society, 250 University Ave, California, PA 15419*

After attending this presentation, attendies will understand how recent U.S. Supreme Court decisions have impacted forensic expert testiomony.

This presentation will impact the forensic science community by explaining how recent U.S. Supreme Court decisions concerning forensic experts and the confontation clause directly affect participation in the criminal justice system.

There is no setting where credible and reliable testimony is more essential than that of the forensic expert in a criminal case. *Williams v. Illinois,* is the latest U.S. Supreme Court decision involving the application of the confrontation clause to forensic evidence.[1] It involved a forensic analyst testifying, in part on a DNA profile performed by someone else, that DNA found inside a rape victim matched DNA taken from the defendant. To understand the issue this fact-pattern presented, it is necessary to give a brief background.

The confrontation clause guarantees the accused the right "to be confronted with the *witnesses* against him." Because "witnesses" are people to give testimony, a broad coalition of Justices held in *Crawford v. Washington,* that the confrontation clause prohibits the prosecution from introducing out-of-court "testimonial" statements without putting the declarants on the stand.[2]

In *Melendez-Diaz v.* Massachusetts, the Court held that forensic reports that certify incriminating test results are testimonial.[3] The case, however, was a closely fought five-to-four decision and last term, in *Bullcoming v. New Mexico*, a five Justice majority reaffirmed *Melendez-Diaz* and made clear that when a prosecution wishes to introduce a certified forensic report, it does not suffice to call a supervisor or other "surrogate" witness to the stand in the place of the actual author of the report.[4]

The *Bullcoming* decision nonetheless left open whether the prosecution could introduce an analyst's testimonial forensic report (or transmit its substance) through an *expert* witness. The Court granted certiorari in *Williams* to answer that question, electing to review the Illinois Supreme Court's holding that the prosecution may introduce testimonial statements in the forensic reports through expert witnesses because statements introduced to show the basis for an expert opinion are not introduced for the truth of the matter (Hearsay Rule).

This conclusion is the most important aspect of *Williams*. Before the Court's decision, numerous state and federal courts had held that the prosecution could introduce testimonial statements not only through forensic experts, but also through mental health experts, "gang experts," and other experts.

So where, in practical terms, does this leave us? In the realm of forensic evidence, the Confrontation Clause continues to deem *formal* forensic reports testimonial. That means that drug, blood, alcohol, fingerprint, ballistics, autopsies, and related reports that typically involve testing by one person and that are incriminating on their face will continue to be inadmissible without the testimony of their authors (or some other method of satisfying the Confrontation Clause). Don't be tempted to get "tricky" with the rule. Justice Thomas in a footnote stated that "informal statements" are also testimonial when made to "evade the formalize process" previously used to generate such statements. It is time for the forensic expert to get an education in courtroom survival.

Forensic Testimony, Expert Testimony, Forensic Expert

E16 Judges' Evaluation of Evidence When Considering Post-Conviction Relief

Kayla A. Burd, BA, and Dawn McQuiston, PhD, Ariz State Univ, 4701 W Thunderbird Rd, Glendale, AZ 85306*

After attending this presentation, attendees will understand how recent U.S. Supreme Court decisions have impacted forensic expert testimony.

This presentation will impact the forensic science community by explaining how recent U.S. Supreme Court decisions concerning forensic experts and the Confrontation Clause directly affect their participation in the criminal justice system.

Any convicted person can file a petition to secure relief, which can include the granting of a new trial or resentencing for the offense. One may be eligible for post-conviction relief if: (1) the conviction violated the U.S. (or state) Constitution; (2) the Court was without jurisdiction to declare the judgment and/or sentencing it rendered; (3) the person's sentence exceeded the maximum allowed by law; (4) a person is held beyond his/her sentence; (5) a defendant failed to file a petition in a timely manner not due to his or her fault; (6) significant changes have occurred in the law that apply to the case; (7) the defendant can demonstrate clear and convincing evidence that the facts of the case are such that no reasonable fact-finder would have found him/her guilty beyond a reasonable doubt; or, (8) newly discovered evidence is found that, if presented at the time of trial, would be verdict-changing. This research examines the last of these criteria by evaluating judges' impressions of newly-discovered evidence and how these impressions impact a petition for relief.

In a post-conviction relief proceeding, a defendant can raise an argument concerning ineffective counsel or can outline a claim that evidence which existed at the time of trial but was only discovered *after* trial would in fact be verdict-changing in the minds of the jurors had it been presented originally. Petitions are initially reviewed by a Superior Court "gate keeper" judge who determines whether the petition is timely and whether a legitimate claim exists under the law. If these requirements are satisfied, the petition is then passed on to the original trial court Judge who determines if the claims necessitate a new evidentiary hearing. If a hearing is granted, the Judge could decide to grant a new trial.

This research aims to discover which evidence is most probative to judges when deciding whether or not to grant evidentiary hearings based on post-conviction relief petitions. The goal was specifically interested in learning about judges' impressions of evidence that reflects changes which have evolved in both science (e.g., DNA typing) and scientific theory (e.g., criteria for diagnosing shaken baby syndrome). Post-conviction petitions used in this research will be modeled after actual petitions filed in the state of Arizona. Judges will be asked to read a post-conviction petition which contains one or more of these types of evidence, and then will be asked questions about their impressions of the evidence presented and how likely they would be to grant an evidentiary hearing. It is predicted that certain changes in science, evidence quality, type of crime, and subjective beliefs will all play a part in the decision-making process when a Judge is appealed to during the post-conviction process.

This research and presentation will impact the forensic and judicial community by giving insight into judges' judgments and decision-making processes during the review of post-conviction relief petitions, and

determining which types of evidence (forensic or other) are most probative when considering these petitions.

Post-Conviction, Decision-Making, Evidence Evaluation

E17 How Many Expert Witnesses Does the Prosecution Need to Admit a Lab Report?

Lisa Kreeger-Norman, JD, 1613 Boyle St, Alexandria, VA 22314*

After attending this presentation, attendees will better understand the facts and holdings of the four Supreme Court cases which prescribe the manner in which the prosecution can admit lab reports into evidence and the number (and role) of the expert witnesses they must call to the witness stand. Expert witnesses who attend will learn "the rules" created by the four cases and will have an understanding of those rules. This understanding will enable forensic expert witnesses to know what to expect to hear about taking the stand from the prosecutor or defense attorney. The attendees will leave the session with an understanding of how the rules fit their discipline as, for example, sometimes DNA is different.

This presentation will impact the forensic science community by giving the necessary tools to prepare for the likelihood – or know there is little likelihood – that they will have to testify about the results reported in their lab report. This presentation bridges a gap in knowledge about what the U.S. Supreme Court has said in all of the opinions that address expert witness testimony that have been issued in 2004, 2009, 2011, and 2012.

Four cases which seemingly address the same Constitutional issue cannot be assimilated without looking at them as a whole. The Sixth Amendment Confrontation Clause guarantees the accused's right to confront the witnesses used against him. In 2004, the Supreme Court held, in *Crawford v. Washington,*[1] that the clause prohibits the Government from introducing out of court statements without putting the declarant on the witness stand. In 2009, in *Melendez-Diaz v. Massachusetts,*[2] the Court reaffirmed the decision, holding that forensic reports that certify results are testimonial statements. In *Bullcoming v. New Mexico,*[3] the Court held that when the prosecution introduces a forensic report, it must call the actual author of the report to the stand, not a supervisor or surrogate witness. *Bullcoming* left open the question of whether prosecutors can introduce an analyst's testimonial forensic report through a testifying expert witness. When can one testifying expert witness be used to admit another's forensic reports? Did *Williams V. Illinois,*[4] issued on June 18, 2012, answer the question?

Williams was issued as a plurality opinion: Judge Alito and three Justices wrote for the plurality, Judge Kagan and three Justices wrote for the dissent and one Justice seemingly ruled for both sides. Ultimately, Judge Thomas, writing alone, affirmed Sandy William's conviction for rape. How will the lower courts interpret *Williams* – narrowly or expansively? The answer is most likely they will do both. Does it depend upon whether it is a jury trial or a judge hearing the case alone? Does it depend upon the discipline the forensic science and author belong to? The final, integrated rule is that reports that are the internal work product leading up to a formal report are not testimonial and therefore not subject to confrontation. Will forensic scientists respond by re-categorizing the procedures that culminate in a final opinion? The *Williams* decision, combined with others, came with several warnings to prosecutors and forensic scientists regarding the number (and role) of expert witnesses that need to be called to the stand to introduce one report.

All four Supreme Court cases which address the issue of the Confrontation Clause as it applies to forensic expert witnesses will be discussed. There will be discussion about the application of the rules to different disciplines and different circumstances. Both forensic scientists and attorneys can, and should, tailor their expectations along the lines of these Supreme Court rules.

Expert Witness, Laboratory Reports, Constitutional Law

E18 Designer Drugs: Legal and Analytical Challenges for Forensic Laboratories and the Courts

Heather L. Harris, JD, 2401 Lombard St, Ste 1, Philadelphia, PA 19146; and Barry K. Logan, PhD*, NMS Labs, 3701 Welsh Rd, Willow Grove, PA 19090*

The goal of this presentation is to describe the evolution of the designer drug market in the United States, and describe the challenges laboratories and the courts are facing in detecting, identifying, quantifying, classifying, and reporting the latest round of synthetic drugs available on the street.

At the conclusion of this presentation, attendees will be able to: list the major classes of designer drugs and recognize something about their chemical differences; describe the limitations of current drug analysis techniques in identifying novel compounds; evaluate some of the approaches used by drug chemists in categorizing drugs; and, plan approaches to the prosecution or defense of drug possession cases based on accurate chemical information.

This presentation will impact the forensic science community by making attorneys and triers of fact more aware of the basis for the reliable forensic identification of novel drugs.

Over the past fifty years, a relatively small group of drugs including marijuana, cocaine, amphetamines, heroin, and a handful of diverted prescription opiates and sedatives made up the vast majority of illicit drug possession cases. The compounds were chemically distinct and diverse, well-characterized and well within the competencies of most forensic laboratories to detect and identify. Novel compounds appeared infrequently, for example MDMA or ecstasy in the late 1970's, and achieved low levels of adoption by the drug using community.

Starting in 2009, entrepreneurial chemists began clandestinely synthesizing drugs developed in the pharmaceutical industry as potential therapeutic agents, but with significant abuse potential, and introduced them first to the European, and in 2010 to the U.S., recreational drug markets.

The most popular of these drugs were synthetic cannabinoid agonists, drugs that bound to the cannabinoid receptors in the brain and produced marijuana-like effects. They included compounds like JWH-018 and HU-210. Around the same time drugs with stimulant and hallucinogenic properties that had been described in patents and publications in the 1980's began to appear, including methylone ("meow, meow"), and naphyrone ("NRG-1").

Following a series of deaths and intoxications resulting in injuries, state and federal legislators in the U.S. moved to schedule these compounds, but in a haphazard way resulting in a patchwork of inconsistent and difficult to interpret, laws and amendments to drug schedules. Drug manufacturers quickly moved to make new compounds whose scheduling status was less clear and possibly evaded the new laws.

The result was a mushrooming in the number of drugs now on the market. Initially dozens, and now hundreds of new chemical entities, are sold on the street, and in more mainstream outlets like smoke shops, convenience and novelty stores. Although the federal government in mid-2012 passed more comprehensive legislation to control these nationally, within weeks new classes of drugs began to emerge.

The compounds present challenges to forensic laboratories first in detecting and identifying the presence of novel compounds that may not be in their libraries or databases, confirming and quantifying drugs for which commercially available standards often don't exist, determining whether they are controlled substances or not, and determining whether they are reportable under the rules of their jurisdictions.

Specific challenges in the analysis and litigation of these cases arise from the fact that traditional analytical methods may not differentiate closely related compounds and even the latest techniques such as time-of-flight (TOF) mass spectrometry which are invaluable in providing molecular formula information, don't differentiate between isomers. Additionally, there has been insufficient time for the field to develop consensus around the interpretation of both legacy and the latest drug analog laws, which give either vague or very complex definitions.

The presentation will include some specific examples of emerging recreational drugs and assess their status as controlled substances or analogs to illustrate the challenges faced by forensic laboratories and the courts.

Designer Drugs, Controlled Drugs, Analog Laws

E19 The Independence of Medical Examiners and Forensic Pathologists — Redux

Lindsey C. Thomas, MD, Minnesota Regional MEO, 1175 Nininger Rd, Hastings, MN 55033; Susan J. Roe, MD, OCME, 200 Feliks Gwozdz Pl, Fort Worth, TX 76104; and Christine Funk, JD, 919 Vermillion St, Ste 200, Hastings, MN 55033*

After attending this presentation, attendees will understand some of the pressures placed on forensic pathologists and medical examiners and how that may affect the ability of defense attorneys to appropriately understand and possibly counter claims of state witnesses.

This presentation will impact the forensic science community by describing the outcome of a case in Minnesota and the response of that state's Supreme Court, addressing the issue of independence of medical examiners.

In 2008, a county attorney in Minnesota sent a threatening email to that county's medical examiner, stating that neither he nor the Sheriff would support her appointment as the county medical examiner if she or others in her office consulted with or testified for defense attorneys. The county attorney was subsequently publically reprimanded by the Minnesota Supreme Court for "engaging in conduct that is prejudicial to the administration of justice."[1] The trial that led to his sending the email was in a different and unaffiliated Minnesota county and the outcome resulted in a young woman being found guilty of pre-meditated murder for the stabbing death of her newborn baby. She was 17-years-old at the time of her baby's death, and was sentenced to life imprisonment without the possibility of release.

After a post-conviction hearing held before the trial judge, postconviction relief was denied. The case was then appealed directly to the Minnesota Supreme Court. The court exercised its supervisory powers and reversed the conviction in the interests of justice, due to the conduct of third-party state actors which undermined "the defendant's constitutional rights, contravened clear legislative intent, and interfered with the statutorily-mandated independence of medical examiners."[2]

The decision of the Supreme Court included clear guidelines regarding the role of medical examiners, stating "It is not a conflict of interest for a medical examiner to consult with criminal defense attorneys or testify at a criminal defendant's request. Indeed, such activity is authorized and protected by law."[3] They also found that "It should be undisputed that the quality of forensic investigation improves when medical examiners operate free from the influence of law enforcement and prosecutors."[4] Particularly heartening was the affirmation that "It is not disloyal for a medical examiner, who may testify as a State expert in the future, to consult with defense counsel or testify as a defense witness. Good medical examiners do not choose sides."[5] In conclusion, the opinion stated, "If Minnesota's law enforcement and prosecutorial communities believe that medical examiners are not independent, autonomous, and neutral actors, we now state clearly that such a belief has no place within Minnesota's criminal justice system."[6]

It remains to be seen if this ruling will have a practical effect on the access of criminal defense attorneys in Minnesota to local forensic pathologists. Many forensic pathologists are reluctant to consult with or testify for defense attorneys. Reasons include the unfortunate competition in Minnesota between medical examiner offices for counties and the perception that county attorneys in the counties being pursued prefer forensic pathologists who do not work with defense attorneys. Additionally, there are few forensic pathologists in the state and concern has been expressed that disagreeing with one another may lead to tension and conflict within this mostly close-knit group. Financial issues, including the perception that a forensic pathologist is "doing it for the money" discourage others from consulting.

This presentation seeks to share the experience in Minnesota and to continue the discussions between forensic pathologists and attorneys on how best to achieve just results in criminal proceedings.

Independence, Expert, Influence

E20 Not a Single Forensic Technique Has Been Examined for Validation or Scientifically Validated During the Four Years Since the National Academy of Sciences Report Issued: Are We Losing This Rare Opportunity to Bolster Credibility in Our Justice System?

Thomas L. Bohan, PhD, JD, MTC Forensics, 54 Pleasant Ave, Peaks Island, ME 04108*

After attending this presentation, attendees will learn of the forensic reform efforts over the past four years and of the conflicting forces displayed in that period that will shape the outcome of those efforts.

This presentation will impact the forensic science community by implementating without further delay the forensic-practices validation studies called for by the National Academy of Sciences recommendations.

In February 2009, the American people were gobsmacked by the National Academy of Sciences Report: *Strengthening Forensic Science in the United States: A Path Forward.* Gobsmacked, because they suddenly learned that their presumptions about the forensic techniques used to convict, incarcerate, and even execute their fellow citizens were misfounded. Whereas they, along with most judges in the country, had not doubted that those techniques were solidly supported by science, a committee of the body the country had relied on for scientific advice for more than a century now said unanimously that apart from forensic DNA not a single forensic practice of the nation's crime labs had ever been validated. Though the committee said much more, none of the rest drew the reaction elicited by the no-validation assertion, coming as it did in the midst of what seemed like weekly announcements of persons being exonerated long after conviction and imprisonment for heinous crimes.

The legal community's reaction was influenced by both the continuing exonerations and *Daubert* and *Kumho Tire.* Those two decisions of the U.S. Supreme Court require that expert-testimony reliability be established before that testimony can be introduced as evidence at trial. Clearly, one cannot establish the reliability of testimony based on a forensic practice that has never been found to be valid.

In contrast to the surprise of the public, the lawyers, and the judiciary, those scientists knowledgeable in forensics were not at all surprised, a circumstance that many news stories about the Report commented on with their own surprise. The scientists had always been

aware of the lack of validation of many forensic practices. They were also aware of the futility of trying to convince non-scientists of this through the adversarial system. For the forensic scientists, therefore, the February 2009 Report represented a long-sought opportunity to move outside the adversarial system to publicly examine the degree to which existing forensic practices have already been validated and, for those found by this examination *not* to have been validated, to measure scientifically the degree to which they *are* valid.

The forensic scientists' optimism in early 2009 was boosted by the swiftness with which the federal government, both the Executive and Legislative branches, reacted to the report (which had been produced in response to a request from Congress). Within months, a subcommittee on forensic science created by the White House and charged with advising the President on how to implement the report's recommendations was staffed and functioning. Concurrently, the Senate Judiciary Committee started holding hearings and meetings aimed at developing forensic reform legislation. It was at this point that conflicts emerged among the different "stakeholder" interests.

The White House subcommittee has had to keep its proceedings confidential until the President decides which of its recommendations are to be accepted. However, the Senate Judiciary Committee's work has been largely open and therefore provides a window into the struggle among those with very different concepts of what should take place, struggles that began just before the report was released and are continuing full throttle today. Those who attended the meetings called by the Judiciary Committee staff and/or attended the formal Committee hearings saw first-hand the lobbying being driven by the struggle. The outcome of the lobbying as of January 2011 can be seen in the form of the bill introduced that month by Senator Leahy, Chair of the Senate Judiciary Committee (the Forensic Reform Act of 2011), and as of July 2012 when a sharply revised version of that bill was released for comment. From the outset, one strong lobbying group has sought to have no important changes occur. A second group sees the reform movement as strictly a means of gaining more resources for crime lab directors. A third group, which may be the same as the first, is probably the strongest and has fought very hard to prevent one of the National Academy of Sciences fundamental recommendations from having any impact. Commenting on the failure of the Department of Justice (DOJ) to have corrected the long-existing failure in forensic practice, the National Academy of Sciences committee strongly expressed its recommendation that future forensic oversight be handled elsewhere than in the DOJ and indeed that the crime labs be removed from law enforcement agencies.

Given the political minefield in which they had to do their work, the Judiciary Committee staffers responsible for drafting the bill did a masterful job. The Forensic Reform Act of 2011 provided for an Office of Forensic Science housed in the office of the Deputy Attorney General (that is, within the DOJ), but for most control and staffing to reside in the National Institute of Technology and Standards (NIST), a purely scientific/technical agency of the federal government. Disappointingly, for those who wish to have scientific and not law-enforcement control of the federal oversight of forensic practice, the version of the bill released for comment 18 months later had been revised so as to effectively lodge control completely within the Department of Justice.

The same month that the revised Senate Judiciary bill was released for comment, a very different forensic-reform bill, the Forensic Science and Standards Act of 2012, was introduced concurrently in the Senate and in the House of Representatives. The new bill, developed by the Senate Commerce Committee, has a narrower focus than the earlier one. Whereas the bill developed by the Judiciary Committee seeks to address most of the recommendations of the National Academy of Sciences Report, the Commerce Committee bill is focused on the validity of forensic practices. In further contrast, the new bill assigns responsibility for the validation work to the National Academy of Sciences, NIST, and the National Science Foundation, with just a minor role for the Department of Justice. Reportedly, this bill was developed with little or no input from the group seeking to minimize change, the group seeking to increase resource allocation to lab directors, and the group that wished to retain in law enforcement the various responsibilities that the National Academy of Sciences Report recommended to be removed from that quarter.

As of August 1, 2012, the hope engendered by the National Academy of Sciences Report that forensic practices were on the verge of examination in non-adversarial setting has been completely unfulfilled. As indicated above, there are many intractable reasons for this failure. One not mentioned is the bundling by both the White House subcommittee and the Senate Judiciary bill of the validation studies into a myriad of other proposed fixes estimated to cost hundreds of millions of dollars and to require a large administrative structure. Both groups have lost sight of the fact that the public was upset because of the validation issue. Its demand was for *that* issue to be dealt with; all the matters that these two groups have spent most of their time dealing with pale into insignificance with that issue. What a disaster it will be if the omnibus solutions fail because of the various parties opposing one or another of their parts and, failing, drag down with them the them the validation work, the validation work which can be completed at a fraction of the cost and a fraction of the time, and would be by far the most important step in establishing the credibility of the nation's crime labs and dedicated forensic practitioners and hence of the US system of justice.

NAS Report, Validation, Poitical Pressures

E21 Ensuring Justice: What Lawyers and Judges Can Do to Carry Out the Goals of the NAS Report

Dave J. Waxse, JD, US Courthouse, 500 State Ave, Rm 219, Kansas City, KS 66101; and Rebecca A. Waxse, JD*, 5669 147th St N., PO Box 548, Hugo, MN 55038*

After attending this presentation, attendees will understand what tools are available to lawyers and judges to fulfill their role in carrying out the goals of the National Academy of Sciences (NAS) Report and ensure that only reliable forensic evidence is used in the court system.

This presentation will impact the forensic science community by exploring and examining what tools exist within the court system and how these tools should be utilized in the effort to carry out the goals of the NAS report. This is beneficial because it will help gain a better understanding of the interplay between forensic science and the courtroom.

The NAS Report entitled, *"Strengthening Forensic Science in the United States: A Path Forward"* was a call to action. Specifically, it was a call to action by the forensic science community. While it did not directly address the trial court's role in making the changes called for by the Report, this does not mean that the entire justice system, including both the trial court and counsel, is off the hook. In fact, because forensic science plays such an important role in so many cases before the court, it is imperative that the justice system take on its own role in implementing the goals of the NAS Report and ensure that justice is being served in our courts.

To ensure that justice is being served in our courts, judges and lawyers must start looking more critically at forensic evidence. As lawyers and judges we need to make sure that the forensic evidence being presented to juries is reliable. In order to determine whether the evidence is reliable, first and foremost, courts must ensure that the evidence being presented is generally accepted by the scientific community. In addition, lawyers and judges need to look at what processes were in place when testing is done. The presentation explores the lawyer role in the need to ensure the proper protocols are followed when testing is done. The judicial systems needs to ensure the proper safeguards are in place when testing is done and that the individuals conducting the testing are qualified. In order to make these determinations, those in the judicial system need to be able to examine the processes, protocols and safeguards.

In this presentation, the tools lawyers and judges have to ensure that only reliable forensic evidence is presented in court to either juries or judges will be presented. Generally, the judiciary looks to *Frye* in some state courts or to *Daubert*, as codified in Rule 702 of the Federal Rules of Evidence, in other state courts and federal court to determine whether the evidence being presented is reliable. This presentation will

examine whether these are the appropriate standards and whether these standards are being applied appropriately? Under *Frye*, the Court is to determine if the evidence being proffered is generally accepted in the general scientific community. If *Frye* is the standard, what additional tools exist to ensure that the procedures and protocols being used are sufficient? Are there other tools within the rules of evidence that should be used to carry out the goals of the NAS Report and ensure that only reliable evidence is being presented? Additionally, this presentation will explore whether lawyers should be challenging the reliability of forensic evidence on a global level or on a case by case basis? Finally, who bears the responsibility of ensuring that only reliable forensic evidence is introduced in court to judges and juries?

This presentation will benefit the forensic science community by exploring and examining what tools exist within the court system and how these tools should be utilized in the effort to carry out the goals of the NAS Report. This is beneficial because it will help us gain a better understanding of the interplay between forensic science and the courtroom.

Reliable Evidence, Frye, Daubert

E22 Forensic Nurse Collaboration With the Legal Team

Joyce P. Williams, DNP, 10809 Stansfield Rd, Randallstown, MD 21133; and L. Kathleen Sekula, PhD*, Duquesne Univ, 600 Forbes Ave, 523 Fisher Hall, Pittsburgh, PA 15282*

The goals of this presentation are to: (1) explore the implications of the Institute of Medicine (IOM) report for the future of forensic nursing specific to practice, education, and research; (2) explain how nurses can be full partners, collaborating with physicians and other forensic science professionals, in pursuing robust prevention pursuits to improve safety; (3) examine the commitment to moving the science forward; and, (4) outline advanced educational and training requirements for forensic nurses. The objective of this presentation is to outline the expertise of the advanced practice forensic nurse in collaborative roles within the legal system.

This presentation will impact the forensic science community by providing a basis for legal professionals to understand the expertise of advanced practice forensics within the legal system.

Regardless of the preparation level of the nurse, the goal of forensic education is to provide nurses who are knowledgeable in the care of all victims and perpetrators of violence and who are prepared to work in collaboration with professionals in the legal system. The advance practice forensic nurse has an educational background in psychiatric assessment and intervention skills, death investigation, forensic wound identification, evidence collection, family violence, sexual assault of all types and in varied populations, introductory law, and principles of criminal justice and forensic science.

Advanced forensic education for nurses prepares them to function in roles not held by nurses before. This is an emerging area of nursing practice and one that is in demand due to the increased incidence of violence within society, in general, and in the health care system, specifically. Among the roles of the advanced practice forensic nurse are that of the forensic nurse expert in the hospital or community setting who provides expertise across disciplines, risk manager, death investigator, nurse coroner, legal nurse consultant, death row mitigator, forensic psychiatric nurse, disaster nurse expert, corrections nurse, among others. These roles prepare nurses to provide expertise as nurse specialists in the courtroom as well as to serve as fact witnesses.

It is only with this advanced education that new roles emerge. In 2010, the Robert Wood Johnson Foundation (RWJF) and the Institute of Medicine (IOM) released an historic report, "*The Future of Nursing: leading change, advancing health."* It was felt that improving health and healthcare for Americans could not be done without the nursing profession. The focused outcome was to be an initiative regarding the Future of Nursing. The committee developed four key messages:

- Nurses should practice to the full extent of their education and training.
- Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.
- Nurses should be full partners, with physicians and other health professionals, in redesigning health care in the United States.
- Effective workforce planning and policy making require better data collection and an improved information infrastructure.

It is this advanced education that prepares forensic nurses to collaborate with professionals within the legal system. Forensic nurses function as experts, fact witnesses, consultants, death row mitigators, nurse lawyers, and in general, serve to connect the health care community with the legal system in serving both victims and perpetrators.

Collaboration, Forensic Nurse, Roles

E23 What Lawyers Need to Know About Forensic Art

Sandra R. Enslow, BA, 4700 Ramona Blvd, Rm LL40, Monterey Park, CA 91754*

After attending this presentation, attendees will understand: (1) the fundamental aspects of forensic art and its part in a criminal investigation; (2) what the prosecution and defense need to know, the qualifications of professional Forensic Artists (FAs); and, (3) the value for detectives in identification will also be covered.

This presentation will impact the forensic science community by raising awareness of the forensic art discipline and understanding how this discipline is an advantage when dealing with forensic drawings in the courtroom.

Forensic art has been used in the United States of America since the 1800s. The first and most common usages were for "wanted posters" of unknown criminals. Diagrams of crime scenes were also important aspects to documenting criminal behavior. Forensic art is an expanding field that is practiced throughout the United States as well as internationally. There are over 175 practicing FAs connected to law enforcement agencies across the country. Forensic artists produce ***information generating images*** that help investigators develop more leads and ultimately solve cases.

Computer facial imaging programs have had limited and disappointing results. Most operators are focused on how to use the software, rather than on their witness and conducting a neutral and productive interview. Few of these operators have the skills to render a lifelike image, and software training is limited.

Composites usually illustrate a suspect's image but may also be of a witness, or another victim that is sought. An illustration of a tattoo, stolen items, or sometimes vehicles are also described to a forensic artist for the creation of an image. The discipline also includes other, equally complex, applications. Principle areas include facial reconstruction, postmortem drawings, age progressions, digital imaging, and approximation drawings from videotape. With each application, the detective is relying upon the professional assistance of a forensic artist to get more information about a person involved in their investigation.

Both prosecution and defense need to know the same things. Is the artist employed by or connected with a law enforcement agency? How the drawing was developed and was it done without prejudice? Was the forensic artist trained specifically in forensic art? Training is key and the cognitive interview, an essential part of that. Composites are an illustration of what the witness recalls. This interview process assists the artist with witnesses who are traumatized by the event, gripped by the fear of retaliation for cooperating with authorities or lying about what they saw.

Tools and methodologies can vary around the country. Many forensic artists use a facial identification reference book, take notes and sign their work while others do not. There is a wide latitude in the construction of the drawing but focused agreement on the narrow

constraints involved for not leading the witness and neutrality in the interview. Certifications are available but not often required and there is no national certification at this time.

In some cases, forensic artwork may outright illicit an identification, in other cases it often plays a supporting role of corroboration or elimination. A jury reacts to a drawing that shows similarity to the defendant, knowing that the victim or witness was sincere in their description. They like to understand the process that developed that image.
